TABLE OF CONTENTS

PLENARY
SESSIONS

PL02 PRESIDENTIAL SYMPOSIUM 1 (LIVESTREAMED), SUNDAY, SEPTEMBER 8, 2024 - 8:30 - 10:00

PL02.04 Phase 3 Study of Ivonescimab (AK112) vs. Pembrolizumab as First-line Treatment for PD-L1-positive Advanced NSCLC: Primary Analysis of HARMONi-2

C. Zhou[1], J. Chen[2], L. Wu[2], L. Wang[1], B. Liu[3], J. Yao[4], H. Zhong[5], J. Li[6], Y. Cheng[7], Y. Sun[8], H. Ge[9], Q. Shi[10], M. Zhou[11], Z. Han[12], J. Wang[13], Q. Bu[14], Y. Zhao[15], J. Chen[16], J. Yang[17], M. Xia[17] [1]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN ,[2]Hunan Cancer Hospital, Changsha/CN ,[3]Harbin Medical University Cancer Hospital, Harbin/CN ,[4]The First Affiliated Hospital of Henan University of Science and Technology, Luoyang/CN ,[5]Shanghai Chest Hospital, Shanghai/CN ,[6]The First Affiliated Hospital of Gannan Medical University, Ganzhou/CN ,[7]Jilin Cancer Hospital, Changchun/CN ,[8]Shandong Cancer Hospital and Institute, Jinan/CN ,[9]The Fourth Hospital of Hebei Medical University, Shijiazhuang/CN ,[10]Fuzhou Tuberculosis Prevention and Treatment Hospital, Fuzhou/CN ,[11]Affiliated Cancer Hospital and Institute of Guangzhou Medical University, Guangzhou/CN ,[12]The Affiliated Hospital of Xuzhou Medical University, Xuzhou/CN ,[13]The Fifth Medical Center of the General Hospital of Chinese People's Liberation Army, Beijing/CN ,[14]The First affiliated hospital of Guangxi Medical University, Nanning/CN ,[15]Henan Cancer Hosptal, Zhengzhou/CN ,[16]Fujian Cancer Hospital, Fuzhou/CN ,[17]Akeso Biopharma, Inc., Zhongshan/CN

This abstract is under embargo until September 8 at 10:00 PDT.

PL02 PRESIDENTIAL SYMPOSIUM 1 (LIVESTREAMED), SUNDAY, SEPTEMBER 8, 2024 - 8:30 - 10:00

PL02.07 Neocoast-2: Efficacy and Safety of Neoadjuvant Durvalumab (D) + Novel Anticancer Agents + CT and Adjuvant D ± Novel Agents in Resectable NSCLC

T. Cascone[1], G. Florian[2], L. Bonanno[3], M. Lieberman[4], O. Bylicki[5], A. Insa[6], L. Livi[7], R. Corre[8], T. Egenod[9], A. Bieslka[10], A. Yohannes[11], R. Mager[11], Y. He[10], A. Dowson[12], L. McGrath[10], R. Kumar[11], I. Grenga[10], J. Spicer[13], P. Forde[14], [1]The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[2]Univ Rouen Normandie, LITIS Lab QuantIF team EA[4108], CHU Rouen, Rouen/FR ,[3]Istituto Oncologico Veneto IRCCS, Padova/IT ,[4]CETOC - CHUM Endoscopic Tracheobronchial and Oesophageal Center, Centre Hospitalier de l'Université de Montréal, Montréal/QC/CA ,[5]Hôpital d'Instruction des Armées Sainte-Anne, Toulon/FR ,[6]Hospital Clínico Universitario de Valencia, Valencia/ES ,[7]University of Florence, Florence/IT ,[8]CH de Cornouaille, Quimper/FR ,[9]Dupuytren University Hospital, Limoges/FR ,[10]AstraZeneca, Waltham/MA/USA ,[11]AstraZeneca, Gaithersburg/MD/USA ,[12]AstraZeneca, Cambridge/GB ,[13]McGill University, Montréal/QC/CA ,[14]Johns Hopkins University, Baltimore/MD/USA

This abstract is under embargo until September 8 at 10:00 PDT.

PL02 PRESIDENTIAL SYMPOSIUM 1 (LIVESTREAMED), SUNDAY, SEPTEMBER 8, 2024 - 8:30 - 10:00

PL02.08 Perioperative vs Neoadjuvant Nivolumab for Resectable NSCLC: Patient-Level Data Analysis of CheckMate 77T vs CheckMate 816

P.M. Forde[1], S. Peters[2], J. Donington[3], S. Meadows-Shropshire[4], P. Tran[4], S. Lucherini[5], C. Coronado Erdmann[4], H. Sun[4], T. Cascone[6], [1]The Bloomberg–Kimmel Institute for Cancer Immunotherapy, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Medicine, Baltimore/MD/USA ,[2]Lausanne University Hospital, Lausanne/CH ,[3]University of Chicago, Chicago/IL/USA ,[4]Bristol Myers Squibb, Princeton/NJ/USA ,[5]Bristol Myers Squibb, Uxbridge/GB ,[6]The University of Texas MD Anderson Cancer Center, Houston/TX/USA

This abstract is under embargo until September 8 at 10:00 PDT.

PL02 PRESIDENTIAL SYMPOSIUM 1 (LIVESTREAMED), SUNDAY, SEPTEMBER 8, 2024 - 8:30 - 10:00

PL02.11 Normalized Membrane Ratio of TROP2 by Quantitative Continuous Scoring is predictive of Clinical Outcomes in TROPION-Lung 01

M.C. Garassino[1,2], J. Sands[3], L. Paz-Ares[4], A. Lisberg[5], M. Johnson[6], M. Pérol[7], D. Carroll[8], H. Sade[9], A. Kapil[9], V. Haddad[8], D. Uema[10], M-J. Ahn[11], [1]University of Chicago, Chicago/IL/USA ,[2]The University of Chicago, Chicago/IL/USA ,[3]Dana-Farber Cancer Institute, Boston/MA/USA ,[4]Universidad Complutense & CiberOnc, Hospital Universitario [12] de Octubre, Madrid/ES ,[5]Jonsson Comprehensive Cancer Center at UCLA, Los Angeles/CA/USA ,[6]Sarah Cannon Research Institute, Nashville/TN/USA ,[7]Léon-Bérard Cancer Center, Lyon/FR ,[8]AstraZeneca, Cambridge/GB ,[9]AstraZeneca, Munich/DE ,[10]Daiichi Sankyo, Basking Ridge/NJ/USA ,[11]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR

This abstract is under embargo until September 8 at 10:00 PDT.

PL02 PRESIDENTIAL SYMPOSIUM 1 (LIVESTREAMED), SUNDAY, SEPTEMBER 8, 2024 - 8:30 - 10:00

PL02.14 Triaging ILST Screening Participants at Program Entry: Comparative Performance of PanCan versus LungRADSv1.1 Protocol

A.M. McWilliams[1,2], M. Tammemagi[3], S. Atkar-Khattra[4], J. Mayo[5], R. Meyers[4], J. Yee[5], J. English[5], H. Marshall[6], L. Passmore[6], R. Bowman[6], I. Yang[6], F. Brims[7], J. San Luigi Gonzaga di Orbassano, Turin/IT ,[17]Merck & Co., Inc., Rahway/NJ/USA ,[18]The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: Neoadjuvant pembrolizumab plus chemotherapy, surgery, and adjuvant pembrolizumab significantly improved OS (HR, 0.72; 95% CI, 0.56-0.93; P = 0.00517) versus neoadjuvant placebo plus chemotherapy, surgery, and adjuvant placebo and had manageable safety in early-stage NSCLC in KEYNOTE-671 (NCT03425643). In addition, event-free survival (EFS; HR, 0.58; 95% CI, 0.46–0.72; P <0.001), major pathologic response (mPR; 30.2% vs 11.0%; P <0.0001), and pathologic complete response (pCR; 18.1% vs 4.0%; P <0.0001) were also significantly improved in the pembrolizumab arm. We present a post hoc analysis of EFS based on the degree of pathologic regression, defined as percent residual viable tumor (%RVT), following resection.

Methods: Patients aged ≥18 years with previously untreated resectable stage II, IIIA, or IIIB (N2) NSCLC per AJCC 8th edition were randomized to pembrolizumab 200 mg IV Q3W or placebo with cisplatin-based chemotherapy for 4 cycles, then surgery and pembrolizumab 200 mg IV Q3W or placebo for ≤13 cycles. EFS and OS were dual primary endpoints; mPR and pCR per blinded independent pathology review were key secondary endpoints. Patients who underwent surgery and had tissue evaluable for blinded independent pathology review were categorized by %RVT in the primary lung tumor and sampled lymph nodes. The data cutoff date was July 10, 2023.

Results: 320 (80.6%) of 397 patients in the pembrolizumab arm and 300 (75.0%) of 400 in the placebo arm had pathologically evaluable tumors. Median (interquartile range [IQR]) %RVT was 29.5% (1.0%–56.0%) in the pembrolizumab arm and 52.0% (29.0%–68.0%) in the placebo arm. For the pembrolizumab arm versus the placebo arm, 31.9% versus 12.3% of patients had %RVT of >0%–5%, 19.1% versus 14.7% had %RVT of >5%–30%, 31.6% versus 38.0% had % RVT of >30%-60%, and 17.5% versus 35.0% had % RVT of >60%. Lower %RVT was associated with longer EFS in both arms. EFS was numerically improved in the pembrolizumab vs placebo arm in nearly every %RVT group (Table).

Conclusions: In this post hoc analysis, neoadjuvant pembrolizumab plus chemotherapy were associated with greater pathological regression based on %RVT than neoadjuvant placebo plus chemotherapy. There was a clinically meaningful EFS benefit for perioperative pembrolizumab across different %RVT. These data support the benefit of a perioperative regimen of neoadjuvant pembrolizumab plus chemotherapy and adjuvant pembrolizumab for early-stage NSCLC.

Table. Relationship Between %RVT and EFS

%RVT	Pembrolizumab Arm n = 320	Placebo Arm n = 300
0%–5%	n = 102	n = 37
Median EFS (95% CI), mo	NR (NR–NR)	NR (38.2-NR)
36-mo EFS rate (95% CI), %	83.0 (72.4–89.8)	75.9 (57.2–87.3)
HR (95% CI)	0.58 (0.27–1.23)	
>5%–30%	n = 61	n = 44
Median EFS (95% CI), mo	NR (34.1–NR)	39.1 (19.6–NR)
36-mo EFS rate (95% CI), %	61.8 (47.2–73.4)	59.0 (41.5–72.9)
HR (95% CI)	0.73 (0.38–1.38)	
>30%–60%	n = 101	n = 114
Median EFS (95% CI), mo	39.2 (26.0–NR)	22.1 (14.9–33.0)
36-mo EFS rate (95% CI), %	54.7 (43.6–64.4)	38.0 (28.2–47.7)
HR (95% CI)	0.65 (0.45–0.94)	
>60%	n = 56	n = 105
Median EFS (95% CI), mo	15.0 (13.1–NR)	18.5 (13.6–22.1)
36-mo EFS rate (95% CI), %	37.7 (24.6–50.7)	29.1 (20.0–38.9)
HR (95% CI)	0.90 (0.60–1.36)	

NR, not reached.

Introduction: IMpower010 (NCT02486718) met its primary endpoint of significant disease-free survival (DFS) improvement with adjuvant atezolizumab vs best supportive care (BSC) in the stage II-IIIA PD-L1 tumor cell (TC)≥1% and all-randomized stage II-IIIA populations, but not in the ITT population, in patients with resected NSCLC post-chemotherapy. Enhanced benefit was also observed in the population with TC≥50% (Felip Lancet 2021). In the recent DFS final analysis and overall survival (OS) second interim analysis, with ≥5 y of follow-up, the significance boundary for DFS in the ITT population was not crossed and OS was similar between arms. The atezolizumab DFS benefit continued to translate into positive OS trends vs BSC in the PD-L1 TC≥1% and TC≥50% stage II-IIIA populations (Wakelee ASCO 2024). We present outcomes by disease and regional lymph node status, and descriptive analyses of sites of relapse and post-relapse treatments in the stage II-IIIA PD-L1 TC≥1% and TC≥50% populations at ≥5 y of follow-up.

Methods: The study design has been reported (Felip Lancet 2021). Briefly, 1005 patients received 1-4 21-day chemotherapy cycles post-surgery and were randomized 1:1 to receive 16 cycles of atezolizumab 1200 mg Q3W or BSC. Clinical cutoff date for this analysis was January 26, 2024.

Results: In the stage II-IIIA TC≥1% and TC≥50% populations, the DFS unstratified HRs (95% CI) were 0.77 (0.52-1.13) and 0.57 (0.32-1.02) for stage II disease; 0.66 (0.47-0.93) and 0.42 (0.24-0.75) for stage IIIA disease; 0.82 (0.45-1.52) and 0.89 (0.37-2.16) for regional lymph node (pN) status N0; 0.65 (0.42-0.99) and 0.40 (0.20-0.81) for pN1; and 0.74 (0.51-1.07) and 0.42 (0.22-0.77) for pN2. Similar patterns were seen for OS, and for DFS and OS when patients with EGFR or ALK alterations were excluded from the TC≥50% population. Overall recurrence, patterns of relapse and post-relapse therapies are shown in the Table.

	Stage II-IIIA PD-L1 TC≥1%		Stage II-IIIA PD-L1 TC≥50%	
Patients, n (%)	**Atezolizumab (n=248)**	**BSC (n=228)**	**Atezolizumab (n=115)**	**BSC (n=114)**
Overall recurrence	91 (36.7)	115 (50.4)	32 (27.8)	54 (47.4)
Relapse sites[a]				
Locoregional only[b]	43 (47.3)	48 (41.7)	18 (56.3)	19 (35.2)
Distant only[c,d]	33 (36.3)	45 (39.1)	9 (28.1)	23 (42.6)
Central nervous system only[e]	9 (9.9)	12 (10.4)	2 (6.3)	7 (13.0)
Locoregional + distant	12 (13.2)	18 (15.7)	4 (12.5)	8 (14.8)
Second primary lung only	2 (2.2)	3 (2.6)	1 (3.1)	3 (5.6)
Post-relapse treatments[a,f]				
Any systemic anticancer therapy[g]	63 (69.2)	78 (67.8)	24 (75.0)	32 (59.3)
Cancer immunotherapy	16 (17.6)	41 (35.7)	5 (15.6)	20 (37.0)
Radiotherapy	43 (47.3)	51 (44.3)	14 (43.8)	26 (48.1)
Surgery	14 (15.4)	14 (12.2)	4 (12.5)	9 (16.7)

[a] The denominators for relapse sites and post-relapse treatments are based on the number of patients with relapse. [b] Patients who had "local recurrence" or "regional recurrence" checked on the "Disease status" case report form were included. One patient with locoregional + second primary lung is included due to no biopsy confirmation. [c] Two patients with distant + second primary non-lung are included due to lack of biopsy confirmation or because "second primary" was diagnosed on the same day as distant recurrence with no clear differentiation. [d] A patient could have more than one distant site. [e] Patients who had central nervous system distant site-only recurrence were included. [f] Multiple uses of a specific medication for a patient were counted once in frequency for the medication. Likewise, multiple uses within a specific medication class for patients were counted once in frequency for the medication class. [g] Systemic anticancer therapy includes chemotherapy, cancer immunotherapy, targeted tyrosine kinase inhibitor therapy, monoclonal antibody therapy, bisphosphonate therapy, corticosteroid therapy, hormonal therapy, somatostatin therapy, and unknown therapy. Clinical data cutoff date: January 26, 2024.

Conclusions: After ≥5 y of follow-up, patients in the atezolizumab arm had greater DFS and OS improvements than those in the BSC arm, regardless of disease stage or pN status (favoring N1/N2). Overall recurrence rates were lower in the atezolizumab arm than in the BSC arm, irrespective of PD-L1 TC≥1% and TC≥50% status. Although patient numbers were small, distant and central nervous system relapse rates were higher in the BSC arm than in the atezolizumab arm in the TC≥50% population. Post-relapse cancer immunotherapy use was higher in the BSC arm.

OA01.05 Neoadjuvant Nivolumab with or without Relatlimab in Resectable NSCLC: Additional Analysis and Extended Follow-up

K. Cuppens[1], P. Baas[2], M. Wiesweg[3], B. Du Pont[1], T. Ploenes[4], D. Theegarten[3], C. Aigner[5], K. Hartemink[2], B. Maes[1], K. Pat[1], M. Schuler[3] , [1]Jessa Hospital, Hasselt/BE ,[2]The Netherlands Cancer Institute, Amsterdam/NL ,[3]University Hospital Essen, Essen/DE ,[4]University Medicine Essen, Ruhrlandklinik, Essen/DE ,[5]Medical University of Vienna, Vienna/AT

Introduction: In patients with resectable NSCLC at high risk of recurrence, immune checkpoint inhibition (ICI) has become a cornerstone in the curative multimodality treatment. The multicentric, non-comparative phase II study NEOpredict-Lung (NCT04205552) confirmed the primary endpoint of feasibility of dual PD-1 and LAG-3 inhibition prior to surgery [Schuler et al. Nature Medicine 2024]. MPR occurred in 30% of patients treated in the combination arm.

Methods: Patients with NSCLC (stages IB, II and selected IIIA) eligible for surgery were randomized (30 per arm) to receive two preoperative doses (q14d) of nivolumab (240 mg, arm A), or nivolumab plus relatlimab (80 mg, arm B). Extended survival outcomes, stage and nodal evolution analysis, recurrence patterns and subsequent therapy were analyzed as of March 1st, 2024. Study design does not allow for formal comparison of treatment arms.Three patients (arm B) were excluded due to stage IV disease which had been undetected at baseline staging. Sixteen (28.1%) patients had cN1 or cN2 disease [7 (23.3%) in arm A; 9 (33.3%) in arm B], confirmed at randomization by EBUS (13), mediastinoscopy (1) or both (2).

Results: Survival: Median follow-up was 29.8 months. In total, 13 patients experienced disease recurrence, and 6 patients died [1 tumor progression, 1 pulmonary embolism, 1 acute liver failure and 3 unknown/lost to follow-up). The 2-year OS and DFS-rates were 92.3% and 75.3% in arm A and 88.6% and 69.1% in arm B. Patients achieving MPR trended towards better DFS (HR 0.41; 95%CI, 0.09-1.78), compared to non-MPR patients.

Stage and nodal evolution: In total, 16 (53.3%) patients treated in arm A and 18 (66.7%) in arm B experienced TNM-downstaging postoperatively. Upstaging occurred in 8 (26.7%) and 6 (22.2%) patients respectively. Nodal downstaging occurred in 2 (28.6%) patients in arm A and in 6 (66.7%) in arm B (all ypN0). A total of 10 (17.5%) patients experienced nodal upstaging [5 (16.7%) arm A; 5 (18.5%) arm B].

Patterns of recurrence and subsequent therapy: Thirteen (22.8%) patients experienced disease recurrence [6 (20.0%) arm A; 7 (25.9%) arm B]. Three patients had a locoregional recurrence, and 10 distant relapse (5 multisite and 5 oligorecurrences). The most prevalent site of recurrence was the contralateral lung (6). Two patients developed adrenal metastasis and 2 brain metastases. All patients with disease-recurrence underwent therapy [locally ablative (5) or systemic treatment (5)]. All locoregional relapses (3) were treated with chemoradiotherapy (+/- consolidation ICI). Of 17 patients with MPR, 2 experienced an oligorecurrence in the contralateral lung, treated with stereotactic radiotherapy. No new safety signals were noted after subsequent therapies.

Conclusions: Updated analyses of the first study on short-course PD-1 and LAG-3 inhibition, NEOpredict-Lung, shows encouraging 2-year OS- and DFS-rates in both treatment arms. In the dual inhibition arm, TNM-downstaging, in particular nodal clearance, appears more pronounced. The majority of recurrences were at distant sites. All relapsed patients received subsequent therapy without new safety signals.

SUNDAY, SEPTEMBER 8, 2024 - 10:45 - 12:00

OA01.06 A Phase II Study of Perioperative Ivonescimab Alone or Combined with Chemotherapy in Resectable Non-Small Cell Lung Cancer

C. Wang[1], X. Zhao[1], L. Zhang[1], D. Yue[1], Z. Zhang[1], M. Wang[1], Z. Tian[2], S. Wang[1], C. Pang[1], B. Zhang[1], Q. Zhang[1], W. Wei[1], Y. Zhang[1], X. Wang[1], Y. Li[1], H. Lv[2], Y. Xia[3], B. Li[3], Z.M. Wang[3], W. Li[3], [1]Tianjin Medical University Cancer Institute & Hospital, Tianjin/CN ,[2]The Fourth Hospital of Hebei Medical University, Shijiazhuang/CN ,[3]Akeso, Inc., Zhongshan/CN

Introduction: Ivonescimab (AK112/SMT112) is a first-in-class anti-PD-1/VEGF bispecific antibody. Previous clinical studies have indicated that ivonescimab showed potential efficacy in patients (pts) with advanced non-small cell lung cancer (NSCLC) and ivonescimab is currently being investigated in four phase 3 clinical trials in NSCLC. This study aimed to evaluate the efficacy and safety of ivonescimab monotherapy or in combination with chemotherapy in the neoadjuvant/adjuvant treatment of resectable NSCLC.

Methods: This was an open-label, multi-center phase II study, pts diagnosed with resectable stage II, IIIA or IIIB (N2) NSCLC per AJCC 8th edition were enrolled into two cohorts. Pts received neoadjuvant ivonescimab (20 mg/kg) monotherapy in cohort 1 or ivonescimab (20 mg/kg or 30 mg/kg) plus cisplatin/carboplatin and paclitaxel in cohort 2 once every 3 weeks for 3-4 cycles, followed by surgery and adjuvant ivonescimab once every 3 weeks for up to 16 cycles. Primary endpoints were safety and major pathological response (MPR).

Results: A total of 60 pts were enrolled from Mar 09, 2022 to Jul 31, 2023 (11 pts in cohort 1 and 49 pts in cohort 2, 24 pts received ivonescimab 20 mg/kg plus chemotherapy, 25 pts received ivonescimab 30 mg/kg plus chemotherapy). Of these pts, the median age at baseline was 64 [range: 31-74] years, 85% were male, 75% with squamous carcinoma, 78% with stage III, and 90% with lymph node metastasis. As of Jan 08, 2024, in cohort 1, 10 pts completed surgery, the rate of MPR was 60% and the rate of pathological complete response (pCR) was 30%. In cohort 2, 39 pts completed surgery, the rate of MPR was 71.8% and the rate of pCR was 43.6%. The pathological response was better in 30 pts with squamous carcinoma: the rate of MPR and pCR were 83.3% and 53.3%, respectively. MPR and pCR occurred in 70% and 40% of pts with ivonescimab 20 mg/kg plus chemotherapy, 73.7% and 47.4% of pts with ivonescimab 30 mg/kg plus chemotherapy, respectively. Median event-free survival and overall survival were not reached with the median follow-up duration of 10.1 months. The treatment was well tolerated during the perioperative period. There were no treatment related adverse events (TRAEs) that led to cancelled or delayed surgery or wound healing complications. The most common TRAEs (incidence ≥5%) of grade 3 or higher were decreased neutrophil count and decreased white blood cell count. The safety profiles were similar in the two groups of ivonescimab 20 mg/kg and 30 mg/kg in cohort 2.

Conclusions: Ivonescimab alone or plus chemotherapy showed a promising MPR and pCR in pts with resectable NSCLC. Higher rates of MPR and pCR were seen with ivonescimab plus chemotherapy than with ivonescimab alone, with ivonescimab 30 mg/kg plus chemotherapy than 20 mg/kg plus chemotherapy, and with squamous NSCLC than non-squamous NSCLC. The safety profile was manageable, and no TRAEs impeded the surgery.

Introduction: Amivantamab is an EGFR-MET bispecific antibody with immune cell-directing activity. Lazertinib is a central nervous system-penetrant 3rd-generation EGFR TKI. In the primary analysis of the phase 3 MARIPOSA study (NCT04487080), at a median follow-up of 22.0 months, amivantamab plus lazertinib significantly improved progression-free survival (PFS) by blinded independent central review vs osimertinib in patients with treatment-naïve, EGFR-mutated advanced NSCLC (HR, 0.70; 95% CI, 0.58-0.85; P<0.001). Early interim overall survival (OS) analysis showed a favorable trend for amivantamab-lazertinib over osimertinib (HR, 0.80; 95% CI, 0.61-1.05; P=0.11). Here, we present updated results with longer follow-up from MARIPOSA.

Methods: MARIPOSA randomized 1074 patients with treatment-naïve, EGFR-mutated (Exon 19 deletions or Exon 21 L858R substitutions) locally advanced or metastatic NSCLC 2:2:1 to open-label amivantamab-lazertinib (n=429), blinded osimertinib (n=429), or blinded lazertinib (n=216; included to assess contribution of components). This updated analysis, requested by health authorities, compares amivantamab-lazertinib with osimertinib.

Results: As of May 13, 2024 (median follow-up, 31.1 months), 44% (185/421) and 34% (145/428) of patients were still receiving treatment in the amivantamab-lazertinib and osimertinib arms, respectively. In total, 155 patients in the amivantamab-lazertinib arm and 233 in the osimertinib arm had investigator-assessed progressive disease and discontinued treatment. Among those, 72% (111/155) and 74% (173/233) initiated subsequent therapy, respectively, with carboplatin-pemetrexed being the most common first subsequent therapy across arms (amivantamab-lazertinib, 26% [29/111]; osimertinib, 28% [48/173]). PFS after first subsequent therapy (PFS2) favored amivantamab-lazertinib (HR, 0.73; 95% CI, 0.59-0.91; nominal P=0.004). Patients receiving amivantamab-lazertinib demonstrated significantly longer median time to treatment discontinuation and time to subsequent therapy vs osimertinib (Table). Intracranial PFS showed a favorable trend for amivantamab-lazertinib vs osimertinib (Table). While not formally tested for significance, median OS was not estimable for amivantamab-lazertinib vs 37.3 months for osimertinib (HR, 0.77; 95% CI, 0.61-0.96; nominal P=0.019). At 24 months, 75% and 70% of patients were alive in the amivantamab-lazertinib and osimertinib arms, respectively; corresponding values at 36 months were 61% and 53%.

Conclusions: Amivantamab-lazertinib continues to show a trend towards improved OS while also improving post-progression outcomes vs osimertinib, reaffirming amivantamab-lazertinib as a first-line standard-of-care for EGFR-mutated advanced NSCLC.

OA02 REDEFINING FIRST-LINE EGFR THERAPY
SUNDAY, SEPTEMBER 8, 2024 - 10:45 - 12:00

OA02.04 A Phase III Study of Rilertinib Versus Gefitinib as First-Line Therapy for Patients with Locally Advanced or Metastatic EGFR-Mutated NSCLC

C. Zhou, A. Xiong, Shanghai Pulmonary Hospital, shanghai/CN

Introduction: Rilertinib (formerly Oritinib, SH-1028) is a novel, selective oral third-generation epidermal growth factor receptor tyrosine kinase inhibitor developed by Nanjing Sanhome Pharmaceutical Co., Ltd,. This trial evaluated the efficacy and safety of rilertinib compared with gefitinib as a first-line treatment for locally advanced or metastatic EGFR mutation-positive non-small-cell lung cancer (NSCLC; ClinicalTrials.gov identifier: NCT04239833).

Methods: This study was a multicentre, double-blind, randomised phase 3 study at 31 sites in China. Patients were randomly assigned 2:1 to receive either rilertinib (200 mg) or gefitinib (250 mg) once daily in 21-day cycles until disease progression or withdrawal criteria were met. The primary end point was progression-free survival (PFS) per independent review committee (IRC) assessment.

Results: Between Apr 10, 2020, and Apr 30, 2021, 420 patients were screened, of whom 246 were enrolled. 245 patients had received at least one dose of study drug were randomly assigned to rilertinib (n=162) or gefitinib (n=83) group and were included in the full analysis set. IRC-assessed PFS was significantly longer with rilertinib compared with gefitinib (hazard ratio, 0.46; 95% CI, 0.33 to 0.65; P < 0.0001). The median PFS with rilertinib was 19.3 months (95% CI, 15.2 to 22.3) versus 9.8 months with gefitinib (95% CI, 7.1 to 12.6). Objective response rate (ORR) and disease control rate (DCR) were similar in the rilertinib and gefitinib groups, the ORR with rilertinib was 72.8% (95% CI, 65.3 to 79.5) versus 78.3% with gefitinib (95% CI, 67.9 to 86.6); the DCR with rilertinib was 93.8% (95% CI, 88.9 to 97.0) versus 97.6% with gefitinib (95% CI, 91.6 to 99.7). The median duration of response was 20.7 months (95% CI, 14.1 to 23.4) with rilertinib versus 11.1 months (95% CI, 6.9 to 12.6) with gefitinib. Treatment-related adverse events of grade ≥ 3 severity were observed in 17.3% and 22.9% of patients in the rilertinib and gefitinib groups, respectively. Treatment-related serious adverse events were reported in 6.2% patients in the rilertinib group and in 9.6% patients in the gefitinib group. No patient in either group died due to treatment-related adverse events judged by the investigators.

Conclusions: Rilertinib is a well-tolerated third-generation EGFR-TKI that demonstrated superior efficacy compared with gefitinib in first-line treatment for patients with EGFR mutation-positive NSCLC, along with an acceptable safety profile without new signals. Rilertinib could serve as a new treatment option for this population.

Introduction: Lazertinib is an oral, central nervous system-penetrant, 3rd-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) that significantly improved progression-free survival (PFS) versus gefitinib in patients with treatment-naïve, EGFR-mutant advanced non-small cell lung cancer (NSCLC; Cho JCO 2023). In the phase 3 MARIPOSA study (NCT04487080), lazertinib combined with amivantamab, an EGFR-MET bispecific antibody with immune cell-directing activity, significantly improved PFS versus osimertinib in the same patient population (HR, 0.70; 95% CI, 0.58-0.85; P<0.001; Cho Ann Oncol 2023). The MARIPOSA study included a lazertinib monotherapy arm to assess contribution of components in the combination. This is the first trial to prospectively evaluate two 3rd-generation EGFR-TKIs in a randomized, double-blind fashion. Herein, we report results from an exploratory analysis of lazertinib versus osimertinib.

Methods: In MARIPOSA, 1074 patients were randomized 2:2:1 to receive amivantamab plus lazertinib, osimertinib monotherapy, or lazertinib monotherapy. These exploratory analyses focus on the 216 patients randomized to receive lazertinib (240-mg daily) and the 429 patients randomized to osimertinib (80-mg daily) in a double-blinded fashion. Serial brain imaging with MRI was required for all patients. Efficacy endpoints included PFS (by blinded independent central review [BICR] per RECIST v1.1), overall response rate (ORR), duration of response (DoR), overall survival (OS), and safety.

Results: At a median follow-up of 22.0 months, median PFS by BICR was 18.5 months (95% CI, 14.8-20.1) for lazertinib versus 16.6 months (95% CI, 14.8-18.5) for osimertinib (HR, 0.98; 95% CI, 0.79-1.22). ORR was 83% (95% CI, 77-88 for lazertinib versus 85% (95% CI, 81-88) for osimertinib, with median DoR of 16.6 months (95% CI, 14.8-20.2) versus 16.8 months (95% CI, 14.8-18.5), respectively, among confirmed responders. At interim survival analysis, median OS was not estimable for both arms (HR, 1.00; 95% CI, 0.73-1.38).

Additionally, we evaluated PFS of lazertinib versus osimertinib in subgroups of high-risk disease. Median PFS for patients with a history of brain metastases was 16.4 months (95% CI, 12.9-19.4) for lazertinib versus 13.0 months (95% CI, 12.2-16.4) for osimertinib (HR, 0.90; 95% CI, 0.65-1.25). Median PFS for patients with detectable circulating tumor DNA at baseline was 18.4 months (95% CI, 14.6-20.1) for lazertinib versus 14.8 months (95% CI, 12.9-16.6) for osimertinib (HR, 0.88; 95% CI 0.66-1.17). Median PFS for patients with TP53 co-mutations was 14.6 months (95% CI, 11.0-19.4) for lazertinib versus 12.9 months (95% CI, 11.1-14.7) for osimertinib (HR, 0.85; 95% CI 0.58-1.23).

The safety profiles of lazertinib and osimertinib were similar, with EGFR-related adverse events (AEs) being the most common. Most individual AEs were grade 1-2. Higher rates of diarrhea, thrombocytopenia, leukopenia, and QT interval prolongation were observed with osimertinib versus higher rates of rash and paresthesia with lazertinib. Treatment-related AEs leading to discontinuations were similar between arms.

Conclusions: Efficacy and safety were similar for lazertinib and osimertinib. Patients with EGFR-mutant advanced NSCLC, including those with high-risk features, may benefit from lazertinib as an important new treatment option.

OA03.04 Predicting Disease Progression to Upfront Pembrolizumab Monotherapy in Advanced NSCLC with Machine Learning and CT Radiomics

I. Janzen[1,2], Q. Ye[2], J. Li[2], C. Ho[1], B. Melosky[1], S. Lam[1], C. MacAulay[1], R. Yuan[1], [1]BC Cancer, Vancouver/BC/CA ,[2]University of British Columbia, Vancouver/BC/CA

Introduction: Health Canada approved pembrolizumab in the first line setting for advanced Non-Small-Cell Lung Cancer with PD-L1≥50% and no EGFR/ALK aberration. The Keynote 024 trial showed 55% of such patients progress on pembrolizumab monotherapy. Thus the clinical question: Can we distinguish the sub-cohort of PDL1≥50% patients that are best treated with pembrolizumab alone or require pembrolizumab + platinum doublet chemotherapy? We propose that a Machine Learning model using baseline CT radiomics features can predict disease progression for patients receiving upfront pembrolizumab monotherapy for advanced non-small-cell lung cancer, prior to the initiation the treatment.

Methods: This study included two retrospective cohorts of patients with advanced NSCLC, a discovery training cohort (Tr-set; N=97, 56F:41M, 73±6yo) and an external validation cohort (X-set; N=17, 9F:8M, 65±10yo). All patients had CT at baseline and additional follow-up CTs 9-12 weeks after receiving 1st-line pembrolizumab. Response was assessed using RECIST v1.1 standard definitions: “disease control, DC” vs “progressive disease, PD” (Tr-set: 60 DC vs. 37 PD X-set: 9 DC vs 8 PD). A radiomic feature extraction pipeline was used to extract 2D radiomic shape, texture, and intensity features from axial CT images of lung tumor lesion(s). A five-fold cross validated ML model (Logisitic Regression; LR) was trained on a combination of patients baseline demographic, clinical, and CT radiomic features to classify DC vs. PD patients. The best-fit LR model was used to calculate the predicted “risk of PD” for each patient and separate patients into “high- vs. “low-risk of PD” groups by comparing the calculated “risk-of-PD” to the Youden cut-off, and Kaplan-Meier plot were used to compare survivals (OS and PFS) and between the two groups.

Results: ROC analysis showed a good performance for the best-fit LR model that integrates a combination of baseline variables in predicting PD (in Tr-set: AUC=0.91±0.06, in X-set: AUC=0.88, CI 95%: 0.72-0.99). The Kaplan-Meier plots suggested that the “predicted high-risk of PD” group had statistically worse OS compared to the “predicted low-risk of PD” group in both Tr- and X-sets (Tr-set: log rank $p<0.0001$; X-set: log rank $p<0.01$ [NB: only X-set shown in Figure 1C and 1D]).

Conclusions: This pilot study suggests that a ML model integrating baseline CT radiomic features can identify patients who may progress on pembrolizumab monotherapy hence can potentially facilitate decision-making for the optimal first line treatment in high PD-L1 cohorts of advanced NSCLC patients.

Keywords: Radiomics, Machine Learning, Treatment Response

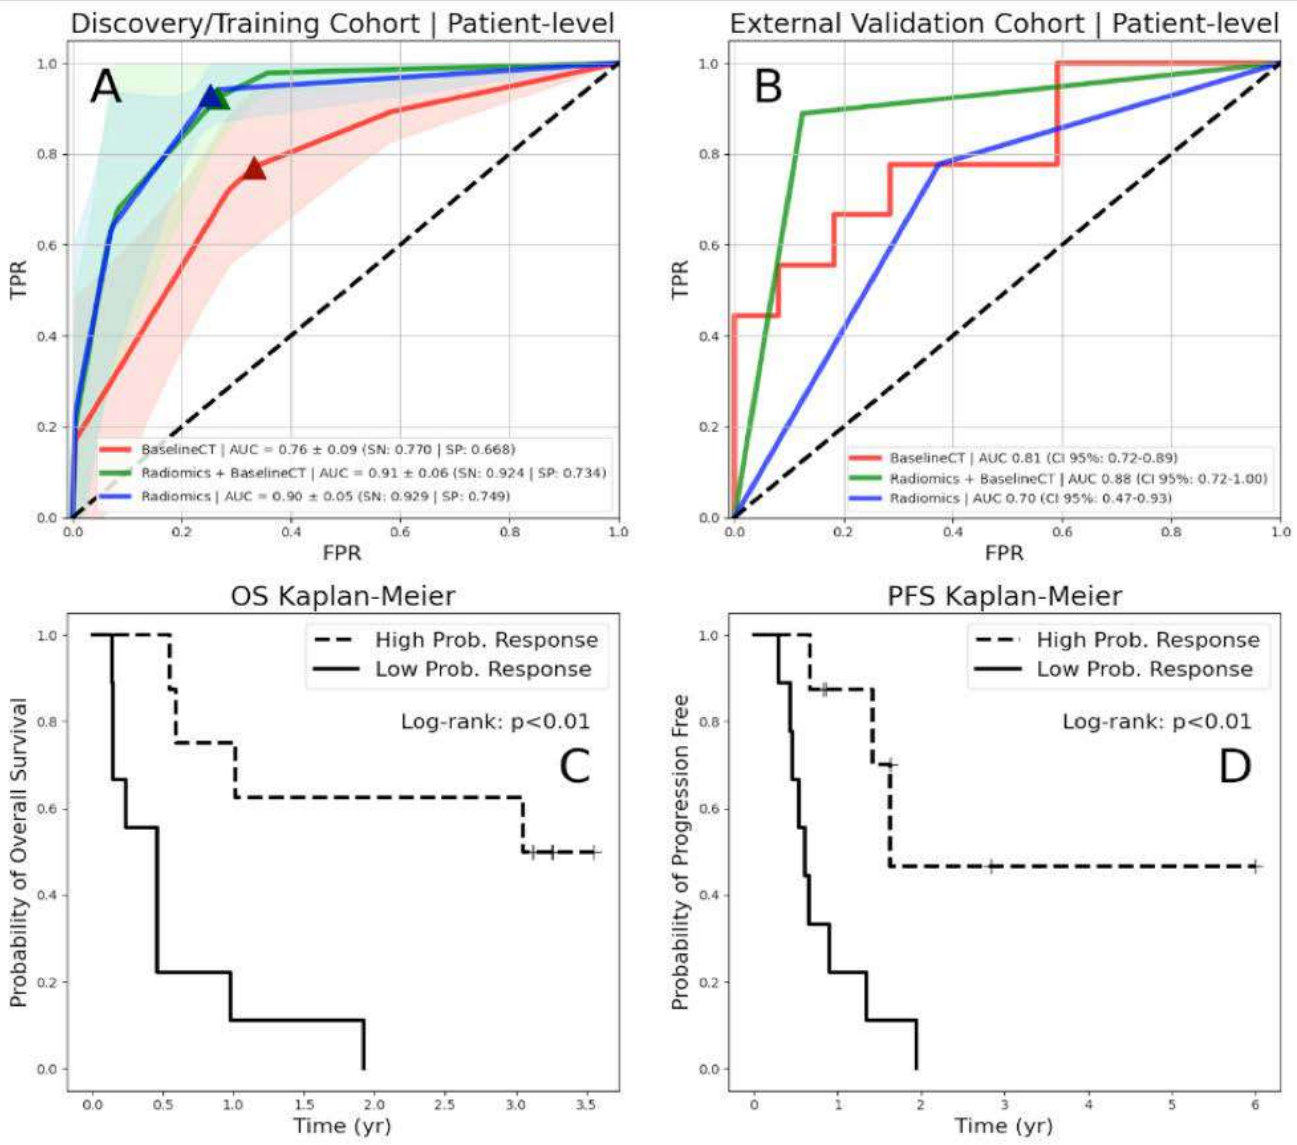

Figure 1: (Color) 5-fold cross validated LR models performance trained with 3 discrete feature sets (up-to 8 features): clinical and demographic features (red), radiomic CT features (blue), and a combination of clinical and demographic features (green). A: ROC curve showing cross validation performance on the Discovery/Training cohort of patients. Optimal prediction thresholds are determined to be the Youden-J threshold (triangle marker) with sensitivities and specificities (SN; SP) are indicated at the optimal threshold in the plot legend. B: ROC curve showing LR model prediction performance on an external validation cohort of patients. One can observe that the addition of clinical/demographic features to complimentary radiomic features increased model generalizability on an external cohort. C and D: Overall survival Kaplan-Meier plot indicating the LR model separation between high and low probability of response for both Overall Survival (OS) and Progression Free Survival (PFS) for the external validation cohort as predicted by the combination LR model (green) in subplot B.

Introduction: Treatment options are limited for patients with extensive stage small cell lung cancer (ES-SCLC) that progresses after platinum-based chemotherapy (chemo) and anti-programmed death ligand 1 (PD-L1) therapy. Sacituzumab govitecan (SG), a Trop-2-directed antibody-drug conjugate, is being evaluated in patients with metastatic or locally advanced solid tumors in TROPiCS-03 (NCT03964727), an open-label, multicohort, phase 2 trial. In a preliminary analysis of the ES-SCLC cohort (N=30), SG demonstrated promising antitumor activity and manageable safety (Dowlati et al, ESMO 2023). Here, we report updated results with additional patients and longer follow-up from the ES-SCLC cohort.

Methods: Adult patients with ES-SCLC that progressed after no more than 1 prior line of platinum-based chemo and anti-PD-(L)1 therapy received SG 10 mg/kg on days 1 and 8 of a 21-day cycle. The primary endpoint was objective response rate (ORR) by investigator assessment per RECIST v1.1. Secondary endpoints included clinical benefit rate (CBR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety.

Results: As of March 8, 2024, 43 patients were enrolled, and the median follow-up was 12.3 months (range, 8.1-20.1). Median age was 67 years (range, 48-83) and 81.4% of patients had an ECOG performance status of 1. Of the 43 patients, 20 (46.5%) patients had platinum-resistant disease (chemo-free interval <90 days). Treatment was ongoing for 7 (16.3%) patients. In the efficacy analysis (n=43), ORR was 41.9% and CBR was 48.8% (Table). The median DOR was 4.73 months (95% CI, 3.52-6.70), median PFS was 4.40 months (95% CI, 3.81-6.11), and median OS was 13.60 months (95% CI, 6.57-14.78). ORRs were 35.0% and 47.8% in platinum-resistant and -sensitive patients, respectively. In the safety analysis (n=43), any-grade treatment-emergent, treatment-related adverse events (TE TRAEs) occurred in 97.7% (grade ≥3, 60.5%) of patients. There were no TE TRAEs leading to discontinuation of study treatment. There was 1 TE TRAE that led to death (neutropenic sepsis).

Conclusions: SG as second-line treatment for ES-SCLC demonstrated promising antitumor activity in the fully enrolled ES-SCLC cohort. This activity was seen in patients with both platinum-resistant and -sensitive disease. Safety was manageable and consistent with that observed in other SG studies.

Introduction: SHR-A1921 is a novel ADC composed of a humanized anti-TROP-2 IgG1 monoclonal antibody attached to a DNA topoisomerase I inhibitor via a tetrapeptide-based cleavable linker. Here, we report the clinical activity and safety of SHR-A1921 in pts with pretreated extensive-stage SCLC, a condition with a poor prognosis and limited therapeutic options.

Methods: This was a first-in-human, dose-escalation, dose-expansion, and efficacy-expansion phase 1 study (NCT05154604). In SCLC expansion cohort, pts with extensive-stage disease who had relapsed to/refractory from platinum-based chemotherapy, regardless of TROP-2 expression level, were enrolled to receive SHR-A1921 at selected dose of 3.0 mg/kg every 3 weeks until disease progression or unacceptable toxicity.

Results: As of Feb 19, 2024, 17 pts were enrolled, among whom, 6 (35.3%) were still on treatment. At the study entry, 52.9% of pts had received ≥2 prior lines of therapy. 64.7% of pts had been treated with anti-PD-1/PD-L1 antibodies and 11.8% had been treated with DNA topoisomerase I inhibitors. TROP-2 expression was detectable in 16 pts, and all showed a low level with an H-Score of 0-50. Median follow-up was 5.3 months (range 1.3-9.4). Among the 15 pts evaluable for tumor response, ORR was 33.3% (95% CI 15.2-58.3), DCR was 66.7% (95% CI 41.7-84.8), and median DoR was 4.4 months (95% CI 2.3-not reached [NR]). Among all pts, median PFS was 3.8 months (95% CI 1.4-NR), and median OS was not reached. All pts experienced treatment-related adverse events (TRAEs), and the most common TRAEs included stomatitis (58.8%), nausea (35.3%), vomiting (23.5%), decreased appetite (23.5%), and anemia (23.5%). 6 pts (35.3%) experienced grade ≥3 TRAEs, with the most common being stomatitis (11.8%). No treatment-related interstitial lung disease/pneumonitis occurred. No TRAEs led to treatment discontinuation or death.

Conclusions: SHR-A1921 showed promising clinical efficacy and a manageable safety profile in pts with heavily pretreated extensive-stage SCLC, even with low TROP-2 expression.

Introduction: ARTEMIS-001 study is a multicenter, open-label phase 1 study investigating the safety and efficacy of HS-20093 (GSK5764227), an antibody-drug conjugate targeting B7-H3, in advanced solid tumors (NCT05276609). Promising antitumor activity was observed across multiple tumor types, particularly in extensive stage small cell lung cancer (ES-SCLC) during the dose-escalation phase of the study (Jie Wang et al., JCO, 2023). Here, we present the latest efficacy and safety results of HS-20093 in ES-SCLC patients (pts) from both the dose-escalation and dose-expansion phases.

Methods: The study is currently at the dose-expansion phase and included 4 cohorts of pts with diverse advanced solid tumors. Within ES-SCLC cohort, pts received HS-20093 at 8.0 mg/kg or 10.0 mg/kg dose every 3 weeks until disease progression. All pts had previously undergone platinum-based standard therapy. Efficacy endpoints were objective response rate (ORR), disease control rate (DCR), duration of response (DoR), progression free survival (PFS) and overall survival (OS). B7-H3 expression in tumor tissue was analyzed retrospectively.

Results: Fifty-six pts received ≥1 dose of HS-20093 at 8.0 mg/kg (N = 31) or 10.0 mg/kg (N = 25). All pts received platinum plus etoposide, 73.2% received immunotherapy (IO), and 23.2% received topoisomerase 1 inhibitor (TOPO1i). Out of 56 pts, 53 pts were evaluable for efficacy (8.0 mg/kg: 31 pts; 10.0 mg/kg: 22 pts). The median follow-up duration was 9.0 and 11.1 months for pts at 8.0 and 10.0 mg/kg dose, respectively (as of 30 Jun 2024). HS-20093 showed encouraging efficacy in ES-SCLC. ORR was 61.3% for pts at 8.0 mg/kg dose and 50.0% for pts at 10.0 mg/kg dose. DCR, median DoR, median PFS for pts at 8.0 and 10.0 mg/kg dose were 80.6% and 95.5%, 6.4 and 8.9 months, 5.9 and 7.3 months, respectively. Median OS was 9.8 months for pts at 8.0 mg/kg dose and not reached for pts at 10.0 mg/kg dose. The ORR in 32 pts who were previously exposed to IO plus platinum but were TOP1i naive was 75.0% and 66.7% at 8.0 and 10.0 mg/kg dose, respectively. No correlation was observed between B7-H3 expression level and tumor objective response to treatment; however, the pts with B7-H3 IHC expression (≥1%) demonstrated a trendency toward prolonged median PFS. Safety profile was consistent with previous reports. Grade ≥3 treatment-related adverse events (with incidence ≥10%) were neutrophil count decreased (39.3%), white blood cell count decreased (33.9%), lymphocyte count decreased (25.0%), platelet count decreased (17.9%), and anaemia (16.1%).

Conclusions: HS-20093 demonstrated encouraging antitumor activity and manageable safety in pts with previously-treated ES-SCLC. A phase 3 study is currently ongoing in China to compare the efficacy and safety of HS-20093 with standard-of-care chemotherapy in pts with relapsed SCLC (NCT06498479). The clinical development program of HS-20093 is planned to be expanded into US, EU, and rest of the world.

OA05.03 Ablation to Oligo-Residual Sites Plus ICIs Improved Survival of Patients with Advanced NSCLC: Preliminary Results of a Prospective Phase II Trial

S. Yang, B. Chen, J. Yu, X. Liu, T. Jiang, F. Wu, A. Li, G. Gao, X. Chen, S. Ren, Tongji University Affiliated Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Local ablative treatments have been validated to prolong the survival benefit of TKIs in patients with oncogenic mutations. Whether ablation improves the survival benefit of ICIs remains unclear. Herein, we initiated a controlled randomized phase II trial to evaluate the impact of ablation to oligo-residual disease on the survival benefit of ICIs in patients with advanced NSCLC.

Methods: Patients achieved oligo-residual disease on ICIs those met inclusion criteria were recruited and randomized to two cohorts with ratio as 2:1, either with ablation (Arm A) or without ablation (Arm B) both with continued ICIs. Survival benefit of ICIs and adverse effects were captured and analyzed (ChiCTR2000032479).

Results: From August 1st 2020 to March 15th 2024, 152 out of 618 patients received ICIs (with or without chemotherapy) as first line treatment achieved oligo-residual disease were screened. Finally, 62 patients met inclusion criteria but not exclusion criteria were enrolled for analyses. Among them, 42 patients were randomized to Arm A, and 20 patients randomized to Arm B with 8 patients received ablation after progressed on ICIs. Clinicopathological characteristics were comparable in two cohorts (Table 1). Patients received ablation showed significantly improved median PFS (26.7 vs. 11.7 months, p<0.001) and OS of ICIs (NA vs. 32.8 months, p=0.012) than patients without ablation (Figure B, C). Multivariate cox regression analysis further demonstrated that ablation significantly associated with improved PFS (HR=0.161, 95%CI 0.07-0.39, p<0.001) (Figure A) and OS (HR=0.215, 95%CI 0.05-11.74, p=0.033). Subgroup analysis unveiled that cryoablation (n=13) plus ICIs yielded prolonged PFS than those with thermal ablation (n=29) (34.9 vs. 22.4 months, p=0.048) and with a trend towards prolonged OS (p=0.241).

Conclusions: Ablation significantly improved the survival benefit of ICIs in patients with advanced NSCLC. Subgroup analysis further demonstrated cryoablation combined with ICIs associated with superior benefit to thermal ablation with ICIs.

SUNDAY, SEPTEMBER 8, 2024 - 14:00 - 15:15

OA05.04 Radiotherapy Improves Survival in Non-Small Cell Lung Cancer Following Oligoprogression on Immunotherapy: A Cohort Study

L.J. Brown[1,2,3,4], J. Ahn[1], B. Gao[1,2,3], H. Gee[1,4,5], A. Nagrial[1,2,3], I.E.D.P. Da Silva[2,3,6], E. Hau[1,2,3,4], [1]Westmead Hospital, Westmead/AU,[2]Blacktown Hospital, Blacktown/AU, [3]University of Sydney, Camperdown/AU,[4]Westmead Institute for Medical Research, Westmead/AU,[5]Children's Medical Research Institute, Westmead/AU, [6]Melanoma Institute Australia, Wollstonecraft/AU

Introduction: The patterns of oligoprogression following first-line immune checkpoint inhibitors (ICI's) for metastatic NSCLC are yet to be well established. There is increasing data to suggest directed radiotherapy improves survival outcomes.

Methods: A retrospective cohort study of patients with metastatic NSCLC who had progressed following first-line PD-(L)1 inhibitors +/- chemotherapy at two high-volume cancer centres was performed. We sought to characterise the frequency and location of oligoprogression and determine the overall survival (OS) following radiotherapy in this population.

Results: One-hundred and fifty-nine patients were included in the study. At first progression, 62 (39.0%) were classified as oligoprogression. Multivariate analysis confirmed the presence of brain metastases was associated with increased likelihood of oligoprogression (OR 2.44; p=0.04) and the presence of liver metastases was associated with decreased likelihood of oligoprogression (OR 0.17; p<0.01). For patients with oligoprogression, those who received radiotherapy had a longer median PFS2 (17 vs. 11.5 months; HR 0.51; p=0.02) and a longer median OS (23 vs. 13 months; HR 0.40; p<0.001) compared to those who did not receive radiotherapy.

Conclusions: In patients with oligoprogressive metastatic NSCLC following treatment with first-line ICI's, radiotherapy significantly improves OS and PFS2 outcomes. Patients with baseline brain metastases are more likely to experience oligoprogression. Further prospective studies in directed, less heterogenous populations of patients with metastatic NSCLC will be fundamental to optimise management.

OA05.05 Pre-Local Consolidative Therapy Circulating Circulating Tumor DNA Defines Molecular Oligometastatic Non-Small Cell Lung Cancer

R. Fu[1], Y. Xiong[2], M. Cai[2], R-R. Chen[2], Y-L. Wu[1], W-Z. Zhong[1], [1]Guangdong Provincial People's Hospital, Guangzhou/CN ,[2]Geneplus-Beijing, Beijing/CN

Introduction: Previous studies have proven that local consolidative therapy (LCT) could prolong survival in induced oligometastatic NSCLC, however, the clinical benefit varies widely and the therapeutic window for LCT remains unclear. We propose that ctDNA can molecularly redefine populations with induced oligometastatic disease and guide LCT timing selection.

Methods: In this observational study, we enrolled patients with advanced NSCLC who developed oligometastatic disease following systemic therapy (referred to as induced oligometastatic NSCLC). Oligometastasis was diagnosed based on radiological findings, following the guidelines of the ESRO consensus1 and pan-European multidisciplinary consensus2. Patients underwent resection and radiotherapy targeting residual lesions after multidisciplinary team discussion. Comprehensive ctDNA monitoring was conducted perioperatively using a highly sensitive panel assay targeting 338 lung cancer-related genes.

Results: A total of 339 plasma samples from 68 eligible patients were analyzed, predominantly with adenocarcinoma (n=63, 92.6%) and oligopersistence (n=58, 85.3%). We propose that patients who meet radiological oligometastatic criteria and have negative plasma ctDNA before LCT should be defined as Molecular Oligometastatic (MO) NSCLC, whereas those with positive ctDNA before LCT should be defined as non-Molecular Oligometastatic (non-MO) NSCLC. Patients with MO NSCLC had better progression-free survival (PFS) compared to those with non-MO disease (p=0.004, HR=3.05, 95% CI=1.16-8.05). Furthermore, regarding the timing of LCT, a longer duration of systemic therapy was associated with better PFS (p<0.05), and among patients with the same duration of drug treatment, patients with MO had longer PFS compared to those with non-MO (p<0.05). We also found that patients who maintained or transitioned to negative ctDNA 1 month after LCT had a higher proportion achieving PFS greater than the median PFS reported in corresponding phase III trials of the respective drugs when compared to those who maintained or transitioned to positive (p<0.05). Of note, resistance mutations were found in the post-LCT ctDNA of 11 patients, 10 of whom experienced disease progression. Moreover, post-LCT ctDNA monitoring revealed potential drug resistance mechanisms up to 14.9 months before radiological progression, with a median lead time of 5.0 months. It allows for immediate modification of treatment regimens based on ctDNA results when there is radiological progression.

Conclusions: Undetectable pre-LCT ctDNA may be truly induced oligometastatic disease, which we define as Molecular Oligometastatic NSCLC. The combination of pre-LCT ctDNA and the duration of systemic therapy assists in the early prediction of clinical outcomes and the determination of the LCT window in induced oligometastatic NSCLC.

OA05.06 Radiotherapy Combined with Enhanced Immunotherapy for NSCLC

C. Miao[1], S. Yuan[2], [1]山东第一医科大学附属癌症医院, 济南/CN,[2]Provincial Hospital Affiliated to University of Science and Technology of China, Hefei/CN

Introduction: Patients with driver gene-negative advanced non-small cell lung cancer (NSCLC) commonly face issues of treatment resistance after first-line therapies, making the exploration of strategies to improve the survival quality of these patients of significant clinical importance. This study aims to evaluate the efficacy and safety of pulsed high-dose fractionated radiotherapy combined with granulocyte-macrophage colony-stimulating factor (GM-CSF) and tislelizumab in treating patients with driver gene-negative Stage IV NSCLC.

Methods: This is a single-arm, single-center, prospective Phase II clinical study. From March 2022 to December 2023, patients with histologically or cytologically confirmed Stage IV NSCLC (excluding those with driver mutations) after treatment were screened and enrolled. The treatment regimen included localized radiotherapy (5-6Gy × 3-10 fractions), tislelizumab (200 mg, starting within a week after radiotherapy, then every 3 weeks), and GM-CSF (starting the second day after radiotherapy, subcutaneous injection of 200ug per dose, for 14 consecutive days). The primary endpoints were to assess the Objective Response Rate (ORR) and Disease Control Rate (DCR), with secondary endpoints including Progression-Free Survival (PFS), Overall Survival (OS), safety, and tolerability.

Results: As of December 1, 2023, 15 patients with treated advanced NSCLC were enrolled, including 8 cases of adenocarcinoma and 7 of squamous cell carcinoma. The observed local ORR was 80.0% (95% Confidence Interval: 54.8%-92.9%), and DCR reached 100.0% (95% Confidence Interval: 79.6%-100.0%), showing statistically significant differences compared to historical data of second-line treatments. Median PFS and OS have not yet been reached. Regarding safety, no Grade 3 or higher treatment-related adverse events (TRAEs) or immune-related adverse events were observed.

Conclusions: The results of this study demonstrate that for patients with driver gene-negative Stage IV NSCLC, pulsed high-dose fractionated radiotherapy combined with GM-CSF and tislelizumab as a second-line treatment regimen showed promising efficacy and controllable safety. This finding highlights the potential value of this treatment strategy and lays the groundwork for further research.

Wu[1], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Blacktown Cancer and Haematology Centre, Blacktown/AU ,[3]Fudan University Affiliated Zhongshan Hospital, Shanghai/CN ,[4]Beijing Cancer Hospital, Beijing/CN ,[5]Peking Union Medical Hospital, Beijing/CN ,[6]The Ohio State University College of Medicine, Columbus/OH/USA ,[7]The First Affiliated Hospital of Nanchang University, Nanchang/CN ,[8]Xinjiang Cancer Hospital, Urumqi/CN ,[9]The First Affiliated Hospital of Zhengzhou University, Zhengzhou/CN ,[10]Shandong Cancer Hospital, Jinan/CN ,[11]Pindara Private Hospital, Benowa/AU ,[12]Cancer Research South Australia, Adelaide/AU ,[13]BeiGene (Beijing) Co., Ltd., Beijing/CN

Introduction: There are limited treatment options for patients with advanced NSCLC who were previously treated with chemotherapy and/or anti-programmed cell death protein1 (PD1)/-programmed deathligand 1 (PD-L1) antibodies. Tislelizumab (TIS) is an anti-PD1 antibody. Sitravatinib (sitra) is a receptor tyrosine kinase inhibitor that can shift the immunosuppressive tumor microenvironment toward an immunostimulatory state. Combining sitravatinib with tislelizumab may potentially overcome initial checkpoint inhibitor resistance. We present efficacy/safety results from an openlabel, randomized, phase 3 trial evaluating TIS plus sitra versus docetaxel (doc) in patients with previously treated locally advanced/metastatic NSCLC (NCT04921358).

Methods: Adults (≥18 years) with unresectable locally advanced/metastatic histologically or cytologically confirmed NSCLC (ECOG PS ≤1), who were previously treated with ≤2 lines of systemic chemotherapy and anti-PD(L)1 antibodies were eligible. Patients were randomized (1:1) to TIS 200 mg intravenously once every 3 weeks (Q3W) in combination with sitra 100 mg orally once daily (TIS+sitra) or doc 75 mg/m2 intravenously Q3W. Patients were treated until disease progression, intolerable toxicity, death, or consent withdrawal. Co-primary endpoints were overall survival (OS) and independent-review committee (IRC)assessed progressionfree survival (PFS). Secondary endpoints included IRCassessed objective response rate (ORR) by RECIST v1.1 and treatmentemergent adverse events (TEAEs).

Results: As of Dec 20, 2023, 187 and 190 patients were randomized to TIS+sitra and doc, respectively (median age [TIS+sitra/doc]: 63.0/63.0 years; median followup: 8.0/7.6 months). Most patients (TIS+sitra/doc) were male (81.8%/79.5%), Asian (93.6%/93.2%), had an ECOG PS 1 (74.9%/75.8%), had received 1 line of prior chemotherapy (75.9%/73.7%), and had metastatic disease (77.0%/74.2%). Median OS (95% confidence interval [CI]) was 11.5 (9.4-14.6) and 11.4 (9.9-15.0) months with TIS+sitra and doc, respectively; hazard ratio (HR) (95% CI), 1.02 (0.75-1.39). Median IRCassessed PFS (95% CI) was 4.4 (4.0-5.7) (TIS+sitra) and 2.9 (2.6-4.2) months (doc); HR (95% CI): 0.82 (0.62-1.07). IRCassessed ORR (95% CI) was 12.3% (8.0%-17.9%) (TIS+sitra) and 12.6% (8.3%-18.2%) (doc). The incidences of TEAEs was higher with TIS+sitra than doc (Table). Grade ≥3 TEAEs occurring in ≥5% of TIS+sitra or doc groups were (TIS+sitra/doc): hypertension (13.4%/1.1%), pneumonia (9.1%/8.5%), palmarplantar erythrodysesthesia syndrome (6.5%/0%), hypokalemia (5.4%/2.3%), white blood cell count decreased (0%/29.4%), neutrophil count decreased (0.5%/28.8%), neutropenia (0.5%/7.3%), and febrile neutropenia (0%/5.6%). The trial was terminated due to safety risks/unfavorable benefit-risk analysis.

Conclusions: In patients with previously treated advanced/metastatic NSCLC, TIS+sitra showed similar efficacy to doc and was associated with a higher incidence of TEAEs.

OA06.04 Phase II Study of Pembrolizumab and Itacitinib for Patients with Metastatic NSCLC Expressing PD-L1: Long-Term Follow up

M.E. Marmarelis[1], D.J. Cantor[2], D. Mathew[2], T. McWilliams[2], J. Bauml[3], W-T. Hwang[4], A. Singh[4], C. D'Avella[4], C. Davis[4], D. Ye[4], L. Sun[4], C. Ciunci[4], C. Aggarwal[4], R.B. Cohen[4], A. Minn[4], J. Wherry[4], C.J. Langer[4], [1]University of Pennyslvania, Philadelphia/PA/USA ,[2]University of Pennsylvania, Philadelphia, PA/PA/USA ,[3]Janssen, Philadelphia/PA/USA ,[4]University of Pennsylvania, Philadelphia/PA/USA

Introduction: Adaptive resistance to immunotherapy in metastatic non-small cell lung cancer (mNSCLC) remains a challenge. Preclinical work suggests that constitutive interferon signaling promotes resistance to immune checkpoint blockade and blocking JAK1/2 later during the course of immunotherapy can reverse this resistance. We present long-term follow up of a phase II clinical trial of pembrolizumab and 6 weeks of itacitinib (INCB039110; JAK1 inhibitor) as first-line therapy in mNSCLC patients (pts) with PDL1 expression ≥50% (NCT03425006).

Methods: Treatment-naïve pts with mNSCLC and ECOG PS 0-1 received pembrolizumab (200mg IV every 21 days). Itacitinib 200mg daily po was started on Cycle 3 Day 1 of pembrolizumab and continued for 6 weeks. Overall response rate (ORR) and best overall response (BOR) were determined by RECIST 1.1. Progression free survival (PFS), and overall survival (OS) were determined using Kaplan Meier methodology. Patients were categorized as having a response to pembrolizumab if their 6-week scan showed a PR/CR by RECIST 1.1 or as response to pembrolizumab + itacitinib if their 12-week (but not 6-week) scan showed a PR. Data cut-off for long-term follow up was December 1, 2023.

Results: Of 31 patients screened, 23 were enrolled between 10/16/2018 and 3/4/2021 and received at least 1 cycle of pembrolizumab: 56.5% female, median age 62 years (range, 41-78), 87% with smoking history, 78% adenocarcinoma, 22% squamous, 9/23 with PD-L1 ≥90%. 20 patients completed 12 weeks of treatment, 3 patients stopped the trial due to pembrolizumab toxicity (1), CNS progression after pembrolizumab (1) and patient decision (1). At 12 weeks ORR was 62% (13 partial response (PR), 6 stable disease (SD), 2 progressive disease (PD)). Best overall response was 66.7% (2 complete response (CR), 12 PR, 6 SD, 1 PD). Median PFS was 12.7 months (95% CI 4.82 - NA) and median OS was 53.4 months (95% CI 27.2 - NA). There was no difference in median PFS or OS between PDL1 50-89% and ≥90% groups. Figure 1 shows change in tumor burden over time in relation to study drug administration.

Conclusions: Treatment-naïve pts with mNSCLC and PD-L1 expression ≥50% treated with pembrolizumab and a brief course of JAK inhibition achieved an ORR of 62% at 12 weeks and improvement in mPFS and mOS compared to historical controls (Keynote 24: mPFS 10.3 mo, mOS 30 mo). Interferon signaling modulation through JAK1 inhibition may help prevent resistance to anti-PD1 therapy and should be studied further in a randomized trial.

OA06 NOVEL IMMUNOTHERAPY STRATEGIES AND COMBINATIONS
SUNDAY, SEPTEMBER 8, 2024 - 15:30 - 16:45

OA06.05 IL15 Superagonist (N-803, Anktiva) + Checkpoint Inhibitor (CPI) Prolongs OS in 2ndline or Greater NSCLC Patients Failing CPI

J. Wrangle[1], S. Reddy[2], P. Soon-Shiong[3], [1]MUSC, Charleston/SC/USA, [2]ImmunityBio,Los Alamitos/CA/USA ,[3]ImmunityBio, El Segundo/CA/USA

Introduction: A majority of NSCLC patients experience progression following CPI, with real-world data OS of 7 to 10 months. Current NCCN guidelines state that CPI is not recommended in NSCL patients after failure of CPI. In these patients with CPI resistance, tumor evasion occurs through MCH-1 loss. Anktiva, a novel IL-15/IL-15 Receptor Alpha complexed protein rescues checkpoint activity through activation of NK cells with induction of CD4+, CD8+ and memory T cells in 2nd line or greater NSCLC patients who failed CPI. QUILT 3.055, a phase 2b study of Anktiva in combination with CPI (nivolumab or pembrolizumab) in multiple tumor types including NSCLC who failed CPI.

Methods: We present mature OS data, based on 16.3 month mean follow-up of 86 patients with 2nd and 3rd line+ NSCLC previously treated and failed CPI alone or failed CPI combination with chemotherapy as their most recent prior therapy. Trial inclusion required investigator assessed progression on their last line of therapy for study entry. Patients received Anktiva 15mcg/kg SC every 3 weeks in combination with the same checkpoint inhibitor with which they had their most recent progression.

Results: The median OS (n=86) was 14.1 months (95% CI 11.7, 17.4) with 24 ongoing survival to date. In 3rd line+ve (n=25) median OS was 14.8 months (95% CI 9.1, 26.7). OS for PDL1+ve (>1%) (N=53) was 13.8 months (95% CI 10.2, 17.4) versus PDL1-ve (N=33) of 15.4 months (95% CI 11.5, 23.6). In 2nd line (n=61) there was no difference in OS between PDL1+ve and PDL1-ve with OS of 13.8 months versus 13.3 months respectively. The most common any grade AEs were injection site reaction 78 (91%), fatigue 46 (53%), chills 36 (42%) with 11 patients (13%) study drug discontinuation due to AEs. Grade 3+ AEs were seen in 35 (41%), no individual AE category was greater than 10%. The KM curve demonstrates long-term survival at ≥18 and ≥21 months of 28/86 (33%) and 26/86 (30%) patients respectively:

Conclusions: Anktiva plus CPI therapy in 2nd line or greater NSCLC demonstrated long-term median OS, independent of PDL1 status, and independent of prior lines of therapy in patients with acquired resistance to CPI. These findings support the novel mechanism of action of Anktiva to rescue CPI activity through the activation of NK and T cells, driving long-term memory, with median OS ongoing survival of 33% and 30% at 18 and 21 months respectively, exceeding the standard of care.

OA07 OPPORTUNITIES FOR OPTIMIZING SUPPORTIVE CARE
SUNDAY, SEPTEMBER 8, 2024 - 15:30 - 16:45

OA07.03 The Effect of Personalized Music Therapy on Perioperative Pain and Anxiety in NSCLC Patients

Y. Yuan[1], Y. Ku[1], W. Huang[2], M. Zheng[1], Y. Zhou[2], Y. Lin[2], R. Te[2], H. Zhou[2], J. Zhao[1], W. Lin[1], Q. Chen[1], B. Rao[2], S. Feng[2], J. Zhong[2], L. Kang[2], H. Long[2], [1]Sun Yat-sen University, Guangzhou/CN ,[2]Sun Yat-sen University Cancer Center, Guangzhou/CN

Introduction: Music therapy, with its advantages of high safety and absence of side effects, has gradually been accepted and applied in medical practice to alleviate patients' negative emotions and feelings. However, there is a lack of in-depth empirical research on the specific impact of music therapy on perioperative anxiety in patients with non-small-cell lung cancer.

Methods: We conducted a single-center, double-arm, open-label, phase 2 trial and randomly assigned patients with stage I or II NSCLC to receive personalized music therapy plus patient-controlled analgesia (PCA) pump (experimental group) or PCA pump alone (control group). Personalized music library was selected by music therapists based on psychosocial evaluation. The timetable of music therapy included: 40 minutes before surgery, during the surgery and 10 a.m./15 p.m./20 p.m. in three days after surgery. The primary end point was visual analogue scale of anxiety (VAS-A). Secondary end points included visual analogue scale of pain (VAS-P), dosage of analgesics and frontal middle theta power (Fmθ).

Results: A total of 45 patients underwent randomization; 30 were assigned to the experimental group and 15 were assigned to the control group. The experimental group showed significantly lower levels of VAS-A and VAS-P at each time point before and after surgery (P<0.01). We also observed a complete mediating role in the effect of music therapy on postoperative dyspnea symptom, with an effect size of 31.23% (Figure 1) and the score of dyspnea was consequently lower in experimental group at each observation time point (P<0.05), assessed by quality of life questionnaire. The electroencephalograph showed an increase in Fmθ power in the experimental group, while remained relatively stable in control group (P<0.05). The dosage of analgesics between two groups hadn't reached statistical difference.

Conclusions: Personalized music therapy significantly alleviating preoperative and postoperative anxiety and improving postoperative respiratory difficulty symptoms. Additionally, we found that the effect of music therapy in reducing dyspnea symptom appears to be achieved through the reduction of anxiety levels. Combining the changes in anxiety levels and Fmθ power before and after the intervention, we speculate that the mechanism by which music therapy improves anxiety may be related to eliciting positive emotions and shifting attention.

OA07.04 Optimising Care of Older Patients with Lung Cancer - An Innovative Nurse-led Model of Care

S. Vinod[1,2,3], N. Knox[3], K. Knight[1], V. Bray[1,4], A. Khoo[5], E. Tcharkhedian[1], J. Campisi[1], P. Dufton[6], G. McErlean[3,7], M. Agar[1,8], L. Hickman[3], [1]Liverpool Hospital, Liverpool/AU,[2]University of New South Wales, Liverpool/AU,[3]University of Wollongong, Wollongong/AU,[4]Western Sydney University, Liverpool/AU,[5]Brellah Medical Group, Sydney/AU,[6]University of Melbourne, Melbourne/AU,[7]St George Hospital, Kogarah/AU,[8]University of Technology Sydney, Sydney/AU

Introduction: Despite being recommended by many international organisations, geriatric screening and comprehensive assessment of older patients with lung cancer has not been adopted routinely. Given the median age of patients diagnosed with lung cancer is 70 years and many have comorbidities, there is a clear need for holistic patient assessment to inform management for this vulnerable group. We previously implemented a medical-led geriatric oncology model of care (ML-GOMOC). Although 85% of patients were screened, only 59% of eligible patients underwent comprehensive geriatric assessment and only 65% of patients were assessed prior to treatment. The ML-GOMOC did not meet the pre-defined criteria for feasibility or acceptability, hence there was an impetus to investigate a new model of care. The aim of this study was to develop, implement and evaluate a nurse-led geriatric oncology model of care (NL-GOMOC).

Methods: A NL-GOMOC was co-designed with key stakeholders including consumers. This involved a nurse using validated tools to screen and assess all new patients with lung cancer aged 65y+ or 50y+ for Aboriginal and Torres Strait Islander peoples. Tools included the Hospital and Anxiety Depression Scale, Geriatric Depression Scale and QLC-C30. Assessments included a Timed-Up-and-Go, miniCOG assessment, postural blood pressure and baseline blood tests. Clinical pathways of care were developed based on the assessments including nursing referrals to allied health and specific triggers for a comprehensive assessment at a multidisciplinary aged care clinic. Patients were subsequently discussed at a weekly multidisciplinary team meeting with clinicians and allied health to finalise management. The nurse conducted a follow-up phone call at 4-6 weeks post-review to assess if recommendations were being implemented.

Results: From June-December 2023, 102 patients were screened of whom 65 met eligibility criteria. 58 (89%) patients were assessed. Median age was 73y (range 65-86y). Twenty-eight patients (48%) were seen on the day of oncology appointment. Of the 53 patients who had treatment, 44 (83%) were seen prior to, 4 (8%) were seen on the day of and 5 (9%) were seen after commencement of treatment. The assessment identified polypharmacy in 26 (45%), cognitive deficits in 11 (19%) and postural hypotension in 2 (3%). Abnormal scores suggested depression in 9/57 (16%) and anxiety in 5/50 (10%) of patients. Referrals were made to dietitian (34, 59%), social work (26, 45%), occupational therapy (21, 36%), physiotherapy (20, 34%), speech pathology (5,9%) and clinical psychology (2, 3%). Six (10%) were referred via their general practitioner to a geriatrician for comprehensive geriatric assessment. All patients were discussed at the multidisciplinary team meeting and all had a follow-up phone call. High levels of satisfaction with NL-GOMOC were near ubiquitous at 98% (49/50) of surveyed patients.

Conclusions: Implementation of a NL-GOMOC for older patients with lung cancer increased the proportion of patients undergoing geriatric screening and assessment, when compared to the previous ML-GOMOC. Innovative models of care improve the uptake of evidence-based care for older people with cancer. Further assessment of NL-GOMOC including acceptability, feasibility and costing will be conducted at 12 months post-implementation.

Introduction: Patients with non-small cell lung cancer (NSCLC) have considerable needs for supportive care, social work and health maintenance before and during treatment. However, these needs are often difficult to identify and address given the complexity of NSCLC care. We implemented 4R Oncology model at 8 centers (4 community, 3 academic, 1 VA) and evaluated its impact on referrals to and receipt of supportive and social care in NSCLC. 4R (Right Info/Care/Patient/Time) facilitates timely delivery of comprehensive care and patient engagement in care with the use of patient and care team-facing care plans called 4R Care Sequences (see Exhibit for an example). Care Sequences encompass guideline-based direct cancer care, supportive care, social work and health maintenance in one concise care plan.

Methods: We compared 7 supportive and social care delivery metrics between the cohort of patients who received 4R (4R cohort, N=61) with the historical control cohort of patients who received care pre-4R implementation at the 8 participating centers (Control cohort, N=112). Each type of care was assessed for two aspects: whether a patient was referred to this care, and whether the referred patient received this care, i.e., completed the referral.

Results: We significantly improved referral rates for all 7 metrics (Table). All referral completion metrics improved numerically and 2 significantly (Table).

Conclusions: Patients who received 4R Care Sequences had markedly improved referrals to and receipt of supportive and social care. There is room to improve all of these metrics, and we continue refining the 4R Oncology model to support patients in completing referrals and in utilizing self-management resources.

Referral and completion of referrals to guideline-recommended care

Metric	NCCN Guideline	% of Patients referred to this care		Pvalue	% of referred patients who completed referrals (obtained this care		Pvalue

Introduction: Cisplatin-based chemotherapy is still back-bone of treatment for advanced non-small cell lung cancer. Co-administration of multiple antiemetics that inhibit several molecular pathways involved in emesis is required to optimize control of cisplatin-based highly emetogenic chemotherapy-induced nausea and vomiting (HEC-CINV). HR20013 is a mixed formulation of HRS5580 (a novel NK-1 receptor inhibitor) and palonosetron (PALO) for intravenous (IV) infusion, which simultaneously inhibit NK-1 and 5-HT3 pathways. The study (NCT05509634) aimed to assess HR20013 versus fosaprepitant (FAPR) plus PALO (FAPR+PALO) regimen in preventing cisplatin-based HEC-CINV.

Methods: This multicenter, randomized, double-blind, double-dummy, positive-controlled, phase 3 trial compared HR20013 (N=373; IV, D1) with FAPR+PALO (N=377; IV, D1) in chemo-naïve patients (pts) receiving cisplatin-based HEC (cisplatin ≥60mg/m2). All pts also received oral dexamethasone (DEX) on days 1-4. Totally, pts were given identical blinded antiemetic treatment for 2 cycles. Stratification factors were gender, age (≥55 vs <55 y), and cisplatin plus other HEC drugs (yes vs no). Primary endpoint was complete response (CR; no emesis/no rescue) rate at overall phase (OP; 0-120 h) after cisplatin-based HEC in cycle 1. A noninferiority test was used for primary endpoint with a noninferiority margin of -10% for difference (D).

Results: Baseline characteristics were comparable between groups. CR rate at OP in cycle 1 was 77.7% vs 78.2% (D=-0.9% [95% CI: -6.7, 5.0]; 1-sided P<0.01), showing primary endpoint met non-inferiority. CR rates at OP in cycle 2, acute phase (AP; 0-24 h), delayed phase (DP; 24-120 h), and 0-168 h in cycle 1 and 2 were similar in the 2 groups, while that at beyond delayed phase (BDP; 120-168 h) in cycle 1 and 2 with HR20013+DEX were higher than FAPR+PALO+DEX (cycle 1: 90.3% vs 86.5%; cycle 2: 92.7% vs 87.8%; Table). Consistently, a trend of higher rates of complete protection (CP; no emesis / no rescue / no significant nausea [visual analogue scale score <25 mm]) and total control (TC; no emesis / no rescue / no nausea [visual analogue scale score <5 mm]) at BDP was noted with HR20013+DEX, particularly in cycle 2 (CP: 90.8% vs 86.3%; TC: 83.8% vs 78.6%). Rates of pts with no significant nausea, no emesis, and no rescue in cycle 1 and 2 were comparable. The 2 groups had a similar safety profile.

Conclusions: HR20013+DEX was non-inferior to FAPR+PALO+DEX in prevention of cisplatin-based HEC-CINV and well tolerated.

Introduction: There remains an unmet need for effective and tolerable treatments of platinum refractory, advanced/metastatic non-small-cell lung cancer (NSCLC) without driver mutations.

Methods: DUBLIN-3 is a multicenter, single-blinded (patient) and randomized, phase 3 trial in 58 medical centers (US, China, and Australia). Patients with epidermal-growth-factor-receptor (EGFR) wild-type NSCLC, who progressed after first-line platinum-based therapy were enrolled. Patients were randomized (1:1) to receive docetaxel (75 mg/m2) on Day 1 and either plinabulin (30 mg/m2) or placebo on Days 1 and 8 in 21-day cycles until progression, unacceptable toxicity, withdrawal, or death. The primary endpoint was overall survival (OS) in the intent-to-treat (ITT) population. Treated patients were included in the safety analysis and ITT in the primary analyses (NCT02504489).

Results: Between 30-Nov-2015 and 06-Jan-2021, 559 patients received either docetaxel plus plinabulin (n=278 [male 199, female 79]) or docetaxel plus placebo (n=281 [male 207, female 74]). The original study was an adaptive design with two planned interim analyses and options to increase the sample size and to stop early due to futility; however, no sample size adjustment was made after the first interim analysis and the study continued without modifications. Plinabulin significantly improved OS; hazard ratio (HR) 0·82 (95% CI: 0·68, 0·99; p=0·0399) in the final analysis. Median OS was 10·5 months (95% CI: 9·34, 11·87) in the plinabulin group vs. 9·4 months (95% CI: 8·38, 10·68) in the control group. With additional 24-month follow-up after database lock, OS benefit sustains in the ITT population with median OS favoring the plinabulin group (10.8 vs. 9.3 month, HR=0.81, p=0.0027), and more pronounced in non-squamous population (11.4 vs. 8.8 months, HR=0.72, p=0.0078). The objective response rate (ORR) was significantly higher in the plinabulin group with 39 patients (14·0%) achieving partial responses compared with 24 patients (8·5%) in the control group (difference: 5·5%, 95% CI: 0·26, 10·72, p=0·0404). Median progression-free survival (PFS) was 3·3 months (95% CI: 2·89, 3·88) vs. 2·8 months (95% CI: 2·76, 2·93) (HR 0·79, 95% CI: 0·66, 0·96, p=0·0174).The 2- and 3-year survival rate was 22·1% vs. 12·5% (p=0·0072) and 11·7% vs. 5·3% (p=0·0393) for plinabulin vs. control group. Plinabulin significantly reduced Grade 4 neutropenia from 27·8% to 5·3% (p<0·0001). Furthermore, OS benefits were observed with more treatment cycles (≥4, 6, 8, 10, or 12 cycles), suggesting a durable anti-cancer benefit with plinabulin. Treatment-emergent-adverse-events occurred in 273/274 (99·6%) of patients in the plinabulin group and 276/278 (99·3%) in the control group. Higher incidences of Grade 3/4 gastrointestinal disorders (46 patients [16·8%] vs. 8 [2·9%]) and transient Grade 3 hypertension (50 patients [18·2%] vs. 8 [2·9%]) occurred in the plinabulin vs. control group. Treatment-emergent-death was 12 (4·4%) in the plinabulin group vs. 10 (3·6%) in the control group.

Conclusions: In patients with advance EGFR wild-type platinum refractory NSCLC, plinabulin combined with docetaxel was well-tolerated and statistically significantly improved OS/PFS/ORR with reduced severe neutropenia. A durable anti-cancer benefit was observed suggesting that plinabulin/docetaxel as a potential practice-changing treatment for advanced/metastatic NSCLC without driver mutations.

Introduction: The phase 3 EVOKE-01 study included patients with metastatic non-small cell lung cancer (mNSCLC) progressing after platinum-based chemotherapy and anti-PD-(L)1 treatment. The primary endpoint of overall survival (OS) was not statistically significant; however, results showed numerical improvement favoring sacituzumab govitecan (SG) vs docetaxel (hazard ratio [HR], 0.84; 95% CI, 0.68-1.04). As response to anti-PD-(L)1 treatment has prognostic impact on OS, best response to last anti-PD-(L)1-containing regimen (non-responsive, stable disease [SD]/progressive disease [PD], vs responsive, complete response [CR]/partial response [PR]) was a stratification factor and prespecified subgroup for analysis. We report patient characteristics and results from this subgroup of the EVOKE-01 study (NCT05089734).

Methods: In EVOKE-01, patients were randomized to receive SG (10 mg/kg IV; days 1, 8) or docetaxel (75 mg/m2 IV; day 1) in 21-day cycles. The primary endpoint was OS. Key secondary endpoints included investigator-assessed progression-free survival (PFS) and objective response rate (ORR). In these subgroup analyses, outcomes were evaluated by objective response to last anti-PD-(L)1-containing regimen. OS of the non-responsive subgroup were further analyzed by histology (squamous and nonsquamous). Descriptive statistics are reported.

Results: The intent-to-treat (ITT) population included 63.5% (n=383) patients with disease non-responsive to last anti-PD-(L)1-containing regimen (n=192 SG; n=191 docetaxel) and 36.3% (n=219) with responsive. In the non-responsive subgroup, patient characteristics were balanced between the treatment arms (Table). In the non-responsive subgroup, median OS was 11.8 months with SG and 8.3 months with docetaxel (HR, 0.75; 95% CI, 0.58-0.97); for the responsive subgroup, HR was 1.09; 95% CI, 0.76-1.56. Improvement in OS with SG was observed regardless of whether patients had SD (HR, 0.79; 95% CI, 0.55-1.13) or PD (HR, 0.67; 95% CI, 0.46-0.98) as best response to last anti-PD-(L)1-containing regimen. The OS benefit of SG over docetaxel in the non-responsive subgroup was similar in both squamous (HR, 0.62; 95% CI, 0.38-1.02) and nonsquamous (HR, 0.79; 95% CI, 0.59-1.07) histology. The Table summarizes additional efficacy results. In the safety population, grade ≥3 treatment-emergent adverse event (TEAE) incidence was 66.6% (SG) and 75.7% (docetaxel). TEAEs led to death in 3.4% (SG) and 4.5% (docetaxel). Treatment-related TEAEs led to discontinuation in 6.8% (SG) and 14.2% (docetaxel).

Conclusions: SG demonstrated clinically meaningful OS improvement vs docetaxel in a subgroup of patients with mNSCLC non-responsive (SD/PD) to last anti-PD-(L)1-containing regimen. The benefit was observed regardless of SD or PD as best response to last anti-PD-(L)1-containing regimen or histology.

Introduction: Pembrolizumab + platinum-based chemotherapy is standard of care first-line (1L) treatment for advanced/metastatic non-small cell lung cancer (mNSCLC) lacking actionable genomic alterations (AGAs) regardless of PD-L1 expression; however, novel combinations are needed to improve outcomes. Sacituzumab govitecan (SG) demonstrated durable activity in mNSCLC and was safely combined with pembrolizumab in the clinical setting. We report initial results by dose and histology from cohorts C (non-squamous) and D (squamous) of patients with mNSCLC treated in 1L setting with SG + pembrolizumab + carboplatin in the ongoing, multicohort, phase 2 study, EVOKE-02 (NCT05186974).

Methods: Adults without prior systemic treatment for mNSCLC, without AGAs, with an ECOG PS of 0-1, and with any PD-L1 tumor proportion score (TPS) via 22C3 assay were eligible. Patients received intravenous SG 10 or 7.5mg/kg (days 1, 8) + pembrolizumab 200mg (day 1; up to 35 cycles) + carboplatin AUC5 (day 1; initial 4 cycles only) in 21-day cycles. A safety run-in was conducted to assess dose-limiting toxicities (DLTs) and determine the recommended SG dose. The primary efficacy endpoint was independent review committee (IRC)-assessed objective response rate per RECIST v1.1. Secondary endpoints included IRC-assessed progression-free survival, duration of response, and safety.

Results: During the safety run-in (SG 10mg/kg, n=5), DLT criteria for dose reduction were not met. At a subsequent planned safety evaluation, SG dose was reduced to 7.5 mg/kg because of myelosuppression, mainly neutropenia. Among patients with non-squamous (n=54) and squamous (n=41) histology, median age was 67 and 68 years, 72.2% and 65.9% had an ECOG PS score of 1, and the majority (85.2% and 80.2%) had PD-L1 TPS <50%. Efficacy results by histology and safety results by dose are shown in the Table. Grade 3 rates of neutropenia were reduced at SG 7.5 mg/kg compared with SG 10 mg/kg (24.2% vs 65.5%).

Conclusions: SG + pembrolizumab + carboplatin demonstrated encouraging activity in patients predominantly with PD-L1 TPS<50% non-squamous and squamous non-AGA-driven mNSCLC. The safety profile of SG with standard doses of pembrolizumab and carboplatin is manageable at the 7.5 mg/kg dose with appropriate supportive measures.

Introduction: SAF-189s (Foritinib Succinate) is a highly-potent and brain-penetrating next-generation ALK/ROS1 inhibitor. SAF-189s has demonstrated promising clinical efficacy in phase II study. Here we report interim analysis (IA) results from REMARK study.

Methods: REMARK study was an open-label randomized phase 3 trial that enrolled previously untreated adult patients (pts) with ALK+ advanced NSCLC. Pts were stratified by baseline ECOG (0/1 vs. 2) and central nervous system (CNS) metastases status and then randomized at 1:1 ratio to receive SAF-189s 160 mg QD or crizotinib 250 mg BID orally. The primary endpoint was the progression-free survival (PFS) assessed by Independent Review Committee (IRC) per RECIST 1.1. Secondary endpoints included PFS by investigator (INV), objective response rate (ORR), time to response (TTR), duration of response (DOR), CNS ORR (C-ORR), C-TTR, C-DOR and time to CNS progression (C-TTP) by IRC and INV, overall survival (OS) and safety. The interim analysis was planned when approximately 83 PFS events were assessed by the IRC.

Results: From 31 Dec 2020 to 31 Mar 2022, 275 pts at 40 centers were randomized to receive either SAF-189s (n=139) or crizotinib (n=136). As cut-off date of 31 Mar 2024, median duration of follow-up was 16.7 months. SAF-189s demonstrated statistically significant improvement of IRC-assessed PFS over crizotinib with a hazard ratio (HR) of 0.23 (95% CI 0.14, 0.38). IRC-assessed median PFS was not reached in SAF-189s arm and 13.93 months in crizotinib arm. SAF-189s significantly reduced the risk of CNS progression compared to crizotinib (HR,0.04 [95%CI 0.01, 0.14]). There was also a trend to improve OS with SAF-189s over crizotinib (HR, 0.60 [95%CI 0.30, 1.20]). ORR was 92.8% in SAF-189s arm, 12% higher than in crizotinib arm (p=0.0035). Grade 3/4 treatment-related adverse events (TRAEs) occurred in 37.7% of pts with SAF-189s compared to 55.6% with crizotinib. Most common grade 3/4 TRAEs for SAF-189s was hyperglycemia, ALT increased and AST increased. No interstitial lung disease or visual loss was observed in SAF-189s arm. No TRAEs leading to death were reported in either arm.

Conclusions: SAF-189s demonstrated statistically significant and clinically meaningful improvement in PFS versus crizotinib. Safety profile of SAF-189s was consistent with previous reports and without new safety signals.

Hegi-Johnson[6], [1]BC Cancer, Vancouver/BC/CA ,[2]National University Cancer Institute, Singapore, Singapore/SG ,[3]University of Sydney, Sydney/AU ,[4]Sunnybrook Health Science Center, Toronto/ON/CA ,[5]Princess Alexandra Hospital, Brisbane/AU ,[6]Peter MacCallum Cancer Centre, Melbourne/AU ,[7]Mount Elizabeth Novena Hospital, Singapore/SG ,[8]Princess Margaret Cancer Center, Toronto/ON/CA ,[9]St Vincent's University Hospital, Dublin/IE ,[10]National University Hospital Singapore, Singapore/SG

Introduction: The timing and benefit of stereotactic radiosurgery (SRS) in the management of untreated brain metastases (BM) in patients with epidermal growth factor receptor mutated (EGFRm) non-small cell lung cancer (NSCLC) is uncertain. Two randomized trials, LUOSICNS and TROG 17.02 OUTRUN, compared upfront osimertinib with salvage local therapies when required to upfront SRS followed by osimertinib. This pooled analysis reports on the primary outcome: intracranial progression-free survival at 12 months (ic-PFS), and secondary outcomes: overall survival (OS), self-reported cognitive deterioration (CD), salvage SRS (sSRS), and radionecrosis (RN).

Methods: Patients with EGFRm NSCLC with up to 10 minimally symptomatic BM at registration were included. SRS was delivered as single or multi-fraction regimens per protocol. In the SRS arm, osimertinib was commenced following the completion of SRS. Intracranial progression was defined per RANO-BM. RN was determined according to MRI and histological confirmation when available. Cognitive function was self-reported using EORTC-QLQ C30. CD was defined as the first of a 10-point decrease from baseline (with no subsequent improvement). A two-stage, fixed-effect Kaplan Meier estimate at 12 months was used for assessing the pooled difference in ic-PFS. One-stage proportional hazards models were used to determine the hazard ratio (HR) for ic-PFS and OS.

Results: Seventy-nine participants were included; 40 were randomized to upfront osimertinib (uOSI) and 39 to upfront SRS (uSRS). Median follow-up was 39 months for LUOSICNS and 33 months for OUTRUN. Median age was 67 years. Participants were predominantly female (67%), of Asian ethnicity (71%), never smokers (72%), and 89% had BM present at the time of their original diagnosis. The ic-PFS at 12 months was 70% (95% CI 52% to 93%) for uSRS, and 53% (95% CI 34% to 81%) for uOSI in LUOSICNS and 67% (95% CI 49% to 93%) for uSRS, and 67% (95% CI 49% to 90%) for uOSI in OUTRUN. The pooled estimate of its difference was 9% (95% CI -13% to 30%) higher for uSRS than uOSI. There was no statistically significant difference between arms for ic-PFS (HR 0.83, 95% CI 0.48 to 1.43) or OS (HR 0.66, 95% CI 0.35 to 1.24). The percentage of participants with self-reported CD at 12 months was 18% (3/18) for uSRS and 18% (2/11) for uOSI. The percentage of participants who had sSRS at 12 months was 5% (2/37) for uSRS and 18% (7/40) for uOSI. Ten percent of participants in the uSRS arm had grade two or more RN events: two grade two, one grade three, and one grade four.

Conclusions: This pooled analysis found insufficient evidence to suggest that upfront SRS improved ic-PFS at 12 months, OS, self-reported CD, or sSRS in patients with minimally symptomatic BM from EGFRm NSCLC. The results of this study should be interpreted within the context of the small sample size of the individual trials. Given the prolonged survival of these patients, differences in outcomes between treatment arms may become more apparent with longer follow-up.

Introduction: Amivantamab plus lazertinib has shown antitumor activity in EGFR-mutated advanced NSCLC. Primary results from the phase 3 PALOMA-3 study (NCT05388669) demonstrated noninferior pharmacokinetics and objective response rate for subcutaneous vs intravenous amivantamab. Subcutaneous administration also offered substantially faster administration times and significantly higher patient-reported convenience (Leighl JCO 2024). Here, we present patient treatment satisfaction and resource utilization for subcutaneous amivantamab, providing further insights into its clinical benefits.

Methods: 418 patients with EGFR-mutated advanced NSCLC whose disease progressed on osimertinib and platinum-based chemotherapy were randomized 1:1 to subcutaneous (n=206) or intravenous amivantamab (n=212), both with lazertinib. Predefined secondary endpoints included resource utilization (assessed by time required for drug administration activities on cycle-1-day-1 [C1D1] and C3D1) and cancer therapy satisfaction (measured by the modified Therapy Administration Satisfaction Questionnaire [mTASQ] on C1D1, C3D1, and end-of-treatment). The mTASQ is a validated 12-item questionnaire where patients rated various aspects such as how restricted they felt during treatment, how bothered they were by administration time, and whether they felt they were losing or gaining time for other activities due to treatment duration.

Results: Across collected measures, subcutaneous amivantamab demonstrated improved resource utilization and patient satisfaction. Patient time in chair was substantially lower for subcutaneous amivantamab (C1D1: median [range], 0.4 [0-12.0] vs 6.5 hours [0-24.0]; C3D1: 0.6 [0-6.6] vs 3.4 hours [0.5-9.0]). This trend was consistent for active healthcare provider time and patient time in room (Figure A). More patients receiving subcutaneous vs intravenous amivantamab reported feeling unrestricted (C1D1, 66% vs 29%; C3D1, 60% vs 42%) and unbothered by administration time (C1D1, 69% vs 30%; C3D1, 71% vs 45%). Furthermore, fewer patients felt they lost time for other activities due to treatment duration (C1D1, 17% vs 46%; C3D1, 21% vs 46%; Figure B). Most patients receiving subcutaneous amivantamab reported mild-to-no pain (C1D1, 86%; C3D1, 84%), swelling (C1D1, 95%; C3D1, 95%), or redness (C1D1, 95%; C3D1, 94%) at the injection site. A higher proportion of patients preferred the subcutaneous injection to an intravenous infusion (C1D1, 77% vs 5%; C3D1, 81% vs 5%).

Conclusions: Intravenous amivantamab has demonstrated superior efficacy across multiple patient populations. Subcutaneous amivantamab provides the additional advantages of lower resource utilization and significantly higher patient satisfaction, and offers a convenient mode of administration for patients and healthcare providers, improving overall treatment experience.

Introduction: Adagrasib (ADA), a KRASG12C inhibitor, demonstrated a significant and clinically meaningful benefit in progression-free survival and objective response rate vs docetaxel (DOCE) in previously treated patients with KRASG12C-mutated advanced NSCLC in the phase 3 KRYSTAL-12 trial (NCT04685135). Here we report initial HRQoL results.

Methods: Patients with KRASG12C-mutated locally advanced or metastatic NSCLC who had previously received both platinum-based chemotherapy and anti-PD-(L)1 therapy were randomized 2:1 to receive ADA (600 mg BID orally) or DOCE (75 mg/m2 Q3W IV). HRQoL was evaluated using the Lung Cancer Symptom Scale (LCSS) and EQ-5D-5L. The LCSS average symptom burden index (ASBI) score evaluated six symptom-specific items using a visual analog scale (VAS; range 0-100), and the 3-item global index (3-IGI) evaluated symptom distress, interference with activities, and HRQoL (range 0-300); higher scores reflect worse symptom burden/HRQoL. The EQ-5D-5L instrument used a VAS (range 0-100) and utility index (UI) score (UK utility range -0.531 to 1); higher scores reflect better HRQoL. Data were collected on Day (D)1 and D15 of 3-weekly cycles (C)1-4, then on D1 of every cycle until the end of treatment visit (28-35 days after last dose). Changes from baseline over time were analyzed using a mixed-effect model for repeated measures (MMRM).

Results: The analysis population included 254/301 (84.4%) patients in the ADA arm and 112/152 (73.7%) in the DOCE arm who had data at baseline and ≥1 post-baseline visit(s) within 6 months. Completion rates among expected patients were >85% at most visits in both arms through C11, when there were ≥10 patients per arm with available data. Mean absolute scores for LCSS ASBI, symptom items, and 3-IGI mostly tended to improve over time in the ADA arm and worsen in the DOCE arm; mean EQ-5D-5L VAS and UI scores were mostly stable over time in the ADA arm and worsened in the DOCE arm (Table). In the MMRM analysis, the overall least squares mean change from baseline in LCSS ASBI score was -4.8 (95% CI, -6.3 to -3.3) with ADA and 4.8 (95% CI, 2.5-7.2) with DOCE, with a mean difference of -9.6 (95% CI, -12.3 to -7.0; P<0.0001). Time to definitive deterioration analyses will also be presented.

Conclusions: These results from KRYSTAL-12 suggest an improvement in symptom burden and HRQoL with ADA vs DOCE. Together with the efficacy results, these findings further support the use of ADA for patients with previously treated KRASG12C-mutated advanced NSCLC.

Introduction: Tarlatamab, a bispecific T-cell engager (BiTE®) immunotherapy that targets delta-like ligand 3 (DLL3) on SCLC cells, showed durable anticancer activity and a manageable safety profile in patients with previously treated SCLC in the DeLLphi-301 phase 2 study. At the primary analysis, median duration of response (DOR) was not reached, and overall survival (OS) data were immature (Ahn MJ, NEJM 2023). Here, efficacy and safety outcomes from longer follow-up of the DeLLphi-301 study are reported.

Methods: Tarlatamab 10 mg or 100 mg (Q2W) was evaluated in patients with SCLC who relapsed after 1 platinum-based regimen (± checkpoint inhibitor) and at least 1 other line of therapy. The primary efficacy endpoint was objective response rate (ORR) per RECIST 1.1 by blinded independent central review.

Results: Overall, 220 patients received tarlatamab. Data for the longer follow-up, median of 13.6 months (range 0.1-20.9) for efficacy outcomes, are shown in the Table. For the 10 mg group, the dose selected for subsequent trials, ORR was 40.4% and median DOR was not estimable, with responses ongoing in 19 of 40 (47.5%) responders at data cutoff. Median progression-free survival was 4.3 months and median OS was 15.2 months for the 10 mg group, with Kaplan-Meier estimates of OS at 6 and 12 months of 73.4% and 56.7%, respectively. The longer follow-up revealed no new safety signals in both dose groups: cytokine release syndrome, primarily grade 1 or 2, and no grade 4 or 5 occurrences, remained the most frequent adverse event (56.8%). Discontinuations due to treatment-related adverse events remained infrequent (2.7%). Results from an even longer follow-up will be presented.

Conclusions: Tarlatamab continued to achieve sustained responses and favorable long-term survival outcomes in patients with previously treated SCLC. Tarlatamab showed a favorable benefit-risk profile, supporting tarlatamab use in patients with previously treated SCLC. The longer follow-up at time of presentation will provide clearer insight on response durability and long-term survival.

OA10.04 Tarlatamab with a PD-L1 Inhibitor as First-Line Maintenance after Chemo-immunotherapy for ES-SCLC: DeLLphi-303 Phase 1b Study

S. Lau[1], M-J. Ahn[2], M. Moskovitz[3], M. Pogorzelski[4], S. Haefliger[5], K.G. Paulson[6], A. Parkes[7], Y. Zhang[8], A. Hamidi[9], M. Introduction: Current first-line maintenance (1LM) therapies for extensive-stage small cell lung cancer (ES-SCLC) provide limited benefit, necessitating novel therapeutic approaches to improve outcomes. Tarlatamab, a bispecific T-cell engager (BiTE®) immunotherapy that directs cytotoxic T cells to delta-like ligand 3 (DLL3)-positive cancer cells, demonstrated durable response and clinically meaningful survival outcomes in patients with previously treated SCLC. Here, safety and efficacy data from the phase 1b, multicenter, open-label DeLLphi-303 study (NCT05361395) evaluating tarlatamab plus PD-L1 inhibitor as 1LM following chemo-immunotherapy are presented.

Methods: Patients with ES-SCLC that did not progress after completing 4-6 cycles of 1L platinum-etoposide with PD-L1 inhibitor (unless unavailable) were eligible. Within 8 weeks of starting the last chemo-immunotherapy cycle, patients received tarlatamab (10 mg IV Q2W) with atezolizumab (1680 mg IV Q4W) or durvalumab (1500 mg IV Q4W) until progression. Primary endpoints included dose-limiting toxicities (DLTs), treatment-emergent and treatment-related AEs (TEAEs, TRAEs). Secondary endpoints included progression-free survival (PFS), overall survival (OS), and disease control rate (DCR).

Results: At data cutoff (31May2024), 88 patients (male: 62.5%, median age: 64.0 years; number of prior 1L platinumetoposide cycles: 4, 86.4%; 5, 5.7%; 6, 8.0%) received tarlatamab with atezolizumab or durvalumab (Table). Median follow-up was 10.0 months (range: 1.4-20.4). No DLTs occurred. The most common all grade TEAEs were cytokine release syndrome (CRS; 53.4%), dysgeusia (47.7%), and fatigue (34.1%). The most common grade ≥ 3 TEAEs were hyponatremia (10.2%), neutropenia (6.8%), and anemia (6.8%). CRS primarily occurred in cycle 1 and was predominantly grade 1-2; grade 3 CRS occurred in 1 patient. Immune effector cell-associated neurotoxicity syndrome and associated neurological events occurred in 11.4%/2.3%/0% (any grade/grade 3/grade 4) of patients.

The median time from initiation of 1L chemo-immunotherapy to start of 1LM was 3.6 months (range 2.9-5.8). Beginning from 1LM, median PFS was 5.6 months (95% CI: 3.6-9.0) and median OS was immature due to insufficient follow-up time; Kaplan-Meier estimate for OS at 9 months was 88.9%. DCR was 62.5% (95% CI: 51.5-72.6); median duration of disease control was 9.3 months (95% CI: 5.6-not estimable).

Conclusions: Tarlatamab in combination with a PD-L1 inhibitor as 1LM demonstrated a manageable safety profile with durable disease control and notable survival outcomes in patients with ES-SCLC. No new or unexpected toxicities were identified. This study supports further investigation of tarlatamab in combination with a PD-L1 inhibitor as 1LM in the ongoing phase 3 DeLLphi-305 randomized controlled study (NCT06211036).

Introduction: Delta-like ligand 3 (DLL3) is expressed on many cancers, including large cell neuroendocrine carcinoma of the lung (LCNEC). Prognosis in patients with locally advanced/metastatic LCNEC is poor (5-year survival is ~5%) and there is a major unmet need for effective treatments. BI 764532 is a DLL3/CD3 IgG-like T-cell engager that binds simultaneously to DLL3 on tumor cells and CD3 on T-cells, resulting in the formation of a cytolytic synapse that initiates a selective, T-cell-mediated immune response directed at DLL3-expressing tumor cells. NCT04429087 is an ongoing Phase I trial of BI 764532 in patients with locally advanced/metastatic DLL3-positive small-cell lung cancer, extrapulmonary neuroendocrine carcinoma, or LCNEC. The key aim of Phase Ia is to determine the maximum tolerated dose (MTD) and/or the recommended dose for expansion of BI 764532. Other objectives include safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary efficacy (investigator review; Response Evaluation Criteria in Solid Tumors version 1.1). Here, we focus on patients with LCNEC.

Methods: BI 764532 was given intravenously in 4 regimens: Regimen A (fixed dose once every 3 weeks; Regimen B1 (fixed dose once weekly); Regimen B2 and Regimen B3 (step-in dose, followed by target dose). Treatment continued until disease progression, unacceptable toxicity, other reasons for withdrawal, or maximum treatment duration (36 months).

Results: As of February 21, 2024, 168 patients had ≥1 dose of BI 764532 (Regimen A: n=24; Regimen B1: n=10; Regimen B2: n=79; Regimen B3: n=55); 32 patients (19%) were ongoing. Six dose-limiting toxicities (DLTs) were reported during the MTD evaluation period: 1 patient on Regimen A (grade 3 confusion) and 5 patients on Regimen B2 (grade 4 cytokine release syndrome [CRS]; grade 3 CRS; grade 5 immune effector cell-associated neurotoxicity syndrome; grade 3 nervous system disorder; and grade 2 infusion-related reaction). No DLTs occurred in patients with LCNEC and the adverse event profile was consistent with the overall population. The MTD was not reached. Fourteen patients with LCNEC were treated. Ten (71%) patients were male. Median age was 58 years (range 32-79). ECOG PS (0/1/missing): 14%/79%/7%. Ten (71%) patients had received prior PD1/PD-L1 treatment and ten (71%) had received ≥2 prior lines of therapy. The incidence of treatment-related adverse events (TRAEs; any/grade ≥3) in patients with LCNEC was 86%/7%. The most common TRAEs (any/grade ≥3) were: CRS (36%/0%); dysgeusia (36%/0%); asthenia (21%/0%); and nausea (21%/0%). One patient (7%) had grade ≥3 eosinophilia. In 13 evaluable patients with LCNEC (Regimen A: n=2; Regimen B1: n=1; Regimen B2: n=6; and Regimen B3: n=4), overall response rate (ORR)/disease control rate across all dose levels was 54%/77% (70%/90% in 10 patients who received ≥90 µg/kg). Median duration of response has not been reached. The estimated 6-month rates of duration of response and progression-free survival (PFS) were 63% and 28%, respectively, and median PFS was 3.6 months (2.4-not calculated). At data cut-off, 5 of 7 responding patients (71%) were still on treatment.

Conclusions: BI 764532 showed promising efficacy and safety in patients with LCNEC, with an ORR of 70% at active dose levels.

MONDAY, SEPTEMBER 9, 2024 - 14:00 - 15:15

OA10.06 Impact of Brain Metastases on Safety and Efficacy of MK-6070, a DLL3-Targeting T Cell Engager, in Small Cell Lung Cancer

N.J. Choudhury[1], H. Beltran[2], M.L. Johnson[3], E.L. Schenk[4], R.E. Sanborn[5], J.R. Thompson[6], H. Mamdani[7], A. Dowlati[8], R.R. Aggarwal[9], A.W. Gramza, MD[10], P. Jain[11], [1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]Dana Farber Cancer Institute, Boston/MA/USA ,[3]Sarah Cannon Research Institute, Nashville/TN/USA ,[4]University of Colorado Anschutz Medical Campus, Aurora/CO/USA ,[5]Earle A. Chiles Research Institute, Portland/OR/USA ,[6]Froedtert and the Medical College of Wisconsin Workforce Health, Milwaukee/WI/USA ,[7]Barbara Ann Karmanos Cancer Institute, Detroit/MI/USA ,[8]University Hospital Siedman Cancer Center, Case Western Reserve University, Cleveland/OH/USA ,[9]University of California, San Francisco, San Francisco/CA/USA ,[10]Harpoon Therapeutics, Inc., a subsidiary of Merck & Co., Inc. (Rahway, New Jersey), South San Francisco/CA/USA ,[11]Roswell Park Comprehenive Cancer Center, Buffalo/NY/USA

Introduction: MK-6070 (aka HPN328) is a DLL3-targeting T cell engager being studied in an ongoing phase 1/2 trial in patients (pts) with high grade neuroendocrine tumors associated with DLL3 expression, including small cell lung cancer (SCLC). Brain metastases (BM) are frequent in SCLC and cause significant morbidity. We analyzed the characteristics and outcomes of pts with SCLC treated to date in the MK-6070 phase 1/2 study (NCTNCT04471727) according to the presence of BM.

Methods: Pts in the phase 1/2 trial receive MK-6070 IV weekly or Q2W with a priming dose preceding the target dose. Pts with BM are eligible if BM are asymptomatic, previously treated, and radiologically stable; radiotherapy for localized BM progression is allowed on study if pts are otherwise benefitting. Objective response rate (ORR) is determined using RECIST v1.1; a modified RECIST v1.1 assessing extracranial response (EC-ORR) is also used to include pts with systemic response and brain-only progression.

Results: As of 09 February 2024, 49 pts with SCLC were treated at ≥ 1.215 mg, the minimum effective dose of MK-6070. Median age was 64 (range, 41-81); 100% had ECOG PS 0-1. Median lines of prior therapy was 2 (range, 1-6), with 100% receiving prior platinum therapy, and 47 pts (96%) receiving prior anti-PD1/PD-L1 therapy. 28 pts (57%) had a history of BM and 21 (43%) had no history of BM. Pts with BM were more likely to have received prior brain radiation (BM, 96%; No BM, 19%); otherwise, baseline characteristics of pts with BM were similar to those without. Pts with BM had a numerically higher ORR (ORR 37% [95% CI, 19-58] with 1 CR, EC-ORR 52% [95% CI, 32-71]) and disease control rate (DCR 78% [95% CI, 58-91]) than those without (ORR and EC-ORR 19% [95% CI, 5-42] and DCR 48% [95% CI, 26-70]). CNS progression events occurred in 9 of 28 (32%) of pts with BM, with no such events observed in those without BM. 4 pts attained an extracranial partial response (EC-PR) but had CNS progression. These pts underwent radiotherapy to their progressive BM and remained on study for a median of 6.2 months (range 5.4-27.8 months, with treatment ongoing in 3 pts). 2 of 14 patients with brain non target lesions (NTLs) had confirmed responses in brain NTLs. TRAEs were similar between groups (BM, 96%; No BM, 95%), including cytokine release syndrome (CRS) (BM, 64%; no BM, 57%). Immune effector cell-associated neurotoxicity syndrome (ICANS) only occurred in pts with BM (BM [n=4] 14%; No BM, 0%). ICANS was G1 in 3 pts, G2 in 1 pt.

Conclusions: MK-6070 shows promising efficacy in pts with SCLC, including pts with BM, with 1 achieving a CR. Pts with EC-PRs were able to remain on study after brain-only progression for ongoing clinical benefit. This trial is ongoing and data continue to mature. Updated safety and efficacy data including duration of response will be presented.

Introduction: Rilvegostomig is a bispecific mAb against PD-1 and TIGIT receptors, designed to enhance antitumour activity beyond PD-(L)1 therapy. The first-in-human study (ARTEMIDE-01, NCT04995523) in checkpoint inhibitor (CPI)-resistant metastatic non-small-cell lung cancer (NSCLC) showed encouraging safety and evidence of antitumour activity (Rohrberg ASCO 2023, #9050; Brandão ESMO 2023, #1446P). Here we report the first analysis of ARTEMIDE-01 in CPI-naïve patients with metastatic NSCLC and PD-L1 tumour proportion score (TPS) of 1-49% or ≥50%.

Methods: In this open-label, global, multicentre study, patients received rilvegostomig in Part C (PD-L1 TPS ≥1%, 750 mg Q3W) and Part D (PD-L1 TPS ≥50%, randomised 1:1 to 750 mg or 1500 mg Q3W). Patients were eligible based on local PD-L1 testing and retrospective central VENTANA SP263 PD-L1 testing was performed. Primary endpoints were objective response rate (ORR) by RECIST v1.1 and safety by CTCAE v5. Key secondary endpoints included duration of response (DoR) and progression-free survival (PFS).

Results: As of 7 July 2024, 95 patients received ≥1 dose of rilvegostomig and had ≥9 weeks follow-up. Of all enrolled patients (n=96), 16.7% had prior chemotherapy for metastatic disease and 13.5% and 21.9% had liver and brain metastases, respectively. Rilvegostomig was well tolerated with few treatment-related discontinuations (4.2%) and Grade ≥3 treatment-related adverse events (10.5%); there were no evident differences between 750 mg and 1500 mg in safety profile. In patients with PD-L1 TPS 1-49% (all received 750 mg), ORR was 29.0% (9/31, all confirmed) based on locally assessed PD-L1 TPS and 34.8% (8/23, all confirmed) based on central testing. In patients with PD-L1 TPS ≥50%, 95.3% (61/64) were randomised between the two doses; those receiving 750 mg had an ORR of 61.8% (21/34, 4 pending confirmation) based on locally assessed PD-L1 TPS and 68.2% (15/22, 3 pending confirmation) based on central testing. Those receiving 1500 mg had an ORR of 36.7% (11/30, 2 pending confirmation) based on locally assessed PD-L1 TPS and 35.7% (5/14, all confirmed) based on central testing. At data cutoff, 53.7% of patients remained on treatment. Response was ongoing in 28 (80%) confirmed responders. Among all confirmed responders (across PD-L1 levels and doses), median DoR was 10.5 months (95% CI, 6.4-not calculable).

Conclusions: In CPI-naïve patients, rilvegostomig showed a favourable safety profile and encouraging preliminary efficacy in those with PD-L1 TPS 1-49% and PD-L1 TPS ≥50%. Data support 750 mg Q3W as the pivotal dose for registrational studies.

Keywords: Metastatic NSCLC, PD-L1 positive, Immunotherapy

Table. Efficacy of rilvegostomig

PD-L1 status (based on local result)	TPS 1–49%	TPS ≥50%	
	750 mg	750 mg	1500 mg
Patients with first dose at least 9 weeks prior to data cutoff[a], N	**31**	**34[b]**	**30**
Confirmed and unconfirmed[c] CR or PR, n (%)	9 (29.0)	21 (61.8)	11 (36.7)
Stable disease, n (%)	11 (35.5)	9 (26.5)	9 (30)
Progression, n (%)	9 (29)	4 (11.8)	8 (26.7)
Not evaluable, n (%)	2 (6.5)	0	2 (6.7)

Data cutoff: 7 July 2024.
[a] Patients had opportunity for disease assessment scan 9 weeks after the first dose.
[b] 3 subjects from Part C had PD-L1 TPS ≥50% and were included in the analysis with patients in Part D.
[c] PR or CR pending confirmatory assessment.

CR, complete response; PD-L1, programmed cell death ligand-1; PR, partial response; TPS, tumour proportion score.

Introduction: Volrustomig, a novel PD-1/CTLA-4 bispecific antibody, has shown robust pharmacodynamic effect and clinical promise in multiple advanced solid tumors (Tran, AACR 2022; Albiges, ASCO 2022; Voss, ESMO 2023), and especially in PD-L1-negative first-line (1L) NSCLC (Ahn, ESMO 2022). PD-L1-negative NSCLC is a disease segment of key unmet need, with limited benefit gained from addition of anti-PD-(L)1 therapy alone to CTx, and where anti-PD-(L)1/anti-CTLA-4 therapy + CTx has previously shown clinical potential (Paz-Ares, Lancet Oncol 2021; Johnson, JCO 2023). Here we report updated results from patients with 1L advanced NSCLC treated with volrustomig 750mg + CTx in a global Phase 1b study.

Methods: Patients with 1L advanced NSCLC were treated with volrustomig 750mg + CTx Q3W based on histology: 120 nonsquamous (Nsq) NSCLC patients enrolled over two different time periods (Cohort 1A: n=66; Cohort 1B: n=54) and 20 squamous (Sq) NSCLC patients (Cohort 2). The primary endpoint was objective response rate (ORR) in the Nsq cohorts and safety in the Sq cohort. Secondary endpoints included safety, tolerability, and disease control rate (DCR). Exploratory endpoints included receptor occupancy and pharmacodynamic biomarkers of CTLA-4 blockade.

Results: Among 140 patients enrolled, 89 had PD-L1 tumor cell expression (TC) <1% NSCLC (63.6%), reflecting the unmet need and previously seen benefit of CTLA-4 inhibition in this population; median age was 68.0 years, 73.6% were males, 67.9% with ECOG performance status 1, 15.7% with liver metastases, and 15% with brain metastases. Efficacy outcomes are shown in the Table. Nearly all patients achieved disease control. Among evaluable patients with PD-L1 TC <1%, ORR in the Nsq (n=78) and Sq (n=10) cohorts was 42.3% and 50.0%, respectively. Median number of cycles was 6 (range 1-39); 97.1% and 75.7% of patients experienced all-grade and grade 3/4 treatment-related adverse events (AE), respectively. Seven treatment-related deaths occurred (two of which were volrustomig-related immune-related AEs): 6 in Cohort 1A, 0 in Cohort 1B, 1 in Cohort 2. Clinical peripheral T cell flow cytometry, TCR sequencing, and single-cell sequencing demonstrated greater T cell proliferation and memory T cell activation with volrustomig 750mg + CTx versus anti-PD1 + CTx.

Conclusions: Volrustomig 750mg + CTx demonstrates robust PD-1/CTLA-4 blockade, manageable safety, and promising efficacy in 1L advanced NSCLC, especially in patients with PD-L1 TC <1%. The ongoing phase 3 EVOLVE-Lung02 trial (NCT05984277) is evaluating volrustomig + CTx for metastatic NSCLC with PD-L1 TC <50%.

Introduction: Prolgolimab is an IgG1 aPD-1 monoclonal antibody with the Fc-silencing 'LALA' mutation. Here we present the results of randomized, multicenter, double-blind, placebo-controlled, phase III clinical trial BCD-100-3/DOMAJOR (NCT03912389) to evaluate the efficacy and safety of prolgolimab in combination with pemetrexed and platinum-based chemotherapy (PTb CT) versus placebo in combination with pemetrexed and PTb CT in patients (pts) with previously untreated advanced non-squamous (a/ns) NSCLC without driving mutations EGFR and ALK and independent of PD-L1 expression level. 45 centers across Russia, EU, China were participated.

Methods: 292 pts with a/ns NSCLC were randomized 1:1 to receive 4 cycles of prolgolimab (3 mg/kg Q3W) together with pemetrexed, platinum drug (cis- or carboplatin) (group A) or placebo together with pemetrexed, platinum drug (cis- or carboplatin) (group B) followed by prolgolimab/placebo with pemetrexed as 1st line therapy for a/ns NSCLC until disease progression or toxicity (≤36 mos). Primary endpoint was OS in intention to treat (ITT) population. The main analysis was planned once 113 deaths have been reached.

Results: After a median follow-up of 18 mos, the median OS was not reached (95% CI 22.28; NA) in the group A versus vs 14.6 mos (95% CI 11.73; 19.15) in the group B (HR= 0.51, 95% CI 0.35; 0.73, p=0.0001). The estimated rate of overall survival at 24 mos was 59.0% in the prolgolimab-combination group vs 36.3% in the placebo-combination group. PD-L1 status is not a statistically significant predictor in both multi- and univariate Cox models (p>0.3). AUC of the time-dependent ROC-curve (AUC=0.6) suggests that level of PD-L1 expression did not predict survival probability. Median PFS was 7.7 mos in group A and 5.5 mos in group B (HR=0.65. 95% CI 0.49; 0.85, p=0.0004). ORR was 50.3% in the prolgolimab-combination group and 27.5% in the placebo-combination group (RR 0.21, 95% CI 0.11; 0.32). Adverse events (AEs) of any grade occurred in 97.2% (139/143) of pts in group A and 89.2% (132/148) in group B. AEs related to study therapy was 64.3% (92/143) in group A and 50% (74/148) in group B. Immune-related AEs occurred in 34.3% (49/143) of pts in prolgolimab-combination group. Discontinuation of the therapy due to AEs was required in 9.8% of pts in group A and in 8.8% pts in group B.

Conclusions: Prolgolimab with chemotherapy demonstrated significantly longer OS, PFS and ORR than chemotherapy alone in pts with a/ns NSCLC. PD-L1 status did not predict survival probability in the prolgolimab-combination group. Prolgolimab in combination with chemotherapy had favorable safety profile without any signs of unexpected toxicity. Most AEs related to study therapy were mild or moderate and did not require treatment discontinuation.

Introduction: Earlier data from EMPOWER-Lung1 have demonstrated a significant survival benefit and generally acceptablesafety profile of first line (1L) cemiplimab monotherapy vs chemotherapy foradvanced non-small cell lung cancer (aNSCLC) with PD-L1 ≥50% of tumor cells andno EGFR, ALK or ROS1 aberrations. Here, we report protocol pre-specified finaloverall survival (OS) analysis (after 476 events) with 5-year (y) follow-up. Wealso report outcomes of patients who continued cemiplimab at diseaseprogression with addition of chemotherapy as allowed in the protocol, investigatinga new alternative for patients progressing on 1L monotherapy.

Methods: EMPOWER-Lung 1 was amulticenter, open-label, randomized, phase 3 study of cemiplimab in patientswith treatment-naïve squamous or non-squamous NSCLC with PD-L1 ≥50%. Patientswere randomized 1:1 to cemiplimab 350 mg IV every 3 weeks for 2 years orinvestigator's choice of chemotherapy. The primary endpoints were OS andprogression-free survival (PFS) per Blinded Independent Review Committee(BIRC). For inclusion in the post progression analysis patients needed to have received1 dose of chemotherapy and have at least 1 scan following disease progression oncemiplimab; response was assessed by BIRC against a new baseline, defined asthe last scan prior to the initial dose of chemotherapy.

Results: Of 712 patients randomized to cemiplimab(357) or chemotherapy (355), 565 patients (284 cemiplimab, 281 chemotherapy) hadverified PD-L1 ≥50%. In this population, the median follow-up was 57.3 months(m; range: 46.5 : 78.4), median OS was 26.1 m (95% CI, 22.1, 31.9) for cemiplimabvs 13.3 m (10.5, 16.2) for chemotherapy, hazard ratio (HR) 0.585 (0.48, 0.72);median PFS was 8.1 m (6.2, 8.8) vs 5.3 m (4.3, 6.1), HR 0.500 (0.41, 0.61); objectiveresponse rate (ORR) was 46.5% (40.6%, 52.5%) vs 20.6% (16.1%, 25.8%). 5-year OSprobability is 29.0% (22.9%, 35.4%) for cemiplimab vs 15.0% (10.5%, 20.2%) for chemotherapy.Improved activity of cemiplimab was observed in patients with PD-L1 ≥90%: medianOS was 38.8 m (22.9, NE), median PFS was 14.7 m (10.2, 21.1), ORR was 60.6% (50.3%,70.3%) and 5-year OS probability is 39.8% (28.0%, 51.3%). Safety profile at 5years remains consistent with previous results for patients who received eitherintervention. Grade ≥3 treatment-emergent adverse events (TEAE) occurred in 45.8%of patients for cemiplimab and 51.6% for chemotherapy. In the 75 patients in the postprogression analysis of cemiplimab + chemotherapy, the ORR was 28.0% (18.2,39.6) and median PFS2 was 6.5 m (6.2, 8.3) in the post progression phase. MedianOS was 27.4 m (23.0, 31.9) from randomization, which includes median of 15.1 m(11.3, 18.0) after adding chemotherapy. The combination was generally welltolerated, with 27 patients (36.0%) experiencing grade ≥3 TEAEs during the postprogression phase.

Conclusions: At 5-y follow-up, 1L cemiplimabmonotherapy continued to show durable clinical benefits vs chemotherapy. Continuedcemiplimab with addition of chemotherapy as 2L therapy provided meaningfulclinical benefit, providing a potential new treatment option for patients whoprogressed on cemiplimab monotherapy.

Introduction: Osimertinib, a third-generation, central nervous system-active EGFR-tyrosine kinase inhibitor, is recommended for EGFR-mutated advanced non-small cell lung cancer (NSCLC) and adjuvant treatment for resected EGFR-mutated NSCLC. In the Phase 3 LAURA study (NCT03521154), osimertinib given post-definitive chemoradiotherapy (CRT) demonstrated a statistically significant and clinically meaningful progression-free survival benefit vs placebo in patients with unresectable stage III EGFRmutated NSCLC without progression during/after CRT (hazard ratio 0.16 [95% CI 0.10, 0.24; p<0.001]). Here, we report an in-depth safety analysis from LAURA.

Methods: Eligibility: ≥18 years old (Japan ≥20 years), unresectable stage III EGFR-mutated (Ex19del/L858R) NSCLC without progression during/after definitive concurrent/sequential (c/s) CRT, WHO performance status 0/1; patients with asymptomatic radiation pneumonitis (RP)/pneumonitis post-CRT were eligible. Stratification: cCRT vs sCRT; stage IIIA vs IIIB/IIIC; Chinese vs nonChinese. Patients were randomized 2:1 to receive osimertinib 80 mg or placebo QD until disease progression (by blinded independent central review)/discontinuation. Open-label osimertinib was offered post-progression in both arms. Safety assessment schedule: baseline, Weeks 2, 4 and every 4 weeks thereafter until Week 24, every 8 weeks until Week 48, then every 12 weeks until treatment discontinuation. Toxicity management guidance required permanent discontinuation for symptomatic Grade (G) ≥3 RP/interstitial lung disease (ILD)/pneumonitis; study treatment could be restarted following interruption for symptomatic G2 events that resolved to G≤1; G1 events could continue with no dose modification.

Results: Overall, 216 patients were randomized: osimertinib n=143, placebo n=73. Baseline characteristics were generally well balanced across arms. Median total vs actual exposures were similar: osimertinib 24.0, placebo 8.3 months vs osimertinib 23.7, placebo 7.9 months, respectively. Incidence of any-cause G≥3 and serious adverse events (AEs): 35% and 38% (osimertinib) vs 12% and 15% (placebo), respectively; rates of exposure-adjusted G≥3 and serious AEs (per 100 patient-years) were similar between arms: 17.7 and 19.5 (osimertinib) vs 12.6 and 15.4 (placebo), respectively. RP (preferred term) was the most commonly reported AE (osimertinib 48%, placebo 38%), and the most common AE leading to protocol-mandated treatment interruption (osimertinib 32%, placebo 14%) and discontinuation (osimertinib 5%, placebo 3%). Most RP (grouped term) events were G1 (osimertinib 15%, placebo 19%) or G2 (osimertinib 31%, placebo 19%), with three G3 (osimertinib 2%) and no G4/5 events reported. Of the 69 osimertinib-treated patients with RP (grouped term), 32% (22/69) continued treatment without dose modification, 62% (43/69) interrupted treatment and subsequently restarted, and 6% (4/69) permanently discontinued treatment; 87% (60/69) continued osimertinib without recurrence of RP. ILD (grouped term) was reported by 8% (11/143) of osimertinib-treated patients; G1 n=4 (3%), G2 n=4 (3%), G3 n=2 (1%), G5 n=1 (<1%).

Conclusions: The safety profile of osimertinib after CRT was as expected and manageable. Dose interruptions due to AEs had limited impact on exposure. The majority of RP events were mild to moderate in severity and were managed effectively per protocol-mandated guidelines, with most patients able to continue or restart treatment without recurrence of RP. These safety data, together with the significant efficacy benefit observed, support osimertinib given post-definitive CRT as the new standard of care for unresectable stage III EGFR-mutated NSCLC.

Introduction: Neoadjuvant chemo-immunotherapy has become a standard of care for patients with resectable stage II-III non-small cell lung cancer (NSCLC). However, while distant failure is greatly reduced in the chemoimmunotherapy arm, this is not the case for the local failure in the CheckMate 816 trial. We hypothesized that adding radiation therapy (RT) might improve local control. Therefore, we conducted a multicenter, prospective, single-arm, phase II trial [SQUAT (WJOG 12119L)], to evaluate neoadjuvant concurrent chemo-immuno-radiation therapy followed by surgical resection and adjuvant immunotherapy for resectable stage III-N2 NSCLC. The primary endpoint was the major pathologic response (MPR) rate according to an independent central review. This was already reported to be 63% with a 90% confidence interval(CI) of 47-78% in 2022. Here, we report the results from the final analysis, focusing on progression-free survival (PFS), overall survival (OS), and safety, which are key secondary endpoints.

Methods: Patients with resectable stage IIIA-B N2 NSCLC (TNM 8th edition) were enrolled to receive concurrent chemo-immuno-radiotherapy [weekly paclitaxel (40 mg/m2)/carboplatin (AUC 2) for 5 weeks plus involved-field RT 50 Gy] and immunotherapy [durvalumab (1500 mg) every 4 weeks for 2 cycles] followed by surgical resection and adjuvant immunotherapy (durvalumab every 4 weeks for up to 1 year). The sample size was determined to be 31 patients by assuming that the threshold and expected value of the MPR rate to be 40% and 65%, respectively, with a significance level α=0.05 (one-sided) and power of 0.8, adding a 10% allowance for ineligible patients.

Results: Between Jan. 2020 and Feb. 2022, 31 patients were enrolled from 10 institutions in Japan. Thirty-one and 30 patients were evaluated for safety and efficacy, respectively. Of 30 patients (median age, 64 years), 70% and 63% had clinical stage IIIA and non-squamous histology, respectively. At the time of data cutoff (Jan. 12th, 2024), the median duration of follow-up was 28 months (IQR 18-33 months). At 2 years, PFS and OS rates were 43% (95% CI 26-60%) and 76% (95% CI 56-88%), respectively. In an exploratory analysis, PFS and OS rates were numerically higher in patients who achieved MPR than those who did not (2-year PFS rate: 58% vs. 18%, 2-year OS rate: 84% vs. 64%, respectively). The incidence of grade 3 or 4 treatment-related adverse events was 48%. One patient had a treatment-related death due to myocardial infarction and interstitial pneumonia.

Conclusions: Our results demonstrated the impact of adding RT to neoadjuvant chemo-immunotherapy on long-term outcomes of patients with resectable stage IIIA-B N2 NSCLC for the first time.This treatment regimen shows high pathologic efficacy and feasibility, and may become a promising treatment for selected patients with stage II-III NSCLC.

Introduction: The standard treatment for unresectable stage III patients is concurrent chemo-radiotherapy followed by durvalumab for 1 year (PACIFIC regimen). All attempts to improve these outcomes have been unsuccessful. All efforts have indeed been in the concurrent or subsequent phase. However, in our NADIM study, the induction regimen with chemotherapy and immunotherapy provides high clinical and pathological response rates. In the present study, we aimed to explore the results of applying induction with chemo-immunotherapy followed by standard treatment with chemo-radiotherapy and subsequent maintenance for 1 year with atezolizumab immunotherapy. To our knowledge, this is the first study conducted in stage III with this approach.

Methods: Non-resectable stage IIIA-IIIB-IIIC NSCLC patients were enrolled in this phase II trial to evaluate the efficacy of the induction treatment (Atezolizumab 1200mg+ Carboplatin AUC5+Paclitaxel 200 mg/m2 for 3 cycles) and concurrent chemotherapy (CT) -radiotherapy (RDT) treatment for 3 cycles. At the end of concurrent treatment, Atezolizumab 1200mg maintenance treatment was administered for 12 months (16 cycles). The primary objective was to assess the progression-free survival (PFS) at 12 months, defining PFS as the time from inclusion until objective tumor progression or death.

Results: Patients were 31.2% female, 100% current/former smokers, 40.6% ECOG PS 0, 68.8% stage IIIB/IIIC (8th edition). Thirty-eight patients were included in the intention to treat (ITT) population and 32 patients in the per protocol population (PP), those who received at least two cycles of induction treatment or had at least the first tumor response evaluation. The maturity data at 24 months were 99.3% and the median follow-up was 25.3 months (95%CI: 23.5-25.7%). All 32 patients started concurrent CT-RDT treatment, 29 started maintenance treatment and 16 completed 16 cycles. In the ITT analysis: PFS at 12 months from the start of induction Ch-atezolizumab was 68.4% (95%CI: 51.1-80.6%). OS at 12 months from the patient enrollment was 86.8 % (95%CI: 71.2-94.3%). In the PP analysis: PFS at 12 months from the start of induction Ch-atezolizumab was 78.1% (95%CI: 59.5-88.9%). OS at 12 months from the patient enrollment was 90.6% (95%CI: 73.6-96.8%). In the ITT population, 94.7% of patients had grade 1/2 adverse effects (AE), and 23.7% had grade 3/4 AE in the induction phase. For concurrent CT-RDT phase and maintenance phase, these percentages were 65.8% and 57.9% for grade 1/2 and 34.2% and 13.2% for grade 3/4, respectively. One grade 5 AE was reported during the maintenance phase and was unrelated to Atezolizumab. We have not observed a significant relationship between primary endpoint and TMB or PDL1 expression or clinical variables.

Conclusions: Our study provides better results than those historically known (PACIFIC trial) and encourages the development of strategies like those already successfully used in earlier stages. Clinical Trial information: NCT04776447.

Introduction: Building on the PACIFIC study, PACIFIC-BRAZIL assessed efficacy and safety of an intensified regimen of induction chemotherapy plus durvalumab followed by concurrent chemoradiotherapy plus durvalumab, followed by consolidation durvalumab for stage III NSCLCs.

Methods: PACIFIC-BRAZIL was a phase 2, single-arm, multicenter trial for treatment-naïve stage III (TNM 8th edition) NSCLC patients, ECOG-PS 0-1, who were candidates for definitive chemo-radiotherapy. Patients received induction chemo-immunotherapy (two 21-day cycles of carboplatin AUC 6, paclitaxel 200mg/m^2 and durvalumab 1500mg) followed by concurrent chemo-immuno-radiotherapy (carboplatin AUC 2 and paclitaxel 50mg/m2 weekly for 6 weeks, plus durvalumab 1500mg every 21 days concurrently with intensity-modulated, image-guided radiotherapy to 60 Gy in 30 fractions over 6 weeks). Patients without progressive disease received consolidation immunotherapy (twelve 28-day cycles of durvalumab 1500mg). The primary endpoint was 12-month PFS (12m-PFS) computed from treatment initiation. A sample size of 48 patients would be necessary to reject the null hypothesis that 12m-PFS was ≤49%, considering a true 12m-PFS of 65% (one-sided alpha of 0.1, power 80%). An exploratory sensitivity landmark analysis was prospectively planned to contrast PFS results with those of PACIFIC, calculating the PACIFIC-BRAZIL PFS from the time of initiation of consolidation durvalumab (NCT04230408).

Results: From March/2021-July/2023, 49 patients were enrolled across 8 institutions (57% female, median age 67, 51% white, 43% black/mixed race, 84% current/former smokers, 41% non-squamous histology, 2%/37%/53%/8% stages IIA/IIIA/IIIB/IIIC, respectively); 94% and 82% of patients initiated concurrent chemo-immuno-radiotherapy and consolidation immunotherapy, respectively. Radiotherapy was given to >59 Gy in 93.4% of patients who initiated concurrent chemo-immuno-radiotherapy. Disease progression occurred in 4% of patients during induction chemo-immunotherapy and in none during concurrent chemo-immuno-radiotherapy. For 94% of censored patients, the minimum follow-up time was 12 months. The 12m-PFS was 68.1% (95%CI 56%-82.8%, P=0.0022 against the null hypothesis of 12m-PFS of 49%, binomial test). In a pre-planned sensitivity landmark analysis exclusively of patients who initiated consolidation immunotherapy (N=40), 12m-PFS was 66.4% (95%CI 51.7%-85.4%). There were no differences in 12m-PFS according to PD-L1 expression. Twelve-month overall survival was 81.2% (95%CI 70.8%-93.1%). The overall incidence of grade≥3 treatment-related adverse events (TRAEs) was 82% (25%, 65%, and 20% during induction chemo-immunotherapy, concurrent chemo-immuno-radiotherapy, and consolidation immunotherapy, respectively). Most common non-hematologic grade≥3 TRAEs were pneumonitis (14%), respiratory infections (6%), pneumonia, dyspnea, diarrhea, fatigue, and infusion-related reactions (4% each). Incidence of any-grade pneumonitis and esophagitis was 27% and 18%. There were seven grade 5 events (2 related, 5 unrelated to treatment): pneumonia (3), COVID-19 (2), sepsis (1), pneumonitis (1); 3 occurred during concurrent chemo-immuno-radiotherapy, and 3 occurred during consolidation immunotherapy.

Conclusions: PACIFIC-BRAZIL met its primary endpoint, demonstrating improved 12m-PFS compared to historical controls, both in the primary intention-to-treat analysis as well as in the sensitivity landmark analysis from initiation of consolidation immunotherapy. Although concurrent chemoradiotherapy followed by durvalumab remains the standard-of-care regimen for stage III unresectable NSCLC, our results may support further evaluation of induction chemo-immunotherapy prior to chemoradiotherapy. Given toxicities observed herein and the negative PACIFIC-2 study, immunotherapy added concurrently during chemoradiation may not be warranted.

Introduction: In the phase 3 AEGEAN trial of patients with R-NSCLC, perioperative durvalumab plus neoadjuvant chemotherapy, versus neoadjuvant chemotherapy alone, significantly improved the primary endpoints of EFS and pCR, at their first planned interim analyses, with a safety profile consistent with the individual agents. Here, we report updated EFS results from the second planned interim analysis, interim DFS and OS results, and updated safety data, after all patients completed/discontinued treatment.

Methods: AEGEAN is a double-blind, placebo-controlled study (NCT03800134). Patients ≥18 years with treatment-naïve R-NSCLC (stage IIA-IIIB[N2]; AJCC 8th ed) and ECOG PS 0/1 were randomized (1:1) to neoadjuvant platinum-based chemotherapy plus durvalumab or placebo IV (Q3W, 4 cycles), followed by durvalumab or placebo IV (Q4W, 12 cycles), respectively, after surgery. Randomization was stratified by stage (II vs III) and PD-L1 status (<1% vs ≥1%; Ventana SP263). Efficacy analyses were performed in the mITT population (or its resected subpopulation), which excluded patients with documented EGFR/ALK aberrations. Primary endpoints: EFS per BICR (RECIST v1.1) and pCR, evaluated centrally. Key secondary endpoints: MPR, evaluated centrally, DFS (per BICR in the resected subpopulation), and OS. Safety was assessed in patients receiving treatment.

Results: 799/802 randomized patients received treatment (durvalumab arm, n=400; placebo arm, n=399). Baseline characteristics were largely balanced. As of 10-May-2024 (DCO), 86.9% and 88.5% had completed 4 cycles of neoadjuvant durvalumab or placebo, respectively, and 77.6% and 76.7% had completed surgery (mITT; durvalumab arm, n=366; placebo arm, n=374). Among patients who started adjuvant treatment (mITT; n=242; n=237), 68.6% and 63.7% had completed and 31.4% and 36.3% had discontinued treatment, most commonly due to progression (n=36 [14.9%]; n=70 [29.5%]). EFS benefit favoring the durvalumab arm remained consistent with that reported previously, including within the planned neoadjuvant platinum subgroups (Table). Clinically meaningful DFS improvement and an OS trend favoring the durvalumab arm were observed (Table). In exploratory analyses, EFS benefit was more pronounced in patients receiving adjuvant treatment and favored the durvalumab arm regardless of pCR status (to be presented), and improvement in lung cancer-specific survival was observed (Table). Maximum grade 3/4 AE rates were similar between arms during the overall period and occurred in 15.4% and 10.6% of patients during the adjuvant period (Table).

Conclusions: These findings, based on 18 months additional follow-up since the primary EFS analysis, further support perioperative durvalumab as a new treatment option for patients with R-NSCLC.

Introduction: ALINA (NCT03456076) is a global, open-label, phase III, randomized trial evaluating the efficacy and safety of adjuvant alectinib versus chemotherapy in patients with resected stage IB (≥4 cm)-IIIA (AJCC 7th edition), ALK+ NSCLC. A significant disease-free survival (primary endpoint) benefit was observed with alectinib versus chemotherapy (hazard ratio: 0.24, 95% CI: 0.13-0.43, p<0.0001; N=257 in the intention-to-treat population). We present additional data on safety outcomes.

Methods: Eligible patients (≥18 years old, with an ECOG PS 0/1 and completely resected, stage IB-IIIA, ALK+ NSCLC) were randomized 1:1 to receive oral alectinib (600 mg twice daily for 24 months) or platinum-based chemotherapy for up to four 21-day cycles. Safety monitoring, including assessment of the nature, frequency, and severity of adverse events (AEs), lasted up until 28 days after the last dose of study drug.

Results: At data cut-off (June 26th, 2023), median safety follow-up was 24.8 months and 3.7 months in the alectinib and chemotherapy arms, respectively. The five most reported AEs in the alectinib arm were: blood creatine phosphokinase (CPK) increased (43.0%), constipation (42.2%), aspartate aminotransferase increased (41.4%), alanine aminotransferase increased (33.6%), and blood bilirubin increased (33.6%). Most of these AEs were of low grade, non-serious, and did not require any dose modification. Table 1 presents time to onset and duration of these AEs. Table 2 presents AEs leading to dose reduction, interruption, and discontinuation in the alectinib arm in ≥3 patients: blood CPK increase led to dose reduction in 6.3% of patients and interruption in 5.5% of patients, and pneumonitis led to treatment withdrawal in 2.3% of patients.

Conclusions: Alectinib had a manageable safety profile; coupled with the previously reported efficacy data, these results support the use of adjuvant alectinib in patients with resected, stage IB-IIIA, ALK+ NSCLC. No new safety concerns were identified.

Keywords: NSCLC, alectinib, safety

Table 1. Time to onset and duration for the most frequently reported AEs in the alectinib arm

AE	Alectinib (n=128)
AST or ALT* increase	
Patients with AE, n (%)	56 (43.8)
Median time to first onset, days (IQR)	28.5 (18.5–68.0)
Median duration of AE, days (IQR)	43.0 (15.0–85.0)
Blood CPK increased	
Patients with AE, n (%)	55 (43.0)
Median time to first onset, days (IQR)	15.0 (15.0–16.0)
Median duration of AE, days (IQR)	18.0 (14.0–43.0)
Constipation	
Patients with AE, n (%)	54 (42.2)
Median time to first onset, days (IQR)	10.0 (5.0–22.0)
Median duration of AE, days (IQR)	184.5 (40.0–765.0)
Blood bilirubin† increase	
Patients with AE, n (%)	50 (39.1)
Median time to first onset, days (IQR)	43.0 (22.0–78.0)
Median duration of AE, days (IQR)	126.0 (43.0–576.0)

AEs, adverse events; ALT, alanine aminotransferase; AST, aspartate aminotransferase; CPK, creatine phosphokinase; IQR, interquartile range. *Includes preferred terms aspartate aminotransferase increased and alanine aminotransferase increased. †Includes preferred terms blood bilirubin increased, bilirubin conjugated increased, hyperbilirubinemia, and blood bilirubin unconjugated increased.

Table 2. AEs in the alectinib arm leading to dose reduction, interruption, or treatment discontinuation in at least three patients

Safety	Alectinib (n=128)
Median treatment duration	23.9 months
Any AE leading to dose interruption, n (%)	35 (27.3)
Blood CPK increased	7 (5.5)
ALT increased	7 (5.5)
AST increased	6 (4.7)
COVID-19	6 (4.7)
Blood bilirubin increased	5 (3.9)
Myalgia	3 (2.3)
Any AE leading to dose reduction, n (%)	33 (25.8)
Blood CPK increased	8 (6.3)
Blood bilirubin increased	5 (3.9)
Any AE leading to treatment discontinuation, n (%)	7 (5.5)
Pneumonitis	3 (2.3)

AE, adverse event; ALT, alanine aminotransferase; AST, aspartate aminotransferase; COVID-19, Coronavirus disease 19; CPK, creatine phosphokinase.

Jaffray[1,3], C. Chung[2,3], N. Vokes[4], J. Zhang[4], J.V. Heymach[4], J. Wu[1,3,4], J.Y. Chang[2], [1]Department of Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[2]Department of Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[3]Institute of Data Science in Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[4]Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: Our recent phase 2 randomized clinical trial (I-SABR, NCT03110978) demonstrated improved event-free survival (EFS) from combining stereotactic ablative radiotherapy (SABR) with immune checkpoint inhibitor therapy for early-stage non-small cell lung cancer (NSCLC) relative to SABR alone. However, not every patient benefits from immunotherapy. We report here a secondary analysis in which clinical-radiomics, with machine learning, was developed into a model to identify patients who would or would not benefit from immunotherapy.

Methods: Subjects were 141 patients with early-stage NSCLC enrolled in the I-SABR trial, 101 in the discovery and 40 in the validation cohort. We used the discovery cohort to develop the I-SABR-SELECT framework to model treatment outcomes and inform patient selection for combining immunotherapy with SABR. We extracted radiomics patterns characterizing the tumor/peritumoral and lung regions and the angiogenesis network surrounding the tumor. Radiomics features were harmonized, qualified, and integrated with clinical factors for downstream selection to mitigate model overfitting. A random survival forest algorithm was applied to model relationships between patient characteristics and treatment outcome separately for I-SABR and SABR-only. Counterfactual reasoning was used to assess treatment effects and optimize selection. The model was evaluated separately in the discovery and validation cohorts and in an independent group of patients treated on the STARS trial of SABR for early-stage NSCLC.

Results: Overall, the modelrecommended that 46 of the 141 (33%) patients enrolled in I-SABR switchtreatments (34 of 75 [45%] in the SABR-only arm and 12 of 66 [18%] in theI-SABR arm). Patients treated according to this recommendation achievedsignificantly improved EFS in both arms during model discovery and validation.Stratified by this recommendation, patients who received I-SABR showed an EFSinterval 1.4 to 1.6 times longer than those who did not receive immunotherapy.Notably, patients who were treated according to the I-SABR-SELECTrecommendation to add immunotherapy had improved EFS with hazard ratio [HR,SABR as reference] = 0.09 ($p<0.001$) and HR = 0.10 ($p=0.0069$) for discoveryand validation cohort, respectively (Fig.1). Interestingly, subgroup ofsingle-arm STARS patients who were treated as recommended had better EFS with[HR, against subgroup as reference] = 0.25 ($p=0.04$). Shapley analysis revealedcertain clinical features including ECOG and radiomics features measuring tumorand surrounding blood vessel were highly associated with model prediction.

Conclusions: I-SABR-SELECT provides an individualized approach for guiding who needs immunotherapy combined with SABR for early-stage NSCLC.

Introduction: Garsorasib (D-1553), a potent inhibitor of KRAS G12C, has shown robust anti-tumor activity and a well-tolerated safety profile in patients with non-small-cell lung cancer (NSCLC) harboring the KRAS G12C mutation, as previously reported (2024 AACR; Lancet Respir Med 2024). Here we provide the updated efficacy and safety data with longer follow-up.

Methods: This is an open-label, multicenter, single-arm phase 2 study (NCT05383898). Enrolled patients received garsorasib 600 mg twice daily in 21-day cycles. Eligible criteria included patients with locally advanced or metastatic NSCLC harboring KRAS G12C mutation, who had disease progression after prior anti-PD-(L)1 therapy and platinum-based chemotherapy or intolerance to the above regimens due to toxicity, and had measurable tumor lesions according to the RECIST, v1.1. The primary endpoint was objective response rate (ORR) evaluated by independent review committee (IRC) per RECIST v1.1. The secondary endpoints included duration of response (DOR), disease control rate (DCR), time to response (TTR), progression-free survival (PFS), overall survival (OS), and safety. Efficacy and safety were assessed in all patients who received at least one dose of garsorasib.

Results: A total of 123 patients (male 88%, median age 64, Asian 100%, prior systemic anticancer therapy 100%) were enrolled and treated. In this updated data cutoff (17 May 2024) compared to the prior data cutoff (17 November 2023), median duration of follow-up has increased from 7.9 months (IQR: 6.3-10.4) to 12.3 months (IQR: 6.6-15.0); 27 patients (22.0%) remain on treatment. IRC-confirmed ORR was 52.0% (95% CI: 42.8-61.1), and the DCR was 88.6% (95% CI: 81.6-93.6). The median TTR and DOR were 1.4 months (IQR: 1.4-1.9), and 12.5 months (95% CI: 8.3-NE), respectively. The updated median PFS was 9.1 months (95% CI:5.6-10.3). The median OS was estimated as 14.1 months (95% CI: 11.5-17.3). A total of 118 (95.9%) patients reported treatment-related adverse events (TRAEs) with 63 (51.2%) patients experiencing grade 3 or higher events. TRAEs led to dose reduction in 37 patients (30.1%), and to drug interruption in 51 patients (41.5%). No TRAE led to permanent discontinuation of garsorasib. The safety profile of garsorasib was similar to previously reported, and most of the adverse events were well managed.

Conclusions: Garsorasib has shown a high tumor response rate and long duration of response in a pretreated population of patients with KRAS G12C-mutated NSCLC. After prolonged follow up, the updated PFS and OS suggest a long-term clinical benefit, which will be further evaluated in a randomized, double-blind, controlled trial.

Introduction: The combination of targeted therapy plus chemo-immunotherapy represents a compelling opportunity to improve upon first-line (1L) outcomes in patients with KRAS G12C-mutant non-small cell lung cancer (NSCLC). Olomorasib is a potent, selective second-generation KRAS G12C inhibitor which has demonstrated promising activity with favorable tolerability in KRAS G12C-mutant NSCLC as monotherapy and combined with pembrolizumab. Here, we report the first clinical data describing olomorasib combined with chemo-immunotherapy.

Methods: In the phase 1 trial of olomorasib (NCT04956640), patients with advanced KRAS G12C-mutant NSCLC were enrolled into multiple cohorts. This includes an expansion cohort studying two doses of olomorasib (50mg and 100mg, orally twice daily) combined with standard chemotherapy platinum/pemetrexed and pembrolizumab (all at labeled doses). Any PD-L1 level (0-100%, via local testing) was permitted; and patients needing timely 1L therapy were permitted one cycle of SOC therapy prior to enrollment. Adverse events (AE) were assessed across all treated patients; objective response rate (ORR) per RECIST v1.1 was assessed in patients with at least one post-baseline response assessment or who had discontinued treatment before the first response assessment.

Results: Overall 89 patients received olomorasib+pembrolizumab (as of 31 May 2024). Here we report on the subset of 20 (50mg, n=9; 100mg, n=11) who also received chemotherapy in that regimen. Median age was 68 years (range, 56-81); 11 (55%) were PD-L1-negative, 7 (35%) were PD-L1-low, 1 (5%) was PD-L1-high and 1 (5%) was unknown; 8 (40%) patients received one cycle of SOC therapy prior to enrollment. Median duration of therapy was 4.2 months (range, 0.3-10.7) and 16 patients (80%) remained on study at time of data-cut. All grade TRAEs in >20% of patients were anemia (40%), nausea (35%), decreased appetite (25%), fatigue (25%), and neutrophil count decreased (25%); grade ≥3 TRAEs in ≥10% of patients were neutrophil count decreased (25%), anemia (20%), white blood cell count decreased (20%), platelet count decreased (15%), and diarrhea (10%). Potential grade 3 immune-related AEs included elevated ALT/AST (5%) and pneumonitis (5%). TRAEs resulted in olomorasib dose reduction in 2 patients (10%). TRAEs led to discontinuation of olomorasib (15%), pembrolizumab (10%), pemetrexed (10%), and platinum therapy (15%). Hematologic toxicity resulted in delay of the subsequent cycle of chemo in 3 patients (15%). Among the 18 efficacy-evaluable patients treated, ORR was 44% (7 partial response, 1 unconfirmed partial response and ongoing; 95% CI, 22-69) and disease control rate was 83% (15/18; 95% CI, 59-96).

Conclusions: Olomorasib combined with chemo-immunotherapy demonstrated a favorable safety profile, consistent with the safety profiles observed with other combinations of chemotherapy and targeted therapy. This demonstrates the feasibility of combining KRAS G12C inhibitors with chemo-immunotherapy. The ORR was lower in this first-line cohort compared to the prior report with olomorasib combined with pembrolizumab, representative of the higher risk patients with PD-L1-negative status, enrolled to the chemo-immunotherapy backbone. A global, registrational study investigating this combination in first-line NSCLC is currently enrolling (SUNRAY-01, NCT06119581).

Introduction: KRAS G12C mutation is a well-recognized and increasingly promising therapeutic target with significant unmet clinical needs in NSCLC pts. IBI351, also known as GFH925, is a potent covalent and irreversible inhibitor of KRAS G12C. Initial results of IBI351 monotherapy in previously treated NSCLC pts with KRAS G12C have been reported in ESMO Asia 2023 (LBA12). Here, we report updated results of this open-label, single-arm, pivotal phase 2 study.

Methods: Eligible NSCLC pts with KRAS G12C who failed standard therapy were enrolled. IBI351 600 mg was orally administered twice daily. Primary endpoint was confirmed objective response rate (ORR) assessed by independent radiological review committee (IRRC) as per RECIST v1.1. Other endpoints were safety, disease control rate (DCR), duration of response (DoR), progression-free survival (PFS) and overall survival (OS).

Results: As of December 13, 2023, 116 pts were enrolled (ECOG PS 1: 91.4%; brain metastasis: 30.2%; prior treatments with both anti-PD-1/PD-L1 inhibitors and platinum-based chemotherapy: 84.5%). As per IRRC assessment, confirmed ORR was 49.1% (95% CI: 39.7-58.6) and DCR was 90.5% (95% CI: 83.7-95.2). In 57 pts with confirmed response, median DoR was not reached with events occured in 22 (38.6%) pts. Median PFS was 9.7 months (95% CI: 5.6-11.0). OS data was immature. Treatment-related adverse events (TRAEs) occurred in 107 (92.2%) pts while 48 (41.4%) pts had grade≥3 TRAEs. Common TRAEs were anemia (44.8%), alanine aminotransferase increased (28.4%), aspartate aminotransferase increased (27.6%), asthenia (26.7%) and protein urine present (25.0%). TRAEs leading to treatment discontinuation occurred in 9 (7.8%) pts. In biomarker evaluable pts (n=95), all pts had positive KRAS G12C in tissue while 72 pts were blood positive and 23 pts were blood negative for KRAS G12C. Pts with KRAS G12C in both blood and tissue had higher tumor burden at baseline ($p < 0.05$) and worse PFS ($p < 0.05$). Tumor mutation profiling identified TP53 (45.3%), STK11 (30.5%) and KEAP1 (21.1%) as the most common genes co-mutated with KRAS G12C. Among 13 genes with mutation frequency ≥5%, mutations of 6 genes (STK11, KEAP1, PIK3CG, POLE, SMAD4, BRINP3) were significantly associated with worse PFS ($p < 0.05$). Mutation in STK11 also showed significant association with higher tumor burden at baseline and lower response rate ($p < 0.05$).

Conclusions: In KRAS G12C mutant NSCLC, updated results of IBI351 monotherapy continues to support its role as a new treatment option with sustained efficacy and manageable safety.

Introduction: Divarasib (GDC-6036), an oral, highly potent, and selective KRAS G12C inhibitor (G12Ci), has shown encouraging clinical activity and tolerability as a single agent in patients with KRAS G12C-positive NSCLC. The tolerability and potent activity of divarasib render it an attractive partner for PD-L1/PD-1 inhibitors where combinations with other KRAS G12Cis have been challenged by toxicity. Here we report safety and clinical activity of single-agent divarasib and in combination with the PD-L1 inhibitor atezolizumab in NSCLC patients.

Methods: As part of an ongoing phase I study (NCT04449874), patients received single-agent oral divarasib 50-400 mg daily, or divarasib 200 or 400 mg daily in combination with atezolizumab (1200 mg IV every 3 weeks), until intolerable toxicity or disease progression. Safety (NCI-CTCAE v5), pharmacokinetics, and preliminary antitumor activity (RECIST v1.1) were assessed.

Results: As of January 1, 2024, a total of 65 NSCLC patients had received single-agent divarasib. Among 31 patients who continued single-agent divarasib beyond one year, 15 (48.4%) experienced a new-onset treatment-related adverse event (TRAE) after a year; no patients experienced new-onset Grade 3-5 TRAEs, and no new-onset TRAEs led to dose reductions or divarasib withdrawal. Among 44 patients who received 400 mg divarasib, the confirmed objective response rate (ORR) was 59.1%, and the median progression-free survival (PFS) was 15.3 months (95% CI, 12.3 to 25.9).

A total of 39 NSCLC patients received divarasib and atezolizumab in combination; 18 patients received 200 mg and 21 patients received 400 mg divarasib (35 patients had prior PD-L1/PD-1 inhibitor; 14 patients at each dose level had no prior KRAS G12Ci exposure). Median lines of prior systemic therapy was 2 (range 1-5) and median time on study treatment was 6.21 months (range 0.1-22.5). At least one TRAE was experienced by 36 (92.3%) patients; the most common TRAEs (≥15%) were nausea, diarrhea, vomiting, aspartate transaminase (AST) increase, decreased appetite, alanine transaminase (ALT) increase, and asthenia. Grade 3 TRAEs occurred in 10 (25.6%) patients, including 2 (5.1%) patients experiencing Grade 3 treatment-related ALT/AST increase (managed with drug interruption and steroids). No Grade 4 or 5 TRAEs were reported. AEs led to divarasib dose reduction in 10 (25.6%) patients. There were no divarasib withdrawals due to AEs; atezolizumab withdrawals due to AEs occurred in 6 (15.4%) patients. The pharmacokinetic profile of divarasib was similar in combination with atezolizumab when compared to single-agent. Among 27 patients with baseline measurable disease who had no prior KRAS G12Ci, the confirmed ORR was 55.6% (15 patients). Median PFS was not estimated due to limited follow-up.

Conclusions: Single-agent divarasib continued to demonstrate encouraging radiographic response rates and durable clinical activity alongside a tolerable safety profile, establishing promising combination potential with other anticancer therapies. Divarasib in combination with atezolizumab demonstrated an acceptable safety profile and preliminary clinical activity in patients with KRAS G12C-positive NSCLC.

OA15.03 Clinicogenomic Landscape of Lymph Node Metastases in TRACERx

T. Karasaki[1], M. Al Bakir[2], A. Huebner[3], J.R.M. Black[3], C. Abbosh[3], N. McGranahan[3], A.M. Frankell[2], M. Jamal-Hanjani[3], C. Swanton[2], [1]Toranomon Hospital, Tokyo/JP ,[2]The Francis Crick Institute, London/GB ,[3]University College London Cancer Institute, London/GB

Introduction: The prognosis of non-small cell lung cancer (NSCLC) is strongly associated with nodal involvement. Systemic chemotherapy and/or immunotherapy are recommended after surgery for patients with LN metastases. However, we do not know who benefits from such additional treatment, and a better risk stratification is warranted. This study aimed to unveil clonal evolution and heterogeneity in lymph node metastases and gain further insights into LN-positive diseases in NSCLC.

Methods: Whole exome sequencing data from 370 primary tumor regions and 129 paired metastatic lymph node samples across 95 tumors from the TRACERx 421 cohort were integrated with anatomical information of lymph node samples. Using mutational profiles, the phylogenies of metastatic clones were inferred. We explored whether a single subclone (monoclonal) or multiple genetically distinct subclones (polyclonal) from the primary tumor were involved in the metastatic dissemination. Additionally, we explored postoperative ctDNA detection, also known as minimally residual disease (MRD), within a landmark analysis framework, where the landmark timepoint refers to establishing the MRD calling of a patient within 120 days following surgery. 112 patients in the TRACERx 421 cohort with postoperative plasma sampling performed were evaluable for landmark analysis based on ≥1 plasma sample obtained within 120 days of surgery before adjuvant therapy or relapse.

Results: In the phylogenetic analysis, 100/129 metastasized LN had monoclonal seeding and 29/129 polyclonal seeding. There were no differences in the modes of dissemination between N1 and N2 nodes (monoclonal: N1, 56/76; N2, 44/53). There were 16 patients with metastatic LNs sampled from multiple LN stations (36 samples). We observed one case whose metastatic clone of N2 node (#7) was disseminated from N1 node (#12). No N2 to N1 metastasis was observed. All other N2 node metastases were inferred as seeded from primary tumors. At the patient level, 7/16 were monoclonal seeding, and 9/16 were polyclonal seeding. These results suggest whilst most LNs are seeded by a single clone from the primary tumor, approximately half of the cases with multi-station LN metastases had distinct clones that metastasized to respective LNs, therefore, polyclonal seeding at a patient level. In the ctDNA analysis, patients with N2 diseases had significantly high landmark MRD positivity compared with N0/N1 (N0, 9/68; N1, 5/24; N2, 13/24; N2 vs N1 p= 0.036, N2 vs N0 p= 0.00015). Landmark-negative patients had better overall survival (OS) than landmark-positive patients, regardless of pN status. Notably, landmark-negative N2 disease patients showed significantly better OS compared with landmark-positive N0/1 patients (HR = 0.35, 95%CI: 0.12-0.98, p= 0.046).

Conclusions: Anatomical site of metastatic LN was not associated with modes of clonal dissemination. N2 disease was associated with a significantly higher rate of postoperative MRD detection supporting the current indication of adjuvant systemic treatment for patients with N2 disease. Furthermore, postoperative assessment of ctDNA may improve the relapse risk stratification compared with current TNM staging.

OA15.04 Multi-Omic Profiling of Paired Non-Small Cell Lung Cancer and Draining Lymph Nodes Reveals Novel T-Cell Differentiation Patterns

V. Gerretsen[1,2], W. de Koning[1], X. Li[3], N. Rozendaal[1], R. Stadhouders[1], M. Schuijs[2,4], B. Lambrecht[1,2], J. Aerts[1], F. Dammeijer[1], [1]Erasmus Medical Center, Rotterdam/NL ,[2]VIB Center for Inflammation Research, Ghent/BE ,[3]Dartmouth Geisel School of Medicine, Hanover/NH/USA, [4]Department of Internal Medicine and Pediatrics, Ghent/BE

Introduction: Cancers including non-small cell lung cancer (NSCLC) contain tumor-infiltrating T-cells (TILs) critical for anti-tumor immunity and immunotherapy efficacy. Although TILs have been widely characterized, their origin remains largely unknown. Preclinical models and studies including mostly metastatic disease patient samples point to tumor-draining lymph nodes (TDLNs) as potential sites of origin for TILs. However, the developmental trajectory of T cells and its relation to other cell types is unclear.

Methods: We present the largest to date cohort of TDLNs and paired primary tumors (n=20) from patients with early-stage NSCLC post-resection. We FACS-sorted these samples for T-cells, myeloid and stromal cells, and performed single-cell RNA, CITE and T-cell receptor (TCR) sequencing.

Results: We identified 206,805 cells including 157,555 T-cells and found shared T-cell clones between TDLN and the primary tumor in all patients. Exhausted CD8+ TILs, characterized by increased expression of CTLA4, TIGIT, and HAVCR2 were markedly expanded, with few cells sharing TCRs with TDLN-T-cells. Instead, clonally related CD8+ T-cells present in both TDLN and tumor were characterized by an effector memory phenotype, belonging to individual clusters expressing GZMK, TNFSF9 (4-1BBL), KLRC1 (NKG2A), and TNFAIP3 (A20). Intriguingly, we could identify at least two different clonal trajectories leading to different TIL phenotypes not discovered before. Clonally related cells obtained different phenotypes when transitioning from TDLN to tumor, suggesting altered differentiation depending on the tissue microenvironment and presence of cognate antigen. More strikingly, cells stemming from the KLRC1/TNFAIP3-differentiation clusters were enriched for tissue resident memory (TRM) signatures. Moreover, these cells shared clonotypes with the TRM cluster in our dataset, pointing to a potential poised differentiation trajectory from this T-cell lineage compared to the GZMK/TNFSF9 clusters.

Conclusions: Using single-cell multi-omic profiling of TDLN and primary NSCLC tissues, we identified significant clonal relatedness between both sites in all patients investigated, and unveiled a yet unexplored complexity of TIL differentiation in NSCLC. Findings on the functional and prognostic consequences of this heterogeneity, and the biological processes driving differential T-cell differentiation will be presented at the conference.

OA15.05 Single-Cell Spatial Architectures of Paratumor Zone Determines the Prognosis of Multiple Lung Cancers

X. Yuan[1], Z. Wang[1], X. Zhang[2], Z. Gao[3], J. Xu[2], Y. Li[1], F. Yang[1], J. Wang[1], K. Chen[1], [1]Peking University People's Hospital, Beijing/CN ,[2]Kanghui Biotechnology Corporation, Beijing/CN ,[3]Infinity Scope Biotechnology Co. Ltd., Hangzhou/CN

Introduction: Prognostic disparities have been observed within multiple lung cancers (MLCs), yet the underlying immune mechanisms remain elusive.

Methods: Twenty-eight patients with MLCs underwent surgical resection. Fifty-one tumors were subjected to imaging mass cytometry across the tumor region, paratumor zone, and adjacent normal tissue. Whole-exome sequencing and bulk RNA sequencing was also conducted. Multiple primary lung cancers (MPLC) and intrapulmonary metastases (IPM) were discriminated based on the mutation-derived probabilities of clonal relatedness.

Results: In comparison with MPLC, the architectures of tumor microenvironment are closer within IPM patients, reflecting the higher inter-tumor genomic similarity. MPLC paratumor regions exhibited greater similarity within individuals than between individuals, indicating the presence of field cancerization. Among the 23 cell subpopulations, the paratumor zone of MLCs is characterized by M2 macrophage compositions when compared with tumor and normal regions, demonstrating depleted CD11c+M2 and enriched CD11-M2 cells. CD21+M2 is another subset decreasing in the normal-paratumor-tumor sequence, which interacts with CCR7+CD4+ central memory T cell and IDO+B cells in MPLC paratumor area but avoids them in IPM. It's significantly closer to the malignant transforming epithelial cells in the IPM paratumor zone. The spatial distance between CD11c+M2 and paratumor epithelial cells in IPM is significantly less than that in the tumor, while the two are similar in MPLC, associated with worse disease-free survival (DFS). We further detected multicellular spatial organizations; one cell neighborhood characterized by three types of M2 macrophages is enriched in MPLC paratumor regions, and its abundance positively correlates with survival, a relationship that was not discovered in tumors. In addition, PNAd+Endothelial cells (representing tertiary lymphatic structure) are enriched in MPLC paratumor zone. CD45RO+CD8+ effective memory T cells, CD45RO+CD4+ effective memory T cells, and CD21- B cells also accumulates around epithelial cells (0-20μm range) of this region, which show strong interactions with malignant HLA-DRhigh epithelial cells, but displaying strong avoidance in IPM. These observations suggest the activation of anti-tumor immunity in MPLC paratumor zone against immune escape in IPM, explaining the superior prognosis of MPLC compared to IPM.

Conclusions: Our study highlights the parantumor immune microenvironment in the progression of MLCs.

OA15.06 Spatiotemporal Genomic and Transcriptomic Analysis Reveal Molecular Landscape and Intratumoral Heterogeneity in Non-Smoking Lung Cancer

W. Wang, Y. He, K. Chen, Peking University People's Hospital, Beijing/CN

Introduction: Lung cancer is the world's leading cause of cancer death and its onset is largely attributable to direct tobacco exposure. However, its incidence in never-smokers remains a significant health problem globally. Previous studies on multiregion sequencing of lung cancer mostly focused on smokers, lacking a comprehensive analysis of lung molecular landscape in non-smokers. Hence, it is crucial to understand endogenous mutagen factors and intratumoral heterogeneity (ITH) underlying the unique characteristics of non-smoking lung cancer.

Methods: We performed comprehensive genomic and transcriptomic analysis of patient-matched early-stage lung cancer tumors, the predominant type of non-small cell lung cancer (NSCLC), and normal adjacent tissues obtained from Chinese CXDY cohort (n=127) representative of the non-smoking population. Compared to the Western smoking cohort (TRACERx cohort, n=421), we revealed the molecular landscape associated with early events and non-smoking-related processes in lung cancer.

Results: We sequenced the whole exome (127 patients, 389 regions) and transcriptome (115 patients, 304 regions) of CXDY lung cancer patients, which were characterized by a higher proportion of female (54.5%), subcapsular nodules (45.5%), adenocarcinoma (84.1%), and a lower proportion of smoking history (21.2%). These results indicate that there are significant differences in the epidemiological and clinicopathological characteristics of lung cancer between East and West. By constructing phylogenetic tree and calculating genome ITH, we revealed that Chinese NSCLC have more stable genomes characterized by higher SNV-ITH and lower SCNA-ITH. This difference is much stronger in smokers as compared to nonsmokers. Moreover, subclonal WGD events are more likely to occur in Chinese population than clonal WGD events. Compared with nonsmokers, mutations in smokers were significantly enriched in N MA (p=0.037) and NDR pathways (p=0.009). Transcriptional ITH was characterized by intratumour expression distance (I-TED), and it was found that smoking history and subclonal mutations (%) were important factors affecting I-TED, while subclonal SCNAs (%) were more important in TRACERx cohort. Transcriptome clustering of regions yielded two subtypes, C1 and C2. Non-smoking, female, stage I and adenocarcinoma were significantly concentrated in C1 subtype, which significantly involved in cell homeostasis and biological function. In contrast, C2 subtype are enriched in pathways related to DNA replication and cell division, suggesting poor prognosis. Immune-ITH was calculated using four common immunoinfiltration algorithms and found that non-smokers had significantly lower immune heterogeneity.

Conclusions: This study elucidated the comprehensive molecular structure and multi-omics ITH of non-smoking lung cancer, providing new insights into the development of treatment strategies for lung cancer.

Introduction: GQ1005 is an innovative antibody-drug conjugate that specifically targets HER2-expressing tumor cells using Topoisomerase I inhibitors (DXd) delivered through a stable and cleavable linker. Preclinical studies have shown that GQ1005 exhibits similar antitumor efficacy to Enhertu and better stability than Enhertu, with a notable absence of toxicity, suggesting a superior therapeutic profile. This report presents initial findings from an ongoing phase I clinical trial, which seeks to assess the safety, tolerability, pharmacokinetics, and antitumor efficacy of GQ1005 in patients with advanced solid tumors expressing HER2 and patients (pts) with HER2-mutated NSCLC.

Methods: Patients aged 18 years and older with locally advanced or metastatic solid tumors previously treated with standard therapy and with a measurable disease according to RECIST v1.1 criteria were included in the study. The Maximum Tolerated Dose (MTD) was determined using the Bayesian Optimal Interval (BOIN) design. GQ1005 was given intravenously at a specified dose (2, 4, 6, 7.2, and 8.4 mg/kg) Q3W until either intolerable toxicities occurring or disease progressed.

Results: As of March 26th, 2024, 131 patients with HER2-expressing or HER2-mutated advanced solid tumors predominantly in breast (70), lung (34) and gastric/gastroesophageal junction (19), were enrolled. Median age was 56 (from 34 to 74), and the patients had median 3 (range, 1-11) prior lines of anti-tumor therapies, 76% had an ECOG performance status of 1. The median exposure time of GQ1005 was 15.9 weeks (range 3.0-60.9). No DLT was observed in all doses, hence MTD was not achieved. Every patient experienced treatment-related adverse events (TRAEs). Drug-related AEs led to discontinuation in 6 patients (4.6%) and death in 1 patient (0.8%). The most common all-grade TRAEs (>15.0%) were elevated aspartate aminotransferase (41.2%), nausea (40.5%), anemia (35.1%), alanine aminotransferase increased (31.3%), leukopenia (26.0%), decreased appetite (26.0%), thrombocytopenia (25.2%), neutropenia (22.9%), vomiting (22.1%), fatigue (19.8%), proteinuria (17.6%), and dry eye (15.3%). Grade ≥3 TRAEs occurred in 21 patients (16.0%), including anemia (3.8%), decreased lymphocyte count (3.8%),γ-glutamyltransferase (GGT) increase (3.8%), leukopenia (2.3%), thrombocytopenia (1.8%) and nausea (0.8%) . Interstitial lung disease occurred in 12 patients (9.2%) and most of them were reported in 8.4mg/kg dose. Among 119 evaluable patients, 1 case had complete response, 52 cases achieved partial response, the unconfirmed ORR was 44.5%, and the unconfirmed DCR was 81.5%. In 34 patients with advanced HER2-mutated NSCLC with median age of 59.5 (range 38-74), 50% had prior ≥2 lines of anti-tumor therapies. No DLTs occurred and Grade ≥3 TRAEs were recorded in 6 pts (17.6%). AEs were manageable and tolerable, consistent with previous findings. 32 pts had at least 1 tumor assessment. Moreover, best tumor response was observed in 12/32 (37.5%) pts, and DCR was 90.6% (29/32).

Conclusions: Based on the initial data from the first-in-human trial, GQ1005 shows great potential for excellent tolerability and promising antitumor activity in patients with heavily pretreated HER2-expressing advanced solid tumors and HER2-mutated NSCLC. The phase Ib trial in four cohorts with a dose of 7.2 mg/kg is ongoing. (NCT06154343)

Introduction: Trastuzumab deruxtecan (T-DXd) 5.4 mg/kg is approved in several regions, including the US and EU, for patients with unresectable or metastatic human epidermal growth factor receptor 2 (HER2) mutant non-small cell lung cancer (NSCLC) who have received prior systemic therapy. HER2 overexpression in NSCLC is associated with limited treatment response and a poor prognosis. In DESTINY-Lung01, T-DXd monotherapy (5.4 mg/kg; n=41) demonstrated encouraging antitumor activity in extensively pretreated patients with unresectable and/or metastatic HER2-overexpressing (HER2-OE) NSCLC; the confirmed objective response rate (ORR) was 34.1% (95% confidence interval [CI] 20.1, 50.6). DESTINY-Lung03 (NCT04686305) is an open-label, multicenter, Phase 1b, multipart study evaluating T-DXd-based treatments in patients with HER2-OE NSCLC. Here, we report the efficacy and safety of T-DXd monotherapy in Part 1 of DESTINY-Lung03.

Methods: Patients with HER2-OE unresectable, locally advanced or metastatic NSCLC with disease progression on or after one or two prior regimens received T-DXd 5.4 mg/kg intravenously every 3 weeks. HER2-OE was defined as ≥25% of tumor cells with immunohistochemistry (IHC) 2+ or 3+ by central testing using the DAKO HER2-low IHC assay. The endpoints of the T-DXd monotherapy arm were investigator-assessed confirmed ORR, duration of response (DOR), and progression-free survival (PFS); overall survival (OS); and safety.

Results: At data cutoff (DCO; October 23, 2023), 36 patients with HER2-OE NSCLC had received T-DXd 5.4 mg/kg; median (range) duration of T-DXd total treatment was 7.2 (0.7-19.8) months and median (range) duration of follow up was 11.7 (1.4-21.2) months. Patients were predominantly female (61.1%) and from Asia (88.9%); median age (range) was 66.5 (47-80) years, and targeted therapy was the most common prior treatment modality (58.3%). Additional patient characteristics and safety data are in the table. The confirmed ORR was 44.4% (95% CI 27.9, 61.9), and median DOR was 12.2 (95% CI 5.5, not estimable) months. Median PFS was 8.2 (95% CI 6.7, 11.1) months and median OS was 14.7 (95% CI 14.6, not estimable) months. At DCO, the adjudication committee determined that there were no cases of drug-related interstitial lung disease/pneumonitis; adjudication committee review is ongoing. Updated efficacy and safety results will be available for the presentation.

Conclusions: T-DXd monotherapy (5.4 mg/kg) demonstrated encouraging antitumor activity in patients with pretreated advanced or metastatic HER2-OE NSCLC, consistent with results from DESTINY-Lung01. The safety profile was acceptable and generally manageable, consistent with the known profile of T-DXd.

OA17 INCREASING ACCESS TO EARLY LUNG CANCER DETECTION
TUESDAY, SEPTEMBER 10, 2024 - 13:30 - 14:45

OA17.03 Missed Opportunities for Early Lung Cancer Detection in a Multi-Disciplinary Thoracic Oncology Clinic Cohort

W.T. Liao[1], A.T. Patel[1], F. Caro[1], J. Roma[1], W. Marshall[1], J. Goss[1], C. Fehnel[1], A. Mehrotra[1], O. Ogbeide[1], P. Lammers[1], k. Tonkin[2], J. Machin[2], M. Ray[3], M.P. Smeltzer[3], R.U. Osarogiagbon[1], [1]Baptist Cancer Center, Memphis/TN/USA ,[2]Baptist Memorial Hospital, Memphis/TN/USA ,[3]University of Memphis, Memphis/TN/USA

Introduction: Lung cancer screening (LCS) reduces mortality, but few eligible patients undergo screening; adherence to subsequent screening rounds is low; eligibility criteria disqualify many people who develop lung cancer. We quantified these barriers in a community cohort.

Methods: We retrospectively evaluated all patients diagnosed with lung cancer from 2015-2023 in a Multi-disciplinary Thoracic Oncology Program. Patients categorized as: eligible, 1 low-dose CT scan (LDCT) before diagnosis; eligible, >1 LDCT done; eligible, no LDCT ('missed opportunity cohort' [MOC]); ineligible for LCS. We compared overall survival (OS) between groups with adjusted hazard ratios (aHR) from proportional hazards models controlling for age, sex, race, insurance, smoking history and Charlson co-morbidity scores.

Results: Of 1,746 patients, 4.5%, 1.5%, 46.0% and 48.0% had 1 LDCT, >1 LDCT, were MOC, and ineligible for LCS, respectively. Among the MOC, 71% were seen in the healthcare system in the 24 months preceding lung cancer diagnosis. Among those ineligible for screening, 24% had never smoked, 62% had insufficient pack-year history or excessive quit duration, 11% were age-ineligible.Age, race, and clinical characteristics across groups are shown in Table. Treatment was surgery alone in 44% v 42% v 20% v 20%, and included surgery (with or without other modalities) in 59% v 50% v 37% v 36%, respectively. OS differed significantly by group (Figure, Table). In multivariable analysis, using the MOC for reference, the aHR were: 0.37(0.23-0.61) for single screening, 0.16(0.04-0.66) for multi-screened and 0.92(0.78-1.08) for ineligible cohorts.

Conclusions: Mismatch between eligibility criteria and true risk was the biggest barrier to LCS; missed opportunity to screen eligible patients was the second largest barrier. The MOC had the worst OS and most had clinical encounters within 2 years of diagnosis. Patients whose cancer was diagnosed after >1 LDCT had better OS than those diagnosed after one LDCT.

OA17.04 Implementation of a Natural Language Processing (NLP) Model to Detect Incidental Lung Nodules in a Nationwide Health Care Network

G. Santiago, C. Baldotto, B. Hochhegger, R. Rodrigues, T. Machuca, K. Martinez, E. Zaidan, M. Conrado, Instituto D'Or for Research and Education, Rio de Janeiro/BR

Introduction: Lung cancer is one of the leading causes of morbidity and mortality worldwide, with late diagnosis contributing to its high lethality rate. Lung cancer screening has shown an overall survival benefit, but its implementation in Brazil is incipient and has many challenges. In this study, we report the first results of an NLP model developed and implemented in a nationwide healthcare network to detect incidental suspicious nodules in chest computed tomography (CT) scans.

Methods: A previously validated NLP approach was applied to chest CT reports in 11 hospitals located in two Brazilian States. The developed algorithm identifies suspicious lesions with a minimum diameter of 6mm associated with pre-defined risk descriptors, including comparative changes. Data were collected from November 2022 to August 2023. All reports identified as positive were referred to a nurse navigator and, if indicated, to an appointment with a multidisciplinary thoracic oncology team. Here, we report the results obtained from one hospital in São Paulo city selected for the pilot study, utilizing the navigation strategy within optimized deadlines (maximum five days), being followed up through a digital communication platform (Redcap).

Results: The program evaluated a total of 67,599 chest CT reports, and 1,212 cases (1.79%) were identified for follow-up investigation in the 11 hospitals. In the specific pilot hospital unit in São Paulo city, 140 CT scans (1.26%) were captured for follow-up out of 11,108 CT scans evaluated. Of these, 104 patients (64.5%) attended consultations with specialists. Seventy-two follow-up CT scans were performed, and 45 patients are still in the program. Fourteen patients (13.4%) underwent transthoracic CT-guided biopsy, of which eight were diagnosed with surgically treatable lung cancer. Two patients were considered inoperable and referred for non-surgical treatment. The confirmation rate of neoplastic diagnosis in incidental findings was approximately 11.57%, with 57% of diagnosed cases eligible for curative surgical treatment.

Conclusions: These first results indicate that the developed NLP algorithm has effective applicability in detecting suspicious lung lesions, with a significant rate of early-stage lung cancer diagnoses. With the implementation of well-defined workflows, it is possible to streamline the investigation and follow-up process of suspicious cases, allowing for earlier diagnoses and a more effective therapeutic approach. This strategy can potentially complement a challenging lung cancer screening program in a continental country like Brazil. Further investigations will address the false-positive rate and long-term patient outcomes.

Keywords: screening, artificial intelligence, lung cancer

OA17.05 A Randomized Controlled Trial of a Digital Lung Health Intervention to Facilitate Smoking Cessation and Lung Cancer Screening

M. Cooley[1], N. Xiong[1], E. Mazzola[1], M. Nayak[1], R. DeMarco[2], A. Borondy-Kitts[3], M. Blazey[4], M. Healey[5], C-F.J. Yang[6], P. Castaldi[5], S. Kim[2], [1]Dana-Farber Cancer Institute, Boston/MA/USA ,[2]University of Massachusetts-Boston, Boston/MA/USA ,[3]Lung Rescue Society, Jupiter/FL/USA ,[4]University of Rochester, Rochester/NY/USA ,[5]Brigham and Women's Hospital, Boston/MA/USA ,[6]Massachusetts General Hospital, Boston/MA/USA

Introduction: A sub-analysis of the National Lung Screening Trial data found that screening with low-dose computed tomography (LDCT) combined with smoking cessation nearly doubled the benefit in reducing lung cancer deaths compared to LDCT screening alone. Despite the fact that US and International guidelines recommend LDCT screening for eligible candidates, uptake remains low. Most research has focused on integrating smoking cessation into lung cancer screening programs. Engaging individuals who are smoking and at high-risk for lung cancer and educating them about LDCT screening is a critical next step to promote lung health. This study tested the efficacy of a digital counseling intervention (video-call counseling, nicotine replacement therapy, digital personal stories and LDCT decision-aide) compared to standard care (brief advice, quitline referral and LDCT decision-aide) on 7 and 30-day point prevalence abstinence (PPA) rates at 3 and 6-months after study entry and lung cancer screening adoption at 6-months.

Methods: Community-based adults who were smoking > 5 cigarettes/day and eligible for lung cancer screening were recruited using multiple methods including Facebook ads across 19 states during the height of covid-19. Data including demographics, tobacco use, and lung health were collected electronically. Participants were randomized on a 1:1 ratio to the intervention (Digital) vs. standard care (Brief) arms after the baseline assessment. Self-reported and biochemically verified 7 and 30-day PPA rates were obtained at 3 and 6-months after entry to the study. Fisher exact test and Wilcoxon rank-sum test were used for analyses. Intent-to-treat analyses examined differences in self-reported 7 and 30-day PPA at 3 and 6-months between the arms.

Results: One hundred-fifty-three participants were randomized to the Digital (n=75) or the Brief (n=78) arms. Mean age of participants was 62.7 years (SD 4.7), 75.7% were female, 93.4% were white, and 27.9% had < high school education. The average age for smoking initiation was 16.4 years (SD 3.2), mean pack-year history was 43.1 (SD 7.7), and 38.1% of participants indicated that they were ready to quit smoking. Overall, 35.3% were extremely worried about getting lung cancer and 61.1% were not aware of or hadn't thought about getting lung cancer screening. As compared to the Brief arm: the Digital intervention had higher rates of self-reported 7-day PPA at 3 (52% vs. 20%, p<0.001) and 6-months (43% vs.13%, p< 0.001); higher rates of self-reported 30-day PPA at 3 (40% vs. 12%, p<0.001) and 6-months (38% vs. 14%, p=0.004); and had higher rates of biochemically verified 7-day PPA at 3 (32% vs. 15%, p=0.008) and 6-months (24% vs.10%, p=0.03). Participants in the Digital arm also had higher rates of lung cancer screening completion at 6-months after study entry (46.7% vs. 22.6%, p<0.001) as compared to the Brief arm.

Conclusions: The Digital intervention increased smoking cessation and receipt of lung cancer screening compared to the Brief arm (standard care) during covid-19. Facebook was the most effective recruitment method. This intervention can be scaled up and implemented broadly across the US to promote lung health, earlier detection of lung cancer and ultimately decreased mortality from lung cancer.

OA17.06 Impact of Using Smoking Duration in Place of Pack-Years as Eligibility Criteria for Lung Cancer Screening to Reduce Racial and Ethnic Disparities

C.C. Su[1], V.Y. Ding[1], K.t. Haaf[2], J.T. Wu[3], N.D. Freedman[4], L.M. Backhus[1], A.N. Leung[1], N.S. Lui[1], C.A. Haiman[5], S-S.L. Park[6], J.W. Neal[1], R. Meza[7], M.C. Tammemägi[8], I. Cheng[9], L.L. Marchand[6], H.A. Wakelee[1], E. Choi[10], S.S. Han[1], [1]Stanford University School of Medicine, Palo Alto/CA/USA ,[2]Erasmus Medical Center, Rotterdam/NL ,[3]Veterans Affairs Palo Alto Health Care, Palo Alto/CA/USA ,[4]National Institutes of Health, Bethesda/MD/USA ,[5]Keck School of Medicine, University of Southern California, Los Angeles/CA/USA ,[6]University of Hawaii Cancer Center, Honolulu/HI/USA ,[7]BC Cancer Research Institute, Vancouver/BC/CA ,[8]Brock University, St Catharines/ON/CA ,[9]University of California, San Francisco, San Francisco/CA/USA ,[10]Weill Cornell Medicine, New York/NY/USA

Introduction: In 2021, the United States Preventive Services Task Force (USPSTF) expanded the lung cancer (LC) screening eligibility criteria by lowering minimum cumulative smoking exposure from 30 to 20 pack-years. Despite this, underrepresented minorities (e.g., African American adults) - who exhibit higher LC incidence at lower cumulative intensity but over longer duration - still experience disparity in LC screening eligibility when using pack-years. Consequently, smoking duration has been proposed as an alternative criterion and shown to reduce the screening disparity between African American and White adults. However, potential disparities across other racial groups when using this measure is unknown.

Methods: We used data from 105,261 adults with smoking history from the prospective, population-based Multiethnic Cohort Study (MEC), which enrolled five US racial and ethnic groups (African American, Japanese American, Latino, Native Hawaiian, and White). We evaluated screening eligibility under the 2021 USPSTF criteria, i.e., USPSTF-2021, (≥ 20 pack-years, ≤15 quit-years, and age 50-80) and identified a smoking duration threshold (smoking duration >30 years, ≤15 quit-years, and age 50-80, i.e., 'duration-based criteria') yielding eligibility closest to USPSTF-2021. Racial disparity was evaluated by calculating eligibility-to-incidence ratio (E-I ratio) by race and ethnicity. Sensitivity, specificity, and number needed to screen (NNS) over six years were used as screening performance indicators. Risk model-based criteria based on a well-established model recently calibrated for race (PLCOm2012update) was also evaluated.

Results: The cohort was 18.3% African American, 25.9% Japanese American, 20.3% Latino, 7.9% Native Hawaiian, and 25.9% White adults. The overall 6-year LC incidence rate was 1.4%. The overall USPSTF-2021 eligibility rate was 24.0%, with >30 years smoking duration threshold yielding the most comparable eligibility rate (27.5%). Under USPSTF-2021, a large disparity was observed especially among African American adults compared to White adults with a 53% lower E-I ratio (E-I ratio: 9.5 vs. 20.3). This disparity was substantially reduced using duration-based criteria (E-I ratio: 13.6 vs. 19.3) while retaining overall screening performance vs. USPSTF-2021 (sensitivity 66.1% vs. 57.7%, specificity 73.0% vs. 76.5%, and NNS 30 vs. 30). After matching eligibility rate of duration-based criteria (using 6-year risk ≥ 1.1%), risk-based criteria further minimized disparities and increased screening performance across all racial and ethnic groups (sensitivity 72.0%, specificity 73.1%, NNS 28, E-I ratio in African Americans vs. Whites 17.5 vs. 21.0, see Table).

Conclusions: Smoking duration could reduce LC screening disparity without compromising screening performance, but risk model-based screening may be superior to either duration-based or USPSTF-21 criteria.

Table. E-I ratio and screening performance of lung cancer screening criteria based on USPSTF 2021 guidelines, smoking duration and risk model by race and ethnicity groups

	Overall cohort			White			African American		
Screening Criteria*	USPSTF-21	Duration-based	Risk model-based	USPSTF-21	Duration-based	Risk model-based	USPSTF-21	Duration-based	Risk model-based
% Eligible	24.0	27.5	27.5	30.2	28.8	31.3	21.4	30.4	39.3
E-I ratio	17.3	19.8	19.8	20.3	19.3	21.0	9.5	13.6	17.5
Sensitivity (%)	57.7	66.1	72.0	70.2	70.7	79.9	44.0	60.9	70.6
Specificity (%)	76.5	73.0	73.1	70.4	71.8	69.4	79.2	70.3	61.4
NNS	30	30	28	29	28	27	22	23	25
	Latino			Native Hawaiian			Japanese American		
Screening Criteria	USPSTF-21	Duration-based	Risk model-based	USPSTF-21	Duration-based	Risk model-based	USPSTF-21	Duration-based	Risk model-based
% Eligible	15.7	25.1	14.4	25.1	26.1	28.2	25.5	26.5	25.3
E-I ratio	21.1	33.7	19.3	16.8	17.5	18.9	22.0	22.9	21.9
Sensitivity (%)	53.5	69.8	59.7	55.2	60.8	64.0	62.5	67.3	72.4
Specificity (%)	84.6	75.3	86.0	75.3	74.4	72.3	75.0	73.9	75.3
NNS	40	49	33	31	29	30	36	35	31

Abbreviations. Eligibility-Incidence ratio (E-I ratio); United States Preventive Services Task Force (USPSTF); Number needed to screen (NNS)

Footnotes:
* Duration-based criterion was determined using smoking duration > 30 years threshold in place of 20 pack-years in USPSTF 2021 guidelines, which yielded eligibility rate closest to that of USPSTF 2021 guidelines; Risk model-based criterion was determined using 6-year risk ≥ 1.1% threshold, which yielded the same eligibility rate as duration-based criterion above.

Introduction: The efficacy and safety of lenvatinib in patients with previously treated thymic carcinoma were explored in the REMORA trial, however, there is scarce data in actual clinical settings.

Methods: We performed a retrospective, multicenter study of consecutive patients with advanced or recurrent thymic carcinoma who received lenvatinib between March 23, 2021, and October 31, 2022. The primary outcome was the objective response rate (ORR) to second- or later-line treatment. Setting the threshold and expected value of the primary outcome at 25% and 38%, the planned sample size was 80 patients. We performed subgroup analysis based on whether patients met the key eligibility criteria for the REMORA trial.

Results: In total, 107 patients from 31 institutions across Japan were enrolled, with 87 receiving lenvatinib as second- or later-line chemotherapy. The median age of these 87 patients was 64 years (range, 38-79), and 56 (64%) were males. The histological type of 71 patients (82%) was squamous cell carcinoma. Seventy-seven patients (89%) had a prior history of taxane-platinum combination chemotherapy. Fifty-one patients (59%) met the REMORA trial eligibility criteria. The median observation period was 13.2 months (interquartile range, 8.8-18.9). Of the 87 patients, 81 patients with target lesions were included in the primary outcome analysis. Among these 81 patients, ORR was 30% (90% confidence interval [CI]: 21.3-39.1). Respective ORR values for patients who met or did not meet the REMORA trial eligibility criteria were 28% and 31%. Among the 87 patients, the disease control rate was 92% (95% CI: 84.1-96.7). The median progression-free survival was 10.2 months (95% CI: 7.0-13.2). The median overall survival was not reached (NR; 95% CI: 18.0-NR). Treatment-related adverse events of any grade occurred in 87 patients (100%), the most common being hypertension (75%), proteinuria (66%), and fatigue or malaise (56%). Grade 3 or higher adverse events occurred in 56 patients (64%), the most common being hypertension (22%), proteinuria (17%), and decreased platelet count (10%). Drug-induced interstitial lung disease occurred in two patients (2%): one patient with grade 2 and one patient with grade 3. Adverse events leading to dose interruption or dose reduction occurred in 75 patients (86%), the most common being proteinuria (23%), hypertension (21%), palmar-plantar erythrodysesthesia syndrome (16%), and decreased platelet count (16%). Adverse events leading to treatment discontinuation occurred in 20 patients (23%), the most common being anorexia (6%), left ventricular systolic dysfunction (2%), and fatigue or malaise (2%). Two patients (2%) died from adverse events, one from arterial thromboembolism and one from pleural infection.

Conclusions: These findings suggest that lenvatinib as a second- or later-line treatment for patients with advanced or recurrent thymic carcinoma is effective but may be less effective in real-world clinical practice than in the REMORA trial. No new safety signals were observed. There was no positive correlation between efficacy and meeting the key eligibility criteria for the REMORA trial. Further investigations are needed to identify factors that influence lenvatinib efficacy. Clinical study information: UMIN000051645.

OA18.04 Pembrolizumab Plus Lenvatinib in Second-Line Pleural Mesothelioma Patients: A Single Arm Phase II Study (PEMMELA Cohort 2)

L.H. Douma[1], V. v.d. Noort[1], F. Lalezari[1], J.F. de Vries[1], M. Vermeulen[1], B. Schilder[1], I. Smesseim[1], P. Baas[1], K. Monkhorst[1], J.A. Burgers[1], C.J. de Gooijer[1], [1]Netherlands Cancer Institute - Antoni van Leeuwenhoek, Amsterdam/NL

Introduction: In the recent findings of PEMMELA cohort 1, the combination of pembrolizumab, an anti-PD-1 antibody, plus lenvatinib, a multi tyrosine kinase inhibitor, showed clinical activity in patients with pleural mesothelioma (PM) who were pre-treated with chemotherapy. The objective response rate (ORR) in that study (58%), was the highest achieved for patients with PM in later-line thus far. As nivolumab plus ipilimumab immunotherapy (nivo-ipi) is currently approved as first-line treatment in patients with PM, we aimed to evaluate clinical activity and toxicity of pembrolizumab plus lenvatinib after first-line nivo-ipi. To our knowledge, this is one of the first studies investigating immunotherapy after progression on immunotherapy in patients with pleural mesothelioma.

Methods: PEMMELA cohort 2 is a prospective single-center, single-arm, open-label, investigator-initiated phase 2 trial of pembrolizumab (200 mg once every three weeks intravenously) plus lenvatinib (20 mg once daily orally) in patients with PM who progressed after nivo-ipi (n=20). Main eligibility criteria were age 18 years or older, histologically proven PM, ECOG PS 0-1, and measurable disease according to the modified Response Evaluation Criteria in Solid Tumors (mRECIST) version 1.1 for PM. Treatment continued up to two years or until unacceptable toxicity or disease progression occurred. The primary endpoint was ORR (proportion of patients with complete response (CR), or partial response (PR)) assessed by the local investigator, taking into account the immunotherapy related rules for response evaluation of iRECIST. Secondary endpoints included safety, disease control rate (DCR) at three and six months, progression-free survival (PFS) and overall survival, as well as ORR and PFS determined by an independent radiologist. (ClinicalTrials.gov, NCT04287829).

We hypothesized that the combination treatment would result in 25% ORR in comparison with 5% response rate using anti-PD-1 monotherapy. The null hypothesis that true response rate is 5% could be rejected with 90% confidence if at least three of 20 patients had an objective response.

Results: Between November 2022 and March 2024, all patients were included. At the data cut-off (31 January, 2024), only 17 patients had received enough cycles of treatment to evaluate response and toxicity. Preliminary results showed that eight patients had reached PR as best overall response (47.1%, 95% CI 23.0-72.2%, p<0.0001), of which 5 a confirmed PR (29%, 95% CI 10.3-56.0%, p=0.001). Eleven (65%) patients developed grade 3-4 treatment-related adverse events (AE's), of which most common grade 3 events were hypertension (29%), malaise (12%), and musculoskeletal pain (12%). No grade 5 events occurred. Six treatment-related serious adverse events were observed in five patients. Thirty-nine% of the patients required at least one dose reduction due to toxicity. Updated results of all patients will be presented at the congress.

Conclusions: This study met its primary endpoint, showing very promising clinical activity of pembrolizumab plus lenvatinib also in patients with PM who progressed after nivolumab plus ipilimumab.

OA18.05 Neoadjuvant Versus Adjuvant Therapy for Locally Advanced Esophageal Squamous Cell Carcinoma: A Randomized Clinical Trial

Y. Zhu[1,2], X. Sun[3], L. Wu[1,2], Q. Chen[4], Q. Wei[5], P. Ye[6], S. Han[2], X. Yu[2], J. Liu[4], Q. Zhao[4], Y. Jiang[4], X. Zhou[4], W. Zhang[7], W. Mao[4], Y. Xu[1,2], [1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]The Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Hangzhou/CN ,[3]The Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Department of Radiation Oncology/CN ,[4]The Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Shanghai/CN ,[5]The Second Affiliated Hospital, Zhejiang University School of Medicine, Shanghai/CN ,[6]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN ,[7]Fudan University, Shanghai/CN

Introduction: Although neoadjuvant concurrent chemoradiotherapy (NCCRT) followed by surgery is the standard-of-care for locally advanced esophageal squamous cell carcinoma (ESCC) in the Western world, adjuvant sequential chemoradiotherapy (ASCRT) remains a primary choice in China. The current study (NEOTERIC Trial) aimed to investigate whether NCCRT followed by surgery is superior to surgery followed by ASCRT for locally advanced ESCC in the Chinese population.

Methods: Patients with clinically resectable, locally advanced (cT1-2N1M0 or T3-4N0-1M0) ESCC were randomly assigned to receive either NCCRT or ASCRT. The primary endpoint was disease-free survival (DFS); secondary endpoints included overall survival (OS), R0 resection rate, and toxicities.

Results: From April 2012 to November 2016, 204 patients were randomly assigned to either NCCRT (n=100) or ASCRT (n=104) arm. NCCRT significantly improved median DFS from 14.0 months to 51.0 months (hazard ratio [HR], 0.652; 95%CI, 0.467-0.910; P=0.010). The 1-year, 3-year, and 5-year DFS rates in the NCCRT group were 76.0%, 54.5%, and 46.6%, compared with 53.6%, 33.9, and 30.0%, respectively, in the ASCRT group. The median OS for patients receiving NCCRT was 79.0 months (95% CI, not estimated [NE]-NE) and 38.0 months (95%CI, 23.7-52.3) with ASCRT (HR, 0.660; 95%CI, 0.456-0.953; P=0.025). The OS rates at 1, 3, and 5 years were 88.9%, 68.7%, and 56.7% in the NCCRT arm, compared with 85.6%, 50.8%, and 39.5%, respectively, in the ASCRT arm. A significant improvement in the R0 resection rate was observed after NCCRT compared with ASCRT (96.6% vs. 85.6%; P=0.012). The in-hospital mortality rates were 3.4% in the NCCRT arm and 1.9% in the ASCRT arm (P=0.662).

Conclusions: NCCRT, compared with ASCRT, demonstrated improvements in DFS with acceptable toxicities in Chinese resectable locally advanced ESCC.

OA18.06 Characteristics and Outcomes of Patients with SMARCA4-Deficient Undifferentiated Thoracic Tumors

A. Cooper[1], B. Ricciuti[2], A. Gagne[2], L. Sholl[2], A. Di Federico[2], M. Awad[2], M. Aldea[3], M.R. Ghigna[3], M. Grecea[3], J. Chaft[1], M. Kris[1], G. Riely[1], C. Rudin[1], I. Dagogo-Jack[4], M. Mino-Kenudson[4], L. Hong[5], N. Kalhor[5], N. Vokes[5], N. Rekhtman[1], A. Schoenfeld[1], [1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]Dana-Farber Cancer Institute, Boston/MA/USA ,[3]Gustave Roussy, Villejuif/FR ,[4]Massachusetts General Hospital Cancer Center, Boston/MA/USA ,[5]MD Anderson Cancer Center, Houston/TX/USA

Introduction: SMARCA4-deficient undifferentiated thoracic tumors (UT) are a recently defined group of highly aggressive cancers in which the effectiveness of standard treatments for non-small cell lung cancer is unknown. We analyzed the clinical and pathologic characteristics and outcomes of a multicenter cohort of patients with SMARCA4-deficient UT.

Methods: We collected clinical and demographic variables from five academic institutions for patients whose tumors met the criteria for SMARCA4-deficient UT (undifferentiated morphology and loss of SMARCA4/BRG1 by immunohistochemistry) described in the 5th Edition (2021) WHO Classification of Thoracic Tumours.

Results: We identified 92 patients with SMARCA4-deficient UT. Median age was 65 (range 32 to 89); 63% were men and 70% were white. Only 3% had never smoked cigarettes; the remaining with a tobacco history had median 40 pack-year exposure. 58 patients (63%) had stage IV disease at diagnosis, with an additional 16 (17%) developing recurrent/metastatic disease. Patients diagnosed with early-stage disease (7% stage I, 7% stage II, 24% stage III) had metastatic recurrence at median 8 months (range 1.7 to 78 months, IQR 13.9). Of tumors tested for PD-L1, 9/55 (16%) had expression ≥ 50% and 24 (44%) were negative. Tumor mutational burden was available in 48 cases (52%); median was 10.5 mutations/megabase (range 1.6 to 48). Next-generation sequencing was performed in 65 cases (71%). Relevant mutations of interest included those in SMARCA4 (75%), TP53 (72%), KEAP1 (26%), STK11 (18%), and KRAS (17%). Of the patients with metastatic disease, 58 (78%) received first-line systemic treatment. Seven of 16 (44%) who did not were considered too ill to receive treatment at presentation. Median number of lines in the metastatic setting was 1 (range 0 to 5). Patients most commonly received combination chemotherapy and immunotherapy (41%), followed by chemotherapy (33%), immunotherapy monotherapy or doublet (16%), and agents on a clinical trial (7%). Median time on first-line treatment was 1.2 months (IQR 4 months). Median progression-free survival (PFS) for patients with metastatic disease receiving first-line treatment was 1.7 months. Patients who received immunotherapy (doublet or monotherapy) as first-line treatment had median PFS 3.0 months, those who received chemotherapy-immunotherapy had median PFS 1.7 months, and those who received chemotherapy alone had median PFS 1.5 months. Median overall survival (OS) from metastatic diagnosis was 6.7 months. There were five patients who experienced durable responses (≥ 2 years) without progression: two of these received combination chemotherapy and PD-1 inhibitor, two received PD-1 inhibitor monotherapy, and one received PD-1/CTLA-4 inhibitor doublet immunotherapy. PD-L1 expression was high in only one of these patients. TMB ranged from 9.1 to 31.6 in these tumor samples.

Conclusions: This multi-institution retrospective cohort analysis revealed a population of patients with highly clinically aggressive disease, with exceptionally short progression-free survival to standard therapies and poor overall survival upon diagnosis. Clinicians treating patients with this disease should be aware of the possibility of rapid progression on standard therapies, though a small proportion of patients may demonstrate remarkable response to immunotherapies. Early enrollment in prospective clinical trials should be considered.

Introduction: Stage III Non-Small Cell Lung Cancer (NSCLC) is a heterogeneous group of tumors with a wide spectrum of clinical presentations and no single definitive therapeutic approach. The role of neoadjuvant alectinib in stage III ALK-positive NSCLC is still unclear. We designed a phase II, open-label, single-arm, multicenter study aimed at investigating the activity and safety of alectinib in potentially resectable locally advanced stage III ALK-positive NSCLC patients (ALNEO trial, EUDRACT number 2020-003432-25).

Methods: Treatment-naïve patients with potentially resectable stage III ALK-positive NSCLC, ECOG PS≤1 were registered to receive neoadjuvant alectinib for 2 cycles (8 weeks) followed by surgery and adjuvant alectinib for 24 cycles (96 weeks). The primary endpoint was major pathological response (MPR). Secondary endpoints included pathological complete response (pCR), objective response (OR), event-free survival (EFS), disease-free survival (DFS), overall survival (OS), adverse events (AEs). According to the Simon's two stage design (P0=20%, P1=40%), an interim analysis was conducted to test if at least 5 major pathological responses (MPR) were documented among the first 18 enrolled patients.

Results: To date, the results are available in 25 patients registered in 20 Italian Oncology Centers from May 2021. Median age was 56 years (Interquartile Range [IQR], 49-67 years), 17 (68%) patients were female and 14 (56%) were never smokers. Clinical stage according to the 8th AJCC TNM was IIIA in 14 (56%) and IIIB in 11 (44%) patients. The most represented stage was T3N2 (n=6, 24%), followed by T1aN2 (n=4, 16%) and T4N2 (n=4, 16%). All the patients completed the neoadjuvant phase and 21 (84%) underwent surgery, which consisted of lobectomy in 17 (81%), pneumonectomy in 2 (9.5%) and other surgery in 2 (9.5%) patients. Among patients who completed surgery, R0 was achieved in 18 (86%) patients. Overall, an OR was observed in 17 of 25 (68%) patients. In the interim analysis population, MPR was achieved in 7 (39%) patients and pCR in 3 (17%) patients. Presently, adjuvant treatment was started in 17 (68%) patients with a median interval from surgery of 5.1 weeks (IQR, 2.7-6.0 weeks). After a median follow-up of 10.8 months (IQR, 5.6-22.5 months), median EFS, DFS and OS were not reached. None of the patients experienced treatment-related Grade≥3 AEs during neoadjuvant phase.

Conclusions: Results of the first stage interim analysis allowed to continue the accrual in order to reach the total of 33 planned patients. Neoadjuvant alectinib appeared to be safe in potentially resectable locally advanced stage III ALK-positive NSCLC patients. The study is partially supported by Roche S.p.A.

MA01.04 AFT-46: CHIO3: Chemotherapy Combined with Immune Checkpoint Inhibitor for Operable Stage IIIA/B Non-Small Cell Lung Cancer

L. Martin[1], X. Wang[2], D. Kozono[3], J. Urbanic[4], S. Graziano[5], R. Osarogiagbon[6], R.J. Mehran[7], J. Wain[8], C. Bestvina[9], J. Gannon[10], S. Wolf[11], T. Stinchcombe[11], J.D. Patel[12], [1]University of Virginia, Charlottesville/VA/USA ,[2]Alliance Statistics and Data Management Center, Duke University, Durham/NC/USA ,[3]Alliance Protocol Operations Office, University of Chicago, Boston/MA/USA ,[4]University of California, San Diego, La Jolla/CA/USA ,[5]State University of New York Upstate Medical University Syracuse-Health Science Center, Syracuse/NY/USA ,[6]Baptist Memorial Hospital and Cancer Center-Memphis, Memphis/TN/USA ,[7]University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[8]Brigham and Women's Hospital, Boston/MA/USA ,[9]University of Chicago Comprehensive Cancer, Chicago/IL/USA ,[10]Alliance Foundation Trials, LLC, Boston/MA/USA ,[11]Duke Cancer Institute, Duke University Medical Center, Durham/NC/USA ,[12]Northwestern University, Chicago/IL/USA

Introduction: The optimal treatment of Stage IIIA/B (N2) NSCLC remains undefined given impressive outcomes with chemoradiation followed by immunotherapy as well as neo-adjuvant or peri-operative chemoimmunotherapy with surgical resection. In other stage III NSCLC trials, nodal downstaging after neoadjuvant therapy has been associated with improved survival. This trial focused on operable stage III (N2) NSCLC and uniquely sought to evaluate N2 nodal clearance (N2NC) rates after treatment with chemotherapy and durvalumab as the primary endpoint. NCT04062708

Methods: This was an open-label, single arm phase 2 trial including participants from 9 US hospitals. Eligible patients had surgically resectable stage III NSCLC with pathologically proven N2 disease, PS 0-1. N3 and EGFR mutation were exclusionary. Patients received 4 cycles of platinum doublet + durvalumab followed by lobectomy or greater, optional postoperative radiation to 54 Gy, and adjuvant durvalumab Q4 weeks for one year. The primary endpoint was an increase in N2NC (ypN0) from a historical rate of 30% with platinum doublet chemotherapy to 50%.

Results: Planned accrual was 55 patients with 42 patients undergoing resection and thus evaluable for N2 status. DSMB recommended study closure as the primary endpoint was met on interim analysis. 37 patients were enrolled and are evaluable for safety; 1 is currently receiving neoadjuvant therapy. 29 patients underwent resection. Reasons for coming off study before surgery were: 4 progressive disease, 2 toxicity. One patient was found to be ineligible after receiving 1 cycle of treatment. N2NC was 75.9%, 95%CI: 56.5-89.7% (22/29 surgical patients) (Table). Pathologic complete response was noted in 8/29 patients (27.6%). R0 resection was achieved in 27/29 patients (93.1%).

Conclusions: Neoadjuvant durvalumab plus chemotherapy followed by resection is an effective strategy for stage III (N2) NSCLC, with N2NC more than twice the historical ypN0 rate with platinum doublet alone. In this locally advanced group with proven N2 disease of NSCLC, surgical resection after chemoimmunotherapy was feasible with low rates of perioperative toxicity and high rates of R0 resection (93.1%).

MA01.05 Efficacy and Safety of Neoadjuvant Camrelizumab and Apatinib Combined with Chemotherapy in Stage IIIA (N2) NSCLC: A Single Arm, Phase II Trial

L. Zhao[1,2], W. Chen[1,2], T. Guo[1,2], Y. Huang[1,2], L. Zhu[1,2], S. Chen[3], X. Chen[3], Y. Zhang[4,5], Y. Yang[4,5], X. Pan[1,2], [1]Shengli Clinical Medical College of Fujian Medical University, Fuzhou/CN ,[2]Fujian Provincial Hospital, Fuzhou/CN ,[3]Fuzhou Pulmonary Hospital, Fuzhou/CN ,[4]Zhangzhou Municipal Hospital of Fujian Province, Zhangzhou/CN ,[5]Zhangzhou Affiliated Hospital of Fujian Medical University, Zhangzhou/CN

Introduction: Camrelizumab (an anti-programmed cell death protein-1 antibody) combined with apatinib (an antiangiogenic agent) has conferred benefits for advanced non-small cell lung cancer (NSCLC). This study aimed to assess the efficacy and safety of camrelizumab and apatinib alongside chemotherapy in patients with resectable stage IIIA (N2) NSCLC as neoadjuvant therapy.

Methods: In this phase II trial, patients with histologically confirmed resectable stages IIIA (N2) NSCLC received the combination of chemotherapy, camrelizumab (200 mg, q3w) and apatinib (250 mg, once daily). Patients underwent surgery after 2-3 cycles of treatment. The primary endpoint was the major pathological response (MPR) rate. Secondary endpoints included pathological complete response (pCR) rate, R0 resection rate, objective response rate (ORR) and safety. This trial was registered with ChiCTR.org.cn (ChiCTR2200059608), and is ongoing but no longer recruiting patients.

Results: Between August 4, 2021 to September 2, 2023, among 29 patients who received neoadjuvant therapy, 19 underwent complete resection. The disease control rate and ORR was 86.2% (95% CI: 72.2%-97.8%) and a downstaging rate of 20.7% (95% CI: 6.9%-36.4%). In the subgroup of 19 patients who underwent surgery, the MPR rate was 36.8% (95% CI: 16.3%-58.7%), and the pCR rate was also 36.8% (95% CI: 16.3%-58.7%). Nonsurgical grade 3/4 adverse events (AEs) were reported in 19 (65.5%) of the 29 patients, with the most common AEs being leukopenia (31.0%), thrombocytopenia (17.2%), rash (17.2%) and fatigue (13.8%). Survival results were not reported due to immature data.

Conclusions: Camrelizumab plus apatinib combined with chemotherapy showed clinically meaningful anti-tumor activity and manageable safety, with few hematologic toxicities, and might be a potential treatment option in patients with resectable stage III NSCLC.

Introduction: The highly active glycolytic metabolism of non-small cell lung cancer (NSCLC) is an attractive target for metabolic therapies. NRG-LU001 (NCT02186847) was a phase II trial that found that the addition of anti-diabetic agent metformin, a mitochondrial inhibitor, to the standard of care cCRT did not improve 1-year progression-free survival (PFS) in locally advanced (LA)-NSCLC. Here, we present the long-term analysis with 5-year follow-up.

Methods: Stage IIIA/B NSCLC, unresected, non-diabetic, patients were randomized (1:1) to either carboplatin-paclitaxel chemotherapy concurrent with chest RT (60Gy), followed by consolidation carboplatin-paclitaxel chemotherapy (Control Arm) or the same and oral metformin (2000mg daily) during cytotoxic therapy (Experimental Arm). The primary endpoint of this trial was 1-year PFS. Secondary outcomes included overall survival (OS), rates of local-regional and distant failure, and rates of adverse events. PFS and OS were estimated with the Kaplan-Meier method; local-regional progression and distant metastasis were estimated using the cumulative incidence method. Adverse events (AEs) were graded with CTCAE v.4.0. Exploratory landmark analysis was conducted to mitigate immortal bias when evaluating outcomes among patients compliant with metformin.

Results: A total of 170 patients were accrued and randomized between Aug. 2014 and Dec. 2016. As of Sep. 2023, minimal additional toxicity was reported and no significant difference was detected in the rates or grade of toxicity between the two arms.1- 2- and 5-year PFS was 60.4%, 40.3% and 29.2% in Control [(95%CI: 48.5, 70.4); (95%CI: 29.2, 51.1); (95%CI: 19.3, 39.7)] vs 51.3%,34.5% and 24.3% in the Metformin arm [(95%CI: 39.8, 61.7), (95%CI: 24.2, 45.1) and (95%CI: 15.5, 34.3)], respectively, (multivariable Cox proportional HR=1.21(95%CI: 0.84, 1.75), p=0.152). OS at 2- and 5-years was 65.3% and 38.1% for Control [(95% CI:53.6, 74.7); (95%CI: 27.1, 49.0)] vs 65.3% and 41.2% for the Metformin arm [(95%CI: 53.1, 74.5); (95%CI: 30.1, 52.0)], respectively, (HR=1.04 (95%CI:0.71, 1.53) p=0.828. Deaths due to disease were 76.5% vs 63.0%, respectively. No significant differences were found in the rates of local-regional and distant failures. In a posthoc analysis investigating the role of metformin compliance, a landmark analysis was conducted among those who survived 3 months or longer. 74 patients received no metformin, 46 patients received >95%of the protocol-recommended drug dose, and 31 received <95% of the recommended dose. 2- and 5-year OS rates in those three groups were 68.1%and 39.7% [(95%CI: 56.0, 77.5), (95%CI:28.3, 50.8)], 75.9% and 55.2% [(95%CI:60.7, 85.9), (95%CI:39.4, 68.4)] and 51.6% and 22.6% [(95%CI:33.0,67.4), (95%CI:10.0, 38.3)], respectively. No formal statistical comparison was made given the exploratory nature of this analysis.

Conclusions: NRG-LU001 long-term outcomes show that oral daily metformin was well-tolerated in combination with cCRT treatment for LA-NSCLC. In the per-protocol analysis, metformin did not improve PFS and OS and did not alter the rates of local-regional failure or distant metastasis. Nevertheless, long-term OS outcomes in this trial compare favorably to those of control and interventional arms of recently reported trials. The impressive OS rates detected in patients of the metformin arm who adhered to the protocol-recommended drug dose warrant further investigation in future studies.

Introduction: Perioperative immunotherapy has shown to improve short-term outcomes for resectable NSCLC patients. However, the long-term benefits still remain unclear. Our study presents the 5-year survival outcomes of the NADIM I trial (NCT03081689).

Methods: NADIM was an open-label, multicenter, single-arm phase 2 trial involving 18 participant hospitals in Spain designed to investigate the feasibility, safety and efficacy of perioperative chemoimmunotherapy in 46 resectable stage IIIA (7th edition) NSCLC patients. Three cycles of neoadjuvant chemotherapy (intravenous paclitaxel and carboplatin) in combination with nivolumab were administered. After surgery, adjuvant intravenous nivolumab monotherapy was administered for 1 year. The 5-year survival outcomes and biomarker analysis were secondary objectives.

Results: According to the analysis of the intent to treat (n= 46) population, the five-year progression-free survival rate was 65.0% (95%CI 49.4-76.9) and the overall survival rate was 69.3% (95%CI 53.7-80.6). The 5-year PFS and OS rates considering only cancer-specific events, were 75.8% (95% CI 60.6-58.8) and 82.2% (95% CI 67.6-90.7), respectively. Patients who achieved complete pathological responses (CPR) showed a significant increase in their 5-year PFS and OS rates, reaching 92.0% (95%CI 70.5-97.9) and 95.8% (95%CI 73.9-99.4), respectively. Moreover, low ctDNA burden at baseline (i.e. SumMAF<1%), ctDNA clearance (i.e. undetectable ctDNA after neoadjuvant treatment), and high adjuvant treatment compliance (i.e received ≥50% of scheduled adjuvant cycles) were associated to better long-term survival. PD-L1 tumor proportion score and tumor mutational burden (TMB) were not associated with 5-year survival outcomes. Additionally, no deaths related to treatment, safety data or unexpected long-term toxicities were observed. PD-L1 tumor proportion score and tumor mutational burden (TMB) were not associated with 5-year survival outcomes. Additionally, no deaths related to treatment, no concerning safety data or unexpected long-term toxicities were observed

Conclusions: These results demonstrate robust long-term benefit of perioperative chemo-immunotherapy in resectable stage IIIA NSCLC patients, with no reported long-term toxicities, reinforcing the use of this therapeutic approach in the future. The study also highlights the importance of complete pathological responses and ctDNA status as prognostic biomarkers in these patients.

MA01 ADVANCES IN TREATMENT FOR STAGE III NSCLC
SUNDAY, SEPTEMBER 8, 2024 - 14:00 - 15:15

MA01.09 Definitive Chemoradiation Followed by Immunotherapy vs. Surgery for cT4N2M0 NSCLC: A Contemporary Nationwide Analysis.

J.H. Rodriguez-Quintero[1], R. Jindani[1], R. Zhu[1], B. Cohen[1], M.K. Kamel[2], N. Mahajan[1], M. Vimolratana[1], N. Chudgar[1], B. Stiles[1], [1]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx/NY/USA ,[2]University of Rochester, Rochester/NY/USA

Introduction: The optimal treatment regimen for cT4N2(IIIB) NSCLC, remains debated. PACIFIC-2 recently reported higher than expected treatment mortality and disappointing DFS, suggested to be due to a preponderance of T4 tumors and need for large radiation fields. Given these results, it is conceivable that surgery may be preferred in carefully selected cT4N2 patients.

Methods: Using the National Cancer Database (2015-2020) we identified patients with cT4N2M0 NSCLC (8thEdition AJCC) who received definitive chemoradiation (54-66 Gy) followed by immunotherapy (PACIFIC) (started within 90 days of chemoradiation) or curative-intent surgery in the setting of a multimodality treatment approach (salvage resections >150 days after chemoradiation excluded). We used logistic regression to identify associations with the use of surgery. After propensity-matching to adjust for differences among groups (age, sex, race, comorbidities, type of facility, and tumor site) overall survival was compared using the Kaplan-Meier method.

Results: A total of 1,908 patients were identified of whom 918 (48.1%) underwent PACIFIC and 990 (51.9%) underwent surgery. Patients who underwent surgery were younger (median 65 vs. 66 years, p<0.001), more often white (85.5% vs. 81.4%, p=0.013), and more likely had no comorbidities (Charlson-Deyo Index=0 65.3% vs. 56.5%, p<0.001) than those who received PACIFIC. In multivariable analysis, female sex (aOR 1.36, 95%CI 1.03-1.80), income above national median (aOR 1.40, 95%CI 1.04-3.52), adenocarcinoma histology, (reference: squamous; aOR 1.49, 95%CI 1.19-1.99,) non-central tumors (reference: central tumors; right tumor: aOR 1.49, 95%CI 1.19-1.99 and left tumor 2.84, 95%CI 1.54-5.23,) and treatment at an academic facility (aOR 1.38, 95%CI 1.03-1.86) associated with increased use of surgery. As expected, later years of diagnosis associated with decreased used of surgery (aOR 0.19, 95%CI 0.16-0.22). A total of 875 (88.4%) patients in the surgery group had a lobectomy, with negative margins in 83.1%(Fig-1A). After matching (1:1, PACIFIC vs. surgery), 1,422 patients were evaluated. Those in the surgery cohort had improved survival compared to the PACIFIC cohort (HR 0.81, 95%CI 0.68-0.95)(3-Yr OS: 60.9% vs. 52.9%, Median OS 54.4 vs. 40.4, p=0.011). In subgroup analysis, the OS benefit was more robust in patients who received neoadjuvant/perioperative approach (N=409)(HR 0.70, 95%CI 0.58 to 0.85)(3-Yr OS: 64.8%, Median OS: not-reached, p<0.001) (Fig 1B).

Conclusions: In selected patients, surgery is associated with improved overall survival compared to chemoradiation followed by immunotherapy. While we need prospective data to validate these findings, clinical stage IIIB(N2) patients should be considered for perioperative regimens in multidisciplinary tumor boards.

MA01.11 Unveiling Gene Expression and Immune Contexture in Stage II/III NSCLC Patients Receiving Neoadjuvant Pembrolizumab and Chemotherapy

Y. Chen[1,2], Y. Su[1,2], R. Zhang[2], S. Wang[3], J. Zhang[3], X. Sun[2], G. Zhao[4], Q. Ou[3], J. You[1,2], [1]Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Tianjin's Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin/CN ,[2]Tianjin Cancer Hospital Airport Hospital, National Clinical Research Center for Cancer, Tianjin/CN ,[3]Nanjing Geneseeq Technology Inc., Nanjing/CN ,[4]Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center of Cancer, Tianjin/CN

Introduction: Neoadjuvant chemo-immunotherapy (NCIT) has the potential to mitigate surgery-induced immunosuppression, thereby improving surgical and survival outcomes of non-small cell lung cancer (NSCLC) patients who present resectable lesions. Nevertheless, there is an unmet clinical demand to identify promising biomarkers through coordinated immune and molecular profiling.

Methods: We performed whole transcriptome sequencing on 26 baseline and 24 surgical samples obtained from 26 patients histologically diagnosed with stage II/III resectable NSCLC who received neoadjuvant pembrolizumab and chemotherapy followed by complete surgery. Our analysis focused on elucidating gene expression patterns and immune cell characteristics within the tumor microenvironment (TME), aiming to decipher their correlation with pathological complete response (pCR) and clinical outcomes, including event-free survival (EFS), disease-free survival (DFS), and overall survival (OS).

Results: Baseline pCR tumors demonstrated upregulated expression of immunomodulator genes, including HLA-C (P=0.02), HLA-E (P=0.01), and B2M (P=0.08) involved in antigen presentation, BTN3A1 (P=0.04) and CD274 (P=0.03) in co-inhibitory pathways, and HMGB1 (P=0.01) in innate immune regulation, compared to non-pCR tumors. In post-NCIT surgical samples from pCR patients, increased expression of IGHD, LILRA6, and ICOSLG was observed, all associated with positive regulation of immune response, while the expression of CEACAM6 participating in cell adhesion and tumor progression was decreased. Additionally, baseline pCR tumors showed higher TMEscore (P=0.09) and infiltration of activated dendritic cells (P=0.06), along with an elevated proportion of naïve B cells in surgical samples of pCR patients. Although plasma cell and NK cell populations consistently decreased in surgical samples compared to baseline tumors regardless of pathological response, non-pCR patients exhibited greater infiltration of CD8+ T cells (P<0.01) and increased immune cell penetration (P<0.001) in surgical samples, indicating a persistent anti-tumor response. Notably, baseline MGAT5B expression predicted pathological response (area under the curve: 0.86) and correlated with shorter DFS and EFS (both P=0.03). Surgical CEACAM6 levels served as an adverse biomarker for DFS and EFS (P=0.03 and P=0.04). A similar trend was observed for OS, although the difference between patients with or without these gene expression signatures did not reach statistical significance, presumably due to restraint sample size.

Conclusions: Our research reinforces the use of pCR as a surrogate endpoint in neoadjuvant settings. Moreover, the identification of molecular biomarkers linked to pathological and survival outcomes provides valuable insight to inform optimal treatment decision-making, guide postoperative therapy, and improve the chances of curing for stage II-III patients with resectable NSCLC.

MA01.12 Survival Outcomes and Pathologic Response after Chemo-Immunotherapy in Resectable NSCLC: An Individual Patient Data Meta-Analysis

D. Marinelli[1], A. Nuccio[2], A. Di Federico[3], F. Ambrosi[3], P. Bertoglio[3], E. Faccioli[4], R. Ferrara[2], A. Ferro[5], R. Giusti[6], F. Guerrera[7], M. Mammana[4], A. Pittaro[8], M. Sepulcri[5], G. Viscardi[9], F.T. Gallina[10], [1]Sapienza - Università di Roma, Rome/IT ,[2]IRCCS Ospedale San Raffaele, Milan/IT ,[3]University of Bologna - Alma Mater Studiorum, Bologna/IT ,[4]Università degli Studi di Padova, Padova/IT ,[5]IOV - Istituto Oncologico Veneto IRCCS, Padova/IT ,[6]AOU Sant'Andrea, Rome, Rome/IT ,[7]Università degli Studi di Torino, Turin/IT ,[8]Azienda Ospedaliera Universitaria San Luigi Gonzaga, Orbassano/IT ,[9]AORN dei Colli Monaldi, Naples/IT ,[10]IRCCS Regina Elena National Cancer Institute, Rome/IT

Introduction: Neoadjuvant chemoimmunotherapy has reshaped the treatment landscape for resectable NSCLC, yet the prognostic significance of pathologic response remains unclear. We conducted a systematic review and individual patient data metanalysis to evaluate the impact of achieving pCR or MPR on EFS and assessed the influence of adjuvant immunotherapy.

Methods: This is an individual patient data metanalysis of randomised clinical trials of neoadjuvant or perioperative anti-PD-(L)1 in combination with platinum-based chemotherapy in patients with resectable NSCLC. IPD was extracted from Kaplan-Meier curves for pCR and/or MPR of the included studies. Survival outcomes were compared between patients achieving pCR or MPR and those who did not, considering both intention-to-treat and resected populations.

Results: Achieving pCR or MPR was associated with improved EFS across all trials (pCR, HR 0.12, 95% CI 0.07-0.20; MPR, HR 0.19, 95% CI 0.14-0.28, respectively, fig.1) with a 24 months EFS rate for patient who achieved pCR of 94% and 87% for those with MPR (p=0.222). Independently from pCR status patients who were randomised to an experimental arm that included adjuvant immunotherapy, did not show improved EFS in ITT and resected population (p=0.222 in pts achieving pCR for no-adjuvant vs adjuvant; p=0.678 for pts with no-pCR for no adjuvant vs adjuvant).

Conclusions: Our study showed a significant survival benefit in patients who achieved either pCR or MPR after neoadjuvant chemo-immunotherapy. No differences in survival were found between pCR and MPR patients. Additionally, the use of adjuvant immunotherapy after tumour resection did not improve survival outcomes in both patients with or without pCR.

MA01.13 Adherence to Treatment Protocol of Patients Submitted to Neoadjuvant (Chemo) Immunotherapy in Resectable NSCLC: Ameta Analysis

F. Guerrera[1], F.T. Gallina[2], E. Balzani[3], D. Marinelli[4], A. Nuccio[5], R. Ferrara[5], A. Di Federico[6], F. Ambrosi[6], E. Faccioli[7], M. Mammana[7], A. Ferro[8], M. Sepulcri[8], R. Giusti[9], A. Pittaro[10], G. Viscardi[11], P. Bertoglio[12], [1]University of Torino, Torino/IT ,[2]IRCCS Regina Elena National Cancer Institute, Rome/IT ,[3]University of Turin, Turin/IT ,[4]Sapienza - Università di Roma, Rome/IT ,[5]IRCCS San Raffaele Scientific Institute, Milan/IT ,[6]Alma Mater Studiorum Università di Bologna, Bologna/IT ,[7]Università degli Studi di Padova, Padua/IT ,[8]IOV - Istituto Oncologico Veneto IRCCS, Padua/IT ,[9]AOU Sant'Andrea, Rome/IT ,[10]Azienda Ospedaliera Universitaria San Luigi Gonzaga, Turin/IT ,[11]AORN dei Colli Monaldi, Napoli/IT ,[12]IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna/IT

Introduction: Neoadjuvant immunotherapy (IO) alone or associated with standard chemotherapy in resectable non-small-cell lung cancer (NSCLC) is currently an area of great interest. Data regarding the adherence to treatment protocols of neoadjuvant treatments including IO will guide the definition of the best course of treatment. We performed a metanalysis including studies on the use of IO neoadjuvant protocols in resectable NSCLC to evaluate the adherence rate to the treatment and surgical outcomes.

Methods: A systematic review of PubMed and Embase with meta-analyses was performed. Included studies were prospective clinical trials of preoperative IO alone or in combination with chemotherapy in resectable NSCLC. Research cutoff was March 2023. Two authors (P.B. and F.G.) independently and in duplicate screened the abstracts of all publications obtained by the search strategies to identify studies. Primary outcomes were adherence to medical treatment (calculated as omission of therapy rate, incomplete therapy rate, omission of surgery rate) and postoperative outcomes (R0 rate and microscopically uncomplete resection rate).

Results: We included 27 studies with a total of 2656 patients. 21 studies were phase 2, 6 phase 3 and one phase 1b. All studies were started in the time frame between 2013 and 2020. In 17 studies IO was associated to chemotherapy per protocol. Figure 1 reported the list of the studies included.As expected, almost all patients received at least one administration of therapy (omission of therapy 0%, 95% CI 0.00-0.01), while 7% of patients received and incomplete number of cycles according to the protocol (95% CI 0.04-0.10, figure 1). Surgery was not performed in the 13% of patients (95% CI 0.10-10.16, figure 1). In those patients who received induction therapy and surgical resection R0 was reached in 94% of cases (95% CI 0.93-0.96) while a macroscopic complete resection or an explorative intervention was reported in 2% of patients (95% CI 0.02-0.03).

Conclusions: The adherence to treatment protocols appears to be a critical point in NSCLC patient's candidate to radical surgery. Data from the present literature showed a low incomplete therapy rate. Nonetheless, 13% of patients could not receive surgical resection. In those patients who concluded the neoadjuvant and surgical treatment, surgical results were satisfactory with a 94% rate of R0.Our data show that IO neoadjuvant treatment currently has an acceptable adherence rate with good surgical results. A better definition of neoadjuvant duration and doses might further improve adherence results.

MA02.03 Circulating T Cell Receptor Repertoire Analysis Improves Cancer Early Detection

Y. Li[1], M. Nahas[1], D. Stephens[1], K. Froburg[1], E. Hintz[1], D. Champagne[1], A. Lochab[1], M. Brown[1], J. Braun[1], M.A. Fortuño[2], M-d-M. Ocón[2], A. Pasquier[2], I.M. Luque[3], C.W. Seder[4], J.A. Borgia[5], L.M. Seijo[3], L.M. Montuenga[6], R. Yelensky[1], [1]Serum Detect, Inc., Newton/MA/USA ,[2]Clínica Universidad de Navarra Cancer Center, Pamplona/ES ,[3]Clínica Universidad de Navarra Cancer Center, Madrid/ES ,[4]Rush University Medical Center Department of Cardiovascular and Thoracic Surgery, Chicago/IL/USA ,[5]Rush University Medical Center Department of Anatomy & Cell Biology, Chicago/IL/USA ,[6]Clínica Universidad de Navarra Cancer Center and CIMA, University of Navarra, Pamplona/ES

Introduction: Cancer screening by liquid biopsy promises to detect cancer early when it can be cured. However, current liquid biopsy approaches based on circulating tumor DNA (ctDNA) detect only a minority of early-stage cancers, because these tumors shed little ctDNA and plasma sample volume is limited. For liquid biopsy to realize its potential for the early detection of cancer, sensitivity for the earliest stage disease must be improved. (This abstract is an update of an abstract previously presented at the AACR 2024 annual meeting.)

Methods: We set out to improve sensitivity of liquid biopsy for cancer early detection by exploiting tumor recognition by T cells through sequencing of the circulating T cell receptor repertoire. Using gDNA extracted from blood buffy coats, we studied a cohort of 439 lung cancer patients (86% with stage I disease) and 553 subjects without cancer, enriched for older individuals with a history of smoking. We performed genomic DNA TCR beta chain sequencing to yield a median of 80,921 TCR clonotypes in cancer patients and 112,083 clonotypes in non-cancer controls. We built a TCR sequence similarity nearest neighbor graph to cluster 69M distinct TCR clonotypes into TCR repertoire functional units (RFUs). The TCR frequencies of RFUs were tested for association with cancer status and significantly associated RFUs were combined using a support vector machine model into a TCR RFU cancer score. This model was evaluated by 10-fold cross-validation (CV) and compared to a ctDNA panel of 237 mutation hotspots in 154 lung cancer driver genes (IDT™) and to a panel of 17 lung cancer related protein biomarkers (Olink®) in 86 subjects.

Results: We identified 197 cancer-associated TCR RFUs at FDR≤0.10, including 110 RFUs that were enriched in cancer samples with a TCR count log2-fold change between 0.06 and 0.61, and 87 that were enriched in controls with a log2-fold change between 0.07 and 0.40. We observed 77 of the 110 cancer-enriched RFUs had decreasing TCR counts with increasing age across the cohort, coupled with the higher counts in cancer patients relative to age-matched controls. The TCR RFU cancer score achieved a cross-validated test ROC AUC of 0.70 for cancer status prediction, with the AUC for stage I cancers exceeding that of stage II-IV (0.71 vs. 0.64). 49% of stage I cancers (test samples of each CV fold) were detected by the TCR model at a specificity of 80%. We saw a substantial gain in sensitivity for stage I cancer when TCR RFUs were added to ctDNA and proteins, with a ~20%-point increase seen at the 90% target specificity level typical for cancer screening tests. Interestingly, sensitivity was not improved by addition of TCR analysis for later stage (II-IV) lung cancer, highlighting the already strong performance of existing plasma analytes for the detection of later stage disease.

Conclusions: We demonstrate detection of a significant fraction of early lung cancer cases from blood by analyzing the circulating TCR repertoire and show that this signal is complementary to established analytes such as proteins and ctDNA.

MA02.04 High Detection Rate of Blood MicroRNA Test in Lung Cancer Screening Eligible Individuals

G. Sozzi, F. Sabia, L. Rolli, M. Segale, P. Suatoni, A. Zanghi', M. Ruggirello, A. Marchiano', M. Boeri, U. Pastorino, Fondazione IRCCS Istituto Nazionale Tumori, Milano/IT

Introduction: Low dose computed tomography (LDCT) lung cancer screening (LCS) can reduce mortality in high-risk individuals, but the majority of heavy smokers proved to be reluctant to undergo radiologic examinations. A non-invasive blood test might circumvent this problem, as it happened with PSA in prostate cancer. The BioMILD trial aimed to test the contribution of blood microRNA assay to LDCT screening in heavy smokers.

Methods: We have evaluated here the diagnostic efficacy of a LCS strategy offering baseline LDCT and one annual repeat only to individuals with positive microRNA assay. Non LCS-eligible BioMILD participants, below the age of 55 years, were excluded from this analysis.

Results: From the total cohort of 3139 participants, 781 (24.9%) had a positive microRNA assay, and among them 37 LCs were detected at 2 years, representing 58.7% of all detected LCs, and 56.5% of stage I/II. LC incidence was 4.7% in microRNA+ and 1.1% in microRNA- subjects (P<0.0001). With the same reimbursement of 120€ given for every blood assay and LDCT, the cost of each detected LC would be approximately 12,000€ for standard LCS and 15,000€ for miRNA based LCS.

Conclusions: In the subset of LCS eligible BioMILD participants, upfront blood microRNA assay showed a high sensitivity for LC detection, particularly in early-stage disease, with reasonable costs. Such a non-invasive blood test strategy might contribute to improve LCS recruitment of heavy smokers aged 55 years or older.

MA02.05 Inter-Reader Agreement of AI Versus Human Readers in Baseline LDCT Lung Nodule Classification; A UKLS Trial Dataset Sub-Study

H.L. Lancaster[1,2], B. Jiang[2,3], J.W.C. Gratama[2,4], M. Silva[5], G.H. de Bock[1], J.K. Field[6], M.A. Heuvelmans[1,2], M. Oudkerk[2], [1]University Medical Center Groningen, University of Groningen, Groningen/NL ,[2]Institute for Diagnostic Accuracy, Groningen/NL ,[3]Erasmus University Rotterdam, Rotterdam/NL ,[4]Department of Radiology, Gelre Hospital, Apeldoorn/NL ,[54]. Scienze Radiologiche, Department of Medicine and Surgery (DiMeC), University of Parma, Parma/IT ,[6]The University of Liverpool, Liverpool/GB

Introduction: Lung cancer screening is a public health focus, with an increasing number of implementation studies, regional, and national programs commencing each year. This has led to a substantial rise in the number of LDCT scans which radiologists need to analyse. AI is being proposed as a solution, especially if it can be used as a first-read-filter to accurately rule-out negative cases where no, or only small lung nodules are present. A key challenge in the analysis of lung nodules on LDCT scans is the high variability in nodule measurement and classification. Therefore we evaluated inter-reader agreement of AI compared to human readers when performing solid (component) nodule classification in a UKLS trial LDCT scan dataset.

Methods: Four manual readers with varying levels of experience (medical researcher to senior radiologist) and AI independently analysed 1253 baseline LDCT scans from the UK lung cancer screening trial. An expert panel reference standard read was performed (blinded from individual results) to serve as a reference standard, against which everything else was judged. In the case of multiple nodules per participant the 'dominant' non-calcified solid component nodule was selected for further analysis. This nodule was categorised based on a 100mm3 threshold, the upper mean threshold for benign nodule growth. Kappa analysis was performed to determine inter-reader agreement between all reads and the reference standard.

Results: From 1253 baseline LDCT scans, the reference standard read categorised 616 (65%) as negative; no nodules or <100mm3. Overall agreement on nodule classification between all human readers, AI, and consensus was moderate (kappa 0.559 [95%CI 0.544-0.573]). An overview of agreement between each read can be seen in Table 1. Substantial inter-reader agreement was only found between readers 3 and 4 (kappa 0.704), and between AI and the reference standard read (kappa 0.757).

Conclusions: Overall inter-reader agreement for the classification of the 'dominant' solid (component) non-calcified lung nodule per participant was moderate, however AI showed potential to have substantial agreement with an experienced expert panel. AI could therefore help standardise lung nodule classification on baseline LDCT scans in a lung cancer screening setting.

MA02.07 AI as Primary Reader in 4-IN-THE-LUNG-RUN Lung Cancer Screening Trial: Impact on Negative Misclassification and Referral Rate

A. Walstra[1], H.L. Lancaster[1,2], M.A. Heuvelmans[1,2], J.W. Gratama[3], M. Silva[4], M. Oudkerk[1], [1]Institute for Diagnostic Accuracy, Groningen/NL ,[2]University Medical Center Groningen, Groningen/NL ,[3]Gelre Hospital, Apeldoorn/NL ,[4]University of Parma, Parma/IT

Introduction: Lung cancer screening (LCS) with low-dose computed tomography (LDCT) has shown significant mortality reduction among high-risk individuals. Artificial intelligence (AI) is commonly used as a secondary or concurrent reader in LCS, while its role as the primary reader can primarily reduce radiologist workload by effectively ruling out negative cases. Our study evaluates AI as a primary reader in the European 4-IN-THE-LUNG-RUN (4ITLR) LCS trial, comparing its false-negative (FN) cases to those of experienced radiologists.

Methods: FN cases were extracted from the 4551 baseline LDCTs of the 4ITLR dataset between 13 December 2022 and 22 September 2023. The LDCTs were read independently by both a radiologist and dedicated AI software. A case was designated as FN when nodules >100 mm3 were present and either the radiologist or the AI solely detected nodules <100 mm3 or no nodules (negative). Hereafter, a distinction was made between the indeterminate (100-300 mm3) and positive (>300mm3) cases. The three-month follow-up CT was assessed of all the indeterminate cases to assess the final classification.

Results: 443 FN cases were identified, of which 33 by AI and 410 by radiologists. There was no overlap in FN cases. Among the 33 AI FN cases identified, 9.1% (3 cases) were classified as positive and 90.9% (30 cases) were indeterminate. Upon review of these 30 follow-up scans, 93.3% (28 cases) were reclassified as negative and 6.6% (2 cases) were discontinued from the program. The AI missed 69.7% (23 cases) due to detection errors, and 30.3% (10 cases) due to segmentation errors. Among the 410 radiologist FN cases identified, 1.0% (4 cases) were classified as positive and 99.0% (406 cases) were indeterminate. Upon review of these 406 follow-up scans, 2.2% (9 cases) were positive, 1.7% (7 cases) required a second three-month follow-up CT scan and 90.0% (366 cases) were reclassified as negative. The remaining 5.9% (24 cases) were discontinued from the program.

Conclusions: This study showed the efficacy of independent CT readings by both radiologists and AI in ensuring no FN cases occur at baseline. AI had a lower occurrence of FN cases compared to radiologists, demonstrating potential in effectively ruling out negative cases as the primary reader, without an increased risk of delayed or missed diagnosis due to FN cases.

MA02.08 Performance of A Blood-based Protein Biomarker Panel in the National Lung Screening Trial

E. Ostrin, E. Irajizad, S.M. Ghasemi, J.F. Fahrmann, J.V. Vykoukal, J.B. Dennison, S.M. Hanash, UT MD Anderson Cancer Center, Houston/TX/USA

Introduction: A 4-protein biomarker panel (4MP) has been shown to improve estimation of lung cancer risk and identify individuals who may benefit most from lung cancer screening. In the current study, we evaluated the performance of the 4MP for risk determination of lung cancer in the multicenter National Lung Screening Trial (NLST).

Methods: The 4MP was assessed in two nested case-control cohorts of plasma samples from the NLST. The first cohort consisted of 675 samples from individuals with CT scans without suspicious findings, including 135 eventually diagnosed with lung cancer and 540 matched control samples. The second cohort consisted of 715 samples from individuals with screen-detected pulmonary nodules, including 143 diagnosed with cancer before the next screening timepoint and 572 matched controls. The 4MP was measured using a multiplex bead-based immunoassay using coefficients fixed from a previously developed logistic regression model. Performance was evaluated using receiver operating characteristic analysis, including computing the area under the curve (AUCs) as well as a net reclassification index (NRI) to estimate how well the 4MP improved existing risk prediction models such as the Brock nodule risk calculator.

Results: In the cohort with negative CTs, for those individuals eventually diagnosed with stage II or higher lung cancer, the 4MP showed an AUC of 0.67 (95% CI 0.59-0.74). For all those with advanced (stage III and higher), AUC was 0.71 (95% CI 0.61-0.81). For individuals diagnosed within 1 year of blood draw, the AUC was 0.71 (95% CI 0.51-0.91). In those with indeterminate nodules, the 4MP showed similar performance, with an AUC of 0.64 (95% CI 0.59-0.70) in those eventually diagnosed with stage II or higher lung cancer. The 4MP, added to the Brock model, showed an NRI of 0.26 compared to the Brock model alone.

Conclusions: The 4MP may be a useful adjunct to screening, especially in identifying those who will develop more advanced stage disease in the following year. This could help to identify individuals who may benefit from closer clinical follow-up.

Introduction: Low-dose computed tomography (LDCT) screening has been used for early detection of lung cancer that led to significant reduction of lung cancer caused mortality. However, only less than 5% pulmonary nodules detected by LDCT are malignant. Most patients with pulmonary nodules are anxious and often overdiagnosed or overtreated in lung cancer screening that may lead to pulmonary injury and fiscal waste. Apparently, more accurate and cost-effective tools are needed to assist nodule diagnosis and management.

Methods: We first performed a genome-wide methylation sequencing in 52 malignant and 76 non-malignant pulmonary nodule tissues and selected a panel of 263 differential DNA methylation regions (DMRs). We then conducted a targeted methylation sequencing on blood cell-free DNA in a prospectively collected and retrospectively analyzed multicenter cohort of 620 participants to develop and optimize a model for risk stratification of pulmonary nodules using machine learning approaches. Forty top-performance markers were finally selected to build a methylation model and risk scores of methylation model were then integrated with age and five CT imaging features to form a combined model. Finally, an independent prospective multicenter cohort with 343 pulmonary-nodule participants were used as an external validation cohort to evaluate the performance of different prediction models.

Results: The performance of the forty-methylation marker model was evaluated in the internal validation cohort (194 malignant and 85 benign) and the external validation cohort (231 malignant vs 112 benign), achieving an ROC AUC of 0.81 (95% CI 0.76- 0.86) in both cohorts, superior to Mayo model (0.66, 0.59-0.72; 0.64, 0.58-0.71) and Brock model (0.72, 0.65-0.78; 0.70, 0.64-0.76). The combined model showed better performance than the methylation model and achieved AUCs of 0.90 (95% CI 0.86-0.94) and 0.89 (95%CI 0.85-0.92) with increases of 0·09 and 0.08 in AUC (95% CI 0.05-0.12, p<0·0001; 95% CI 0.04-0.11, p<0.0001) in internal and external validation cohorts, respectively. We applied two cutoffs (0.22 and 0.94) simultaneously to classify pulmonary nodules into lowrisk (risk score <0.22), intermediaterisk (risk score from ≥0.22 to <0.94), and highrisk (risk score ≥0.94) groups. The combined model could accurately identify high-risk nodules with 90.4% specificity and 93.9% accuracy, as well as low-risk nodules with 98.1% sensitivity and 91.8% accuracy in the combined validation cohorts. The model can reduce 89.9% unnecessary invasive surgeries and avoid 64.8% delayed treatments.

Conclusions: We have developed an integrated model consisting of forty methylation markers, one clinical and five CT imaging features for accurate diagnosis and management of pulmonary nodules.

MA02.11 Validation of the Sybil Deep Learning Lung Cancer Risk Prediction Model in Three Independent Screening Studies

R. Phellan Aro[1], S. Lam[2,3], M.T. Warkentin[1,4], G. Liu[5,6], B. Diergaarde[7,8], J-M. Yuan[7,8], D.O. Wilson[9], R. Meza[3], R. Myers[2], R.J. Hung[1,6,], [1]Lunenfeld-Tanenbaum Research Institute, Toronto/ON/CA ,[2]University of British Columbia, Vancouver/BC/CA ,[3]British Columbia Cancer Research Institute, Vancouver/BC/CA ,[4]University of Calgary, Calgary/AB/CA ,[5]Princess Margaret Cancer Centre, Toronto/ON/CA ,[6]University of Toronto, Toronto/ON/CA ,[7]University of Pittsburgh School of Public Health, Pittsburgh/PA/USA ,[8]UPMC Hillman Cancer Cente, Pittsburgh/PA/USA ,[9]University of Pittsburgh, Pittsburgh/PA/USA ,[10]Cancer Care Ontario, Toronto/ON/CA

Introduction: Lung cancer is the leading cause of cancer death worldwide. Early diagnosis with low-dose computed tomography (LDCT) can reduce lung cancer morbidity and mortality. However, efficient patient management in LDCT screening programs remains challenging. Sybil is a deep learning model designed to predict future lung cancer risk by analyzing a single whole LDCT image. We aim to validate Sybil using three independent screening studies and evaluate its performance.

Methods: Based on 38 922 LDCT images and 2 010 confirmed lung cancers from the Pan-Canadian Early Detection of Lung Cancer, Pittsburgh Lung Screening Study, and Toronto Screening Program, we used Sybil to estimate lung cancer risk for year 1 to 6 and estimated the area under the receiving operating characteristics curve (AUC). We also evaluated the AUC by nodule diameter, solidity, and nodule presence.

Results: Based on the 3 studies, the AUC for Sybil was 0.93 for lung cancer diagnosed within 1 year, down to 0.79 within 6 years (see Table 1). When restricting the analysis to those with pulmonary nodules, the AUCs of Sybil remained comparable. However, when focusing on individuals with no baseline nodules, the AUC from Sybil reduced to 0.65.

When stratified by nodule diameter, Sybil performs better among larger nodules (maximum diameter > 10 mm), with AUCs of 0.91 for year 1 vs 0.86 in those with small nodules. When stratified by solidity, Sybil performs better in ground glass opacity nodules, with AUC above 0.93 in years 1 and 2, but it performs better in partially solid nodules in years 3 to 6, with AUC above 0.81.

To assess if Sybil can predict lung cancer risk in the absence of nodules, we used LDCT scans for patients with a known lung cancer diagnosis but no apparent nodules at baseline. 91 patients did not have nodules at baseline but were diagnosed with lung cancer between 1 to 6 years. 83 of 91 had low Sybil scores at baseline, which suggests that Sybil's predictive performance may be suboptimal in the absence of nodules.

Conclusions: We evaluated the predictive performance of Sybil in three independent lung cancer screening studies. The performance was best within 1 year. A decline in accuracy was observed for predictions after 3 years. We also found that Sybil may not be able to predict lung cancer risk without the presence of nodules and may have limited clinical use for fast-growing nodules, not present at baseline.

Area under the receiver operating characteristic curve (AUC) values obtained during Sybil evaluation

	Risk of developing cancer within					
	1 year	2 years	3 years	4 years	5 years	6 years
No. LDCT images analyzed	37 609	37 898	38 192	38 459	38 735	38 922
No. confirmed lung cancer	697	986	1 280	1 547	1 823	2 010
AUC	0.93	0.88	0.85	0.83	0.80	0.79

MA02.12 UC Screen California: A Statewide Participatory Informatics Approach to Lung Cancer Screening

A.L. Cummings[1], H.I. Tupper[1], Y. Lin[1], H.B. Keshava[2], G. Sadigh[2], B.A. Glenn[1], D. Hamilton[1], R. Bastani[1], W. Hsu[1], J.W. Goldman[1], A. Ghasemiesfe[3], E.K. Tong[3], H. Leisy[3], J. Seibles[3], L. Rios[3], M. Chen[3], T. Yarbrough[3], M. Vella[4], B. Antonelli[4], Y. Gesthalter[4], D.R. Strong[5], G. Cheng[5], N. Patel[5], J. Hudson[5], D. Moghanaki[1], D.T. Cooke[3], A. Prosper[1], [1]University of California, Los Angeles, Los Angeles/CA/USA ,[2]University of California, Irvine, Irvine/CA/USA ,[3]University of California, Davis, Davis/CA/USA ,[4]University of California, San Francisco, San Francisco/CA/USA ,[5]University of California, San Diego, San Diego/CA/USA

Introduction: The US healthcare system is fractured and complicated. Almost one-third of tobacco users do not have a PCP and 84% of eligible individuals are unaware of lung cancer screening (LCS). Despite these challenges, we can leverage widespread cellphone access to connect patients to healthcare, including LCS. In California, 99.0% of households have telephone services and 93.5% have internet access with smartphones being the most common type of computing device. Multiple LCS websites are available in the US, but few offer direct navigation to screening assessment, coordination and scheduling. To address low LCS rates in California, the University of California (UC) Lung Cancer Consortium's Screening and Prevention Taskforce developed a novel web-based screening platform to connect Californians with screening resources and programs. We sought to evaluate public engagement with this tool.

Methods: Taskforce experts collaborated with Chorus Innovations (Long Beach, CA) to develop ucscreenca.org, a participatory informatics platform available in the public domain that can be shared on multimedia devices with web-browsing, voice or text-messaging features. The platform has 3 domains: 1) A user-facing engagement domain, which includes a simplified eligibility assessment module, shared decision-making tools, educational LCS materials, and care navigator connectivity; 2) a secure, interactive dashboard for care navigators; and 3) an analytics dashboard. The modular platform is readily adaptable to different LCS needs. To facilitate dissemination in-person and on social media platforms, a QRFY-generated QR code was linked to ucscreenca.org, and the platform was advertised at UC-sponsored screening events. Using the analytics dashboard, site metrics were tracked from 11/4/23 to 2/29/24. Additional QR code user demographics were captured through QRFY. A 3-question Likert-type survey was also administered via Qualtrics at public LCS awareness events across the UCs in November 2023 to evaluate site usability.

Results: Between November 2023 and February 2024, there were 1077 site visitors, of which 65.6% were in November (n=706), and 8462 individual ucscreenca.org page views. The top 5 pages visited were the homepage, the screening eligibility assessment, the screening assessment results, LCS educational materials (general overview page), and the screening location search function. Site visitors initiated a total of 590 screening assessments and 17.4% (n=101) were eligible for LCS. The average time to screener completion was 102 seconds. Among the 208 users who reported a smoking history, 67 (32.3%) did not complete one or more component questions for the pack-years calculation. Of these 67, the majority (83.6%, n=56) omitted the "packs per day" question. In assessing QR code reach, 223 of the 367 QR codes scanned were from devices registered in Los Angeles and the original languages for these devices were diverse, including Chinese, Spanish, Korean, Bokmal, and French. Finally, amongst 117 Likert-type survey respondents, 95.7% recommended the ucscreenca.org platform and 90.6% found it easy to use.

Conclusions: Mobile and web-based participatory platforms are an important way to reach individuals and families about screening. Our participatory informatics tool demonstrated ease of use and effectiveness. Further dissemination and iterative development of a platform for broader health system-agnostic use in California is ongoing.

MA02.13 Deep Learning-Based Multiomic Model for Lung Cancer Diagnosis

M. Zhao, Y. She, Shanghai Pulmonary Hospital, Tongji University, Shanghai/CN

Introduction: Rapid identification of lung cancer from indeterminate pulmonary lesions (IPLs) and avoiding unnecessary invasive biopsies in patients with benign diseases are equally desirable outcomes that are often at odds with one another. A multi-omics deep learning model (RadmC) was proposed in our study to facilitate these outcomes.

Methods: A total of 1236 cfDNA samples and CT images were collected from 1236 participants who carried IPLs in 5 clinical centers. RadmC was constructed by involving radiomics and epigenomics features, including 5-methylcytosines, 5-hydroxymethylcytosines, and the 5-methylcytosines /5-hydroxymethylcytosines ratio in training cohort (n=864), and assessed by area under the curve (AUC), sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy. The net clinical benefit of RadmC in reclassifying IPLs and the biological basis of RadmC were evaluated to enhance the interpretability of RadmC.

Results: RadmC outperformed single-omics model with an improved AUCs of 0.908, 0.897 in the internal (n=187) and external (n=185) validation cohort, maintaining the best sensitivity (0.823, 0.864), specificity (0.870, 0.822), PPV (0.951, 0.938), NPV (0.615, 0.661), and accuracy (0.834, 0.854) in both validation cohorts. Its superiority performance was well maintained in various clinical scenarios, including different ages, sexes, lesion locations, lesion types, sizes, and substages of adenocarcinoma. For IPLs with medium-risk identified by Mayo and Brock models, RadmC could correctly reclassify 64.5% and 80.3% of cancers, 86.1% and 88.1% of benign diseases, respectively, and reduce unnecessary invasive procedures by 96.7% and delayed treatment by 37.7%, providing additionally clinical benefits for IPLs management. Biological exploration analysis revealed that features into RadmC were significantly enriched in cancer proliferation-related pathways, and lower expression of activated-T-cells which indicating a progressed stage of tumor.

Conclusions: RadmC provided a more accurate, robust and noninvasive tool for early diagnosis of lung cancer, showing potential in guiding the clinical management for IPLs.

MA03.03 The Impact of AI-driven 3D Reconstruction on Pulmonary Surgery Planning (AIR-SURGE): A Multi-Center Multi-Reader Multi-Case Study

X. Chen[1], C. Dai[2], M. Peng[3], D. Wang[4], X. Sui[1], L. Duan[2], X. Wang[3], X. Wang[1], W. Weng[1], S. Wang[1], H. Zhao[1], Z. Wang[1], J. Geng[1], C. Chen[3], Y. Yan[3], Q. Hu[3], C. Jiang[2], H. Zheng[2], Y. Bao[2], C. Sun[1], Z. Cui[1], X. Zeng[1], H. Han[1], C. Xia[4], J. Liu[4], B. Yang[4], J. Qi[4], F. Ji[4], S. Wang[4], N. Hong[1], J. Wang[1], Y. Zhu[2], F. Yu[3], F. Yang[1], [1]Peking University People's Hospital, Beijing/CN ,[2]Shanghai Pulmonary Hospital, Shanghai/CN ,[3]The Second Xiangya Hospital of Central South University, Changsha/CN ,[4]Infervision Medical Technology Co., Ltd, Beijing/CN

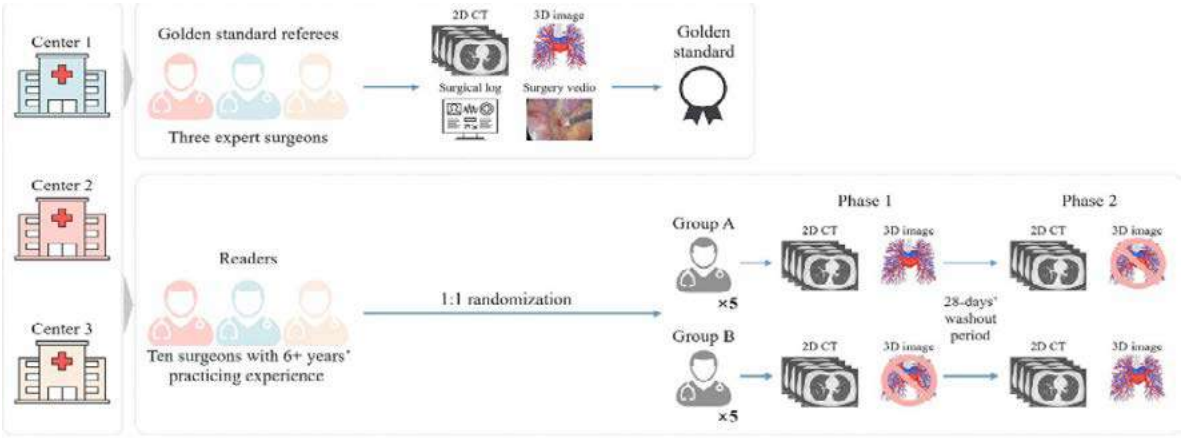
Introduction: The complexity of lung cancer surgery and the global shortage of thoracic surgeons necessitate enhanced efficiency and precision in the management of early-stage lung cancer. The advent of deep learning algorithms presents a promising avenue for efficient transitioning from conventional two-dimensional (2D) chest computed tomography (CT) scans to three-dimensional (3D) reconstructions. However, the clinical impact of these technological advancements remains to be evaluated.

Methods: We conducted a multi-reader, multi-case (MRMC) study, employing a novel two-phase crossover design, to assess the utility of an artificial intelligence (AI) system for preoperative planning. In the initial phase, half of the readers utilized standard 2D CT imaging, while the remainder utilized both 2D CT images and AI-enhanced 3D reconstructions. Following a 28-day washout period, the groups switched methodologies. Each reader was tasked with determining the extent of resection and identifying anatomical variants using a pre-defined surgery planning chart, comprehensively evaluating the system's precision and utility.

Results: The study enrolled 10 thoracic surgeons and 140 cases across three centers. The utilization of the AI system led to a significant 8% improvement in the accuracy of anatomical variant identification and a 41% reduction in error rates. Furthermore, accuracy in selecting the appropriate resection extent increased by 8%, accompanied by a 35% reduction in errors. Notably, the time required for preoperative planning was reduced from 253 to 191 seconds, with an outstanding 99% satisfaction rate among surgeons regarding the model's independent performance.

Conclusions: Our study demonstrates that AI-driven 3D reconstruction enhances preoperative planning in lung cancer surgery by improving accuracy and substantially decreasing error rates in anatomical variant identification and resection extent decision. These initial findings regarding the early role of AI in the thoracic surgery process necessitate further research to fully understand the potential and limitations of integrating AI into thoracic surgical practices

Keywords: Lung surgery, 3D reconstruction, artificial intelligence



The workflow of the MRMC study
A total of 16 thoracic surgeons from three top-tier hospitals in China participated in this clinical trial. Three surgeons collected 400 patients consecutively and enrolled in the study according to inclusion and exclusion criteria. A total of 140 cases were randomly selected from eligible cohorts. Three expert surgeons from three centers established the golden standard based on collected surgical logs, videos, CT scans, and manually constructed 3D reconstructions. The other 10 surgeons were divided into two groups randomly and took part in the MRMC study in which two rounds of fully crossed pre-operative planning simulations were conducted with an interval of 4 weeks, either with or without the aid of AI-derived 3D reconstructions of pulmonary vessels.

Inclusion criteria for readers and golden standard referee

1. Certified attending physician in thoracic surgery department.
2. Practicing thoracoscopic surgery independently for at least one year.
3. Physicians with national license for clinical practicing.
4. Physicians with a good clinical practice certificate.
5. The expert group consists of thoracic surgeons with associate senior clinical titles or above, and their professional direction is lobectomy and segmentectomy.

MA03.04 A Deep Learning Model to Predict Occult Lymphatic Metastasis in Clinical Stage I Non-Small Cell Lung Cancer Based on Chest CT

Y. Fu[1], R. Hou[1], X. Fu[1], L. Qian[2], W. Feng[1], Q. Zhang[1], Z. Ding[2], W. Yu[1], X. Cai[1], J. Liu[1], [1]Department of Radiation Oncology, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[2]Department of Oncological Surgery, Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Surgery and stereotactic body radiation therapy (SBRT) are both major curative local treatments for clinical stage I non-small cell lung cancer (NSCLC), but the choice between the two still needs to be discussed. One of the decisive factors is the correct diagnosis of lymph node staging. About 10% of clinical stage I lung cancer is surgically diagnosed with occult lymphatic metastasis (OLM), so we aimed to develop a deep learning model based on chest CT to predict the OLM of clinical phase I NSCLC and guide individualized precision treatment.

Methods: In this study, patients clinically diagnosed as stage I and pathologically determined as NSCLC who received surgery and lymph node dissection from 2015 to 2017 and 2021 to 2022 in our institution were collected to form a retrospective and prospective cohort, respectively. We extracted deep image representations from preoperative chest CT images of patients in the retrospective cohort by developing an adaptive dense connectivity network and fused them with 13 relevant clinical features by the logistic regression to achieve accurate prediction of OLM. After the model training was completed, its generalization was verified on the prospective cohort. The ROC curve was used to evaluate the predictive performance of the model, and the optimal cut-off value based on the maximum Youden index was used to divide the high and low risk group of OLM and help recommend suitable treatment decisions.

Results: A total of 2489 and 322 patients who met the inclusion criteria were finally enrolled to form the retrospective cohort and prospective cohort, respectively. The retrospective cohort was randomly divided into the training, validation and test sets in an 8:1:1 ratio. Finally, the AUCs of the constructed image-clinical fusion model for predicting OLM in the retrospective and the prospective test set were 0.915 and 0.921, which were significantly higher than those of the clinical model (0.830 and 0.790). The sensitivity, specificity and accuracy were 88.9%, 82.7%, 83.6% and 95.9%, 82.8%, 84.8% in the retrospective and the prospective test set, respectively. Besides, the patients could be significantly divided into the high and low risk group of OLM by the cut-off value of the model as the threshold ($P<0.001$). Among them, radical surgical resection combined with lymph node dissection was first recommended for patients in the high-risk group to avoid probably-missed cure of metastatic lymph nodes, and SBRT could also be another treatment option for patients in the low-risk group especially when they were contraindicated or unwilling to operate.

Conclusions: In our study, a three-dimensional adaptive convolutional neural network model based on chest CT was constructed through deep learning to predict OLM in patients with clinical stage I NSCLC which showed better prediction performance and clinical consistency than the clinical model. It might assist doctors in accurately staging before surgery in patients with early-stage NSCLC and screening the applicable population for surgery or SBRT so as to further improve the level of individualized precision treatment.

MA03.05 Intraoperative Visualization of Pulmonary Nodules with Indocyanine Green Inhalation Under Near-Infrared Window I and II

H. Xu, F. Yang, Y. Li, J. Zhou, Peking University People's Hospital, Beijing/CN

Introduction: Accurate intraoperative location of pulmonary nodules is crucial for precise resection of these lesions. This study aimed to explore the effectiveness and safety of ICG inhalation for intraoperative localization of pulmonary nodules under NIR-I and NIR-II.

Methods: Patients who underwent thoracoscopic surgery with pulmonary nodules ≤ 2 cm in depth and ≤ 2 cm in size were selected. All patients received ICG inhalation after anesthesia. Patients were randomly divided into five groups based on the duration of ICG inhalation: 5, 10, 15, 20, and 25-minutes (doses of 4.7, 9.4, 14.1, 18.75, and 23.4 mg). Intraoperatively, fluorescence visualization of nodules was performed under NIR-I and NIR-II. The primary outcomes were the location rate and background-tumor ratio (BTR) of nodules. The secondary outcomes were the inhalation-related complications.

Results: A total of 140 patients (186 nodules) were enrolled, with 32, 41, 44, 38, and 31 nodules in 5, 10, 15, 20, and 25-minute groups, respectively. Under NIR-I, the nodule localization rates in five groups were 56.3%, 75.6%, 72.1%, 88.9%, and 79.4%, with a significant difference (P=0.038). There were significant differences in BTR between groups (P<0.001), with the highest BTR occurring in 20-min group. Among 120 nodules that could only be located by palpation, the fluorescence localization rate of each group was significantly different (P=0.048), and the 20-min group was the highest (85.7%). Additionally, 18 nodules were unable to be located by palpation, the 20-minute group had the highest rate (66.7%). There were 165 nodules visualized under NIR-II, with 30, 33, 35, 35, and 31 nodules in five groups. Under NIR-II, the location rate in five groups were 70%, 78.8%, 88.6%, 94.3%, and 84.4%, respectively, with no significant difference (P=0.088). There were significant differences in BTR between groups (P<0.001), with the highest BTR occurring in 20 and 25-min groups. Additionally, 15 nodules were unable to be located by palpation, with an average localization rate of 60%, and the 20-minute group demonstrated a 100% rate. Compared to NIR-I, the average localization rate under NIR-II was significantly higher (83.6% vs. 75.2%, P<0.001). Moreover, the localization rates under NIR-II in all groups were significantly higher than those under NIR-I (all P<0.05). During inhalation, 26 patients (18.6%) experienced transient hypoxemia (SpO2≤ 90%). No other complications were observed.

Conclusions: This study demonstrated the feasibility and safety of ICG inhalation for intraoperative localization of pulmonary nodules and verified that NIR-II can further improve the localization of pulmonary nodules.

Keywords: Pulmonary nodule location, Near-infrared fluorescence, Indocyanine green inhalation

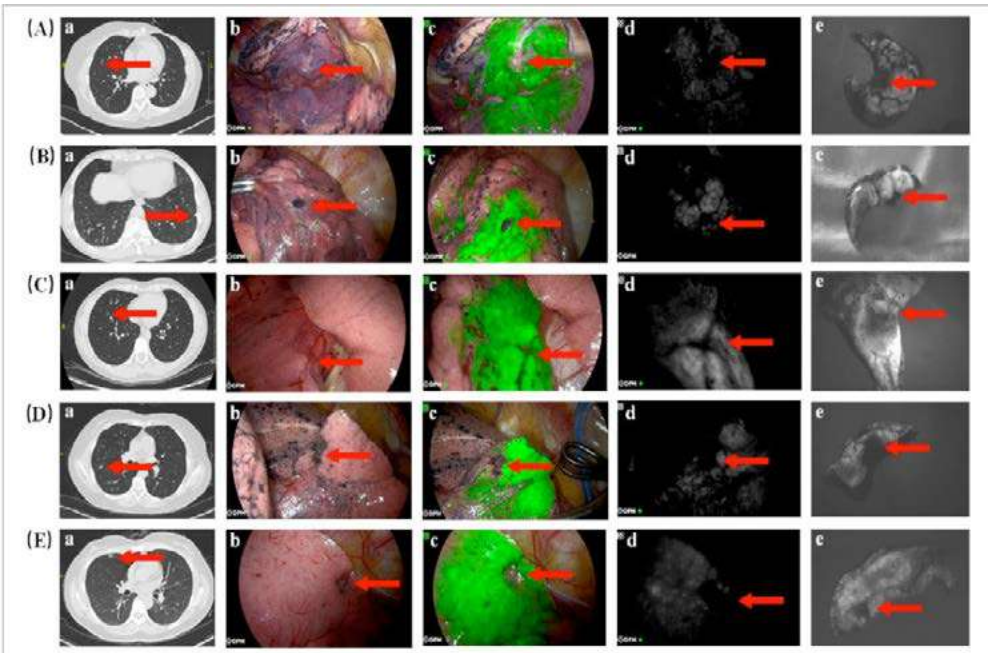

Figure 1. Fluorescence imaging of pulmonary nodules in different time groups. Figures (A) to (E) respectively represent examples of fluorescence imaging of pulmonary nodules in the 5, 10, 15, 20, and 25-minute groups. In each subfigure, a, b, c, d, e represent the chest CT image of the pulmonary nodule, the white-light window image during surgery, the overlap window image, the NIR-I window image, and the NIR-II window image, respectively. The red arrows indicate the location of the pulmonary nodules.

MA03.07 Outcomes of Older Patients in CALGB 140503 (Alliance): Lobar vs Sublobar Resection for Peripheral Stage IA Non-Small Cell Lung Cancer

A.K. Ganti[1], B. Damman[2], X. Wang[3], T.E. Stinchcombe[3], N. Altorki[4], [1]VA Nebraska Western Iowa Healthcare System and University of Nebraska Medical Center, OMAHA/NE/USA ,[2]Mayo Clinic, Rochester/MN/USA ,[3]Duke University, Durham/NC/USA ,[4]Weill Cornell Medicine, New York/NY/USA

Introduction: In the CALGB 140503 trial sublobar resection was not inferior to lobar resection for non-small cell lung cancer (NSCLC) patients with small peripheral tumors. This analysis compares the effect of age on post-operative complications and outcomes with the two surgical approaches.

Methods: Patients enrolled on CALGB 140503 were categorized into three groups based on age: <65 years, 65-75 years and >75 years. Baseline characteristics, surgical approaches, pathological findings, disease-free survival (DFS), overall survival (OS), ≥grade 3 adverse events (AEs) and 90-day mortality were compared. Comparison of continuous variables were tested with Kruskal-Wallis test, and discrete variables were tested with either chi-square or Fisher's exact test. Survival outcomes were compared using the stratified log-rank test.

Results: Of the 697 patients in CALGB 140503, 254 patients were < 65 years old, 314 were 65-75 years, while 129 patients were >75 years. Baseline characteristics were matched between the three cohorts, except for smoking status (57.9%, 32.5% and 27.9% current smokers in the <65, 65-75 and >75 cohorts; p=<.0001) and mean percent predicted FEV1 (82.4, 83.9, 87.9 respectively; p=0.03). There were no differences in the three groups for number of lymph nodes sampled and T-stage, but a higher proportion of patients <65 (5.5%) and >75 (4.7%) had N1 disease, compared to the 65-75 years group (1.6%) (p=0.03). When compared to <65 cohort, patients >75 who underwent lobar resection had a lower DFS [hazard ratio (HR): 1.67; 95% CI, 1.06 – 2.62] and OS (HR: 2.73 95% CI, 1.61 – 4.64). There was no difference in DFS or OS in the group that underwent sublobar resection. There were no differences in DFS or OS between sublobar resection and lobar resection in any of the three age-based cohorts. There was no association between age and ≥grade 3 adverse events and 90-day mortality in either the lobar or the sublobar resection groups. These results are summarized in Table 1.

Conclusions: Older patients tolerated surgical resection in CALGB 140503 well, with similar adverse events and 90-day mortality as younger patients. The reasons for a lower DFS and OS in patients >75 who underwent a lobectomy need to be studied further. Surgical resection for early-stage NSCLC should be offered to all appropriate patients regardless of age.

MA03.08 Differential Impact of Sublobar Resection on Visceral Pleural Invasion Classification

D. Lee[1], S. Park[1], S.J. Lee[1], T.Y. Yoon[1], J.H. Park[1], B.S. Na[1], K.J. Na[1], I.K. Park[1], C.H. Kang[1], Y.T. Kim[1], [1]Seoul National University Hospital, Seoul/KR

Introduction: Visceral pleural invasion (VPI) is a well-known unfavorable prognostic factor in lung cancer. However, VPI is not always considered when deciding on sublobar resection at the time of surgery for small tumors. Therefore, we aim to evaluate the impact of sublobar resection on small-sized non-small cell lung cancer (NSCLC) according to VPI classification.

Methods: From July 2017 till March 2023, we retrospectively reviewed 4505 of surgically resected NSCLC patients with ≤3cm and VPI (PL1 and PL2) in Seoul National University Hospital. VPI classification was determined by three dedicated pulmonary pathologists based on the elastic layer stain. Relapse free survival (RFS) was evaluated with Kaplan-Meier analysis. Cox-proportional hazards model was employed for prognostic factors.

Results: A total of 509 patients (PL1 = 465 patients and PL2 = 44 patients) were included with a mean follow-up duration of 38.6 ± 20.4 months. Distant metastasis was the dominant pattern of recurrence in both group (PL1 = 74.7% and PL2 = 85.7%). A significant difference was observed between PL1 and PL2 group in RFS (5y-RFS; PL1 vs PL2 = 83.9% vs. 68.2% p = 0.004). There was a trend indicating that the impact of sublobar resection was different according to PL1 or PL2 (p-value=0.057 for interaction). Within PL1 group, there was no difference in RFS between sublobar and lobar resection (5y-RFS; sublobar vs lobar = 85.3% vs. 83.6% p=0.931), whereas PL2 group showed a significant difference between resection types (5y-RFS; sublobar vs lobar = 50% vs. 71.1% p = 0.022) (Figure 1). In a multivariable analysis, sublobar resection did not influence on RFS in PL1 group (p = 0.511, HR = 0.754 [CI 0.325-1.749]. However, sublobar resection was associated with worse RFS compared to lobar resection in PL2 group (p = 0.018, HR = 0.071 [CI 0.008-0.632]).

Conclusions: We revealed that sublobar resection has a differential impact on prognosis according to VPI classification. Sublobar resection should be cautiously utilized in NSCLC with ≤3cm and PL2.

MA03.10 Association of Surgical Margin Distance, Locoregional Recurrence, and Survival Among Patients Undergoing Sublobar Resection in CALGB140503

L.W. Martin[1], C-F. Yang[2], X. Wang[3], B. Damman[4], T.E. Stinchcombe[3], J. Mentlick[4], R. Landreneau[5], D. Wigle[4], D.R. Jones[6], M. Conti[7], A.S. Ashrafi[8], M. Liberman[9], M. de Perrot[10], J.D. Mitchell[11], R. Keenan[12], T. Bauer[13], D. Miller[14], N. Altorki[15], [1]University of Virginia, Charlottesville/VA/USA ,[2]Massachusetts General Hospital, Boston/MA/USA ,[3]Duke University, Durham/NC/USA ,[4]Mayo Clinic, Rochester/MN/USA ,[5]Tampa General Hospital, Tampa/FL/USA ,[6]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[7]Institut Universitaire de Cardiologie et Pneumologie de Québec, Quebec/QC/CA ,[8]Surrey Memorial Hospital, Surrey/BC/CA ,[9]Centre Hospitalier de l'Université de Montréal, Montreal/QC/CA ,[10]University of Toronto, Toronto/ON/CA ,[11]University of Colorado, Aurora/CO/USA ,[12]Moffitt Cancer Center, Tampa/FL/USA ,[13]Hackensack Meridian Health Center, Hackensack/NJ/USA ,[14]Emory University, Atlanta/GE ,[15]Weill Cornell Medicine, New York/NY/USA

Introduction: In a randomized trial of lobectomy vs sublobar resection (CALGB 140503, NCT00499330) for stage IA (<2cm) lung cancer, sublobar resection was non-inferior to lobectomy for the primary endpoint of disease-free survival (DFS), and secondary endpoint of locoregional recurrence. Despite this, questions remain about adequacy of local control with sublobar resection. In this post-hoc analysis, we evaluate the association between surgical margin distance (SMD) and locoregional-recurrence-free survival (LRFS) and overall survival (OS) within the cohort undergoing sublobar resection.

Methods: Patients who underwent sublobar resection for cT1a-bN0 NSCLC in CALGB 140503 were grouped by presence or absence of locoregional recurrence [LRR]. The SMD, as determined by the operating surgeon, and the ratio between the SMD and tumor size ("margin-to-tumor size ratio") were evaluated. Multivariable Cox proportional hazards modeling was used to evaluate association between SMD and LRFS, OS. The association between margin-to-tumor size ratio and LRFS, OS was similarly analyzed. Patients who died within 90-days of surgery, and patients lost to follow-up were excluded from this analysis.

Results: A total of 329 evaluable patients underwent sublobar resection (201 [61.1%] wedge resection, 128 [37.9%] segmentectomy), of whom 45 (13.7%) developed a LRR during a median follow-up of 7 years. Of these patients, 208 (135 [64.9%] wedge resection, 73 [35.1%] segmentectomy) had known SMD data, of which 29 (13.9%) experienced LRR. There were no significant differences in SMD between patients who did and did not have a LRR (mean SMD in cm [SD]: 1.9 [1.46] vs. 2.0 [1.19], P=0.33). Margin-to-tumor size ratio was similar between patients with and without LRR (mean [SD]: 1.2 [1.0] vs. 1.5 [1.0], P=0.11). There were no independent predictors of LRFS (Figure). Tumor size >1.5 cm (aHR 2.11: 95%CI: 0.96- 4.66, P=0.06) and margin-to-tumor size ratio <1 (aHR: 2.12: 95% CI: 0.69 - 6.94, P=0.19) trended towards but did not achieve statistical significance. There was no association between SMD nor margin-to-tumor size ratio and OS.

Conclusions: In this analysis of the sublobar resection cohort in CALGB 140503, 13.7% experienced LRR. Surprisingly, neither SMD nor margin-to-tumor size ratio were predictive of LRFS or OS.

MA03.11 Postoperative Complications Compromised Disease-Free and Recurrence-Free Survival in CALGB 140503 Trial Patients

D.L. Miller[1], X. Wang[2], B. Damman[3], J. Mentlick[3], R. Landreneau[4], D. Wigle[3], D. Jones[5], M. Conti[6], A. Ashrafi[7], M. Liberman[8], J. Port[9], M. de Perrot[10], J. Mitchell[11], R. Keenan[12], T. Bauer[13], T. Stinchcombe[2], N. Altorki[9], [1]Medical College of Georgia, Augusta/GA/USA ,[2]Duke Cancer Institute, Durham/NC/USA ,[3]Mayo Clinic, Rochester/MN/USA ,[4]University of Pittsburg, Pittsburgh/PA/USA ,[5]Memorial Sloan Kettering, New York/NY/USA ,[6]University of Delaval Quebec, Montreal/QC/CA ,[7]University of British Columbia, Surrey/BC/CA ,[8]University of Montreal, Montreal/QC/CA ,[9]Cornell Medicine, New York/NY/USA ,[10]University of Toronto, Toronto/ON/CA ,[11]University of Colorado, Denver/CO/USA ,[12]Moffitt Cancer Center, Tampa/FL/USA ,[13]Hackensack Meridan Health, Neptune City/NJ/USA

Introduction: The CALGB/Alliance 140503 phase III trial revealed that sublobar resection (SLR) had non-inferior disease-free survival (DFS) and similar recurrence-free survival (RFS) and overall survival (OS) compared to lobar resection (LR) in patients with peripheral cT1a,bN0 NSCLC. Adverse events (AEs) grade ≥ 3 occurred in less than 15% of patients. The influence of these more severe complications on the patients' cancer-related survivals have not been analyzed. We investigated the impact of AEs grade ≥ 3 on cancer recurrence, cancer-specific survivals and overall survival.

Methods: Between 6/2007 and 3/2017, 697 patients were randomized to LR (357) or SLR (340); 80.2% of the resections were via VATS approach. Adverse events were graded using the AEs version 4.0 and were grouped into a Low-Grade (LG) group (AEs ≤ 2) and a High-Grade group (HG) (AEs ≥ 3); Grade 5 AE (Death) was excluded from survival analyses. Survival endpoints were estimated by the Kaplan-Meier estimator and tested by stratified Log-rank test. The Chi-square test was used to compare the distribution of LG AEs vs HG AEs among various groups. Locoregional recurrence (LRR) and distant recurrence (DR) - free survivals were also calculated.

Results: High-Grade AEs occurred in 102 patients (14.6%) in the study population, 15.4% of the LR patients and 13.8% of SLR patients.(Chi-square, p = 0.555) The three most common HG AEs were pulmonary (8.0%), infection (6.7%), and cardiovascular (2.7%) related. There was no difference in the association of HG AEs and type of surgical procedure (Chi-square, p = 0.159) or the site volume.(Chi-square, p = 0.119) Five-year OS was 81.1% after LG AEs and 75.5% after HG AEs.(Log rank, p = 0.205) Five-year DFS was 66.9% after LG AEs and 49.6% after HG AEs.(Log rank, p = 0.006) Five-year RFS was 72.9% after LG AEs and 56.9% after HG AEs.(Log rank, p = 0.006) Five-year LRRFS was 88.9% after LG AEs and 76.4% after HG AEs (Log rank, p = 0.054) and five-year DRFS was 85.1% after LG AEs and 80.4% after HG AEs (Log rank, p = 0.109). Multivariate analysis showed that age > 70 years, male gender, and decreased %FEV1 increased HG AEs and significantly affected disease-free, recurrence-free and locoregional recurrence-free survivals.

Conclusions: In this large, prospective randomized trial, HG AEs negatively influenced DF and RF survival, but not overall survival. LRR and DR survivals were also affected, but not significantly. This analysis shows that even in patients who undergo resection for the smallest (< 2 cm) of NSCLCs, postoperative HG AEs can decrease cancer-specific survivals. Prevention of postoperative HG AEs is mandatory in patients undergoing surgical treatment for early-stage NSCLC to reduce recurrence and maximize survival.

MA04.03 Bringing Equity to the Community: The Dana-Farber Cancer Care Equity Program's Lung Cancer Screening Initiative

N. Florez, S. Pohl, Z. Wei, L. Kiel, T. Patwary, E. Mazzola, L. Garber, E. Harding, L. Svoboda, C. Lathan, Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Disparities in lung cancer (LC) screening and survival persist among Black and Hispanic communities. The Dana-Farber Cancer Institute (DFCI) Cancer Care Equity Program (CCEP) diagnostic clinic was established in 2012 to reduce cancer health disparities through facilitating access to screening, treatment, prevention, and survivorship services in Greater Boston.

Methods: We evaluated lung cancer-focused CCEP services at two federally qualified community health centers in underserved Boston areas. Data included single-patient visits since CCEP began LC screening in 2014 among 391 patients who consented to a larger cohort study. Descriptive statistics summarized demographics and experiences from patients' CCEP initial consults.

Results: 101 patients had at least one CCEP consult for LC screening between January 22, 2014, and May 10, 2023. The mean age was 61 years; 44% were female. Most (69%) identified as Black or African American and 47% as Hispanic; 54% spoke English, 33% spoke only Spanish, and 13% spoke both languages. Nearly all had Medicare or Medicaid as primary insurance (47% and 41%). Among 101 patients referred for LC screening, 97% (98) reported current or past tobacco use, 52% (50) reported smoking ≥20 cigarettes daily, and 30% (29) reported smoking 11-20 cigarettes daily. The mean pack-years smoked was ≥29 years (range: ≥1-50+ years, among 96 patients). Most (79%, 80) identified as active tobacco users at the time of consultation, and a large majority (91%, 73) received CCEP smoking cessation counseling; smoking cessation materials were provided to 96% (70) of these patients, with 93% reporting wanting to participate in a smoking cessation program. Though most patients (80%, 81) were referred to CCEP for LC screening, a notable 20% underwent recommended LC screening despite being referred for another reason; 60 additional patients were referred for LC screening but did not consent to the larger cohort study. Following their consult, 80% (81) of patients had a radiology test ordered, including low-dose CT (LDCT; 79%, 64) or standard chest CT scans (21%, 17). CT scans were often ordered as follow-up to prior abnormal scans (11) or due to symptoms such as cough or shortness of breath (6). A median of 3 CT and 7 LDCT scans were ordered annually, though 21 LDCT scans were distinctly ordered in 2015, the year that LDCT scans were approved through Medicare. LDCT scans were ordered for 87% (39) of the patients who smoked ≥20 cigarettes daily (mean smoking time: 41 years), including 80% (56) of active tobacco users. LDCT and CT scans were ordered for 80% (45) and 20% (11) of Black patients and 85% (22) and 15% (4) of the patients who solely spoke Spanish. Notably, 85% (69) of patients completed their LDCT/CT scans; reasons for missing the appointment included not wanting to go (6) or forgetting (3). Three of the 101 patients were diagnosed with lung cancer.

Conclusions: The DFCI CCEP aims to improve access to cancer care for local marginalized communities. CCEP's integration of LC screening and smoking cessation services among vulnerable populations demonstrates that tailored interventions can be impactful in promoting equity.

MA04.04 Treatment Patterns and Survival of Screen-Detected Lung Cancer in the Real World Versus the National Lung Screening Trial

A. Potter[1], Q. Guo[1], P. Senthil[1], D. Srinivasan[1], M. Yang[1], L. Chelala[2], C-F.J. Yang[1], [1]Massachusetts General Hospital, Boston/MA/USA ,[2]University of Chicago Pritzker School of Medicine, Chicago/IL/USA

Introduction: While lung cancer screening has been shown to increase the detection of early-stage lung cancers amenable to curative treatment in clinical trial settings, concerns about the efficacy of screening in the real world remain. Outside of clinical trials, patients often have more comorbid conditions and face greater difficulty accessing cancer care, which may prevent patients with screen-detected lung cancer from receiving curative treatment. We evaluated treatment patterns and outcomes for stage I lung cancer detected via screening using a US national sample from SEER-Medicare and compared these treatment patterns and outcomes to that in the National Lung Screening Trial (NLST).

Methods: Patients aged 65-78 with stage I non-small-cell lung cancer (NSCLC) detected via low-dose computed tomography (LDCT) screening from 2015-2017, with follow-up through 2019, in the SEER-Medicare database ("SEER-Medicare cohort") and patients aged 65-78 with stage I NSCLC detected via LDCT screening in the NLST ("NLST Cohort") were identified for analysis. In the SEER-Medicare cohort, patients who received >1 LDCT scans during the 18 months before their lung cancer diagnosis were considered to have screen-detected lung cancer. The proportions of patients who received surgery, radiation, other or no treatment in the SEER-Medicare cohort were compared to those proportions in the NLST cohort. Three-year overall and lung cancer-specific survival in each cohort were evaluated.

Results: A total of 461 patients in the SEER-Medicare cohort and 168 patients in the NLST cohort met inclusion criteria. Among patients in the SEER-Medicare cohort, 73.8% (n=340) underwent surgery, 21.0% (n=97) underwent radiation, and 3.3% (n=15) underwent other treatments; only 2.8% (n=13) received no treatment. In comparison, in the NLST cohort, 94.6% (n=159) underwent surgery, 2.4% (n=4) underwent radiation, 1.8% (n=4) underwent other treatments, and 1.2% (n=2) received no treatment (Figure). Three-year overall and lung cancer-specific survival in the SEER-Medicare and NLST cohorts are shown in the Figure. Both patients in the SEER-Medicare and NLST cohorts had excellent 3-year lungcancer-specific survival at 93.1% (95% CI:90.1-95.2%) and 91.6% (95% CI:86.2-94.9%), respectively.

Conclusions: In this US national analysis of patients diagnosed with screen-detected stage I NSCLC, nearly all patients received either surgery or radiation, only 3% of patients received no treatment, and 3-year lung cancer-specific survival was 93%. These findings suggest that—even outside of rigorous clinical trial conditions—a very high proportion of patients with screen-detected lung cancers can receive curative treatment and can achieve survival outcomes comparable to that observed in the NLST.

Keywords: Lung cancer, Lung cancer screening, Early-stage

Figure. Three-year overall and lung cancer-specific survival among all patients and stratified by treatment type in the SEER-Medicare cohort and NLST cohort.

MA04.05 An Evolution and Expanding Engagement to Excel in Lung Cancer Screening

M.R. Gieske[1], I.A. Budhani[2], D.A. Alkapalan[2], J.A. Ries[2], [1]St Elizabeth HealthCare, Edgewood/KY/USA ,[2]St. Elizabeth Healthcare, Edgewood/KY/USA

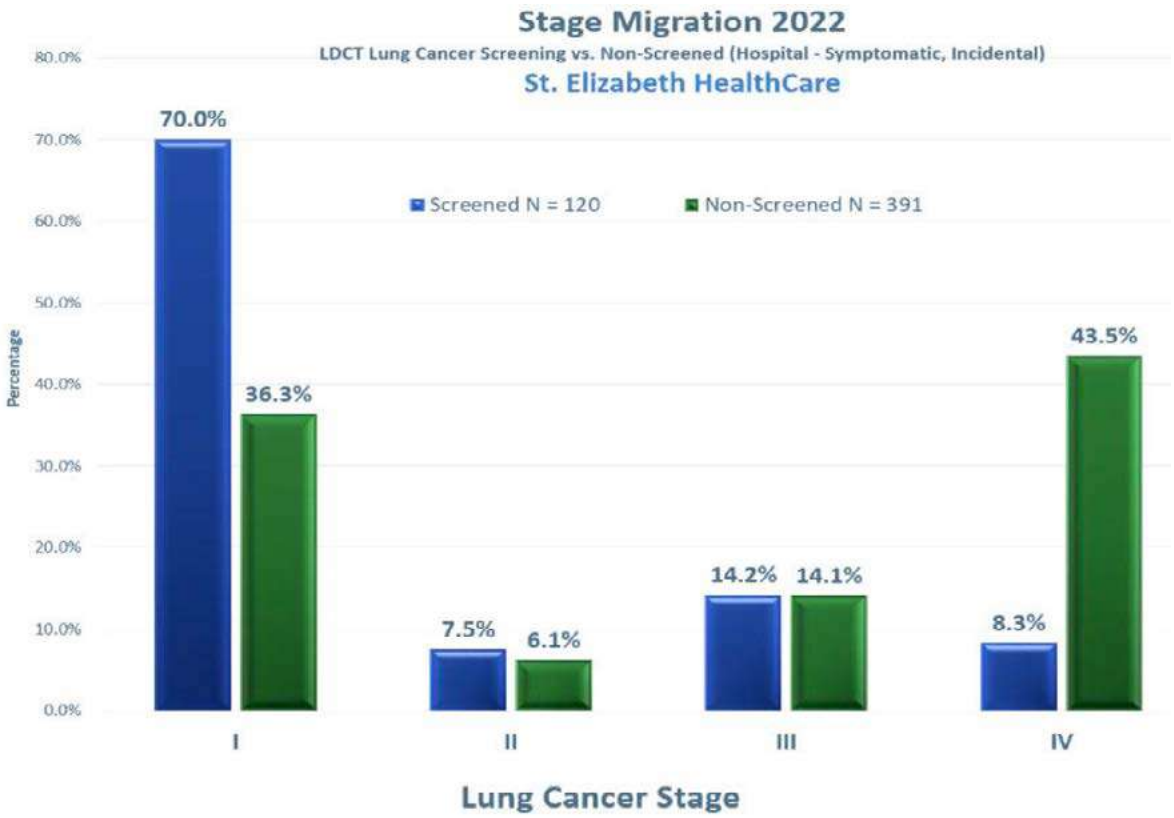
Introduction: St. Elizabeth Healthcare, a community-based hospital system serving Northern Kentucky and Southeastern Indiana, initiated its Lung Cancer Screening Program (LCSP) in 2013. Over the past decade, our program has evolved and expanded, exceeding initial benchmarks and showcasing the transformative power of collaboration and outreach efforts. With a commitment to continual improvement, we have achieved significant advancements in early detection and stage migration, workup, and treatment, positively impacting patient outcomes, improving year over year.

Methods: With over 40,000 LDCT lung cancer screens conducted to date, our program employs a comprehensive approach to screening and care coordination. We have discovered 638 lung cancers (LCs), one for every 28 unique patients screened, over 400 in stage I (62.7%). Uptake of United States Preventive Services Task Force 2021 screening eligible individuals attributed to our primary care providers is 46.8%. Lung-RADS category 4 nodules undergo weekly review by our dedicated nodule review board, ensuring timely and efficient management. Our team of three LCS nurse navigators plays a pivotal role in facilitating communication and streamlining patient care. Data tracking through a centralized Compendium enables ongoing evaluation and conveyance of our results. Regular reporting and collaboration with our 41 primary care sites network and 191 providers enhances program performance and accountability. Our Population Health Support Services team of twelve RN outreach specialists follows up on outstanding orders and monitors their completion of orders and screens.

Results: There has been a notable rise in stage I diagnoses over recent years. Stage migration analysis illustrates a progressive shift towards earlier stages of disease, with stage I diagnoses comprising 50.8% in 2021 (n 33), 70.0% 2022 (n 84) as illustrated in the stage migration chart below), 71.6% 2023 (n101), and thus far this year 79.4% (n 27). Overall, our healthcare system has seen a 23.1% decline in late-stage lung cancers from 2015 to 2022, with early-stage LCs surpassing late-stage in 2022. With an adherence rate exceeding 60% over the past three years, emphasis on annual follow-up has contributed to long-term screening success.

Conclusions: Despite inherent challenges, our experience underscores the value of a programmatic approach and interdisciplinary collaboration in optimizing LCS outcomes. As evidenced by our evolving results and continued stage migration, the maturation of a well-coordinated screening program yields tangible benefits in early detection and improved patient prognosis. We remain steadfast in advancing our efforts, leveraging innovation and partnership to further enhance the effectiveness and reach of LCS initiatives.

Keywords: lung cancer screening, stage migration, collaboration



MA04.07 Low-Dose Computed Tomography Lung Cancer Screening Participants Live Longer Than Matched Controls, A Case-Control Study

R. Dziedzic[1], P. Kanyion[1], B. Koń[2], M. Kruk[3], E. Szurowska[1], T. Zdrojewski[4], J. Polańska[5], W. Rzyman[6], [1]Medical University of Gdansk, Gdansk/PL ,[23]- Narodowy Fundusz Zdrowia, Polska (eng. National Health Fund, Poland), Warszawa/PL ,[33]- Narodowy Fundusz Zdrowia, Polska (eng. National Health Fund, Poland), Warszawa/PL ,[4]Medical University of Gdansk,, Gdansk/PL ,[5]Silesian University of Technology, Gliwice/PL ,[6]Medical University of Gdansk, Gdańsk/PL

Introduction: The current evidence from randomized controlled trials has supported a reduction in mortality caused by LDCT lung cancer screening. There is limited data on the impact of screening on mortality in observational trials. The study aims to assess the 10-year overall survival of the lung cancer LDCT screened group compared to a propensity matched unscreened control group.

Methods: In this observational case-control study, the data of 43,686 patients from the database of the National Health Fund (NFZ) aged 50-75 were analyzed. The study group consisted of 7281 individuals who underwent LDCT lung cancer screening in Pilot Pomeranian Lung Cancer Screening Program (PPLCSPP) between 2009-2011 and matched controls from a general Polish population. Data on comorbidities and survival of program participants and the general population were collected and analyzed from the NFZ registry covering medical services for almost all Polish citizens. This registry contains the data on all medical events provided both in hospital and outpatient settings. The survival and comorbidities of 7281 participants of PPLCSPP and 36,405 matched controls selected from the population of 9.81 million people from the NFZ registry were analyzed and compared. The control group was randomly selected from among 9.81 million people from the NFZ database using the 1:5 propensity score matching method. For each screened person, 5 people were matched using the following variables: age, sex, chronic and acute diseases, neoplasm, demographic indicators regarding the number of physicians per 10,000 inhabitants, and the average monthly salary in the place of residence. The former two variables were selected to diminish the potential effect of disparities in access to the health care system in Poland. Patients were followed for at least 10 years for events requiring treatment and diseases, and for death.

Results: During over 10 years of follow-up, hypertension, chronic coronary artery disease, hypercholesterolemia, diabetes, unstable coronary artery disease, COPD, atrial fibrillation and heart failure was diagnosed in 52.2%, 20.5%, 13.2%, 13.0%, 11.4%, 5.6%, 2.8%, 2.0%, respectively. A multivariate analysis showed a beneficial effect on long-term survival of participation in the screening study HR=0.653, occurrence of hypertension HR=0.882, hypercholesterolemia HR=0.567, female gender HR=0.527. Factors negatively affecting survival are lung cancer diagnosis HR=5.141, stroke HR=2.451, colorectal cancer HR=2.166, heart failure HR=2.061, chronic kidney disease HR=2.044, breast cancer HR=1.837, COPD HR= 1.766, atherosclerosis HR=1.503, diabetes HR=1.471. The 10-year survival of the screening group was statistically more favorable and amounted to 86.9%, the control group 81.3%, $p<0.001$.

Conclusions: Participants of LDCT lung cancer screening have reduced all-cause mortality compared to the general population of people at the age 50-75.

Introduction: Lung cancer screening (LCS) can reduce mortality in high-risk individuals, but recruitment of heavy smokers to repeated low dose computed tomography (LDCT) examinations has proven critical, particularly in the most deprived subset of the population at higher lung cancer (LC) risk. The RISP national network represents a unique experience of web-based screening with accelerated recruitment and randomized design.

Methods: The RISP program (acronim for Italian Lung Screening Network) was funded in 2021 by the Ministry of Health, that selected 18 highly specialized clinical centers across the country with the aim of proving the feasibility and cost/effectiveness of a national LCS network, by the implementation of centralized web-based recruitment facilities and automated second reading of all LDCT images with the same software for artificial intelligence (AI) analysis (Coreline, AVIEW). Eligible participants were also randomized to annual vs. biennial LDCT interval. Approval by the ethics committees and administrative boards of participating centers was obtained by July 2022.

Results: From October 2022 to March 2024, a total of 20,704 volunteers individually registered in the national RISP web site, 10,582 (51%) proved to be eligible for LDCT screening (age 55-75 years, ≥ 35 pack/year or PLCOm12 ≥ 2.6% at 6 years), and 8,747 (83%) received baseline LDCT. The analysis of the first 8747 LDCTs showed 80% global concordance in LungRADS classification of local radiologists vs. AI second reading. AI analysis also revealed a similar quantification of the individual risk profile obtained with the top 192-slice LDCT scanners compared to all other scanners: 4% vs. 5% Brock score ≥10 and 14% vs. 16% coronary artery calcification (CAC score) ≥400, respectively. After a median follow-up of 12 months, 91 (1.0%) LCs were detected, of which 50 (54.9%) were stage I and 70 (76.9%) resected.

Conclusions: The present data show the feasibility, high 18-months recruitment, early LC detection and resectability rates of a national web based LCS network. Further data on the cost/efficacy evaluation by site and LDCT scanner will be presented.

MA04.09 An International Qualitative Study of Healthcare Provider Perspectives of the Psychosocial Impacts and Barriers to Lung Cancer Screening

K. McFadden[1], B. Nickel[2], N. Houssami[1,2], N. Rankin[2,3], R. Dodd[1], [1]The Daffodil Centre, The University of Sydney, a joint venture with Cancer Council NSW, Sydney/AU ,[2]Sydney School of Public Health, Faculty of Medicine and Health, The University of Sydney, Sydney/AU ,[3]Melbourne School of Population and Global Health, Faculty of Medicine, Dentistry and Health Sciences, The University of Melbourne,, Melbourne/AU

Introduction: Many countries are (or are considering) implementing lung cancer screening (LCS) following landmark trials demonstrating the effectiveness of screening with low-dose computed tomography for reducing lung cancer mortality. Psychosocial outcomes are a key consideration for LCS programs, ranging from harm to individuals to impacts on screening participation, and downstream effects on medical help-seeking generally. This study aimed to investigate the psychosocial aspects of LCS for participants from the perspective of healthcare providers from a diverse range of trial and service designs across the globe.

Methods: We conducted semi-structured interviews between August and December 2023 with (1) health professionals involved in delivering or designing LCS including physicians, nurses, trial assistants/coordinators, and researchers, and (2) primary care practitioners not previously involved in LCS. Participants were recruited internationally to include experiences across programs, jurisdictions, and policy landscapes. Interviews were recorded and transcribed verbatim and the study authors participated in coding data and developing themes. Data were analysed thematically.

Results: Twenty-seven healthcare providers were interviewed. Most (n=20) had experience in providing LCS. Participants were from England (n=11), Australia (n=10), Canada (n=3), Ireland (n=2) and New Zealand (n=1), representing six established LCS trials/programs. Themes generated included: (1) anxiety, worry, and fear are central harms and barriers to uptake; (b) positive psychological responses to LCS are common; (c) lung cancer fatalism is ingrained and underpins anxiety; (d) smoking stigma is pervasive and interacts with LCS invitation; (e) family, community, and other social influences (e.g., reduced psychological harm during LCS from social network support); and (f) issues specific to LCS-eligible populations (e.g., correlated disadvantage, comorbidities). Each theme was associated with psychosocial barriers to appropriate engagement (e.g., fear of cancer, nihilism - “what’s the point?”, avoiding judgement or lecturing about smoking, lack of social support). Key considerations for LCS service design for managing psychosocial outcomes and barriers were also identified. These were aggregated across countries, trials and programs, and included both purposeful, top-down aspects of program design, as well as self-taught or unmandated strategies patient-facing providers used in practice. Example considerations included: public awareness/education to reduce lung cancer fear and fatalism, program navigation and continuity of care throughout the LCS pathway, cultural safety and support for different participant groups, and designed wording for reducing stigma, communicating risk, and delivering results.

Conclusions: We identified similarities in provider perspectives about the psychosocial aspects of LCS across countries and trial/programs designs. This suggests that international best-practice guidance could be developed for LCS programs to manage participants psychosocial outcomes and potentially reduce barriers to screening uptake. Further work investigating communication methods specific to managing stigma and communicating lung cancer risk is needed. Additionally, LCS programs should consider sociocultural influences for LCS participants, and how these may be leveraged in recruitment and managing psychological burden.

Keywords: psychosocial, lung cancer screening

MA04.11 Women Enrolled in Lung Screening as a Result of Direct Outreach Are More Likely to be Cancer Survivors

S. Faltaous[1], S.A. Deppen[2], S. Joyner[2], A. Paulson[2], S. Valenti[2], E.A. Kazerooni[3], R.A. Smith[4], C. Thomson[5,6], K.L. Sandler[2], [1]Vanderbilt University School of Medicine, Nashville/TN/USA ,[2]Vanderbilt University Medical Center, Nashville/TN/USA ,[3]University of Michigan, Ann Arbor/MI/USA ,[4]American Cancer Society, Atlanta/GA/USA ,[5]Mount Auburn Hospital, Cambridge/MA/USA ,[6]Harvard Medical School, Boston/MA/USA

Introduction: Lung cancer screening (LCS) with low-dose CT (LDCT) reduces mortality. Randomized controlled trials have suggested that the mortality benefits may be greater in women than men, and research has shown that women with a prior history of any cancer are at greater risk for developing a primary lung cancer. LCS is underutilized compared to screening mammography. The CALM study (Coordinate A Lung Screening with Mammography) successfully enrolled women in LCS through outreach at the time of breast cancer screening. Here we compare the demographic characteristics of women enrolled in CALM with those who underwent LDCT without direct outreach.

Methods: A retrospective cohort study of women enrolled in LCS from September 2021 to October 2022 was performed. This included women who enrolled because of direct outreach from the CALM study and those who enrolled without this intervention. Direct outreach consisted of generating a monthly list of women undergoing screening mammography and notifying referring providers of their patients' lung screening eligibility based on USPSTF guidelines. Demographic characteristics of screening participants were collected at the time of the shared decision-making visit (SDMV), including those needed to calculate lung cancer risk using the PLCOm2012 model. Differences in the two groups' demographics and lung cancer risk were assessed with Pearson's Chi-Square test and two-sample t-test, respectively.

Results: Screening was initiated in 459 women: 113 after provider outreach (CALM participants) and 346 without outreach. Race and ethnicity between the two groups were similar (81% white in the outreach group and 85% non-outreach group (p=0.35)). Adherence rates were similar (55% outreach group and 53% non-outreach group (p=0.77)). Women responding after outreach had a non-statistically significantly lower baseline lung cancer risk, but a higher personal history of cancer (34.5% vs 14.2%; p<0.001) (Table 1).

Conclusions: Women who enrolled in LCS as part of the CALM study had a statistically significantly higher likelihood of having a prior cancer. This suggests that women who are cancer survivors are receptive to undergoing lung screening, though they may not have been aware of their eligibility prior to the CALM intervention. We plan to design future intervention strategies to improve lung screening enrollment for women as part of cancer survivorship.

Personal History of Cancer	14.2%	34.5%	p<0.001

MA04 REAL-WORLD IMPLEMENTATION OF EARLY LUNG CANCER DETECTION
MONDAY, SEPTEMBER 9, 2024 - 14:00 - 15:15

MA04.12 Uncovering Disparities and Trends in Lung Cancer Screening Based on Patient Race and Insurance Status

E.J. Zolfaghari[1], R. Tseng[2], P. Sather[2], T. Ermer[2], V. Mase[2], F. Detterbeck[2], L. Tanoue[3], G.A. Woodard[2], [1]Yale New Haven Hospital, New Haven/CT/USA ,[2]Yale New Haven Hopsital, New Haven/CT/USA ,[3]Yale New Haven Hopsital, Division of Pulmonology, Yale School of Medicine/CT/USA

Introduction: Recognizing disparities in lung cancer screening by patient race and insurance status is crucial for advancing public health equity. This enables targeted interventions, addressing disproportionate risks and access barriers faced by certain demographic groups. Understanding differences in access facilitates tailored lung cancer screening programs, optimizing resource allocation and outcomes. Identifying patterns in screening across different racial and insurance groups helps providers implement strategies to ensure equitable access to detection and treatment.

Methods: A prospectively collected and maintained Lung Cancer Screening Dashboard from a large Northeast hospital system electronic-medical record database retrospective review was performed. Patient insurance status (Medicare, Private Insurance, Medicaid, self-pay or worker's compensation, Other) and race (White, Black/African American, Asian, Other, None of the Above) for all adult screening chest computed tomography (CT) scans ordered between Jan 1st, 2018 to March 9th, 2024 were collected and evaluated for growth trends. Predictive measures were used to estimate projections for the remainder of 2024, whereas growth calculations used 2023 data as that was the most recent full calendar year.

Results: Overall growth and increased lung cancer screening adoption was seen over the study period with a total of 1,317 scans in 2018 verses 5,014 scans in 2023. Most screening CT scans are performed through Medicare (57.3% in 2023), followed by Private Insurance (21.38%) and Medicaid (19.6%). In the study period, White patients with Medicare were more likely to be screened for lung cancer than other ethnicities (77.5% Medicare in 2023). Interestingly, Black Medicare patients experienced the greatest increase in screening scans with a 4.5-fold increase between 2018 and 2023 vs 3.5-fold increase among White Medicare patients. Increases in screening were similar among Medicaid patients, White (3.9-fold increase) and Black (3.8-fold increase), whereas Black Private Insurance patients saw a notable increase in screening scans (6.7-fold increase) vs White (3.3-fold increase). Since 2020, an increasing number of African Americans have received lung CT screenings.

Conclusions: Increased lung cancer screening among White patients accounts for a disproportionate share of the increases in lung cancer screening. Screening outreach efforts should focus on Black and other patient populations for more equitable use of this important health service. Recognizing trends in lung cancer screening informs policymaking, driving initiatives to address systemic inequities in healthcare delivery. Acknowledging and addressing disparities in lung cancer screening empowers healthcare systems to deliver more equitable and effective care, reducing the burden of disease on vulnerable populations.

MA05.03 A Phase II Study of Tislelizumab Combined with Chemotherapy in Patients with Thymic Carcinoma

L. Wu, J. Li, Y. Kong, B. Chen, Y. Zhou, X. Pu, Y. Luo, L. Xu, Q. Wang, Hunan Cancer Hospital/The Affiliated Cancer Hospital of Xiangya School of Medicine, Changsha/CN

Introduction: Thymic carcinomas are rare malignancies that in general arise in the prevascular (anterior) mediastinum. Studies are hampered by the paucity of these tumors, the large variety of carcinoma subtypes, and the lack of unique morphologic and immunophenotypic features. The standard diagnosis and treatment mode of thymic carcinoma has not been established. At present, most scholars prefer systemic treatment for primary thymic carcinoma .

Methods: From Sep 2022 till Dec 2023, We included all patients diagnosed with thymic carcinoma who had never received systemic treatment. Patients received tislelizumab 200 mg IV Q3W in combination with paclitaxel 175mg/m2 IV Q3W and carboplatin AUC 5 IV Q3W . The primary objective of the study was to assess the objective response rate (ORR). Secondary objectives included assessments of safety and progression-free survival (PFS); exploratory objectives included the disease control rate (DCR), overall survival (OS). Tumor response was assessed by investigators per RECIST v1.1. All adverse events (AEs) were monitored and recorded.

Results: 17 patients were enrolled; the median age was 61.0 years (range 41-67). At data cutoff (Jan 31, 2024), 14 patients (82.3%) were undergoing treatment. Discontinuations occurred in 3 patients (17.6%)—2 (11.8%) primarily due to disease progression, 1 (5.8%) due to an AE. Efficacy analyses included 17 patients. The ORR of tislelizumab in combination with chemotherapy was 41.7% (7/17) in the evaluable population; the DCR was 100% (17/17). Median PFS and OS was not reached (95% CI not estimable). Treatment-emergent (TE)AEs of any grade and of grade ≥3 severity occurred in 47.1% (8/17) and 5.8% (1/17) of the 17 enrolled patients, respectively; the most common treatment-related AE was leukopenia (any grade: 29.4% [5/17]; grade ≥3: 5.8% [1/17]) and thrombopenia(any grade: 17.6% [3/17]; grade ≥3: 5.8% [1/17]).1 patient (5.8%)occurred immune related myocarditis and hepatitis.

Conclusions: In the first-line systemic treatment of malignant thymic carcinoma, the combination of PD-1 monoclonal antibody and chemotherapy has a obviously anti-tumor therapeutic response.The safety is mainly similar to chemotherapy. It provides a new therapeutic option for clinical practice.

MA05.04 Targeting TROP-2 In Diffuse Pleural Mesothelioma

M.D. Offin, S. Tischfield, P. Manoj, P. Agrawal, S. Tendler, E.C. Pratt, W. Travis, A. Rimner, C.B. Simone, E. de Stanchina, J. Qiu, V. Markov, M. Donoghue, J.S. Lewis, M.G. Kris, J.L. Sauter, P.S. Adusumilli, C.M. Rudin, A. Quintanal Villalonga, M.G. Zauderer, Memorial Sloan Kettering Cancer Center, New York City/NY/USA

Introduction: Diffuse pleural mesothelioma (DPM) is a nearly universally fatal malignancy with limited treatment options. There is a lack of validated biomarkers, other than histology, and no approved targeted strategies. Utilizing our patient derived xenograft (PDX) library, we identified TROP-2 as a candidate target. TROP-2 expression has been shown to correlate with tumorigenesis in several solid tumors but has not been adequately assessed in DPM.

Methods: TROP-2 expression was evaluated by flow cytometry (PE anti-human) in PDX and by immunohistochemistry (IHC; ENZ-ABS380) in a DPM patient tumor microarray (TMA). Transcriptomic analysis of publicly available datasets (MESOMICS and TCGA) was performed and correlated with TROP-2 expression. The oncogenicity (colony formation, proliferation, migration/invasion) of TROP-2 overexpression and knockout (KO) was evaluated in isogenic cell lines derived from epithelioid (H2452, H28) and biphasic (MSTO-211H) DPM. RNAseq was performed to identify pathways altered by TROP-2 expression. The metastatic potential of TROP-2 was evaluated via intracardiac injection. The efficacy of the TROP-2 antibody drug conjugate (ADC) Sacituzumab Govitecan (SG) was assessed in PDXs with high (MSK_LX307) and intermediate/low (MSK_LX707, MSK-LX606, MSK_LX13) TROP-2 expression (n=10/cohort): vehicle, chemotherapy (gemcitabine; 40 mg/kg/week), and SG (0.5 mg/mouse/twice a week). ImmunoPET was performed with a novel tracer ([89Zr]Zr-DFO-SG) on MSK-_LX13 and MSK_LX606 to evaluate TROP-2 expression.

Results: 73% (8/11) of PDXs expressed TROP-2 by flow cytometry and 54% (34/63) of TMA samples expressed TROP-2 by IHC. Transcriptomic analyses of publicly available DPM cohorts correlated high TROP-2 expression with a pro-metastatic, stem-like phenotype. TROP-2 overexpression increased tumorigenicity in vitro (proliferation, colony formation, migration and invasion) in all cell lines, whereas TROP-2 KO exerted the opposite effects. TROP-2 expression induced pro-oncogenic pathways including MAPK and AKT signaling, as well as stemness and metastasis markers. Intracardiac injection of DPM cell lines associated TROP-2 overexpression with increased metastatic colonization, while TROP-2 KO led to abrogation of metastasis. immunoPET showed avidity for both PDXs and was confirmed with a terminal biodistribution study. Treatment of PDXs with SG was well tolerated, and tumor growth was significantly slowed in PDXs treated with the TROP-2 ADC compared to gemcitabine.

Conclusions: TROP-2 exerts pro-oncogenic effects in DPM by increasing oncogenic signaling and metastatic potential. The TROP-2 ADC, SG, blunted tumor growth in PDX models. These data confirm TROP-2 as a therapeutic target in mesothelioma. Based on these findings, we are opening an investigator initiated single arm phase 2 trial to assess the overall response rate of SG in patients with previously treated recurrent/metastatic DPM.

MA05.05 External Validation of Proposed 9th Edition of TNM Classification for Thymic Epithelial Tumours: Institutional Series of 436 Cases

Y.Z. Zhang[1], A. Rice[1], K. Wassilew[1], C. Brambilla[1], J.L. Robertus[1], L. D'Sa[1], E. Lim[1], S. Begum[1], S. Buderi[1], S. Jordan[1], V. Anikin[1], J. Finch[1], N. Asadi[1], E. Beddow[1], J.L. Garner[1], J. Morjaria[1], R. Lee[2], F. McDonald[2], N. Tokaca[2], G. Antoniou[3], C.A. Ridge[1], S.P. Padley[1], P. Dalal[1], P.L. Shah[1], A. Devaraj[1], S. Popat[2], A.G. Nicholson[1], [1]Royal Brompton and Harefield Hospitals, London/GB ,[2]Royal Marsden NHS Foundation Trust, London/GB ,[3]Mount Vernon Cancer Centre, London/GB

Introduction: The 9th Edition of TNM classification (TNM9) for thymic epithelial tumours has been proposed as an improvement to the 8th edition (TNM8) by introducing a size descriptor for pT1 category and re-classification of lung or phrenic nerve invasion as pT2. We aim to perform an independent validation of the proposed TNM9 classification, with a comparison of the prognostic characteristics with TNM8 and the Masaoka-Koga (M-K) classifications.

Methods: This is a single institutional, retrospective study including all thymic epithelial tumours underwent surgical resection with curative intent during a 31-year period (1991-2022), irrespective of resection status. Clinical and pathological variables, as well as recurrence and survival data were retrieved from an institutional thymoma database. Survival analysis was performed using univariate Cox regression, Statistical significance was defined as P<0.05.

Results: This study includes a total of 436 cases, with a documented recurrence rate of 12.6% (55/436). Thymoma, thymic neuroendocrine tumour and thymic carcinoma comprise 90.8% (396/436), 3.4% (15/436), 5.7% (25/436) of cases respectively. The overall stage re-assignment rate of TNM9 from TNM8 was 5.3%. Prognostic significance was observed with proposed TNM9 in terms of recurrence free survival (RFS), although only borderline statistical significance was seen with proposed pT1b category (pT1a vs pT1b, P = 0.057). No prognostic relevance was seen with overall survival (OS). No statistical significance in RFS was observed between T2 N0 M0 tumours and T3 N0 M0 tumours with lung invasion only (TNM8), therefore our data supported re-classifying the latter as pT2 in TNM9. We were unable to assess the prognostic impact of phrenic nerve invasion independent of N and M status, as all six cases in our study population were stage IV. In comparison with TNM8 and M-K classifications, TNM9 showed similar prognostic characteristics by identifying a single favourable prognostic group (stage I), with less pronounced differences between stage II-IV. M-K classification, on the other hand, identified two relatively distinct prognostic groups (favourable: I-IIb, unfavourable: III-IVb) with less pronounced difference within each group.

Conclusions: The findings from our study generally supported the proposed TNM9 classification for thymic epithelial tumours in relation to RFS. The lack of prognostic significance with the proposed pT1b category may be due to the limited sample size of our study. Furthermore, our data suggested TNM9 and M-K classifications are complementary to each other. Provision of both staging parameters is therefore recommended over TNM9 as the sole staging parameter for surgically resected thymic epithelial tumours.

MA05.08 Follow-Up after First-Line Nivolumab Plus Ipilimumab in Patients with Pleural Mesothelioma: A Real-World Dutch Cohort Study (FLORA-Study)

L.H. Douma[1], M.M. Hofman[2], F. Zwierenga[3], A.I.G. Buma[4], J.H. Schouwink[5], J.A. Burgers[6], I. Smesseim[6], D.W. Dumoulin[2], J.G.J.V. Aerts[2], C.J. de Gooijer[6], [1]Netherlands Cancer Institute - Antoni van Leeuwenhoek, Amsterdam/NL ,[2]Erasmus MC Cancer Institute, Rotterdam/NL ,[3]University of Groningen, Groningen/NL ,[4]Radboud University Medical Center, Nijmegen/NL ,[5]Medisch Spectrum Twente, Enschede/NL ,[6]Netherlands Cancer Institute, Amsterdam/NL

Introduction: Pleural mesothelioma (PM) is an aggressive malignancy, with treatment options limited to palliative systemic therapy (platinum-based/pemetrexed combination). The registration of nivolumab/ipilimumab (nivo/ipi) in 2022 has replaced chemotherapy as the standard of care in the first-line for most patients. For second-line treatment, chemotherapy remains a rational option after nearly 20 years of experience. After first-line chemotherapy, approximately 37-47% of patients may be candidates for additional treatment, while after nivo/ipi in the Checkmate 743 trial, this was 44.9%. The proportion of patients who receive second-line treatment after nivo/ipi is unknown in real-world. The aim of this study is to provide an overview of subsequent therapy in patients with PM who progressed on nivo/ipi, based on real-world data, and to evaluate the efficacy of second-line platinum-based/pemetrexed combination treatment in this patient cohort.

Methods: FLORA is an observational, multicenter cohort study in five Dutch medical centers. Clinical data from patients with PM treated with first-line nivo/ipi were obtained from the medical records. The primary endpoint was median overall survival (mOS) of patients receiving second-line platinum-based/pemetrexed treatment. Secondary endpoints included mOS of first-line nivo/ipi, objective response rate (ORR) and median progression-free survival (mPFS) of second-line chemotherapy and subgroup analyses (non-responders and responders to first-line treatment and histological subtype).

Results: Between May 2021 and July 2023, 267 patients with PM who received first-line nivo/ipi were included (Figure 1). Of these patients, 227 were male (85%), with a median age of 72 (IQR 67-77) years. The histological subtypes were epithelioid (n=167, 62%), sarcomatoid (n=59, 22%), mixed (n=34, 13%), and unknown (n=7, 3%). Ninety-one (49%) patients received a second-line treatment, of which 73 (39%) patients received second-line platinum-based/pemetrexed chemotherapy (Figure 1). Among these 73 patients, 55 (75%) had a WHO performance score of 0-1, and 9 patients had a score of 2 (12%), while data for 9 patients were unavailable. mOS for second-line chemotherapy was 8.1 months (95% CI 7.7-8.5). Secondary endpoints will be presented at the congress.

Conclusions: This study provides the first real-world data on subsequent treatment options for patients with PM who progressed on nivoipi, with a mOS of 8.2 months after second-line chemotherapy

MA05.07 Pretreatment with Cisplatin or Radiation Therapy Enhances CAR T-Cell Therapy Efficacy

R. Bellis, M.S. Skovgard, H.T. Quach, A. De Biasi, J. Villena-Vargas, P.S. Adusumilli, Memorial Sloan Kettering Cancer Center, New York/NY/USA

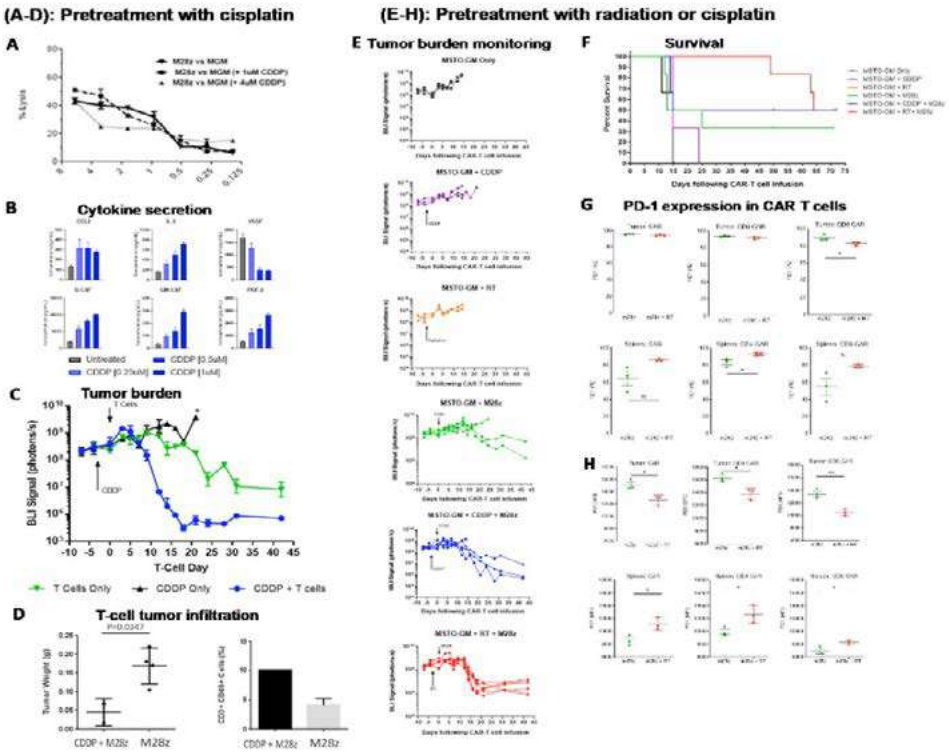
Introduction: With recent advances in immunotherapy for thoracic cancers, including malignant pleural mesothelioma (MPM), we sought to evaluate the feasibility and efficacy of combination therapy of pretreatment with cisplatin or tumor-targeted, non-ablative radiation with mesothelin (MSLN)-targeted CAR T cells (M28z) in an orthotopic mouse model of MPM.

Methods: In vitro, the effects of pretreatment with cisplatin or radiation on mesothelioma cells (MSTO-211H) were assessed by cytokine analysis (multiplex bead-based enzyme-linked immunosorbent assay) and cytotoxicity (chromium release assay). In vivo, in mice established with orthotopic MPM using MSTO-211H cells transduced to express green fluorescent protein (GFP) and MSLN (MGM), a single dose of cisplatin or low-dose, tumor-targeted radiation was administered 3 days prior to intravenous administration of a single, low-dose of M28z CAR T cells. Tumor burden was assessed via bioluminescent imaging (BLI). Safety and efficacy of the combination therapies was evaluated by overall survival (OS), flow cytometry quantification of tumor-infiltrating T cells, and serum cytokine/chemokines.

Results: Pretreatment with either cisplatin (0.25uM-1uM) or radiation (2Gy, 4Gy, 10Gy) of mesothelioma cells (MSTO-211H) did not effect cytotoxicity (Fig. 1A), increased chemokines/cytokines, including GM-CSF, FGF-2, IL-6, and VEGF in a dose-dependent manner (Fig. 1B), reduced tumor burden significantly (Fig. 1C&D), and augmented tumor infiltration of T cells (Fig. 1D). Tumor-bearing mice treated with combination of cisplatin or radiation followed by 1 x 105 M28z CAR T cells had improved median OS (not reached and 67 days, respectively, Fig. 1E&F) compared to cisplatin alone (15 days), radiation alone (15 days), and M28z alone (40 days). Even with a low dose of M28z CAR T cells (5 x 104 cells), tumor eradication was observed in mice pretreated with 4Gy tumor-targeted radiation (Fig. 1F). Serum of tumor-bearing mice showed an increase in multiple cytokines, including FGF-2, IL-10, and VEG-F in mice pretreated with cisplatin or radiation followed by M28z compared to mice receiving M28z CAR T cells only. PD-1 expression in CAR T cells by percentage and intensity of expression is lower compared to in spleen of mice that received combination therapy (Fig. 1G&H).

Conclusions: Our results demonstrate increased survival of mice pretreated with cisplatin or tumor-targeted radiation in combination with M28z CAR T cells even with a low dose of CAR T cells compared to single treatments alone (cisplatin alone, radiation alone, or M28z alone). Our results provide strong rationale to translate combination therapy regimen to treat patients with MPM.

Keywords: Chemotherapy, CAR T cell therapy, Radiation therapy



Cisplatin or radiation has the potential to enhance M28z efficacy both in vitro and in vivo.

(A) M28z showed no increase in cytotoxicity when cocultured with MGM tumor cells that had been pretreated with cisplatin (1uM or 4uM) as measured by cytotoxicity assay (chromium release assay). **(B)** Supernatant of MSTO-211H cells 72hrs after treatment with varying doses of cisplatin (CDDP) show increases in cytokines/chemokines in a dose-dependent manner. **(C)** Tumor burden as assessed by bioluminescence imaging of mice inoculated with 1 x 10^6 MGM cells received either no treatment, M28z only, or a single dose of CDDP via intraperitoneal injection 3 days prior to M28z injection. **(D)** Mice inoculated with MGM followed by either 2 x 10^6 M28z or pretreatment with a single dose of CDDP 3 days prior to M28z CAR T cell injection were euthanized 7 days after CAR T cell injection. Tumor weights and percentage of CD3+ CD45+ tumor infiltrating T cells was assessed with flow cytometry. **(E-F)** Tumor burden as assessed by BLI and survival curves of mice inoculated with 1 x 10^6 MGM cells followed by no treatment, M28z only, treatment with either CDDP or RT alone, or combination treatment of either CDDP or RT 3 days prior to M28z injection. **(G-H)** PD-1 percentage and MFI of M28z CAR T cells in both tumor and spleen of mice who received intra-pleural injection of 1 x 10^6 MGM cells showed increased infiltration and less exhaustion in mice who received pretreatment RT compared to M28z alone.

MA05.08 Follow-Up after First-Line Nivolumab Plus Ipilimumab in Patients with Pleural Mesothelioma: A Real-World Dutch Cohort Study (FLORA-Study)

L.H. Douma[1], M.M. Hofman[2], F. Zwierenga[3], A.I.G. Buma[4], J.H. Schouwink[5], J.A. Burgers[6], I. Smesseim[6], D.W. Dumoulin[2], J.G.J.V. Aerts[2], C.J. de Gooijer[6], [1]Netherlands Cancer Institute - Antoni van Leeuwenhoek, Amsterdam/NL ,[2]Erasmus MC Cancer Institute, Rotterdam/NL ,[3]University of Groningen, Groningen/NL ,[4]Radboud University Medical Center, Nijmegen/NL ,[5]Medisch Spectrum Twente, Enschede/NL ,[6]Netherlands Cancer Institute, Amsterdam/NL

Introduction: Pleural mesothelioma (PM) is an aggressive malignancy, with treatment options limited to palliative systemic therapy (platinum-based/pemetrexed combination). The registration of nivolumab/ipilimumab (nivo/ipi) in 2022 has replaced chemotherapy as the standard of care in the first-line for most patients. For second-line treatment, chemotherapy remains a rational option after nearly 20 years of experience. After first-line chemotherapy, approximately 37-47% of patients may be candidates for additional treatment, while after nivo/ipi in the Checkmate 743 trial, this was 44.9%. The proportion of patients who receive second-line treatment after nivo/ipi is unknown in real-world. The aim of this study is to provide an overview of subsequent therapy in patients with PM who progressed on nivo/ipi, based on real-world data, and to evaluate the efficacy of second-line platinum-based/pemetrexed combination treatment in this patient cohort.

Methods: FLORA is an observational, multicenter cohort study in five Dutch medical centers. Clinical data from patients with PM treated with first-line nivo/ipi were obtained from the medical records. The primary endpoint was median overall survival (mOS) of patients receiving second-line platinum-based/pemetrexed treatment. Secondary endpoints included mOS of first-line nivo/ipi, objective response rate (ORR) and median progression-free survival (mPFS) of second-line chemotherapy and subgroup analyses (non-responders and responders to first-line treatment and histological subtype).

Results: Between May 2021 and July 2023, 267 patients with PM who received first-line nivo/ipi were included (Figure 1). Of these patients, 227 were male (85%), with a median age of 72 (IQR 67-77) years. The histological subtypes were epithelioid (n=167, 62%), sarcomatoid (n=59, 22%), mixed (n=34, 13%), and unknown (n=7, 3%). Ninety-one (49%) patients received a second-line treatment, of which 73 (39%) patients received second-line platinum-based/pemetrexed chemotherapy (Figure 1). Among these 73 patients, 55 (75%) had a WHO performance score of 0-1, and 9 patients had a score of 2 (12%), while data for 9 patients were unavailable. mOS for second-line chemotherapy was 8.1 months (95% CI 7.7-8.5). Secondary endpoints will be presented at the congress.

Conclusions: This study provides the first real-world data on subsequent treatment options for patients with PM who progressed on nivo/ipi, with a mOS of 8.2 months after second-line chemotherapy

MA05.10 Presenting Features and Diagnostic Delays of NUT Carcinoma: A Report from the NUT Carcinoma Registry

J. Luo[1], S.A. Walton[1], J.J. Kim[1], F. Paoloni[1], J.W. Liew[2], Z.Z. Cotzany[1], T. Nguyen[1], P.K. Paik[3], J.E. Chaft[3], R. Hsu[4], S.A. Piha-Paul[5], P.A. Jänne[1], D.A. Barbie[1], L.M. Sholl[6], S.G. DuBois[1], G.J. Hanna[1], G.I. Shapiro[1], C.A. French[6], [1]Dana-Farber Cancer Institute, Boston/MA/USA ,[2]Boston Medical Center, Boston/MA/USA ,[3]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[4]University of Southern California, Los Angeles/CA/USA ,[5]MD Anderson Cancer Center, Houston/TX/USA ,[6]Brigham and Women's Hospital, Boston/MA/USA

Introduction: Diagnostic delays are common for patients with NUT Carcinoma (NC), an aggressive poorly differentiated/squamous cell cancer of lung/head and neck origin driven by the NUT fusion oncoprotein. Rapid diagnosis is essential for treatment initiation and trial consideration in a disease with a mOS in metastatic disease of 6.7 mo and no approved targeted therapies. We investigated presenting features of NC and associations with time-to-diagnosis.

Methods: We included U.S. participants enrolled in the NC registry from 2007-2024 with adequate records. Medical records and pathology reports were manually reviewed. Time from symptom to diagnosis (TSD) was defined as time from initial symptom onset until NC diagnosis (NCDx). Time from biopsy to diagnosis (TBD) was defined as time from initial biopsy until NCDx. We examined associations between age, gender, or race with TSD/TBD as dichotomized outcomes in separate models, using univariable logistic regression.

Results: We analyzed 100 patients with median age 37 (range 7-81) years; 49.0% were female, 82.7% (n=62/75) were White, 5.3% (n=4/75) were Black/African American, 6.7% (n=5/75) were Asian, and 3.4% were Hispanic (n=3/87). Initial cancer diagnosis was at an academic center in 37.0%. At presentation, 54.0% had metastatic disease, 68.0% had a thoracic primary, and 28.0% had a head and neck primary. The most common presenting symptoms for patients with thoracic primary were cough (48.5%, n=33/68) and dyspnea/fatigue (42.6%, n=29/68); for those with a non-thoracic primary, swelling/mass (40.6%, n=13/32) and congestion (34.4%, n=11/32). Infection (48.0%, n=48/100) was most common initial clinical diagnosis. TSD was an average of 4.3 months (median 3.0, range 0.3-32.5); TBD was an average of 41 days (median 20 days, range 1-919). Overall, 87.0% of initial biopsies had malignant cells; 28.0% needed a second biopsy. The first finalized pathology report showing cancer was NC in only 23.0% (n=20/87); the most common other diagnoses were poorly differentiated/squamous cell cancer 86.6% (n=58/67) and carcinoma 10.4% (n=7/67). Of pertinent IHC, 86.1% (n=62/72) were keratin (+), 83.3% (n=30/36) were p63 (+), and 88.9% (n=32/36) were p40 (+), 81.5% (n=22/27) had Ki-67 ≥50%. NC was diagnosed via NUT IHC in 85.0%, NUT FISH in 7.0%, and RNA fusion testing in 8.0%. For the TSD outcome, non-White race (OR=4.17, 95%CI 1.05-14.81) was associated with longer interval to NC diagnosis; age ≥50 (OR=2.79, 95%CI 0.99-8.05) and female sex (TSD: OR=0.65, 95%CI 0.28-1.51) were not. In contrast, for the TBD outcome, age ≥50 (OR=3.33, 95% CI 1.23-9.43) was associated with longer interval to NC diagnosis; non-White race (OR=0.57, 95%CI 0.18-1.76) and female sex (OR=0.84, 95% CI 0.38-1.83) were not. Of 24 patients who started treatment before a NC diagnosis, 83.3% were on a regimen used in NC. After a diagnosis of NC, 37.2% (n=35/94) participated in a clinical trial.

Conclusions: NUT carcinoma almost always presents as a squamous/poorly differentiated non-small cell lung (NSCLC) or head and neck cancer. Overall, 77% of NC diagnoses were initially missed, and 28% needed a second biopsy. After a diagnosis of NC, only 37% participated in a clinical trial. Results suggest widespread education on diagnosing NC is needed.

MA05.11 Phase 3 Trial of Pleurodesis for Malignant Pleurisy: Sterile Graded Talc vs. OK-432 WJOG8415L (J-PLEURA)

H. Saka[1,2], C. Kitagawa[2], Y. Shiraishi[3], Y. Sato[4], M. Yamaguchi[5], S. Sugawara[6], M. Oki[2], K. Nishino[7], K. Hosoi[8], S. Suzuki[9], A. Kubo[10], E. Tabata[11], K. Yoshimura[12], M. Ando[13], K. Nakagawa[9], N. Yamamoto[14], I. Okamoto[3], [1]Matsunami General Hospital, Kasamatsu/JP ,[2]NHO Nagoya Medical Center, Nagoya/JP ,[3]Kyushu University, Fukuoka/JP ,[4]Kobe City Medical Center General Hospital, Kobe/JP ,[5]NHO Kyushu Cancer Center, Fukuoka/JP ,[6]Sendai Kousei Hospital, Sendai/JP ,[7]Osaka International Cancer Institute, Osaka/JP ,[8]Itami City Hospital, Itami/JP ,[9]Kindai University, Osaka Sayama/JP ,[10]Aichi Medical University, Nagakute/JP ,[11]Ikeda Municipal Hospital, Ikeda/JP ,[12]Nagoya City University, Nagoya/JP ,[13]Nagoya University, Nagoya/JP ,[14]Wakayama Medical University, Wakayama/JP

Introduction: WJOG8415L (J-PLEURA), was designed to evaluate the effectiveness and safety of sterile graded talc for pleurodesis in treating malignant pleural effusion, against OK-432, a lyophilized substance derived from group A Streptococcus pyogenes, which has been inactivated and processed with penicillin, the standard in Japan.

Methods: The primary endpoint was the success rate of pleurodesis effectiveness 30 days after the procedure, specifically looking at the absence of pleural fluid reaccumulation. Secondary endpoints included the duration until the reaccumulation of pleural effusion, the quarterly rate of patients remaining free of pleural effusion, assessments of quality of life (QoL), and the recording of side effects.

Participants included patients diagnosed with malignant pleural effusion associated with lung or gastrointestinal cancers, presenting symptoms such as dyspnea. The study consisted of two groups: Group A received intrathoracic OK-432, dosed at 0.2 KE/kg up to 10 KE, and Group B received 4g of sterile graded talc intrathoracically. Both groups had the therapeutic agents suspended in saline and injected into the chest cavity, followed by saline flushes to aid distribution. Fluid was then drained until daily volumes were at or below 150mL before drain removal. A secondary administration could be considered after seven days if necessary.

Candidates were eligible if they had a confirmed diagnosis through tissue or cytology, exhibited symptoms of respiratory distress due to pleural effusion, were expected to survive beyond 30 days post-procedure, and were over the age of 20 at consent. The study aimed to enroll 300 patients over two years, with a subsequent year of follow-up, and a final year dedicated to analysis.

Efficacy was gauged by the percentage of patients free from pleural effusion recurrence at 30 days and at subsequent time points. Safety was monitored by the incidence and grade of adverse events as per the CTCAE v4.0.

Results: 43.9% in the OK-432 group and 29.6% in the talc group met the primary endpoint, though without statistical significance (p=0.9965). A marginal benefit was noted for OK-432 in terms of three-month non-recurrence survival (p=0.0319). Safety profiles were similar across both treatments, and no significant difference in QoL was observed. However, there was one instance of treatment-related mortality in the OK-432 group due to pneumonia.

Conclusions: The trial determined no substantial difference between talc and OK-432 regarding pleurodesis efficacy in malignant pleural effusion. Both treatments had equivalent safety outcomes and similar impacts on QoL. While OK-432's insignificant advantage in non-recurrence survival rates over three months positions it as a viable option, the singular treatment-related death necessitates cautious interpretation, although it does not undermine its overall efficacy comparable to that of talc.

Introduction: Unecritinib (TQ-B3101), a novel multi-tyrosine kinase inhibitor targeting ROS1, ALK, and c-MET, had shown promising antitumor activity and acceptable safety profile in ROS1 inhibitor-naive patients with ROS1-positive advanced NSCLC from the phase II TQ-B3101-II-01 study (NCT03972189): objective response rate (ORR) was 80.2% and the median progression-free survival (PFS) was 16.5 months (data cut-off: Dec 20, 2021). Here we report updated data.

Methods: ROS1 inhibitor-naive patients with histologically confirmed locally advanced or metastatic NSCLC with ROS1 rearrangements received unecritinib 300 mg BID orally in continuous 28-day cycles until disease progression or unacceptable toxicity. The primary endpoint was ORR assessed by independent review committee (IRC) per RECIST 1.1. Secondary endpoints included duration of response (DOR), disease control rate (DCR), PFS, intracranial ORR, intracranial DOR, intracranial time to progression (TTP), intracranial PFS, overall survival (OS) and safety.

Results: The cutoff date for this analysis was Jun 20, 2022. Among 111 efficacy evaluable patients, ORR was 81.08% (95% CI, 72.55-87.89), the median PFS and DOR were 17.25 months (95% CI, 11.86-26.71) and 20.30 months (95% CI, 12.88-26.12), respectively. The median OS was not reached. Among 33 patients with baseline brain metastases, ORR was 72.73% (95% CI, 54.48-86.70), the median PFS, DOR and OS were 10.09 months (95% CI, 5.52-11.89), 9.23 months (95% CI, 7.36-11.04) and 28.22 months (95% CI, 19.25-36.53), respectively. Among 48 patients who had previously received chemotherapy, ORR was 79.17% (95% CI, 65.01-89.53), the median PFS and DOR were 19.32 months (95% CI, 10.12-not evaluable [NE]) and 20.30 months (95% CI, 11.04-NE), respectively. Among 11 patients with intracranial target lesions at baseline, the median intracranial DOR and intracranial TTP per RANO-BM were 9.36 months (95% CI, 7.39-26.12) and 17.25 months (95% CI, 8.25-NE), respectively. In the safety population (n=113), grade ≥3 treatment-related adverse events (TRAEs) occurred in 51.33% of patients. Treatment-related dose interruption, reduction and discontinuation occurred in 40.71%, 20.35% and 1.77% of patients, respectively. No patients died due to TRAEs. No grade ≥3 ocular disorders and neurotoxicity occurred.

Conclusions: In this updated analysis with longer follow-up, unecritinib continued to show the clinical benefit and manageable toxicities in ROS1-positive advanced NSCLC patients. Further analysis of OS will be performed as survival data mature.

Introduction: Early-generation ROS1 tyrosine kinase inhibitors (TKIs) approved for the treatment of ROS1-positive (ROS1+) non-small cell lung cancer (NSCLC) exhibit antitumor activity, but resistance commonly develops, and their intracranial activity is suboptimal. Lorlatinib, a ROS1 and anaplastic lymphoma kinase (ALK) inhibitor, demonstrates properties of brain-penetration and overcoming resistance to crizotinib driven by ROS1 mutations. Robust antitumor activity of lorlatinib was observed among patients with ROS1+ NSCLC, including those with central nervous system (CNS) metastases, in a global Phase I/II study (B7461001). Herein, we present the efficacy and safety results from a Phase II, multi-center, single-arm study in China (NCT05297890) investigating lorlatinib in patients with locally advanced or metastatic ROS1+ NSCLC.

Methods: Adult patients with advanced ROS1+ NSCLC pre-treated with crizotinib and platinum-based chemotherapy were enrolled in the study. All patients received lorlatinib 100 mg QD continuously. The primary endpoint was objective response rate (ORR) assessed by independent central radiology (ICR) per RECIST v1.1. Secondary endpoints included ICR-assessed parameters, such as duration of response (DoR), intracranial ORR (IC-ORR), IC-DoR, progression-free survival (PFS), as well as overall survival (OS) and safety. Adverse events (AEs) were graded per NCI-CTCAE v5.0.

Results: As of the data cutoff date (26 December 2023), 70 patients were enrolled. Median age was 55.0 years (range 32-80). Other characteristics included: female (61.4%); brain metastasis (62.9%); adenocarcinoma (94.3%). Median treatment duration was 7.4 months (range 0.2-19.0). The study met its primary objective by demonstrating a clinically meaningful and statistically significant improvement in ICR-assessed ORR. Among evaluable participants (n=65), the ICR-assessed ORR was 44.6%. Among 37 participants with baseline intracranial lesions, the IC-ORR was 43.2% and 8 (21.6%) participants achieved CR. Detailed efficacy results are shown in the table. All 70 patients experienced at least one all-causality treatment-emergent AE (TEAE); the most common TEAEs (by cluster term*/PT) were hypercholesterolemia* (95.7%) and hypertriglyceridemia* (85.7%). Grade ≥3 treatment-related AEs (TRAEs) occurred in 30 (42.9%) patients; the most common Grade ≥3 TRAEs were hypertriglyceridemia* (27.1%) and hypercholesterolemia* (15.7%). TRAEs leading to dose reduction were reported in 12 (17.1%) patients. No TRAE leading to permanent treatment discontinuation or TRAE leading to death was reported.

Conclusions: Lorlatinib demonstrated robust and durable objective response and notable intracranial activity in patients with advanced ROS1+ NSCLC pre-treated with crizotinib and chemotherapy. Lorlatinib was well-tolerated, and safety data from this study was consistent with the known safety profile of lorlatinib.

Table: Lorlatinib Efficacy in Patients with Advanced ROS1+ NSCLC (Assessed by ICR)

Best overall response (ERAS[a])	
No. of patients in analysis	N=65
ORR (CR+PR) (%)	29 (44.6)
95% exact CI[b]	(32.3, 57.5)
PR	29 (44.6%)
Duration of objective response	
No. of patients in analysis	N=29
Number (%) of Patients with Events	5 (17.2)
Median (months) (95% CI[c])	NR(13.8, NR)
6-mo estimate(95% CI[d])	88.4%(68.0%, 96.1%)
Progression-free survival (SA)	
No. of patients in analysis	N=70
Number (%) of Patients with Events	27 (38.6%)
Median (months)(95% CI[c])	17.9(6.9, NR)
Best intracranial overall response (SA[e])	
No. of patients in analysis	N=37
IC-ORR (CR+PR) (%)	16 (43.2)
95% exact CI[b]	(27.1, 60.5)
CR	8 (21.6%)
PR	8 (21.6%)
Duration of intra-cranial objective response	
No. of patients in analysis	N=16
Number (%) of patients with Events	3 (18.8)
Median (months)(95% CI[c])	13.8 (6.8,NR)

CI: confidence interval; CR: complete response; ERAS: evaluable for response analysis set; ICR: independent central radiology; IC-ORR: intracranial objective response rate; NSCLC: non-small cell lung cancer; NR: not reached; PR: partial response; SA: safety analysis set. a. MA06.07 Patterns of Progression with Lorlatinib and Insights into Subsequent Anticancer Therapy Efficacy in Advanced ALK+ NSCLC

T. Mok[1], B.J. Solomon[2], M.R.G. Campelo[3], Y-L. Wu[4], G. Streich[5], M. Zemanova[6], G. Zalcman[7], A. Bearz[8], G-C. Chang[9,10,11], M. Setti[12], A. Polli[12], Y. Goto[13], [1]State Key Laboratory of South China, Chinese University of Hong Kong, Hong Kong/CN ,[2]Peter MacCallum Cancer Centre, Melbourne/AU ,[3]University Hospital A Coruña, A Coruña/ES ,[4]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital and Guangdong Academy of Medical Sciences, Guangzhou/CN ,[5]Centro Médico Austral, Buenos Aires/AR ,[6]Charles University, Prague/CZ ,[7]Hôpital Bichat-Claude Bernard, Paris/FR ,[8]CRO National Cancer Institute of Aviano, Aviano/IT ,[9]Chung Shan Medical University, Taichung/TW ,[10]Chung Shan Medical University Hospital, Taichung/TW ,[11]National Chung Hsing University, Taichung/TW ,[12]Pfizer, Milan/IT ,[13]National Cancer Center Hospital, Tokyo/JP

Introduction: Lorlatinib, a brain-penetrant, third-generation anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitor (TKI), demonstrated statistically significant and clinically meaningful improvement in progression-free survival (PFS) vs crizotinib in the phase 3 CROWN study in patients with previously untreated advanced ALK+ non-small cell lung cancer (NSCLC; NCT03052608). This study investigated the efficacy of subsequent treatments following discontinuation of lorlatinib or crizotinib in the CROWN study after 5 years of follow-up and different characteristics of early progressors to lorlatinib and patients who remained progression free after 5 years.

Methods: Patients were randomized 1:1 to receive oral lorlatinib 100 mg once daily or crizotinib 250 mg twice daily. The primary endpoint was PFS by blinded independent central review. Secondary endpoints included time from randomization to the date of disease progression with first subsequent systemic anticancer therapy or death (PFS2).

Results: As of October 31, 2023, after 5 years of follow-up, first-line lorlatinib showed prolonged benefit, with median PFS not reached (NR) and 60% of patients being progression free. At the time of data cutoff, 75 of 149 (50%) and 135 of 142 (95%) patients had discontinued lorlatinib and crizotinib, respectively. Among patients who discontinued lorlatinib, only 8 progressed intracranially. Of the 38 patients in the lorlatinib group and 109 in the crizotinib group who received ≥1 subsequent systemic anticancer therapy, ALK TKIs were the first subsequent treatment in 23 (61%) and 101 (93%), respectively, and chemotherapy was the first subsequent treatment in 15 (39%) and 4 (4%). Median duration of the first subsequent treatment was 9.3 months (IQR, 2.6-22.6) with lorlatinib and 14.9 months (IQR, 5.3-38.4) with crizotinib. Objective response rates with the first subsequent systemic anticancer therapy were higher in patients previously treated with lorlatinib than with crizotinib (Table). With a median follow-up for PFS2 of 61.4 months (95% CI, 59.2-62.5) with lorlatinib and 58.4 months (95% CI, 56.8-61.9) with crizotinib, median PFS2 was NR (95% CI, NR-NR) with lorlatinib and 37.9 months (95% CI, 27.4-50.1) with crizotinib (HR, 0.43; 95% CI, 0.30-0.62). Additional analyses are ongoing to assess different clinical and molecular characteristics of patients who progressed during the first year of treatment vs those who remained progression free after 5 years.

Conclusions: In patients who discontinued lorlatinib due to any reason, subsequent systemic treatments appeared to offer additional benefit demonstrated by clinical outcomes and prolonged PFS2.

MA06.08 Kinetics and Management of Adverse Events Associated with Lorlatinib after 5 Years of Follow-Up in the CROWN Study

T. Bauer[1], B.J. Solomon[2], J. Mazieres[3], D-W. Kim[4], D. Cortinovis[5], T. Inoue[6], R. Sharma[7], H. Thurm[8], A. Polli[9], G. Liu[10], [1]Greco-Hainsworth Centers for Research/Tennessee Oncology, Nashville/TN/USA ,[2]Peter MacCallum Cancer Centre, Melbourne/AU ,[3]Toulouse University Hospital, Toulouse/FR ,[4]Seoul National University College of Medicine and Seoul National University Hospital, Seoul/KR ,[5]San Gerardo Hospital, Monza/IT ,[6]Osaka International Cancer Institute, Osaka/JP ,[7]Artemis Hospital, Gurugram, Haryana/IN ,[8]Pfizer, San Diego/CA/USA ,[9]Pfizer, Milan/IT ,[10]Princess Margaret Cancer Centre, Toronto/ON/CA

Introduction: Lorlatinib is approved for the treatment of patients with metastatic ALK+ non-small cell lung cancer (NSCLC). Because lorlatinib has a unique safety profile, in this post hoc analysis, we present kinetics of selected adverse events (AEs) from the CROWN study after 5 years of follow-up to suggest optimized therapy management strategies.

Methods: In the CROWN study, patients with previously untreated advanced ALK+ NSCLC were randomized 1:1 to receive oral lorlatinib 100 mg once daily or crizotinib 250 mg twice daily. Safety analyses include incidence, prevalence, time to onset, and duration for selected AEs associated with lorlatinib that led to dose reduction or interruption.

Results: As of October 31, 2023, with a median duration of follow-up for progression-free survival (PFS) of 60.2 months (95% CI, 57.4-61.6 months), median PFS was not reached (95% CI, 64.3 months-not reached) with lorlatinib (n=149). All-cause AEs led to lorlatinib dose reduction in 23% of patients, temporary discontinuation in 62%, and permanent discontinuation in 11%. Dose reduction within the first 16 weeks did not impact PFS or time to intracranial progression. Most common AEs leading to dose reduction (in ≥3% of patients) were edema (7%), hypertriglyceridemia (4%), cognitive effects (3%), mood effects (3%), and peripheral neuropathy (3%); AEs leading to temporary discontinuation (in ≥5% of patients) were hypertriglyceridemia (8%), pneumonia (8%), cognitive effects (6%), SARS-CoV-2 test positive (6%), edema (5%), peripheral neuropathy (5%), and mood effects (5%); and AEs leading to permanent discontinuation (in >1% of patients) were cognitive effects (1%) and cardiac failure (1%). Median time to onset and duration of most common lorlatinib-related AEs leading to dose reduction or interruption are shown in Table. Additional analyses to explore the outcomes of selected AEs following therapy management is ongoing.

Conclusions: This post hoc analysis after 5 years of follow-up suggests that with long exposure to lorlatinib, treatment discontinuation due to AEs remained low, and most AEs were effectively managed with dose modifications. Systemic and intracranial outcomes in patients who underwent dose reduction were similar to those in patients who did not undergo dose reduction, indicating that dose reductions may be an effective strategy to mitigate toxicity without compromising efficacy of lorlatinib. ClinicalTrials.gov NCT03052608

MA06.09 Predictors of Long-Term Ensartinib Response from the eXalt3 Trial

L. Hill[1], P. Reddy[1], B. Mertins[1], E. Sanchez[2], G. Selvaggi[2], C. Bulow[1], [1]resistanceBio, Menlo Park/CA/USA ,[2]Xcovery Holdings, Inc., Palm Beach Gardens,/FL/USA

Introduction: We profiled enrollment samples from patients in the eXalt3 Phase 3 trial and have continued to follow patient outcomes to assess biomarker predictive value. Here we profile three patients who, as of December 2023, have continued to respond to ensartinib, despite showing biomarkers of resistance to other ALK inhibitors.

Methods: We obtained 13 clinical samples (FFPE) before treatment with ALKi and performed spatial transcriptomics using the Visium CytAssist platform. We followed three patients who continued to respond to ensartinib for at least 72 cycles or five years. The REvolution system nominated biomarkers of resistance and response to ensartinib, using long-term (>3 months) culture of cells without the need for passaging and conserving resistance pathways over time. We cultured two ALK-dependent, NSCLC cell lines in the presence of ensartinib. H3122 cells became resistant within 14 days, while H2228 cells remained sensitive to ensartinib for over 42 days, despite becoming resistant to alectinib, lorlatinib, and crizotinib in a parallel experiment. We used the H3122 and H2228 evolved populations to nominate ensartinib resistance and response biomarkers, respectively.

Results: 3 patients were found to continue to respond to ensartinib despite displaying clinically validated ALK inhibitor resistance mechanisms, including sub-populations with EGFR, YAP1, and MET activation. Analysis of enrollment biopsy samples showed these mechanisms were present intrinsically, prior to treatment. We identified eight potential biomarkers of ensartinib long-term response using cells evolved in REvolution. We found that these biomarkers were activated (>4.3 Log2FC) in susceptible H2228 evolved cells and not changed or deactivated (up to -4.7 Log2FC) in resistant H3122 resistant evolved cells. The three long-term responding patients exhibited between one and four of the ensartinib response biomarkers. The sub-populations expressing general ALK inhibitor resistance mechanisms tended to coexpress ensartinib response biomarkers in these patients.

Conclusions: We profiled three patients who have continued to respond to ensartinib for over 70 cycles, despite exhibiting clinically validated resistance mechanisms to other ALK inhibitors at enrollment. The REvolution, long-term evolution system, identified biomarkers which predicted response to ensartinib.

MA06.11 Phase II Trial of Ensartinib for Advanced or Metastatic Non-Small-Cell Lung Cancer with MET Exon 14 Skipping Mutations

Y. Xia[1], M. Zhou[1], P. Tian[2], J. Zhao[3], Y. Jin[4], Z. Guo[5], D. Miao[1], Y. Lu[1], X. Le[6], Y. Zhang[7], W. Li[1], [1]Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, Zhejiang/CN ,[2]Sichuan University, Chengdu, Sichuan/CN ,[3]Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education, Beijing), Peking University Cancer Hospital & Institute, Beijing/CN ,[4]Hubei Province Key Laboratory of Biological Targeted Therapy, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei/CN ,[5]Handan Central Hospital, Handan,Hebei/CN ,[6]University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[7]Hunan Cancer Hospital/ The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, Hunan/CN

Introduction: Met proto-oncogene exon 14 skipping (METex14) mutations have been identified as treatable non-small cell lung cancer (NSCLC) tumor driver genes. Ensartinib is originally considered as a second-generation ALK inhibitor, our pre-clinical and pilot clinical data have exhibited the potential of ensartinib as a MET inhibitor. Current study aimed to evaluate the efficacy and safety of ensartinib for advanced or metastatic NSCLC with METex14 mutations.

Methods: This is a single-arm, multi-center, phase II study (ChiCTR2100048767). Eligible patients (aged ≥18 years) were histologically/ cytologically confirmed advanced or metastatic NSCLC with METex14 mutations, wild type EGFR/ALK/ROS1, TKI-naïve, with ≥1 measurable lesion, and had disease progression or intolerance after ≥1 cycle of platinum-based chemotherapy, ECOG PS ≤2 and the predicted survival time was ≥3 months. Patients received oral ensartinib 225 mg once daily until disease progression or intolerance. The primary endpoint was objective response rate (ORR). Secondary endpoints were duration of response (DOR), disease control rate (DCR), progression-free survival (PFS), and safety.

Results: From July 2021 to February 2024, 31 patients (15 males, median age, 72 years [range, 47-84]) were enrolled and received ensartinib therapy; of whom, the majority was adenocarcinoma (28/31, 90.3%), TNM stage IV (25/31, 80.6%), and ECOG PS ≤1 (20/31, 64.5%). In 30 evaluable patients, the median follow-up time was 11.1 months (range, 4.1-18.1). 23 patients (76.7%) had a decrease in tumor burden compared with baseline, the ORR was 53.3% (16/30; 95% CI, 36.1%-69.8%) and the DCR was 86.7% (26/30; 95% CI, 70.3%-94.7%). The median time to first response was 0.93 months (95% CI, 0.87-0.99 months) and the median DOR was 7.9 months (95% CI, 2.9-12.9 months). Median PFS was 6.0 months (95% CI, 4.4-7.6 months). 4 of 5 patients with brain metastases at baseline had achieved partial response. Adverse events (AEs) were reported in 24 patients (80%), with 7 (23.3%) of grade 3. The most common AEs were rash (14/30, 46.7%), anemia (7/30, 23.3%), ALT increased (7/30, 23.3%), AST increased (7/30, 23.3%), and pruritus (6/30, 20%). No serious events and treatment-related death occurred. In addition, we estimated the association between ctDNA clearance(baseline, V0; after 4 weeks treatment, V1) and therapeutic efficacy in 17 patients, showing that complete clearance (ctDNA positive at V0 and negative at V1) was corelated with best ORR (80%; 95% CI, 37.6%-96.4%), followed by patients with ctDNA negative at both V0 and V1 was 42.9% (95% CI, 15.8%-75.0%), the response rate was worst in patients with non-clearance (ctDNA positive at both V0 and V1; 20%; 95% CI, 3.6%-62.5%).

Conclusions: This phase II study demonstrated that ensartinib had an encouraging anti-tumor activity and manageable safety profile in patients with advanced or metastatic NSCLC harboring METex14 mutations. This regimen is expected to provide a promising treatment option for this population.

KG, Essen/DE ,[11]Bayer AG, Berlin/DE ,[12]Bayer S.p.A., Milan/IT ,[13]Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital & Institute, Beijing/CN ,[14]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[15]Weill Cornell Medical College, New York/NY/USA

Introduction: NTRK gene fusions are oncogenic drivers in a variety of cancers including lung cancer. Larotrectinib is the first-in-class, highly selective, CNS-active TRK inhibitor approved in the tumor-agnostic setting for patients with TRK fusion cancer based on a robust and durable efficacy demonstrated in patients with various tumor types. Here, we report updated efficacy and safety data along with biomarker analysis in patients with TRK fusion lung cancer treated with larotrectinib.

Methods: Patients with TRK fusion lung cancer treated with larotrectinib in 2 clinical trials (NCT02122913 and NCT02576431) were included. Larotrectinib was administered at 100 mg twice daily. Response was assessed by an independent review committee (IRC) per Response Evaluation Criteria in Solid Tumors version 1.1. The data cutoff was July 20, 2023.

Results: As of the data cutoff, 32 patients with a median age of 55.5 years (range 25-81) with TRK fusion lung cancer were enrolled, including 12 with CNS metastases at baseline. NTRK gene fusions were identified locally by next-generation sequencing (NGS) in all patients. The gene fusions involved NTRK1 (n=24; 75%) and NTRK3 (n=8; 25%). Patients had received a median of 2 prior lines of systemic therapies; 1 patient was treatment-naïve. The overall response rate per IRC was 66% (95% confidence interval [CI] 47-81): 4 complete responses, 17 partial responses, 7 stable disease, 2 progressive disease, and 2 not evaluable. The median time to first response was 1.8 months (range 1.5-7.3). The median duration of response was 34 months (95% CI 10-not estimable [NE]) with a median follow-up of 26 months. The median progression-free survival was 22 months (95% CI 10-NE) with a median follow-up of 28 months. The median overall survival was 39 months (95% CI 17-NE) with a median follow-up of 33 months. The duration of treatment ranged from 2 to 75+ months. At the time of data cutoff, 11 patients had progressed, of whom 6 continued treatment post-progression for ≥4 weeks due to continued clinical benefit. Treatment-related adverse events (TRAEs) were predominantly Grade 1/2. Grade 3/4 TRAEs were reported in 9 patients. One patient discontinued treatment due to TRAEs (increased alanine aminotransferase, aspartate aminotransferase, and gamma-glutamyltransferase). Baseline genomic data derived from either circulating tumor DNA (ctDNA; n=15 patients) or tissue DNA (n=13 patients) were available for a total of 16 patients. Baseline ctDNA analysis detected NTRK gene fusions in 6 of 15 patients. Additional baseline NTRK and known or likely oncogenic co-occurring mutations were identified in 6 of the 16 patients. Post-baseline potential oncogenic mutations were identified in 7 of 13 patients that had available DNA samples. Five patients had acquired potential resistance mutations: 2 patients had on-target mutations, 2 patients had off-target mutations and 1 patient had both.

Conclusions: Larotrectinib continues to demonstrate rapid and durable responses, extended survival benefit, and a favorable safety profile in patients with advanced TRK fusion lung cancer. These results support the use of NGS panels, including ctDNA, to detect NTRK gene fusions in patients with lung cancer to identify those who may benefit from targeted treatment.

Alcasid[13], T. Usari[14], X. Zhang[15], G. Riely[9], [1]Leiden University Medical Center, Leiden/NL ,[2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR ,[3]Massachusetts General Hospital, Boston/MA/USA ,[4]Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona/ES ,[5]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna/IT ,[6]Dana-Farber Cancer Institute, Boston/MA/USA ,[7]Tennessee Oncology, Sarah Cannon Research Institute, Nashville/TN/USA ,[8]The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[9]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[10]Winship Cancer Institute of Emory University, Atlanta/GA/USA ,[11]Earle A. Chiles Research Institute, Providence Cancer Institute, Portland/OR/USA ,[12]Pfizer, La Jolla/CA/USA ,[13]Pfizer, Collegeville/PA/USA ,[14]Pfizer, Milan/IT ,[15]Pfizer, South San Francisco/CA/USA

Introduction: The combination of encorafenib (BRAF inhibitor) and binimetinib (MEK inhibitor) showed meaningful clinical benefit and a manageable safety profile in the phase 2 PHAROS study (NCT03915951) in patients with BRAF V600E-mutant metastatic non-small cell lung cancer (mNSCLC). This updated analysis reports the safety profile of the combination after an additional 10 months of follow-up since the primary analysis.

Methods: PHAROS is an ongoing study evaluating encorafenib 450 mg once daily plus binimetinib 45 mg twice daily in patients with BRAF V600E-mutant mNSCLC who were either treatment-naïve or had received 1 prior therapy for metastatic disease. We investigated the treatment-related adverse event (TRAE) profile by treatment line and time to onset of specific clusters of TRAEs, which were selected based on prior clinical trial experience.

Results: As of July 19, 2023, encorafenib plus binimetinib treatment was ongoing in 19 (32%) treatment-naïve (n=59) and 4 (10%) previously treated patients (n=39). Median duration of treatment was 16.3 months for treatment-naïve and 5.5 months for previously treated patients; 41% and 10% of patients have received >2 years of treatment, respectively. The most common (>30% in either arm) TRAEs were similar in treatment-naïve and previously treated patients: nausea (59% and 41%), diarrhea (41% and 49%), fatigue (31% and 33%), and vomiting (31% and 28%) (TRAEs in ≥10%; Table). All treatment-related pyrexia events were Grade 1 or 2 in treatment-naïve (10% and 2%) and previously treated patients (3% and 0%). In previously treated patients with (n=24) and without (n=15) prior immunotherapy, the most common (>30%) TRAEs were diarrhea (50% and 47%), fatigue (50% and 7%), nausea (46% and 33%), and vomiting (33% and 20%). In the overall population, the most common specific TRAE clusters were retinopathy excluding retinal vein occlusion (26%), rash (24%), and liver function test abnormalities (16%), with median times to onset of 0.1, 2.0, and 1.8 months, respectively. In the overall population, TRAEs led to dose interruptions, reductions, and permanent discontinuations of encorafenib in 48%, 31%, and 18% of patients, respectively, and of binimetinib in 54%, 33%, and 19% of patients, respectively.

Conclusions: This updated safety analysis after 10 months of additional follow-up of encorafenib plus binimetinib in patients with BRAF V600E-mutant mNSCLC showed similar TRAE profiles in treatment-naïve and previously treated patients. The safety profile remained manageable and generally consistent with that seen in the earlier analysis and that established for patients with BRAF V600E/K-mutant metastatic melanoma.

MA07.03 Systematic Engineering of TROP2 CAR T Cell Therapy to Overcome Resistance Pathways in EGFRmutant NSCLC

E.J. Brea[1], S. Baldacci[1], S. Chakravarti[1], A.P. Mottram[1], F. Facchinetti[1], A. Ramasubramanian[1], N. Savage[1], K. Ngo[1], H.V. Vo[1], B.A. Leeper[1], E.V. Ivanova[1], A. Saldanha[1], M-A. Locquet[1], A. Salamah[1], C. Stornante[1], M. Campisi[1], N.R. Mahadevan[1], T.C. Thai[1], T.J. Haggerty[1], C. Nie[2], C. Deng[2], X. Wang[2], L.L. Liu[2], P.C. Gokhale[1], C.P. Paweletz[1], P.A. Jänne[1], D.A. Barbie[1], E.L. Smith[1], [1]Dana-Farber Cancer Institute, Boston/MA/USA ,[2]Nona Biosciences, Suzhou/CN

Introduction: While tyrosine kinase inhibitors in EGFR mutant (EGFRm) NSCLC have shown excellent response rates, durable responses are rare in the advanced/metastatic setting. After the development of acquired resistance, second line therapies have low response rates. Immune checkpoint inhibitors have not demonstrated any benefit in patients harboring EGFRm NSCLC. There is an unmet need for therapies which can lead to durable activity in patients with EGFRm NSCLC. Antibody drug conjugates (ADC) have shown activity in the second line setting in NSCLC, though durable responses are rare. We propose utilizing TROP2 directed CAR T to treat EGFRm NSCLC including in the setting of resistance to EGFR inhibitors and ADC.

Methods: We developed a novel approach to treat EGFRm NSCLC by targeting the protein TROP2 using CAR T. We also developed novel fully humanized VH binders against TROP2 in CAR T constructs. We evaluated our CAR utilizing in vitro and in vivo models of EGFRm NSCLC including in patient derived xenografts.

Results: We show that CAR T cell therapy has a high degree of cytotoxicity in pre-clinical models of EGFRm NSCLC such as cell lines (93% cytotoxicity at 1:1 E:T against PC9 at 24 h compared to control CAR $p < 0.01$), in patient derived samples, and in the setting of acquired resistance to EGFRi. We also demonstrate that in the setting of resistance to TROP2 ADC due to low epitope expression such as TROP2 T256R mutation and mutations in the topoisomerase pathway, CAR T based killing is maintained (TROP2 T256Rm TROP2 CAR 61% cytotoxicity vs 19% in TROP2 ADC $p<0.01$). We developed novel fully human VH CAR T constructs that are highly active against EGFRm NSCLC models including prolonged survival compared to our benchmark sacitizumab based CAR T (Median survival 83 days vs not reached at day 122; p-value 0.049). We map the epitopes of our novel TROP2 VH CAR T constructs which revealed ability to target novel epitopes not accessible to traditional antibody based single chain variable fragment (scFv) based approaches.

Conclusions: We evaluated the activity of TROP2 CAR T in EGFRm NSCLC including in EGFRi resistant and TROP2 ADC resistant setting. We demonstrate a high degree of in vivo activity of our TROP2 CAR T against multiple in vivo models of EGFRm NSCLC. We map the epitopes targeted by scFv based TROP2 ADC as well as developed novel TROP2 fully human VH based CAR T that target novel epitopes of TROP2.

MA07.04 Targeting CD24 Enhances the Response to Third-Generation Tyrosine Kinase Inhibitors in EGFR-Mutant Non-Small Cell Lung Cancer

J. Liang, Zhongshan Hospital Fudan University, Shanghai/CN

Introduction: Approximately 10-20% of NSCLC patients have EGFR activating mutations. Osimertinib, a third-generation EGFR TKI, selectively inhibits both EGFR-TKI sensitizing and resistant mutations, making it the first-line treatment for EGFR-mutant advanced NSCLC. Several other third-generation EGFR TKIs, such as almonertinib and furmonertinib, have been developed and approved in China. However, these treatments hardly eliminate disease, and most patients develop tumor resistance and disease progression. While the addition of platinum-based chemotherapy or immunotherapy to osimertinib showed superior efficacy in advanced or recurrent EGFR-mutant NSCLC patients, there are currently no promising treatments for cases with TKI-refractory diseases. This emphasizes the need for new EGFR TKI-refractory NSCLC treatments.

Methods: Three acquired resistant cell models with cross-resistance to third-generation EGFR TKIs were generated from three patient-derived EGFR-mutant NSCLC cell lines. Cell models were used to examine drug responsiveness, tolerance, and resistance expression changes during TKI-resistance evolution using RNA sequencing. RNA or single-nucleus RNA sequencings were performed on tumor specimens from 17 patients with EGFR-mutant NSCLC, including nine who had received TKIs for locally advanced disease with incomplete response. Transgenic mouse models were used using Cre/LoxP-inducible expression of L858R/T790M mutant human EGFR, which developed lung adenocarcinomas after induction with AAV. Mass spectrometry-based phospho-proteomics and 3C-sequencing were conducted to investigate the transcriptomic expression changes in cells with TKI-resistance.

Results: We investigate cell surface proteins that could be targeted and identify CD24 as being consistently heightened in responsive, tolerant, and resistant cells in response to TKI compared to their parental cells according to RNA profiling. Single-nucleus RNA sequencing data of clinical tumors indicates elevated CD24 expression in cancer cell cluster in the TKI-refractory tumors compared to the TKI-naïve group. Moreover, high CD24 expression was associated with increased risk of tumor relapse compared with the low-CD24 group in patients who have received adjuvant osimertinib. CD24 promotes cell survival and phagocytic resistance by macrophages in TKI-refractory tumor cells. Knock out of CD24 gene or anti-CD24 antibody enhances the PC9 xenograft eradication by osimertinib. In transgenic mouse models, anti-CD24 and osimertinib synergistically suppresses the growth of EGFR-mutant tumor expressing humanized CD24. Finally, we demonstrate that EGFR TKI suppresses YY1 phosphorylation at the S247 site, which increases CD24 gene transactivation via an enhancer-promoter structural interaction.

Conclusions: Enhanced CD24 expression in response to third-generation TKI treatment plays a critical role in surviving during the initial treatment in EGFR-mutant NSCLC. Targeting of CD24 in combination with third-generation TKI synergizes to eradicate EGFR-mutant NSCLC.

MA07.05 Unbiased Functional Genomics Screen Identifies Unique Therapeutic Vulnerabilities in Osimertinib-Resistant NSCLCs

A.J. Gooding, K.C. Wood, Duke University, Durham/NC/USA

Introduction: Osimertinib is a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) with marked clinical efficacy in early- and late-stage non-small cell lung cancer (NSCLC) patients harboring EGFR mutant tumors, particularly exon 19 deletions or L858R mutations. Despite a significant survival advantage conferred by osimertinib monotherapy, most late-stage patients will develop progressive, osimertinib-resistant disease that is only marginally responsive to currently available salvage therapies. Mounting evidence suggests that the evolutionary pressures exerted on malignant cells during their acquired resistance to molecularly targeted therapies often lead to the acquisition of common and exploitable cellular traits, so-called 'collateral sensitivities,' that arise irrespective of the genomic changes that engender resistance. We hypothesize that osimertinib-resistant NSCLCs are functionally dependent upon convergent, actionable, and EGFR-independent cellular processes which can be therapeutically targeted to overcome the diversity of osimertinib-resistant cellular populations present among EGFR-mutant NSCLC patients.

Methods: We generated models of osimertinib resistance using a diverse series of patient-derived EGFR-mutant NSCLC cell lines, including several derived from the tumors of patients who were either EGFR TKI-naïve (e.g., MGH-119 and MGH-1109) or who had disease progression while on EGFR TKI therapy (e.g., MGH-134 and MGH-141), as well as multiple prototypic EGFR-mutant NSCLC cell lines (e.g., PC9, HCC827, and H1975). These cell lines were rendered osimertinib-resistant via long-term propagation (~10-14 weeks) in escalating concentrations of osimertinib until a durable >10-fold increase in GI50 was obtained. We then performed whole-genome (i.e., MinLib sgRNA library) CRISPR-Cas9 loss-of-function screens on a subset of these parental and osimertinib-resistant NSCLC derivatives. Following pooled library deep sequencing at >500x coverage and subsequent deconvolution, gene-level 'essentiality scores' were derived from differentially enriched or depleted sgRNAs to allow for the identification of differentially essential genes in parental and osimertinib-resistant populations.

Results: Of the top 500 differentially essential genes within each patient-derived cell line (e.g., genes most essential to the outgrowth of osimertinib-resistant cells but most dispensable to drug-sensitive cells), 8 genes were commonly represented among all 6 cell lines screened to date and a further 85 genes commonly represented among permutations of 4 screened cell lines, quantities significantly exceeding that which would be expected by chance. Interestingly, these overlapping essential genes were highly enriched for members of the heme biosynthesis pathway (e.g., CPOX, PPOX, and ALAD), as well as other candidate collateral sensitivities involving the unfolded protein response and ubiquitin-proteasome system. Accordingly, genetic and pharmacologic inhibition of heme synthesis not only reduces clonogenic colony formation in osimertinib-resistant NSCLC derivatives to a significantly greater extent than in their respective parental derivatives, but also partially restores osimertinib sensitivity in osimertinib-resistant cells.

Conclusions: Our findings suggest that diverse populations of osimertinib-resistant NSCLCs are uniquely and convergently vulnerable to perturbations in heme synthesis and homeostasis, a candidate EGFR-independent collateral sensitivity which is known to impact cellular metabolism, ROS production, apoptosis, and sensitivity to ionizing radiation, thereby warranting further preclinical investigations into modulating heme homeostasis as a means to overcoming osimertinib resistance.

MA07.06 Eradicating Drug Tolerant Persisters (DTPs) In EGFR-Mutated Non Small Cell Lung Cancer (NSCLC) By Targeting TROP2

Introduction: EGFR tyrosine kinase inhibitors (TKI) have dramatically impacted the outcome of EGFR-mutated NSCLC patients, but relapse frequently occurs due to incomplete eradication of all tumor cells and the establishment of DTP cells which can evolve into develop diverse mechanisms of drug resistance. Eradicating EGFR-TKI-DTPs induced therapeutically may thus enhance initial durable responses. By systematically evaluating cell surface proteins upregulated by osimertinib in DTPs, we identified TROP2 as a potential target for antibody-drug conjugate (ADC) or CAR T-cell-based approaches.

Methods: We evaluated TROP2 expression after osimertinib treatment in EGFR-mutated NSCLC cell lines in vitro (Western blots, surface cytometry, quantitative-PCR) and patient derived xenografts (PDXs) in vivo (single cell RNA-sequencing (scRNAseq), immunofluorescence). We further assessed TROP2 expression at the mRNA (quantitative-PCR) and protein levels (immunohistochemistry (IHC)) in tumor samples from patients with EGFR-mutated NSCLC, at diagnosis or EGFR TKI minimal residual disease (MRD) state. We then performed in vitro assays and in vivo studies to assess the efficacy of sacituzumab-govitecan (SG), an FDA approved anti-TROP2 ADC, or a sacituzumab scFV-based CAR T-cell targeting TROP2 to eradicate DTPs and prevent relapse following osimertinib therapy.

Results: We performed scRNAseq of DTPs following osimertinib treatment of EGFR-mutant NSCLC cell line xenografts and PDXs in vivo, which identified significant induction of TROP2 (TACSTD2) gene expression. We confirmed high levels of TROP2 cell surface protein expression in vitro and in vivo in these models and further TROP2 induction in the osimertinib induced DTP state. In diagnostic tumor samples from patients with EGFR-mutated NSCLC, TROP2 IHC expression was also elevated compared with EGFR wild type NSCLC, including patients with EGFR-mutated NSCLC treated with neoadjuvant EGFR TKI followed by surgery. We treated a novel in vivo EGFR TKI DTP model (EGFR-mutated NSCLC PDX DFCI243) with the TROP2 ADC SG after achieving MRD with osimertinib, which slightly improved relapse free survival, but all mice relapsed. We therefore evaluated whether immune-based strategies to eliminate DTP could be more effective. Osimertinib induced DTP were completely eradicated by sacituzumab scFV-based anti-TROP2 CAR T-cells in vitro. Furthermore, treatment with a single dose of TROP2 CAR T-cells was significantly more effective than repeated dose SG at administered during osimertinib induced MRD in the DFCI243 PDX model. Median relapse free survival was significantly longer in mice treated with anti-TROP2 CAR T-cells compared to osimertinib alone (210 days vs. 99 days; $p<0.0001$) and compared to the administration of SG (210 days vs. 130 days; $p=0.0014$). Importantly, no tumor regrowth was observed in half (5/10) of the PDX in the osimertinib-TROP2 CAR T group, while 100% (10/10) of the PDX in the osimertinib-SG group experienced regrowth.

Conclusions: Our findings provide a preclinical rationale for targeting TROP2 in DTP of EGFR-mutated NSCLC. In an aggressive PDX model which recapitulates the clinical phenomenon of DTP, targeting of TROP2 with CAR T-cells leads to extended and complete tumor responses. This work demonstrates that immune-based targeting of DTP is a viable strategy to pursue with immune effector cellular therapies that cannot be achieved with chemotherapy or ADC-based approaches.

MA07.08 Proteogenomic Analysis of CSF Reveals Distinct Molecular Patterns of Leptomeningeal Metastases in EGFR-Mutated NSCLC

M-M. Zheng[1,2], S-H. Lin[3], Y-S. Li[1], K. Yin[1], P. Li[3], X-C. Zhang[1], S-X. Gao[4], Q. Zhou[1], H-Y. Tu[1], J-J. Yang[1], H-J. Chen[1], Y. Pan[1], B-C. Wang[1], Z. Wang[1], C-R. Xu[1], F-M. Xiao[1], W-Z. Zhong[1], H-H. Yan[1], L-B. Tang[1], L. Wu[1], L. Zeng[1], S-Y.M. Liu[5], C.C. Wong[4], Y-L. Wu[1], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Guangdong Cardiovascular Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[3]Guangzhou Institutes of Biomedicine and Health, Chinese Academy of Sciences, Guangzhou/CN ,[4]Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing/CN ,[5]Institute of Hematology; Jinan University, Guangzhou/CN

Introduction: Leptomeningeal metastases (LM) is becoming frequent in EGFR-mutated advanced NSCLC and causes dismal prognosis due to limited treatment options. Previous studies prove that cerebrospinal fluid (CSF) ctDNA indicates poor prognosis. However, a deeper understanding of the molecular phenotypes of LM is lacking, hindering the exploration of potential therapeutic targets.

Methods: Using Data-independent Acquisition and ctDNA next-generation sequencing, we characterized 135 CSF from 120 patients with advanced EGFR-mutated NSCLC and LM (n=69), or brain metastases (BM, n=43), or non LM/BM (n=8). Proteomic data was available for 135 samples and genomic data available for 86 smaples. We established mouse model of LM: iterative in vivo selection of leptomeningeal adaptive cancer cell by injection into the cisterna magna; and next identifying leptomeningeal metastatic cells following hematogenous dissemination. ELISA, qPCR and WB were applied to test protein expressions.

Results: To explore the proteomic correlates of CSF ctDNA detection which represented an aggressive cancer phenotype, we compared the proteomic profiles between positive and negative CSF ctDNA. We found genes (MUC1, SUSD2, RNPEP, SETPB, PDCD6IP, AMY2B, and etc) and gene sets (cell cycle, metabolic and inflammatory response) significantly up-regulated in ctDNA-positive CSF. We then looked further into the molecular patterns using quantitatice proteomic data. CSF in the LM group was distinct from those in the BM or non LM/BM group: a significantly higher number of proteins were detected in the LM group; upregulated proteins of LM fell in 5 functional categories: disruption of blood brain barrier, increased tumour growth and migration, endocytosis and dysregulated immune response. Differential expression of proteins compared to BM and non LM/BM group were selected as LM-specific and highlighted the molecular heterogeneity in LM: we used LM-specific proteomics to stratify LM into two subtypes, each of which was related to different clinical features and survival outcomes. Subtype I, which was characterized by disrupted extracellular matrix and increased endocytosis, was associated with significantly shorter overall survival. Patients of subtype I had higher rate of positive CSF cytology and concurrent TP53 alterations detected by CSF ctDNA. By integrating a comparison between pre- and post-LM in two more cases, we found 18 LM-associated proteins, high expression of which constituted a signature specific to LM. Among them, the increased expression of polymeric immunoglobulin receptor (pIgR) might be correlated to higher propensity to LM development, attested by the external datasets of single cell RNA sequencing of CSF from patients with NSCLC and LM and bulk RNA sequencing of cell lines; the higher expression of pIgR also indicated poor prognosis. ELISA testing indicated elevated expression of pIgR in the CSF from LM in a cohort of 30 patients. PIgR was upregulated in leptomeningeal metastatic models. Mechanistically, we found that pIgR enhanced the stemness of cancer cell to sustain cancer growth within the leptomeningeal space.

Conclusions: We connected genomic aberration to proteomics which consistently revealed a more aggressive cancer phenotype. More importantly, we revealed the proteomic stratification of LM which provided insight into the underlying biology of this deadly complication, and suggested the opportunity for a therapeutic target.

MA07.09 Genome-Wide CRISPR Screen Identifies SFRP2 as a Novel Stromal Target to Enhance Abscopal Effect of Radioimmunotherapy

Z. Yanpei, Z. Guo, X. Cai, X. Bai, D. Wu, Nanfang Hospital, Guangzhou/CN

Introduction: The abscopal effect of radiotherapy, where tumor shrinkage occurs beyond the irradiated field, can be enhanced by immune checkpoint blockade and holds great promise. Nevertheless, the abscopal effect following radioimmunotherapy remains clinically infrequent, and mechanisms underlying this effect are neither fully appreciated nor therapeutically leveraged.

Methods: In vivo genome-wide CRISPR-Cas9 screening were performed in the bilateral LLC1-sgLkb1 murine lung cancer model to identify the key regulator of abscopal effect, validated by a genetically engineered mouse strain. Single-cell multi-omics technique and genetic lineage-tracing assays were integrated to interrogate the underlying mechanisms. An immune system-tumor double humanized lung cancer patient-derived xenograft (PDX) models were established to evaluate the efficacy of targeting this signaling cascade.

Results: In vivo genome-wide CRISPR-Cas9 screens and MAGeCK analyses identified Sfrp2 as a pivotal stromal regulator of abscopal effect, specifically expressed in cancer-associated fibroblasts (CAFs). Depleting Sfrp2 in CAFs using transgenic mice could promote this effect of radioimmunotherapy. Spatial profiling analyses indicated that SFRP2+ CAFs wrapped around the vessels and were accompanied by a substantial number of immunosuppressive macrophages and sparse cytotoxic cells, whereas blockade of SFRP2 resulted in a resurgence of CD8+T cell infiltration. Single-cell transcriptomic and serum proteomics analyses uncovered that irradiated tumor-derived PAI-1 triggered cell-fate transition of pericytes into SFRP2+ CAFs, leading to impaired cytokine and cell adhesion signaling and hindering the trafficking of CD8+T cells. Furthermore, low expression of SFRP2 or PAI-1 was associated with the occurrence of abscopal effect in an in-house cohort of radioimmunotherapy. Notably, targeting SFRP2 or PAI-1 could effectively diminish tumor burden and enhance abscopal effect of radioimmunotherapy in both syngeneic and humanized PDX models.

Conclusions: This study performed a large-scale unbiased genomic investigation to demonstrate SFRP2 as a stromal setpoint that dictates the abscopal effect, providing a potential predictive marker and therapeutic target for radioimmunotherapy of lung cancer.

MA07.11 AGRN-Positive Tumor Cells Promoting Immunotherapy Resistance in Lung Adenocarcinoma by Reshaping the Immune Microenvironment

H. Zhang, X. Leng, Y. Han, J. Li, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu/CN

Introduction: Lung adenocarcinoma (LUAD) is one of the most common tumor types worldwide, which brings a great burden to society and the economy. Immunotherapy is a promising area in treating LUAD, however drug resistance poses a formidable challenge. Thus, exploring targets to improve the efficacy of immunotherapy is a research hotspot.

Methods: We performed single-cell RNA sequencing and multiplex immunofluorescence to identify the key gene associated with anti-PD1 tolerance. Organoid model, in vitro coculture system, metabolomics, transcriptomics, Lactation modification omics, and multiplex immunofluorescence were used to explore the biological function of agrin (AGRN) on tumor glycolysis and immune escape. Molecular and biochemical strategies like RNA-sequencing, CoIP-MS, mass spectrometry, and CUT&Tag were used to gain insight into the underlying mechanisms of AGRN.

Results: We revealed that the proportion of AGRN-positive tumor cells significantly increased in tumor tissues from patients with anti-PD1-resistant LUAD. AGRN upregulates GLUT1 expression on LUAD cell membranes by interacting with GLUT1, thereby promoting glycolysis and lactate accumulation. These changes subsequently induce histone lactylation modification in macrophages, leading to M2-like polarization and CD8+ T cell suppression, eventually resulting in an immunosuppressive microenvironment and immunotherapy resistance. Notably, we synthesized a monoclonal antibody targeting AGRN, and verified that the antibody can reset the tumor microenvironment and restore sensitivity to anti-PD1 by blocking the AGRN/GLUT1/lactate axis.

Conclusions: We found that AGRN can induce macrophage lactate modification by promoting glycolysis and lactate secretion in LUAD cells, leading to an immunosuppressive tumor microenvironment. We also propose that the AGRN/GLUT1/lactate axis is critical for triggering immune evasion and anti-PD1 tolerance. Inhibiting this axis with antibody overcomes anti PD1 resistance in LUAD.

MA07.12 Unleashing the Potential of the Probiotic F.prausnitzii to Optimize PD-1 Inhibitor Efficacy in NSCLC Treatment

L. Jiang, Q. Luo, Shanghai Chest Hospital , Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Lung cancer, specifically Non-Small-Cell Lung Cancer (NSCLC), remains a primary contributor to cancer mortality rates worldwide, with limited efficacious treatment strategies available. While PD-1 inhibitors have gained regulatory approval for NSCLC treatment, their effectiveness is hindered by individual immune response differences. Existing research elucidates the significant role of gut microbiota in modulating the efficacy of immunotherapy. However, these studies principally identified deleterious bacteria, posing specific targets for clinical application and feasibility into question due to the non-specificity associated with eradicating harmful bacteria. In an innovative divergence from this established focus, our study pioneers in identifying a beneficial probiotic, Faecalibacterium<F.> prausnitzii, aiming to expand the utilities of PD-1 inhibitors in NSCLC treatment. The possibility of clinical application through supplementation of this probiotic, rather than elimination of harmful ones, instils a realistic optimism for achieving enhanced treatment outcomes in NSCLC patients.

Methods: We analyzed fecal samples from nine NSCLC patients pre-treatment to identify F.prausnitzii concentration via metagenomic sequencing. Utilizing an animal model, we examined PD-1 inhibitors' impact on tumor growth in the presence of F.prausnitzii and its supernatant. Through flow cytometry, we studied CD8+ T cell activation, exhaustion, and production of IFN-γ and Granzyme B. Using RNA-seq, we explored metabolic changes after F.prausnitzii exposure. High-throughput sequencing and bioinformatics were used to investigate F.prausnitzii's impact on immunotherapy.

Results: Upon prospective collection of fecal samples from 9 NSCLC patients undergoing neoadjuvant immunotherapy, we observed that 6 patients achieved a major pathological response (MPR) while 3 did not. Metagenomic sequencing indicated a higher abundance of F.prausnitzii in responders. Our animal model indicated that PD-1 monoclonal antibody inhibited tumor growth; this effect augmented upon gavage with either F.prausnitzii or its supernatant (F.prausnitzii sp.). Flow cytometry results showed an increase in CD8+ T cell infiltration in tumor tissues and a decrease in CD8+ T cell exhaustion upon using F.prausnitzii sp. with PD-1 monoclonal antibody. Further, the combination enhanced secretion of effector molecules (IFN-γ and Granzyme B). RNA-seq differential analysis revealed a decrease in tryptophan decomposition metabolic pathway and IL4I1 expression post-intervention with F.prausnitzii sp. UPLC-MS demonstrated a decrease in the levels of tryptophan metabolites (KYNA and I3A) in mouse serum when treated with F.prausnitzii sp. in combination with PD-1 monoclonal antibody. Lastly, upon integrating high-throughput sequencing and bioinformatics analysis, it was discovered that F.prausnitzii sp. activated transcription factor RUNX3, thereby inhibiting the transcriptional activity of IL4I1 promoter. Knocking down RUNX3 in NSCLC cells completely reversed the inhibitory effect of F.prausnitzii sp. on IL4I1.

Conclusions: The tentative findings emphasize the promise of probiotics and F.prausnitzii, in particular, in refining NSCLC immunotherapy outcomes. Future research must prioritize uncovering the specific microbial and functional metabolites that enhance PD-1 inhibitor response. The supplementation of probiotics, specifically F.prausnitzii, is a pivotal innovation in boosting immunotherapy efficacy and is anticipated to contribute to personalized NSCLC treatment strategies.

MA07.13 Neoadjuvant Chemotherapy Is Associated with Optimized Spatial Landscape of Tissue-Resident Memory T Cells in Non-Small Cell Lung Cancer

G. Yang[1], S. Cai[1], L. Xing[1], X. Sun[1], [1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, Shandong/CN

Introduction: Neoadjuvant chemotherapy (NAC) combined with immunotherapy is increasingly used in non-small cell lung cancer (NSCLC). Tissue-resident memory T (TRM) cells are the primary immune subset in response to immunotherapy. However, the immunomodulating effect of NAC on TRM cells remains unknown.

Methods: We established two NSCLC cohorts including patients who underwent upfront surgery (US) or NAC followed by surgery. Beyond unpaired comparison between US cohort (n=122) and NAC cohort (n=141) with resection samples, 58 post-NAC resection samples with matched pre-NAC biopsy samples were available for paired comparison. Using multiplex immunofluorescence, we characterized CD103+CD8+ TRM cells and four TRM subsets, including naive TRM1 (PD-1-Tim-3-), pre-exhausted TRM2 (PD-1-Tim-3-) and TRM3 (PD-1-Tim-3-), and terminally exhausted TRM4 (PD-1-Tim-3-). Cell density, cytotoxicity (GZMB positive rate) and two spatial features (infiltration score and cancer-cell proximity score) were defined to evaluate the effect of NAC on TRM subsets.

Results: Cell densities, infiltration scores and cancer-cell proximity scores of TRM cells, especially TRM1&2 subsets, were increased after NAC, which were associated with longer disease-free survival (DFS). Contrarily, no significant change was observed in TRM4 subset, which were associated with shorter DFS. Besides, cytotoxicity of TRM subsets was unaltered after NAC. Patients achieving major pathologic response (MPRs) have higher cell density of TRM1&2 and higher cancer-cell proximity score of TRM2&3 compared with non-MPRs.

Conclusions: NAC may remodel an anti-tumorigenic landscape of TRM cells by increasing cell density and promoting spatial distribution of immunoreactive TRM subsets.

MA08.03 Survival Validation and Gene Mutations of N Descriptors in the Ninth Edition of the TNM Classification for Lung Cancer

F. Fu, Fudan University Shanghai Cancer Center, Shanghai/CN

Introduction: The IASLC Staging Committee recently unveiled the ninth edition of TNM staging system for lung cancer. This study aims to investigate survival, stage grouping, as well as gene mutation of N descriptors in this new classification system.

Methods: Data were extracted from the lung cancer database of Fudan University Shanghai Cancer Center spanning from 2008 to 2020. Patients, who underwent radical resections and had a pathology of N2, were collected. Subsequently, cases were further categorized into N2a (single-station N2) and N2b (multiple-station N2) based on the N descriptors from the ninth edition of lung cancer TNM staging system.

Results: Among the 1263 cases with pN2, 711 were classified as pN2a, and 552 as pN2b. Patients with pN2a exhibited statistically higher overall survival (OS) compared to patients with pN2b (P<0.001). The survival rate for individuals classified as T1N2a was comparable to those categorized as T2N1/T3N0 (IIB) and notably better than those identified as T1N2b/T2N2b (IIIA). Conversely, the survival rate for T2N2b was lower than T1N2b/T2N2a (IIIA) and akin to T3-4N2b (IIIB). Furthermore, the survival rate for T3N2a was similar to T1N2b/T2N2a (IIIA) and significantly better than T3-4N2b (IIIB). The incorporation of single and multiple N2 in the ninth TNM staging system improved its ability to stratify the survival of N2 patients compared to the eighth TNM system. In patients who possess common driver mutations such as EGFR mutation, KRAS mutation, and ALK fusion, a significant survival difference between N2a and N2b has been observed. However, this distinction is not apparent in patients without common driver mutations.

Conclusions: This study represents the first external validation confirming the prognostic accuracy of N descriptors and staging groups in the ninth edition of the TNM classification for lung cancer, which provides significant evidence for the clinical application of this classification system.

MA08.04 Exploration on the Prognostic Heterogenicity in Stage IIB (the 9th Edition of TNM Classification) NSCLC Patients with Different Nodal Statuses

J-S. Cai[1], T. Wu[2], K-Z. Chen[2], [1]Peking University People's Hospital, Beijing/CN ,[2]Peking University People's hospital, Beijing/CN

Introduction: The latest 9th edition of the lung cancer tumor-node-metastasis (TNM) staging system downgrades certain stage IIIA patients from stage IIIA (N2a) to IIB. This study aims to investigate potential prognostic differences among IIB patients with different nodal statuses.

Methods: Consecutive stage IIB and IIIA non-small cell lung cancer (NSCLC) patients who underwent lobectomy with systematic lymph node dissection were included. Staging was reassigned according to the 9th edition of the lung cancer TNM classification. Subgrouping was done based on lymph node involvements: IIB N2a1 (single-station N2 without N1 involvement), IIB N2a2 (single-station N2 with N1 involvements) and IIB N0-1. Survival analysis was conducted using the Kaplan-Meier method, with propensity score matching (PSM) employed to mitigate potential biases. COX regression models were utilized to assess prognostic differences.

Results: A total of 224 patients with stage IIB NSCLC was evaluated. Among them, there were 38, 66 and 120 patients in the IIB N2a1, IIB N2a2 and IIB N0-1 subgroups, respectively. Univariate COX analysis indicated comparable prognoses between the stage IIB N0-1 and stage IIB N2a1 patients, whereas stage IIB N2a2 patients exhibited poorer outcomes. Upon combining the IIB N2a1 and IIB N0-1 subgroups, multivariate COX analysis demonstrated a significantly worse prognosis for stage IIB N2a2 patients compared to those with stage IIB N2a1/0-1 tumors (OS HR: IIB N2a1/0-1 vs. IIB N2a2 = 1 vs. 1.556, P=0.035; DFS HR: IIB N2a1/0-1 vs. IIB N2a2 = 1 vs 1.626, P=0.021). Further comparison between stage IIB N2a2 and stage IIIA patients, following PSM analysis, indicated similar survivals (5-year OS survival rate: 59.5% vs. 56.4%, P=0.390; 5-year DFS survival rate: 35.5% vs. 46.2%; P=0.210). Multivariate COX analysis further confirmed no significant difference in prognosis between the two groups (OS HR: IIB N2a2 vs. IIIA = 1 vs. 0.775, P=0.294; DFS HR: IIB N2a2 vs. IIIA = 1 vs. 0.770, P=0.254).

Conclusions: The prognosis of stage IIB N2a2 patients was worse than that of remaining stage IIB patients but comparable to that of stage IIIA patients. We proposed that stage IIB N2a2 patients should be reclassified as stage IIIA. However, further validation with a larger dataset is necessary to confirm these observations.

MA08.05 Lung Cancer in Young Adults is Associated with Advanced Disease at Diagnosis and Increased Frequency of Targetable Mutations

F. Oezkan[1,2], M. Webendoerfer[2,3], J. Winantea[2,4], M. Wiesweg[2,3], M. Metzenmacher[2,3], D. Theegarten[2,3], K. Darwiche[2,4], S. Bölükbas[2,5], F. Doerr[2,5], C. Taube[2,4], M. Stuschke[2,3], M. Opitz[6], M. Schuler[2,3], W.E.E. Eberhardt[2,3], [1]University Medicine Essen- Ruhrlandklinik, West German Cancer Center, Essen/DE ,[2]National Center for Tumor Diseases (NCT) West, Essen/DE ,[3]West German Cancer Center, University Hospital Essen, Essen/DE ,[4]University Medicine Essen- Ruhrlandklinik, Essen/DE ,[5]University Medicine Essen - Ruhrlandklinik, West German Cancer Center, Essen/DE ,[6]University Hospital Essen, Essen/DE

Introduction: Most patients diagnosed with lung cancer are 65 years or older with an increased risk above the age of 55 in the smoking population, as reflected in most screening cohorts. Risk factors for younger patients ≤ 45 years of age remain largely undefined and only smaller cohorts have been described in the literature. Here, we report the largest European cohort of young adults with lung cancer to date, diagnosed at the West German Cancer Center from 2019 to 2023.

Methods: All patients diagnosed with lung cancer at the West German Cancer Center between 2019 and 2023 were included (n = 3561). Electronic medical records of patients ≤ 45 years (a) (n = 71; YC) and 45 y (n = 3490; OC) of age were reviewed for sex, smoking history, tumor stage at diagnosis, histopathology, and genomic alterations. Fisher's exact test was used to compare significance levels between the groups ($\alpha = 0.05$). Significant p-values are marked with an asterisk.

Results: 71/3561 patients with lung cancer (1.99% of the entire cohort) were ≤ 45 years (YC; median 39 years, Q1: 35.5; Q3: 44) with comparable gender distribution (YC vs. OC; 47.89% vs. 45.11% females). YC were more frequently never smokers (23.94% vs. 6.93%, p < 0.05*), diagnosed with advanced disease stage (IVA and IVB: 53.52% vs. 23.48%, p < 0.05*), more advanced lymph node metastases (N+: 70.42% vs. 52.66%, p < 0.05; N3: 32.39 vs. 20.09%, p < 0.05*) and high prevalence of brain metastases (16.9% vs. 12.03%, p = 0.2). Adenocarcinomas (63.27% vs. 51.81%, p = 0.11) and undifferentiated tumors (18.37% vs. 4.98%, p < 0.05*) were the dominant histological subtypes in the YC with NSCLC (n = 49; 69.01% of YC vs. 80.56% of OC; p = 0.31), while there was only a single squamous cell carcinoma. Neuroendocrine differentiation was more frequent in the YC group (30.99% vs. 15.36%, p < 0.05*), particularly carcinoid tumors (n = 16; 68.18% vs. 21.83%), while SCLC was less common (31.82% of NET; 9.86% of YC) compared to OC (78.17% of NET; 12.01% of OC). Genomic alterations in patients with NSCLC in the respective cohorts are presented in the table below.

Conclusions: Lung cancer in young patients is characterized by distinct biologies with high prevalence of driver oncogenes, neuroendocrine differentiation, and non-smokers. The predominance of advanced disease at diagnosis suggests that increased awareness in the medical community is required.

MA08.07 Transthoracic Versus Transbronchial Approaches for Diagnosis of Pulmonary Nodules Located in the Middle Lung Zone

T. ISHIWATA, A. Gregor, T.K. Waddell, K. Yasufuku, K. Czarnecka-Kujawa, Toronto General Hospital, TORONTO/ON/CA

Introduction: Transthoracic biopsy (TT) and transbronchial biopsy (TB) are the two main modalities for diagnosis of pulmonary nodules (PN). Generally, TT has a higher diagnostic yield and complication rate. The approach for PN biopsy often depends on local expertise, resources, patient factors, and nodule characteristics. TT is used commonly for peripheral nodules, while TB is favored for central nodules. Limited data exist on the optimal diagnostic approach for middle lung zone nodules. The purpose of this study was to compare the diagnostic performance, complication rate, and attributable cost of a clinician-directed, TT- vs. TB-driven approach to the workup of middle lung zone PNs using real-world data.

Methods: This is a retrospective cohort study of prospectively collected data on consecutive patients referred to a tertiary thoracic oncology center from January 1, 2015 to June 30, 2016, including 5-year follow-up to confirm pathological accuracy. Patients requiring pathological diagnosis of PNs located in the middle third lung zone were included. Three independent clinicians with expertise in CT chest interpretation localized nodules in the middle lung zone using a concentric division method from the hilum as reported previously. The diagnostic approach was at the discretion of the managing clinician. Based on the first invasive diagnostic test performed, patients were classified into two groups: transthoracic biopsy first (TTF) or transbronchial biopsy first (TBF). We compared the diagnostic yield, complications, diagnostic workup length, and associated costs (in 2023 Canadian dollars [$CDN] {$1CDN=$0.741US}) between the two diagnostic approaches.

Results: The cohort included 207 patients; 99 were classified as TTF, and 108 as TBF. Compared to the TTF group, the TBF group had larger nodules (mean diameter ± SD, 43 ± 19 vs. 35 ± 24 mm, p = 0.0087), more nodules with a positive bronchus sign (94% vs. 68%, p <0.0001), and more patients with suspected clinical stage III lung cancer (38% vs. 19%). The diagnostic yield of the first diagnostic procedure was higher in the TTF group (90% vs. 78%, p = 0.0238). Throughout the diagnostic workup, pneumothorax rate was higher in the TTF group (28% vs. 3%, p <0.0001), including pneumothorax requiring chest tube placement (8% vs. 0%, p = 0.0023). There was no severe bleeding requiring advanced intervention in both groups. Diagnostic workup was longer in the TTF group (mean ± SD, 44 ± 29 vs. 31 ± 19 days, p = 0.0001). The overall TTF and the TBF workup costs were similar (median [IQR], $1,641 [951-2,897] vs. $1,809 [1,274-2,689], p = 0.5474). However, in patients requiring pathological mediastinal nodal staging, costs were higher in the TTF group (median [IQR], $3,061 [2,401-3,690] vs. $2,122 [1,724-2,875], p <0.0001).

Conclusions: Experienced clinician-driven diagnostic assessment of middle lung zone PNs results in comparable diagnostic workup costs for TTF and TBF approaches. Workup duration and cost for patients requiring invasive mediastinal nodal staging are lower with a TBF approach. This population-based study may guide clinicians and policymakers to improve the cost-effectiveness of PN diagnostic workup.

MA08.08 Association of FDG-PET/CT Findings with Sufficient Amount of Tissue Samples for Gene Panel Testing in TBB/TBNA

A. Tamura[1,2], R. Ko[1], H. Kenmotsu[1], T. Kawata[1], S. Matsuda[1], M. Morita[1], M. Sekikawa[1], K. Doshita[1], M. Yabe[1], H. Kodama[1], K. Miura[1], Y. Iida[1], N. Mamesaya[1], H. Kobayashi[1], K. Wakuda[1], A. Ono[1], T. Naito[1], H. Murakami[1], H. Nokihara[2], M. Hojo[2], T. Takahashi[1], [1]Shizuoka Cancer Center, Shizuoka/JP ,[2]National Center for Global Health and Medicine, Tokyo/JP

Introduction: Application of gene panel testing has become the golden standard for deciding treatment of stage IV non-small cell lung cancer (NSCLC) patients and achieving adequate amount of tissue samples in biopsy is essential for its success. Fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) has high sensitivity for detecting viable tumor cells, and its efficacy has been shown in selecting biopsy sites of mediastinal lymph nodes for staging in preoperative settings. However, it remains to be seen whether FDG-PET/CT is also effective in acquiring sufficient amount of tissue for gene panel testing.

Methods: We retrospectively reviewed patients with stage IV NSCLC patients who underwent transbronchial lung biopsy (TBB) (including transbronchial lung cryobiopsy [TBLC]) or endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) for gene panel testing in Shizuoka Cancer Center from January 2022 to January 2024. For each patient multiple FDG-PET/CT parameters were obtained, including standardized uptake values (SUVs) and presence of necrosis (PET-necrosis) at the biopsy site, along with other clinical data of the patients. PET-necrosis was defined as areas of low/no FDG uptake surrounded by those with FDG uptake, whose CT level also indicated necrosis (between 10 and 30 Hounsfield units). The primary outcome was panel-biopsy failure, which was defined as cases that required re-biopsy, single-plex testing, or gene panel testing by cell blocks, due to inadequate or negative tissue samples in the initial biopsy. The association of FDG-PET/CT parameters with panel-biopsy failure was analyzed, using logistic regression analysis, adjusting for factors which have been shown to contribute to panel-biopsy failure in previous studies (TBB: tumor locations, EBUS-TBNA: number of biopsies).

Results: A total of 239 patients with stage IV NSCLC underwent bronchoscopy, including 176 patients with TBB and 63 with EBUS-TBNA. Panel-biopsy failure was observed in 33 patients (18.8%) with TBB and 15 (23.8%) with EBUS-TBNA. In patients who underwent TBB, univariate analysis of the risk of panel-biopsy failure revealed that the risk increased in the presence of PET-necrosis (OR 3.22; 95%CI 1.24-8.36, p=0.017), whereas the risk did not correlate with SUVs (OR 1.03; 95%CI 0.96-1.11, p=0.4). Likewise, in logistic regression analysis adjusting for tumor locations (right or left, upper/middle or lower lobe, central or peripheral) and tumor diameter, presence of PET-necrosis resulted in significantly higher risk of panel-biopsy failure (OR 5.60; 95%CI 1.62-19.30, p=0.0064), whereas no association was seen in terms of SUVs (OR 1.05; 95%CI 0.97-1.15, p=0.24). In patients who underwent TBNA, univariate analysis showed increased risk of panel-biopsy failure in the presence of PET-necrosis (OR 5.52; 95%CI 1.00-30.50, p=0.05), whereas the risk was not associated with SUVs (OR 0.98; 95%CI 0.87-1.11, p=0.75). In logistic regression analysis adjusting for number of biopsies, presence of PET-necrosis showed tendency of higher risk of panel-biopsy failure (OR 5.13; 95%CI 0.86-30.60, p=0.073), whereas the risk was not related to SUVs (OR 1.00; 95%CI 0.88-1.14, p=0.98).

Conclusions: PET-necrosis was associated with panel-biopsy failure in both TBB and TBNA. In choosing biopsy site for gene panel testing, FDG-PET/CT findings had better be considered, and lesions with PET-necrosis might not be optimal target of biopsy.

Keywords: FDG-PET/CT, PET-necrosis, gene panel testing

TUESDAY, SEPTEMBER 10, 2024 - 11:15 - 12:30

MA08.09 Predictive CT Features of Visceral Pleural Invasion in Lung Cancer with Ground Glass Opacity

N. Hayashi, K. Suzawa, K. Okada, T. Ryuko, Y. Tomioka, S. Tanaka, K. Miyoshi, K. Shien, M. Okazaki, S. Sugimoto, S. Toyooka, Okayama University Hospital, Okayama/JP

Introduction: Visceral pleural invasion (VPI) is an independent prognostic indicator in patients with non-small cell lung cancer (NSCLC). However, radiological features of VPI in pure ground-glass opacity (GGO) and part-solid tumors (subsolid tumors) has not been sufficiently investigated. To determine the appropriate policy and timing of therapeutic intervention, it is important to diagnose VPI based on radiological findings. The objective of this study is to clarify the predictive CT features of VPI in patients with lung cancer presenting subsolid tumors.

Methods: We retrospectively reviewed the medical records of patients who underwent surgical resection for lung cancer between January 2012 and December 2017. The inclusion criteria were radiological subsolid tumors, and tumors in contact to the pleura. We evaluated the radiological features of the tumors from the preoperative thin-section CT scans, including the tumor diameter, distance from the solid component to the pleura, and CT numbers of the contact area with the pleura.

Results: A total of 193 tumors were eligible for this study. Of these, 192 tumors were adenocarcinoma, and the remaining one tumor was adenosquamous cell carcinoma. The median total tumor size was 19mm (range, 6 -53mm), and the median solid size was 9mm (range, 0 - 30mm). The median CT number of the contact area of the pleura was -336HU (range, -820 -247 HU). VPI (PL ≧ 1) was pathologically confirmed in 7 out of 193 tumors (3.62%). All tumors with VPI were part-solid tumors, and VPI was not confirmed in tumors without direct contact of solid component with the pleura. In 80 tumors with the solid component in direct contact with the pleura, the median CT number of the contact area with the pleura was -12 HU (range, -123 - 247HU). Univariate analysis for predictive radiological features of VPI revealed significant differences in contact between solid component and the pleura (p = 0.002), consolidation tumor ratio (CTR) (cutoff, 0.5, p = 0.050), solid component tumor size (cutoff, 10mm, p = 0.002), SUVmax on FDG-PET (cutoff, 2.5, p = 0.0001), and CT numbers of the contact area with the pleura (cutoff, -336, p =0.0067).

Conclusions: VPI was confirmed in part-solid tumors with direct contact of the solid component with the pleura. Early surgical resection is encouraged for these tumors.

MA08.11 Incidental Lung Nodule Program: A New Approach for Early Detection and Management of Lung Cancer

J.J. Zulueta[1], N.J. Ayoub[1], H.Y. Wang[1], J. Qi[1], S. Adler[1], S. Chen[1], S. Lim[1], S. Luby[1], A. Velo[1], M. Sangro[2], [1]Mount Sinai Morningside Hospital, MAnhattan/NY/USA ,[2]Clinica Universidad de Navarra, Manhattan/NY/USA

Introduction: Outside of lung cancer screening, more than 1.5 million new incidental lung nodules (ILN) are detected yearly in the United States 1. More than 60% of ILNs may be lost to follow-up2. We implemented an ILN program as a safety net to prevent losses to follow up and improve early detection of lung cancer. Earlier versions of this abstract have been submitted to the 2024 ATS and CHEST meetings.

Methods: We searched for lung nodules in all chest-related radiological reports using natural language processing (NLP) from Mount Sinai Morningside and West hospitals. All reports included a radiologist recommendation. After applying exclusion criteria, imaging studies were classified according to the presence or absence of an established follow-up pathway. Patients in the latter category were contacted and offered a pathway including a nodule clinic. Studies with established pathways were only tracked and patients were contacted if the follow-up was incomplete. A completed follow-up was defined by any of the following occurring on or before the due date: a test to assess the nodule or an encounter indicating no further follow-up is necessary. We also searched for lung nodules before the implementation of the program to assess compliance with follow-up recommendations.

Results: Between 1/2023 - 4/2024, we identified 4,614 studies potentially containing lung nodules, of which 2973 (64.4%) were enrolled in the program. After reviewing the medical records, 1,968 (66.2%) had an established follow-up pathway, 808 (27.2%) did not, 2 were pending assessment, and 195 (6.6%) were closed for various reasons. As of 4/2024, 622 (58.6%) of the tracked studies were pending follow-up, 184 (17.3%) had been successfully followed-up, and 255 (24.0%) had not followed-up by due date. Upon further engagement, 71 (28%) of the initially unfollowed patients completed their follow-up, 138 (54%) were pending scheduled follow-up, and 46 (18%) were closed for various reasons. Of the 1,061 patients tracked after program engagement, 10 patients were diagnosed with lung cancer with 7 (70%) in stages I/II and 3 (30%) in stages III/IV. Of the 1,968 patients tracked without any engagement by the program due to the existence of an established follow-up pathway, 30 were diagnosed with lung cancer with 11 (36.7%) in stages I/II and 19 (63.3%) in stages III/IV. Because of the program, 188 follow-up CT scans, 23 positron emission tomography scans, 244 lung nodule clinic visits, 33 biopsies, and 2 surgeries were conducted. Between January-February 2022, we identified 809 scans with lung nodules, of which 374 (46.22%) were enrolled in this study. Of these, 209 (55%) did not complete the recommended follow-up. As compared to the outpatient setting, studies ordered for ED and hospitalized patients were less likely to have follow-ups (OR 0.230, [95% CI 0.119-0.443] and OR 0.137, [95% CI 0.054-0.347], respectively).

Conclusions: An ILN program mitigates the high risk of loss to follow-up of lung nodules. Navigating patients that do not have established pathways in the health system despite radiologist's recommendations, can lead to a high proportion of early-stage lung cancer diagnoses.

MA08.12 Semi-Sold Lung Nodule Growth Rates, Need for Treatment, and Cancer-Specific Verses All-Cause Mortality in a Large North American Population

G.A. Woodard, E. Kane, S. Prince, J. Blasberg, A. Dhanasopon, D. Boffa, V. Mase, S. Dacic, A. Bader, F. Detterbeck, Yale School of Medicine, New Haven/CT/USA

Introduction: Semi-solid lung nodules (SSN) on chest CT pose a continued clinical dilemma as they often require no treatment but have the potential to be invasive lung adenocarcinoma. An improved understanding of the outcomes of patients, particularly non-Asian populations, with SSN is needed to improve treatment recommendations for patients at risk of invasive disease.

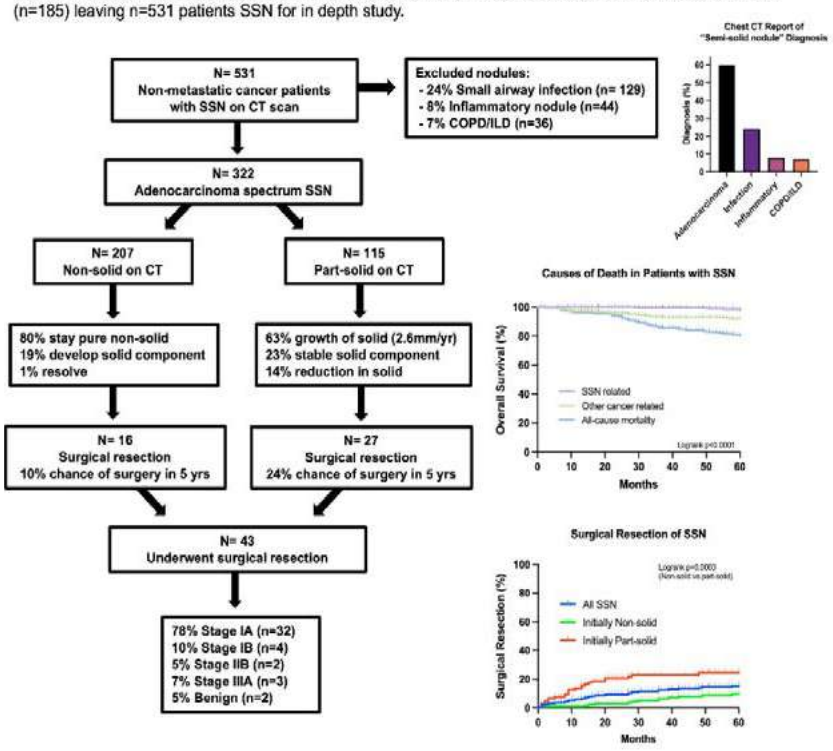
Methods: Patients with SSN reported on outpatient chest CT were identified retrospectively from all 2017 radiology reports in a large Northeast health system by natural language search. Manual chart review was performed for demographics, nodule size, growth on subsequent CT, suspected diagnosis, treatment, pathology, and survival.

Results: A total of 17,276 chest CT identified 952 patients with SSN (positive findings on 7% of all CT). Patients with metastatic cancer and limited documentation were excluded (n=421). Of patients with radiographic SSN, 25% of SSN were evaluated as small airway infection, 8% were inflammatory, and 7% were COPD/ILD related. The remaining 322 (34%) patients were thought to have nodules in the adenocarcinoma spectrum SSN. These SSN patients were predominately female n=242 (75%), median age 70.5 years, 87% white, 8% black, 3% Asian, 2% white-Hispanic, 81% ever-smokers, 19% never-smokers, and 12% had previously treated lung cancer. At diagnosis, n=115 (36%) SSN had a solid component in the SSN and n=207 (64%) were non-solid. In part-solid lesions over time, 23% had a stable solid component, 63% had growth of the solid component, and 14% had a reduction in size. Among non-solid SSN, 80% remained non-solid, 19% developed a solid component, and 1% resolved. Five-year all-cause mortality of those with SSN (n=322), was 80.1% overall survival, with 97.9% 5-year SSN-related survival, 91.9% 5-year other cancer-related survival (including n=2 who died of new second primary lung cancer). Within 5 years, n=43 (13%) underwent surgical resection, and patients with originally semi-solid SSN more likely to undergo resection than originally non-solid SSN (p=0.0003). On pathology 95% were lung adenocarcinoma, and positive lymph nodes were found in <5% of patients. Second primary lung cancers requiring treatment were identified in 34.9% within 5-years of surgery.

Conclusions: Patients found to have SSN should be reassured as to the slow growth and excellent survival associated with SSN. Most patients, particularly those with non-solid lesions, do not require surgical resection. Overly aggressive treatment of SSN should be tempered, particularly given high rates of developing multiple nodules and second primary lung cancer which may pose a greater mortality risk.

Keywords: ground glass opacity, semi-solid lung adenocarcinoma, lung nodules

Figure 1: Growth Patterns, Treatment and Survival of Semi-solid Lung Nodules (SSN). All 17,276 outpatient chest CT from 2017 were screened with natural language search yielding N=952 unique patients with SSN. Manual chart review removed patients with metastatic cancer (n=236) and those with limited documentation (n=185) leaving n=531 patients SSN for in depth study.



MA09.03 Plasma Proteomics-based Models for Predicting Immunotherapy-and Chemotherapy-Related Toxicity in NSCLC Patients

Introduction: Patients with metastatic non-small cell lung cancer (NSCLC) are typically treated with PD-1/PD-L1-based immune checkpoint inhibitors (ICIs) depending on tumor characteristics and line of therapy. Toxicities resulting from such treatments can substantially affect quality of life and treatment trajectory. Currently, there are no reliable biomarkers for predicting the development of ICI-induced immune-related adverse events (irAEs) and chemotherapy-related adverse events (chemo-AEs). Here, we describe plasma proteomics-based models for the pretreatment prediction of severe irAEs, specific irAEs and chemo-AEs in patients with NSCLC.

Methods: Pretreatment plasma samples were collected from 426 NSCLC patients receiving PD-1/PD-L1 inhibitors with or without chemotherapy, and 138 NSCLC patients receiving chemotherapy alone. Proteomic profiling of plasma was performed using aptamer-based technology, covering ~7000 proteins per sample. Toxicity data were identified and graded using CTCAE v. 4.2. Toxicity data were collected and attributed to either immunotherapy or chemotherapy by the treating medical oncologist, and verified by two independent medical oncologists with irAE expertise. irAEs were defined as toxicities requiring treatment hold or immunosuppressive therapy, depending on the grade. In the ICI-treated cohort dataset, proteins associated with severe irAEs (defined as grade ≥3 irAEs or those resulting in ICI discontinuation within the first 100 days) were identified using a cross-validation approach and called Toxicity-Associated Proteins (TAPs). As a proof of concept for predicting specific irAE types, a similar approach was employed to identify proteins associated with ICI-induced skin rash (irAE-rash) termed rash-TAPs. Similarly, proteins associated with chemo-AEs in the chemotherapy cohort were classified as chemo-TAPs. TAP sets were integrated into three distinct machine learning-based models, where each model computes the probability of developing the respective toxicity type (i.e., severe irAE, irAE-rash or chemo-AE). Bioinformatic analyses were performed on all TAP sets.

Results: The models displayed significant predictive performance as demonstrated by area under the curve (AUC) of receiver operating characteristic (ROC) plots (severe irAE model: AUC=0.62, p-value=0.004; irAE-rash model: AUC=0.75, p-value<0.0001; chemo-AE model: AUC=0.67, p-value=0.002) as well as high correlations between predicted AE probability and observed AE rate (severe irAE model: R2=0.88, p-value=0.0016; irAE-rash model: R2=0.91; p-value=0.018; chemo-AE model: R2=0.80, p-value=0.01). The severe irAE, irAE-rash and chemo-AE models were based on 231, 108 and 114 proteins, respectively. Only two proteins were common to all three TAP sets, suggesting that these are independent models that reflect different biological mechanisms per toxicity type. The severe irAE TAP set displayed significant enrichment of inflammation and an abundance of neutrophil- and monocyte-related proteins. Multiple TAPs that were higher in patients who have experience ICI-related skin rash are significantly enriched with proteins related to gdT-cells, basophils, and inflammation. The chemo-TAP set displayed significant enrichment of angiogenesis pathways.

Conclusions: We describe three novel computational models for predicting severe irAEs, a specific irAE type and chemo-AEs based on pretreatment plasma proteomic profiles. Our findings also provide biological insights into treatment-related toxicity. Overall, the study demonstrates a viable framework for developing predictive models specific to different classes of treatment-related toxicity.

MA09.04 Differential CD8+FoxP3+ T Cell Infiltration Patterns Associate with Pathologic Response after Neoadjuvant Anti-PD-1 in NSCLC

M. Fotheringham[1], B. Green[2], J.S. Roskes[2], E. Cohen[1], B. Zhang[2], L.L. Engle[2], D. Wang[2], D. Jimenez-Sanchez[2], J.X. Caushi[2], J. Zhang[2], N. D'Amiano[2], J.C. Sunshine[2], J.S. Deutsch[2], S. Uttam[1], A. Fiorante[1], N.A. Espinosa[1], T. Popa[1], A. Ogurtsova[2], S. Soto-Diaz[2], M. Eminizer[2], D. Medvedev[2], J.E. Chaft[3], J.R. Brahmer[2], M. Conroy[2], J. Reuss[2], H. Ji[2], P.M. Forde[2], D.M. Pardoll[2], K.N. Smith[2], A.S. Szalay[2], J.M. Taube[2], T.R. Cottrell[1], [1]Queen's University, Kingston/ON/CA ,[2]Johns Hopkins University, Baltimore/MD/USA ,[3]Memorial Sloan Kettering Cancer Center, Middletown/NJ/USA

Introduction: Neoadjuvant immune checkpoint blockade (ICB) with anti-PD-1 based therapies is emerging as the new standard of care in resectable non-small cell lung carcinoma (NSCLC)1,2. Single-cell RNA sequencing performed by our group demonstrated CD8+FoxP3+ cells have a cytotoxic phenotype, suggesting a potential role in the anti-tumor immune response3. Building on this and our previous identification of CD8+FoxP3+ cell densities as a predictor of response to neoadjuvant ICB in NSCLC3, this study aims to evaluate the quantity and spatial dynamics of CD8+FoxP3+ cells in pre- and on-treatment tumor specimens from patients treated with neoadjuvant ICB as part of a phase 2 clinical trial.

Methods: All NSCLC tumor specimens were collected from patients enrolled in the first neoadjuvant clinical trial of anti-PD-1 (NCT02259621). Formalin-fixed, paraffin embedded sections of pre-treatment biopsies (n=25) and on-treatment resections (n=35), including n=23 pre/on-treatment pairs, were stained with a 6-marker multiplex immunofluorescence (mIF) panel (PD-1, PD-L1, CD8, CD163, FoxP3, and cytokeratin). Following whole-slide scanning, comprehensive cellular maps were generated using the AstroPath platform4. Wilcoxon signed-rank and Mann-Whitney U tests were used to compare immune cell densities between pre- and on-treatment specimens and across two thresholds of pathologic response5: ≤10% residual viable tumor (RVT) (i.e. major pathologic response (MPR)) and ≤50% RVT. Cell probabilities as a function of distance to the tumor-stroma boundary were plotted.

Results: The tumor microenvironment maps included a total of 18,515,905 cells. The densities of CD8+FoxP3+ cells significantly increased following neoadjuvant ICB (0.96 vs. 8.80 cells/mm2, for pre- vs. on-treatment specimens, respectively, p=<0.0001). Among on-treatment specimens, the densities of CD8+FoxP3+ cells were not significantly different in patients with and without MPR (median densities 10.94 vs. 7.59 cells/mm2, respectively, p=0.504). We next evaluated the spatial distribution of CD8+FoxP3+ cells to assess infiltration across the tumor-stroma boundary. Across all specimens, the probability distributions demonstrated a 5.8-fold increase in tumor infiltration by CD8+FoxP3+ cells in on-treatment vs. pre-treatment specimens (Figure 1). Moreover, tumor infiltration by CD8+FoxP3+ cells was increased (~2-fold) in on-treatment specimens with evidence of pathologic response to therapy (MPR and ≤50% RVT) relative to those without pathologic response (RVT>50%). These findings support a role for CD8+FoxP3+ cells in the anti-tumor immune response following ICB, including among partially responding tumors.

Conclusions: While CD8+FoxP3+ cells expand broadly in on-treatment tumors following neoadjuvant ICB, their infiltration across the tumor-stroma boundary coincides with pathologic response. Deeper spatial profiling of on-treatment specimens with additional mIF panels is ongoing.

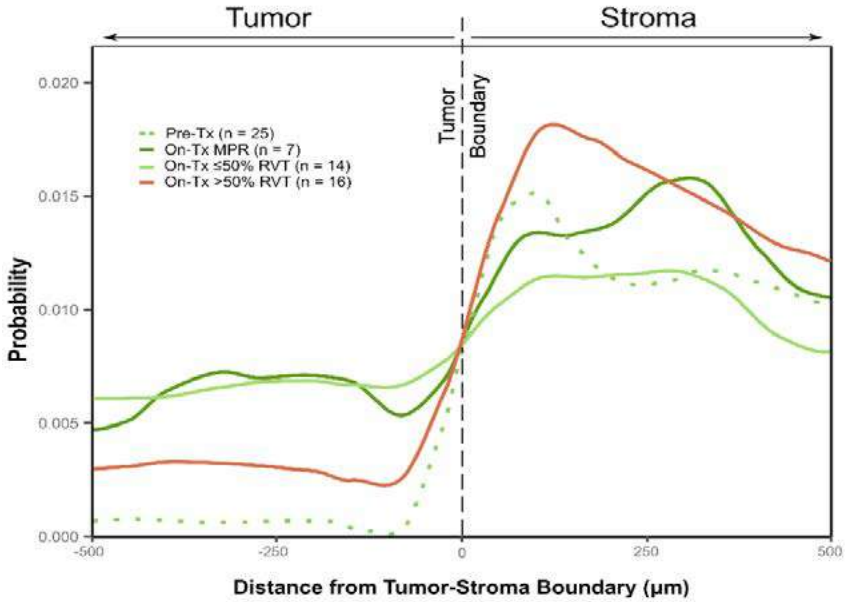

Figure 1. Probability distribution of CD8+FoxP3+ cells at tumor border. Probability distributions calculated from cell densities observed in pre-treatment biopsies (n=25; dotted light green line), and on-treatment resections achieving ≤10% (MPR; n=7; solid dark green line), ≤50% (n=14, including MPR; solid light green line), and >50% RVT (n=16; solid orange line) were plotted as a function of distance from the tumor-stroma boundary.

MA09.05 Circulating Protein Signatures and Immune Cells Are Predictive and Prognostic Markers for Patients with NSCLC in the SAKK 17/18 Trial

A. Rigutto[1], Y. Feng[2], P. Shichkova[2], L. Raess[2], S. Schaer[2], R. Bruderer[2], M. Tognetti[2], M. Joerger[3], S. Hayoz[3], V. Somasundaram[3], N. Nuñez[4,5], N. Fournier[6], J. Lourenço[6], R. Gottardo[6], B. Becher[5], A. Addeo[7], A. Gupta[1], A. Curioni-Fontecedro[1,8], [1]Faculty of Science and Medicine, University of Fribourg, Fribourg/CH ,[2]Biognosys AG, Schlieren/CH ,[3]Swiss Group for Clinical Cancer Research (SAKK), Bern/CH ,[4]Facultad de Ciencias Químicas, Universidad Nacional de Córdoba (UNC), Córdoba/AR ,[5]Institute of Experimental Immunology, University of Zürich, Zürich/CH ,[6]TDS, Swiss Institute of Bioinformatics, Lausanne/CH ,[7]Oncology Service University Hospital Geneva, Geneva/CH ,[8]Clinic of Oncology, Cantonal Hospital Fribourg, Fribourg/CH

Introduction: The multicentric phase II clinical trial (SAKK17/18) met its primary endpoint of ORR 31% in patients with non-small cell lung cancer (NSCLC) who progressed on immunotherapy. Advanced proteomics on plasma samples and high-dimensional analysis of circulating immune cells identified novel predictive markers of response in these patients.

Methods: Patients received atezolizumab and gemcitabine at day1 and gemcitabine alone at day 8 q3w until progression. Longitudinal blood samples were collected at baseline, at cycle1-day8 and at cycle 2-day1. High-dimensional spectral flow cytometry, analyzing 40 surface markers and transcription factors, was applied to characterize the circulating immune cell subsets over time. From plasma samples (1) extracellular vesicles (EVs) were analyzed by data-independent acquisition (DIA) mass spectrometry (MS) and (2) whole-plasma proteome profiling using Biognosys' enrichment workflow was performed.

Results: According to the Response Evaluation Criteria in Solid Tumors (RECIST 1.1.), patients were classified as partial response (PR, n=11; 31%), stable disease (SD, n=8; 22 %), progressive disease (PD, n=12; 33%), and no tumor assessment post baseline (NTA, n=5; 14%). Patients with NTA had a progression of disease before the scheduled first-restaging. Median overall survival (mOS) was 8.2 months (m) in these heavily pretreated patients. Based on the analysis of EVs, plasma of patients with NTA cluster together with PD, revealing their similar outcome. Strikingly, specific protein signatures were found in the plasma of patients with either PR, SD and PD. Low frequencies of CD8+ T cells and high frequencies of NK cells at baseline correlated with longer overall survival (CD8+ T cells high with mOS 6.7m, CD8+ T cells low with mOS 11m, p = 0.013. NK cells high with mOS 9.5m, NK cells low with mOS 7m, p = 0.021). Increase in CD4+ T cells at cycle1-day8 and cycle2-day1 also correlated with longer overall survival (at C1D8, CD4+ T cells high with mOS 10m, CD4+ T cells low with mOS 6.7m, p= 0.011. At C2D1, CD4+ T cells high with mOS 9.8m, CD4+ T cells low with mOS 6.6m, p=0.018). A broader characterization of T cell subsets revealed decreased frequencies of central memory CD8+ T cells at baseline in PR (p= 0.021).

Conclusions: Specific immune cell subtypes and protein signatures correlate with response to treatment and outcomes in patients with NSCLC included in the SAKK 17/18 ORIGIN trial. This data give new insights about treatment-related antitumor mechanisms in these patients.

MA09.06 Use of Biosimulation to Predict Chemotherapy Benefit in Patients with Metastatic NSCLC Being Treated with Immunotherapy

M. Klein[1], D. Watson[2], S. Kapoor[2], P.R. Nair[2], S. Rajagopalan[2], M. Glaser[1], N. Sharif[1], M. Stonebarger[3], A. Westanmo[1], D.A. Lala[2], A. Kumar[2], J. Chauhan[2], P. G[2], Y.S. Ullal[2], S. Kulkarni[2], A. Ghosh[2], Y. Narvekar[2], M. Patil[2], M. Castro[2], M. Macpherson[2], J. Wingrove[2], T. Patil[4], A. Ganti[5], C. Aggarwal[6], [1]Minneapolis VA Health Care System, Minneapolis/MN/USA ,[2]Cellworks, South San Francisco/CA/USA ,[3]St. Cloud VA Healthcare System, St Cloud/MN/USA ,[4]University of Colorado, Denver/CO/USA ,[5]University of Nebraska Medical Center, Omaha/NE/USA ,[6]University of Pennsylvania, Philadelphia/PA/USA

Introduction: Combination chemo-immunotherapy has emerged as a standard treatment option in patients with non-small cell lung cancer (NSCLC). Although PD-L1 is used as a biomarker to select patients for therapy, it is imperfect and the additive value of chemotherapy may not be the same in all patients. A mechanistic computational biology model was developed by Cellworks that integrates a patient's tumor-based genomic profile as determined via next-generation sequencing, revealing signaling pathway dysregulation and variable drug response. Model output was converted to a quantitative score called the Therapy Response Index (TRI) and then further dichotomized into Favorable and Unfavorable Risk Groups allowing identification of patients who may or may not respond to chemotherapy during immunotherapy treatment, independent of TMB and PD-L1 status.

Methods: The TRI algorithm was trained in a real-world retrospective cohort of 553 NSCLC patients from the U.S. Veteran's Health Administration (VHA) system who received tissue-based comprehensive genomic profiling. Of these patients, 223 received immunotherapy (IO) and 330 received immunotherapy plus chemotherapy (IO+C). The TRI, computational model and clinical thresholds were locked and then prospectively validated in 710 advanced NSCLC front-line patients receiving either IO (n = 251) or IO+C (n = 459), obtained from the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine NSCLC clinico-genomic database (FH-FMI CGDB). The de-identified data originated from approximately 280 US cancer clinics (~800 sites of care).

Results: In the validation set, the TRI was significantly associated with OS after adjustment for clinical and genomic risk factors, including PD-L1 levels (LR p = 0.0355). Patients in the TRI Unfavorable Risk Group (TRI < 32) received an estimated incremental benefit in median OS of ~ 3 months with the addition of chemotherapy to immunotherapy. In contrast, patients in the TRI Favorable Risk Group (TRI ≥ 32) showed no improvement in median OS when receiving chemotherapy in addition to immunotherapy. A statistical test of interaction between TRI and chemotherapy treatment was marginally significant in the validation set (LR p = 0.1361) after adjustment for clinical and genomic risk factors, despite the study being inadequately sized for this type of analysis.

Conclusions: In this study, TRI was predictive of OS and incremental chemotherapy benefit in two real-world cohorts of patients with NSCLC receiving IO or IO+C. These results support the use of TRI to identify patients who may benefit from a combination of immunotherapy and chemotherapy and those unlikely to respond to immunotherapy alone, independent of PD-L1 levels. Future studies will be performed to confirm the hypothesis that TRI has utility in deciding whether patients should be offered chemotherapy.

MA09.08 The Mechanical Change and Metastasis Promoting in Lung Adenocarcinoma Progression: From AIS, MIA to IAC

M. Li, J. Xi, M. Feng, Q. Wang, Zhongshan Hospital Fudan University, Shanghai/CN

Introduction: The driving factors that promote invasive acquisition and change in tumor during the progression of lung adenocarcinoma still need to be explored. We explored the mechanical process and molecular mechanism of tumor invasion and metastasis from the intersection of mechanics and oncology.

Methods: The study qualitatively describes the mechanical rigidity of lung adenocarcinoma cells by analyzing the reflection spectrum characteristics of cell protein skeleton color rendering and simulating mechanical signals. Quantitative measurement of the mechanical rigidity of a single cell membrane is achieved through the capture and movement of microbeads attached to the cell membrane based on magnetic tweezers' micro rheology under the light field.

Results: The attributes of the cytoskeleton proteins can be displayed in spectral form. During the evolution of lung adenocarcinoma from AIS, MIA to IAC, it can be observed that there is a significant difference in spectral characteristics between the wavelength of 420 nm and 650 nm, indicating a significant change in the average cellular mechanical stiffness characteristics related to cytoskeletal protein characteristics per unit area of tumor tissue. Through computer mechanical signal simulation, we found that during the "AIS-MIA-IAC" progression of early lung adenocarcinoma, the mechanical rigidity heterogeneity of tumor cells gradually increased, indicating the presence of tumor cell heterogeneity during tumor progression, which may be closely related to the acquisition and enhancement of invasion and early metastasis ability of some tumor cells. Quantitative characterization of the mechanical stiffness of a single-cell membrane was achieved through the capture and movement of microspheres attached to the cell membrane based on magnetic tweezers under the light field. Bioinformatics analysis and in vitro experimental results indicate that changes in ARNTL2 expression can alter the mechanical rigidity of tumor cells through the ERK signaling pathway, thereby enhancing tumor cell migration, invasion, metastasis and promoting tumor progression.

Conclusions: Mechanical factors play an important role in lung adenocarcinoma progression from AIS, MIA to IAC. The change in mechanical rigidity of tumor cells may be a driving factor for the acquisition of invasion and metastasis ability of early lung adenocarcinoma cells. The expression of some key genes and activation of signaling pathways may be related to the change in mechanical rigidity of tumor cells.

MA09.09 Genomic Mapping of Evolutionary from Pre-Invasive to Advanced Stage in Lung Adenocarcinoma

Y-D. Lin[1,2], H-J. Li[1,2], H-Z. Hong[2], Y-F. Qi[2], Y-L. Wu[2], W-Z. Zhong[2], [1]School of Medicine South China University of Technology, Guangzhou/CN ,[2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN

Introduction: Lung adenocarcinoma presents significant heterogeneity, with an extremely low survival rate in advanced stage, while the pre-invasive and early invasive lesions can be cured. Previous studies have focused on molecular events between pre-invasive and invasive adenocarcinoma (IAC), yet there remains a lack of continuous insight into identifying the genomic and evolutionary profiles from pre-invasive to advanced stage.

Methods: A total of 1525 next-generation sequencing (NGS) samples of adenocarcinoma, encompassing clinical stages 0-IV lung adenocarcinoma according to the Eighth Edition of the International Association for the Study of Lung Cancer TNM Classification, were retrospectively analyzed to identify key genomic profiling at different stages. The dataset of East Asian ancestry from OncoSG was used for prognostic assessment.

Results: Pre-invasive lesions and IAC of stage IA, stage IB-II, stage III, and stage IV accounted for 220, 884, 216, 118, and 87 samples, respectively. ERBB2, MAP2K1, BRAF, MED12, and TSC1 were significantly enriched in pre-invasive lesions. Meanwhile, EGFR, TP53, and LRP1B were notably enriched in IAC of stage IA, and APC, KEAP1, and POLE were exclusively observed in IAC. ERBB2 exhibited a continuous significant decrease from IAC of stage IA to stage IB-II, whereas TP53 showed a continuous significant increase. PTEN and BRCA2 were also enriched in stage IB-II. TP53 and RB1 were identified as key mutations in stage III compared to IB-II. No notable mutations were found between stage III and IV. Mutations including PTEN, STK11, APC, BRCA2, and LRP1B were associated with poor survival. In terms of oncogenic pathways, RTK-RAS was predominantly involved in pre-invasive lesions. TP53, Cell Cycle, WNT, and NRF2 were initially activated in IAC of stage IA, while PI3K and TGF-β were initially activated in stage IB.

Conclusions: This study provides a continuous depiction of the mutational features from pre-invasive to advanced lung adenocarcinoma. Elucidating this topic facilitates a systematic understanding of tumorigenesis and progression.

Keywords: Genomic mapping, Evolutionary profile, Adenocarcinoma

MA09.10 Spatial Transcriptomics and Next-Generation Sequencing Reveals the Gene Expression Andmolecular Immune Characteristics in LUAD

Y. Liu[1],[2], J. Zhang[1], T. Bian[1], J. Feng[1], T. Wang[3], S. Lu[4], [1]The Affiliated Hospital of Nantong University, Nantong/CN ,[2]The Warren Alpert Medical School of Brown University, Providence/RI/USA ,[3]The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou/CN ,[4]Rhode Island Hospital, Department of Medicine, The Warren Alpert Medical School of Brown University, provindence/RI/USA

Introduction: The individual prognosis of lung adenocarcinoma (LUAD) depend on their histologic growth pattern. The micropapillary component (MPC) is a poor prognostic indicator of LUAD. However, the transcriptome characteristics that lead to poor prognosis remain unclear, especially the spatial transcriptome (ST).

Methods: Spatial transcriptomic analysis of gene expression from 4 LUAD cases was performed with 10X Genomics. Targeted next-generation sequencing (NGS) was used to evaluate 72 LUAD samples. Tissue sections from 160 LUAD patients were stained with TCF12 and PD-L1 antibodies.

Results: We mapped the transcriptome of LUAD for the first time and revealed its broad heterogeneity, in which micropapillary (MP) pattern was associated with cAMP signaling and immune response. Moreover, the targeted next-generation sequencing results showed that MP-containing LUAD were mainly enriched in the cAMP signaling pathway, consistent with the ST results. Furthermore, the expression of the cAMP response element binding protein-TCF12 was elevated in the micropapillary region of LUAD. Next, the immunohistochemical results indicated that elevated TCF12 production was tightly connected to the poor survival and lymph node metastasis of MP patients. Finally, we detected a significant correlation between the PD-L1 heterogeneous expression and the presence of MP patterns. This is the first study to integrate spatial transcriptomics and targeted next-generation sequencing to illuminate the relationship between tissue structure and biological behavior in LUAD.

Conclusions: Our current results revealed the spatial heterogeneity of LUAD and identified molecules that can be used as a target for accurate LUAD diagnosis and treatment.

MA09.12 The Role of Different Lepidic Patterns for Determining Whether it is a Multiple Primary Pulmonary Adenocarcinoma

H. Xie[1], C. Wu[1], J. Guo[1], [1]Shanghai Pulmonary Hospital, Shanghai/CN

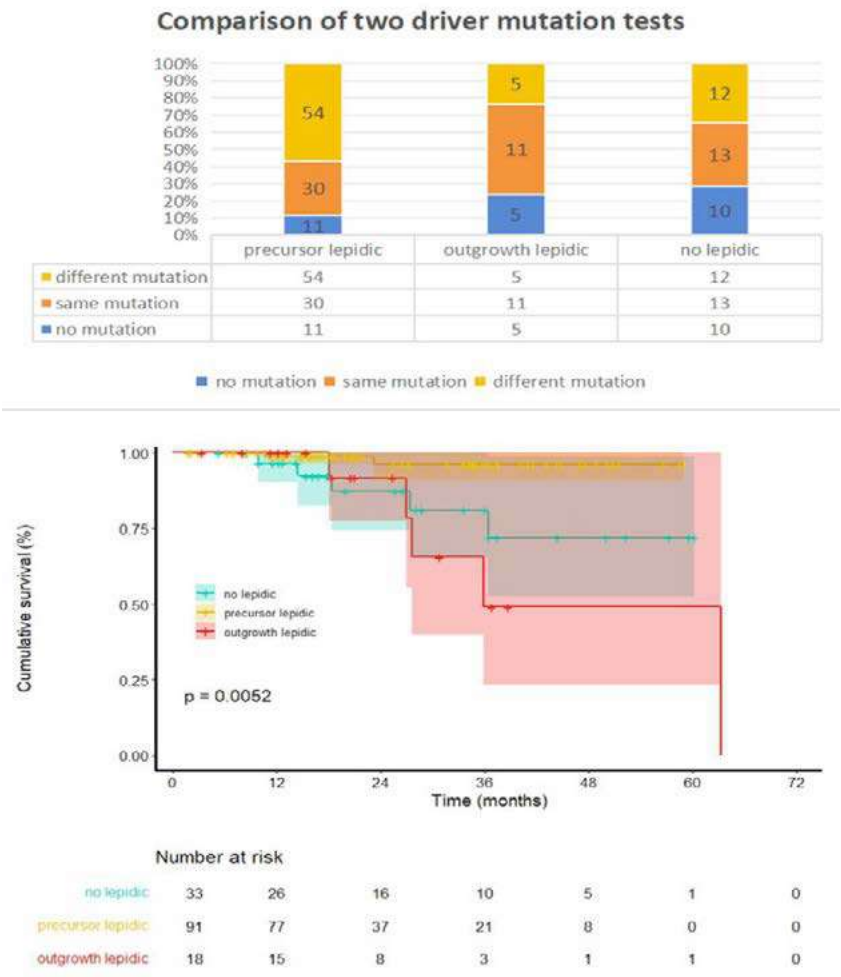
Introduction: Determining whether a second occurrence of lung adenocarcinoma is metastatic or a second primary is of great clinical significance, but sometimes it's difficult. The presence of carcinoma in situ (lepidic pattern) in the second tumor is one of the markers of double primary tumors, which can simplify the process of determining metastasis or double primary tumors. Outgrow lepdic was also judged to be a lepidic pattern according to the latest WHO classification and was considered not to need to be differentiated from precursor lepidic in clinical practice. We wanted to assess whether outgrow lepdic also had a role in determining whether the second lung adenocarcinoma was primary or metastatic by comparing the patient's prognosis and driver mutations between the two tumors.

Methods: We included 151 patients who underwent two times of surgery in Shanghai Pulmonary Hospital from September 2014 to January 2024, both of which were pathologically diagnosed as lung adenocarcinoma and had undergone at least 5 gene tests (EGFR, ALK, KRAS, BRAF, ROS1). We re-read all the slides and recorded the adenocarcinoma pattern they contained, especially the lepdic pattern in the second tumor, even if it was less than 5%. All patients were followed up for prognosis.

Results: There were 126 cases with at least one driver mutation in two tests, 116 cases with lepdic pattern in the second tumor (95 precursor lepidic cases, 21 outgrow lepdic cases). The mutation concordance rate was 31.57% and inconsistency rate was 56.8% in cases with precursor lepidic. The mutation concordance rate was 52.4% and inconsistency rate was 23.8% in cases with outgrow lepdic. Patients with precursor lepidic in the second tumor had a better prognosis than those with outgrow lepdic and those without lepidic pattern.

Conclusions: In multiple lung adenocarcinomas, patients with precursor lepidic in the second tumor have a lower probability of mutation coincidence and a better prognosis, which can be used as a basis for determining whether it is a multiple primary adenocarcinoma. Outgrow lepdic should not be used as a basis for determining whether it is a multiple primary adenocarcinoma. It should be distinguished from precursor lepidic in cases requiring confirmation of metastasis or a second primary.

Keywords: Outgrow lepdic, Driver mutation, multiple primary pulmonary adenocarcinomas



MA09.13 Clinical Outcome of Bilateral Invasive Mucinous Adenocarcinoma(IMA) without Mediastinal Nodal Involvement from SEER Database

J. Kim, Y.J. Heo, W. Woo, S. Kim, Y.K. Chae, Northwestern University Feinberg School of Medicine, Chicago/IL/USA

Introduction: Invasive mucinous adenocarcinoma (IMA) represents a distinct subset of lung adenocarcinomas, accounting for 5%-10% of cases, characterized by unique histopathological and molecular profiles. Despite its distinctive features, IMA's prognostic factors and clinical course remain underinvestigated. This study analyzes various prognostic factors of IMA, including bilateral lung involvement without mediastinal nodal involvement, and their impact on clinical outcomes.

Methods: We analyzed data from the SEER database for patients diagnosed with IMA from 2000 to 2020. Kaplan-Meier survival curves and log-rank tests were utilized to assess OS and lung cancer-specific survival (LCSS) across different cohorts. Additionally, Cox regression models were used to evaluate the hazard ratios (HRs) of risk factors impacting survival outcomes.

Results: Among stage IV IMA patients (n= 3211), those with bilateral parenchymal IMA (BP-IMA) without mediastinal lymph node involvement (n= 86, 2.68%) exhibited significantly better overall survival (OS: median 0.71 years vs. 0.42 years; p=0.047) and lung cancer-specific survival (LCSS: median 0.83 years vs. 0.50 years; p=0.024). Notably, survival rates for patients with BP-IMA were not significantly different from patients with stage III IMA (OS, p=0.097; LCSS, p=0.095). Furthermore, analysis identified bilateral tumors without mediastinal lymph node involvement(MLNI) (HR=0.71 [0.53-0.94], p=0.015), advanced T stages (HR=1.19 [1.09-1.30], p<0.001), age (≥70, HR=1.34 [1.23-1.45], p<0.001), and gender (male, HR=1.17 [1.07-1.27], p<0.001) as significant prognostic factors influencing survival in IMA patients.

Conclusions: Our study reveals that BP-IMA without mediastinal nodal involvement shows a more favorable prognosis than typically seen in other stage IV IMA. This finding underscores the need for a tailored approach for stage IV IMA patients lacking extensive lymph node involvement. Further prospective studies are warranted, given the complexity of IMA.

Keywords: Mucinous adenocarcinoma, SEER, histopathology

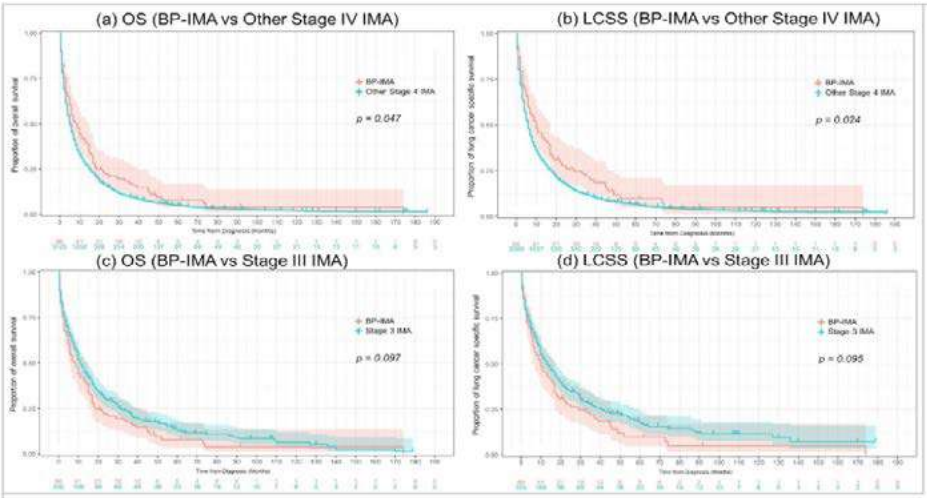


Table. Prognostic Factors of Stage IV Invasive Mucinous Adenocarcinoma

Factor	Hazard Ratio (95% CI)	P-value
Bilateral IMA without MLNI	0.71 (0.53-0.94)	0.015
T Stage (Ref. T1, T2)		
T3, T4	1.19 (1.09-1.30)	<0.001
Sex (Ref. Female)		
Male	1.17 (1.07-1.27)	<0.001
Age (Ref. age under 70)

MA10.03 Paying the Price: How Lung Cancer Care Impacts Wallets and Well-Being

D.L. Pottinger[1], S. Olisakwe[2], C. Williams[1], Q. Hussaini[1], Y. Boumber[1], U.B. Roy[3], J. Feldman[4], G. Rocque[1], M. Khalil[1], A. Desai[1], [1]UAB Hospital, Birmingham/AL/USA ,[2]University of Alabama at Birmingham, Birmingham/AL/USA ,[3]Lungevity Foundation, Chicago/IL/USA ,[4]EGFR Resisters, Chicago/IL/USA

Introduction: While advances in lung cancer treatment have improved clinical outcomes, it is unclear the extent to which treatment initiation is accompanied by financial hardship that can negatively impact the quality of life of patients and their families. We investigated financial hardship and related sociodemographic inequities among patients with lung cancer.

Methods: This secondary analysis of standard-of-care treatment planning survey data included patients with lung cancer diagnosed from 2017 to 2023 at the University of Alabama at Birmingham. Surveys included two measures of financial hardship. The first was the validated Comprehensive Score for financial Toxicity (COST) tool (scored from 0 to 44, with lower scores indicating more financial distress). The second was a list of questions measuring 10 individual domains of financial difficulty, including: trouble paying for basic needs, utilities, transportation or lodging for treatment, medications, medical supplies, upfront medical payments, insurance or medical bills, child or eldercare, and employment or disability issues. The total number of patient-reported financial difficulties was measured, with values ranging from 0/10 to 10/10. Analysis was based on the first survey completed post-diagnosis, and subgroups were compared using independent-samples t-tests.

Results: Among 253 patients with financial toxicity survey data, median age was 67 years (range: 29 to 94). The cohort was majority male (53%) and White (65%; 21% minority groups, including those identifying as Black, Asian, and Hispanic; 12% missing race/ethnicity). Among the 204 patients (81%) which had COST data, median scores were 28.0 (IQR 17.3). Patients belonging to a minority group and those under the age of 65 reported more financial distress compared to White or older patients (>65y), with a mean difference in COST scores of -5.4 (95% CI -9.3 to -1.5) and -6.8 (95% CI -9.8 to -3.7), respectively. Minority and younger patients also reported greater financial difficulties compared to White or older (>65y) patients, with mean differences in reported financial difficulties of 1.5/10 (95% CI 0.5 to 2.6) and 1.3/10 (95% CI 0.5 to 2.1), respectively. When asked whether they had enough in savings to pay for their treatment, 47.8% of patients answered “Somewhat”, “Very much”, or “Quite a bit”. Additionally, patients reported an average of 2.5/10 financial difficulties (N=253). Among all patients, the most commonly endorsed domains of financial hardship were: upfront medical payments (n=91, 36.0%), insurance or medical bills (n=87, 34.4%), and medications (n=75, 29.6%).

Conclusions: In a sample of patients initiating treatment for lung cancer, financial hardship was greater among minoritized racial or ethnic groups and younger patients. Additional study of this cohort is ongoing, including construction of models to predict patients at higher risk of financial toxicity, and whether it impacts clinical trial participation. Finally, routinely delivered interventions to identify and address financial hardship before treatment onset, such as oncology financial counseling, warrant further investigation.

MA10.04 The Financial Toxicity of Lung Cancer Impacts All Spheres of Life

D. Villalón[1], A. Aguarón[2], M. O'Sullivan[2], E. Pataki[2], A. Hans[2], D. Montague[2], L. Magee[2], M. Forsblom[2], E. Szmytke[2], A-M. Baird[2], [1]Fundación MÁS QUE IDEAS, Barcelona/ES ,[2]Lung Cancer Europe, Bern/CH

Introduction: Anecdotal evidence within the European lung cancer community has strongly suggested that a lung cancer diagnosis results in a significant economic burden. The aims of this study were to (i) assess if financial toxicity existed and the impact of it, and (ii) identify possible interventions.

Methods: This work was a descriptive research analysis that explored the economic burden of lung cancer, as reported by people diagnosed with the disease and those in a caregiving capacity. A survey was developed following an extensive literature review and discussion among the LuCE Report Working Group. The survey was translated into 16 languages and disseminated primarily via LuCE and its members through social media platforms. It was active for approximately 6 weeks and data was collected via an online platform.

Results: The survey was completed by 1,161 participants (834 people with lung cancer and 327 caregivers) across 28 European countries. Most participants experienced both medical (73.5%) and non-medical expenses (87%), with the primary cost most often relating to travel for medical reasons (84%). Approximately half of the participants (49.5%) experienced an income decrease of more than 30%. This was due to inability to work (1 in 4), being absent from work (28%) and the need to retire due to their diagnosis (27%). Nearly 40% found it difficult to live on their current household income. Almost 9 in 10 people (88%) felt that at least one sphere of their lives was negatively impacted due to the financial situation caused by lung cancer, predominately their mental health (67.5%). Additionally, they felt that these issues were a barrier to treatment, recovery, and care. Worryingly, more than a quarter (26.5%) had to make difficult decisions that affected their self-care or adherence to treatment. Overall, nearly half (47%) felt financially distressed after diagnosis (an increase of 19% from baseline), and 29% could not meet their monthly expenses, which was a doubling from baseline levels. Few participants sought help with their difficulties (approximately 21%), but even of that between 30-41% of participants did not receive the required support. Financial support in relation to medication and healthcare costs were identified as a high priority (53%).

Conclusions: Financial toxicity is common in Europe. People impacted by lung cancer need access to allied healthcare professionals who can screen for financial vulnerability and put assistance measures in place. Government policies must prioritise income replacement programmes to assist those struggling with the financial impact of a cancer diagnosis.

MA10.05 Characterization of the Basic Financial Needs of Those Living with Lung Cancer

B.N. Nichols, A. Ciupek, M. Rigney, M. Goff, GO² for Lung Cancer, Washington/DC/USA

Introduction: Financial toxicity is a pervasive issue for patients, particularly in lung cancer, which is among the most expensive cancers to treat. As therapeutics and survival improve, survivors can struggle to balance personal financial goals with medical costs. Here, we sought to better understand the impact of these costs on personal finances.

Methods: GO2 for Lung Cancer has regular contact with survivors and caregivers through an email and phone call-based helpline, allowing those impacted by lung cancer to reach out for support. We analyzed contacts received between 11/28/17-12/31/23, looking at contact demographics and the nature of their financial request.

Results: There were 11375 total contact-points, with 1563 (11.7%) having Financial Assistance as the primary support need. 1730 reported needs were spread out across 34 deductive categories. The top 5 identified were Co-Pays (16.8%), Transportation (16.1%), Insurance (7.2%), Treatment-Chemotherapy (6.1%), and Treatment-Targeted Therapy (5.8%). We further categorized needs into those that were "Basic," or essential to maintain daily life for the caller and their dependents. These included housing, food, dependent care, prescriptions, and utilities. Almost 19% (18.8%) requested aid for at least one basic need. GO2 could only successfully refer to financial assistance 36.5% of the time due to funds being closed. The most common sources referred to were cancer-specific organizations (35.8%), other non-profits/charities (24.3%), and case managers/navigators (16.7%). There is a circuitous nature to financial aid referrals, as the leading referral sources to GO2 were also cancer-specific organizations, other non-profits/charities, and healthcare professionals. Callers were evenly represented between caregivers (40.6%) and patients (44%), primarily female (76%), had non-small cell lung cancer (57.2%), and late-stage disease (60.5%). The average age at diagnosis was 61.8 years. This mirrors current literature, showing those diagnosed <65 are more likely to face financial hardship. The most common treatments were chemotherapy (39.6%) and radiation (23.7%). Of those reporting insurance information, 45.8% had Medicare, 22% had private insurance, 17% received Medicaid, and 13.7% were uninsured. Starting in 2021, GO2 began recording patient reported barriers to care. Those most identified were Trouble Affording Co-Payments (16%), Housing Instability (11.6%), Under-insurance (11.6%), Lack of Income/Unemployment (10.5%), and Transportation (7.7%).

Conclusions: This analysis underscores the variety of financial resources needed for lung cancer patients. In addition to high treatment costs, nearly 1/5th of patients lack basic necessities. This can contribute to higher physical/mental stress, which may negatively impact their prognosis/adherence. Insurance status presents an issue, as the uninsured rate we found is higher than the 2022 data showing 8% of Americans are without health insurance. Care teams should utilize validated measures to identify how their patients are at risk to ensure they receive adequate support throughout their care. Policy makers must also consider the landscape of financial assistance, and how it can be transformed to aid cancer survivors and their families.

MA10.07 Understanding Symptom Burden in Young Adults with Lung Cancer Based on an Analysis from the E2C2 Pragmatic Clinical Trial

K. Smith, K. Leventakos, V. Grzegorczyk, J. Griffin, B. Liu, S. Mina, D. Pachman, K. Ruddy, A. Cheville, Mayo Clinic, Rochester/MN/USA

Introduction: There is limited data on the symptom burden that young adults with lung cancer experience. In this large pragmatic trial, we evaluated patient-reported outcomes for patients with lung cancer based on age (<50 or >= 50 years old), gender, and history of smoking.

Methods: We conducted a subgroup analysis from the Enhanced, EHR-facilitated Cancer symptom Control (E2C2) study, which is a stepped-wedge, cluster-randomized pragmatic trial evaluating a collaborative care model for the assessment and management of six symptoms: Sleep disturbance, Pain, Physical function impairment, Anxiety, Depression, and Energy deficit/fatigue (SPPADE). Symptoms are rated on an 11-point numerical rating scale. Symptom severity is classified as mild (0-3), moderate (4-6), or severe (7-10). Our analysis included patients with any diagnosis of lung cancer who completed at least one survey regardless of the timepoint in their treatment course, then summarized SPPADE symptom data reported from their initial survey. We utilized a chi-square test with the binary outcome of symptom score >=7 or symptom score < 7.

Results: 5,039 patients with lung cancer completed a survey between March 2019 and January 2023. Of those patients, 2,651 identified as female (52.6%) and 2,388 identified as male (47.4%). 342 patients were <50 (6.8%) and 4697 were >=50 (93.2%). There was a history of smoking in 158 patients <50 (43.9%) and 3,519 patients >=50 years (74.9%). Patients <50 were more likely to report severe anxiety (16.22% vs 11.30%, p = 0.006). Women were more likely to report severe anxiety (13.82% vs. 9.2%, p < 0.001) and depression (10.14% vs. 7.98%, p = 0.008) compared to men. Women <50 were more likely to report severe pain (17.86% vs 7.69%, p = 0.007) and insomnia (20.92% vs 12.59%, p = 0.046) than men in this age group. Patients with a history of smoking were more likely to report severe anxiety (12.39% vs. 9.34%, p = 0.003), depression (9.74% vs. 7.33%, p = 0.01), fatigue (21.92% vs. 16.54%, p < 0.001), pain (14.31% vs. 8.19%, p < 0.001), impaired physical function (16.96% vs. 11.28%, p < 0.001), and insomnia (16.18% vs. 10.96%, p < 0.001) compared to patients who never smoked. Younger patients with a history of smoking reported more severe anxiety (22.29% vs. 10.67%, p = 0.004), depression (15.92% vs 7.3%, p = 0.013), fatigue (27.39% vs. 10.67%, p < 0.001), and impaired physical function (20.38% vs. 11.17%, p = 0.02).

Conclusions: Young patients with lung cancer experience more severe anxiety compared to older adults. Within the <50 cohort, women were more likely than men to report severe pain and insomnia, and younger patients with a smoking history had more severe anxiety, depression, fatigue, and physical dysfunction compared to patients who never smoked. A tailored approach to supportive care resources may be needed for these different patient populations. Further study will focus on understanding how patients utilize supportive care services, if symptom burden evolves over time, the incidence of co-occurring symptoms, and the ideal strategies to improve the quality of care for these patients.

MA10.08 Unravelling the Impact: Understanding Caregivers in the Lung Cancer Community

B. King-Kallimanis[1], A-M. Baird[2], M. Belesis[3], T. Chihuri[1], K. Glynn[1], S. Wing[4], U.B. Roy[1], [1]LUNGevity Foundation, Bethesda/MD/USA ,[2]Trinity College, Dublin/IE ,[3]Caregiver, New York/FL/USA ,[4]EmpiraMed, Boston/MA/USA

Introduction: Primary informal caregivers are with their person living with lung cancer the most and play a critical care role in the care pathway. Yet, these informal caregivers are too often an undervalued member of the healthcare team. In this study, we sought to understand how caregivers providing care for <1 year compared to those providing care for 1 or more years with respect to time spent on different care tasks, changes to employment, support networks, and well-being.

Methods: We analyzed data from LUNGevity Foundation's longitudinal study on the experiences of people living with lung cancer (Project PEER). In this analysis, we looked at respondents who identified as a caregiver (n=79). All caregivers completed an initial assessment survey online that includes questions on the diagnostic pathway of the person they care for and caregiver-specific questions and validated questionnaires (the CareGiver Oncology Quality of Life questionnaire (CarGOQoL) and ENRICHD Social Support Instrument (ESSI)). We focused on caregivers providing care for <1 year (n=37) and 1 year or more (n=42).

Results: Half of the caregivers were spouses/partners (40% wives/10% husbands) with a median age of 57 and a quarter were children (20% daughters/5% sons) with a median age of 41. The remainder were a mix of other family and non-relative caregivers. Time spent on medical decision-making and household tasks were similar between the groups. However, looking at time spent in the last month on caregiving activities, differences were observed between caregivers of <1 year and long-term caregivers on daily tasks involved with caregiving (median hours per month were 9 and 1.5, respectively) and emotional support (median hours per month were 20 and 30, respectively). Caregivers, regardless of length of time caregiving, spent an average of 70 hours a month on unpaid caregiving tasks. Regarding changes to employment, 22% of <1yr caregivers and 31% of long-term caregivers reported a change. More long-term caregivers reported retiring early or quitting their job. Both groups reported taking leaves of absence and decreasing hours of paid employment. For social networks, long-term caregivers reported less support for daily chores (Most/all the time: 34% vs. 55%), however a larger proportion of caregivers of <1yr did not have someone they could trust and regularly confide in (none/a little of the time 21% vs. 14%). Psychological well-being was similar between groups, median score of 37 for <1yr vs. 41 for long-term caregivers (higher scores (maximum 100) indicate better well-being).

Conclusions: Around a quarter of the sample reported changing their employment by taking early retirement, decreasing hours at work, or taking medical leave to accommodate extra tasks. The long-term financial implications of decreasing paid employment for caregivers have been documented. Psychological well-being was similar between the groups; however, was lower than what was reported in the initial validation papers for the CarGOQoL, which included lung cancer caregivers, but not exclusively. Our findings underscore the need to develop caregiver support services to address the evolving needs of caregivers based on the duration of caregiving.

MA10.09 Mapping of Patient-Reported Outcome Items to Symptomatic Adverse Events of Tyrosine Kinase Inhibitors in Non-Small Cell Lung Cancer

E.L. Paton[1], J.P. Cetnar[1], J. Freeman-Daily[2], J. Feldman[3], B.L. King-Kallimanis[4], [1]Oregon Health and Science University, Portland/OR/USA ,[2]The ROS[1]ders, Sacramento/CA/USA ,[3]EGFR Resisters, Deerfield/IL/USA ,[4]LUNGevity Foundation, Bethesda/MD/USA

Introduction: Patient-reported outcomes (PROs) are critical for assessing symptomatic adverse events (AEs) in non-small cell lung cancer (NSCLC) clinical trials. However, PROs may not fully capture tyrosine kinase inhibitor (TKI)-specific AEs in metastatic NSCLC, impacting patient treatment expectations. This study evaluates the coverage of TKI-related symptomatic AEs by commonly used PRO item libraries.

Methods: A list of FDA-approved TKIs for NSCLC with alterations in EGFR, ALK, ROS1, RET, MET, and NTRK was compiled by physicians and patient advocates. Symptomatic AEs were extracted from drug labels using drugs@FDA. European Organisation for Research and Treatment of Cancer (EORTC), Patient-Reported Outcomes Measurement Information System (PROMIS), and Patient-Reported Outcomes Common Terminology Criteria for Adverse Events (PRO-CTCAE) item libraries were searched for items assessing the presence, frequency, and/or severity of symptoms corresponding to these AEs. Descriptive statistics were used to summarize AE coverage by items in each library. Items were classified based on whether they assessed an AE's physical, functional, or social/emotional impact.

Results: AE data from 29 clinical trials of 17 TKIs were analyzed. By TKI, EORTC included items that covered the highest average percentage of AEs (98%) followed by PRO-CTCAE (86%) and PROMIS (47%). Of the top 15 most common AEs across TKIs, 8 were covered by all 3 item libraries. EORTC and PRO-CTCAE covered all 15, while PROMIS covered 8 out of 15 (53%). Of these 8 AEs covered by all 3 item libraries, PROMIS included the greatest number of items assessing the functional impact of AEs compared to EORTC or PRO-CTCAE (12% vs 3% vs <1% respectively) as well as social/emotional impact (23% vs 10% vs 0%). For TKI-specific dermatologic AEs, EORTC and PRO-CTCAE covered all 5 identified reactions, while PROMIS covered 1 out of 5 (20%).

Conclusions: While EORTC and PRO-CTCAE covered most symptomatic AE occurrences, PROMIS showed potential in capturing the impact of AEs on patient wellbeing. No libraries addressed all TKI-specific adverse reactions, indicating a need to expand or combine PRO item libraries. These findings underscore the importance of tailoring PRO assessments to specific NSCLC treatments to enhance patient-centered care and shared decision-making between physicians and patients. Our study did not assess how PROs are administered during clinical trials. Future work should be done to address the timing of PRO administration (to capture symptoms at their peak severity) and the evolving drug tolerability over extended treatment durations that are common with targeted therapies.

MA10.11 Patient-Reported Doctor Communication and Preference on Treatment Decision Making: Oligometastatic vs Metastatic Lung Cancer

T. Chihuri[1], U.B. Roy[1], K. Glynn[1], S. Wing[2], B. King-Kallimanis[1], [1]LUNGevity Foundation, Bethesda/MD/USA ,[2]Empiramed, Boston/MA/USA

Introduction: Oligometastatic NSCLC is a complex term, defining 1-5 metastatic sites in a controlled primary tumor with increased overall survival on treatment. Additional emerging terms (e.g., synchronous, oligo-progression) further complicate communication around the diagnosis, and shared decision-making (SDM) between patient and doctor. Our aim was to assess how a diagnosis of oligometastatic NSCLC impacts patient-reported preferences in SDM and provider-patient communication across patients with oligometastatic vs advanced NSCLC.

Methods: LUNGevity Foundation's Project PEER is an ongoing observational study aimed at understanding experiences of people living with lung cancer, currently with 410 patient participants. We focused on the subgroup with advanced (stage III and IV) NSCLC (n=237), comparing advanced disease (59%, n=139) and oligometastatic disease (41%, n=98).

Results: Participants reporting oligometastatic vs advanced disease were similar: Average age 57 vs 56 years, female gender 85% vs 80%, <2 years since diagnosis 49% vs 53%, adenocarcinoma prevalence 88% vs 81%, specific biomarkers 81% vs 82% and 1 line of treatment 35% vs 47% for participants with advanced vs oligometastatic disease respectively. Actual and preferred SDM were similar: 55% vs 54% and 78% vs 74% between participants with advanced vs oligometastatic disease respectively, though there were minute differences between actual and preferred for both groups (see table). Participants in the oligometastatic group were asked if their doctor explained the term, 66% reporting their doctor did not. In this group, fewer participants reported shared decision making (45%) than those whose doctors did explain (64%). Additional comparisons surrounding patient concerns, future treatment and provider communication between these groups showed a similar pattern. No patterns on access to multidisciplinary teams or prognostic awareness were observed between the groups.

Conclusions: We used the complex term of "oligometastatic disease" as a proxy to understand patient-provider communication and found that participants whose doctor explained oligometastatic disease were more likely to report SDM, and greater comfort talking to their doctor about their symptoms, care, and treatment trajectory than either those who reported advanced disease only or whose doctor did not explain oligometastatic NSCLC. Clinicians should be aware that in-depth discussions of complex terms, alternative treatments, and uncertainties are relevant to conversations that extend beyond the initial treatment plan and impact comfort in discussing other care issues (concerns, side effects).

Keywords: Oligometastatic disease, Shared decision making

	Advanced disease (n=139)	Oligometastatic Disease (n=98)	Doctor explained oligometastatic disease (n=33)	Doctor did not explain oligometastatic disease (n=58)
Role in shared decision making (SDM)				
Shared decision	76(55%)	53(54%)	21(64%)	26(45%)
Doctor led decision	41(29%)	27(28%)	8(24%)	18(31%)
Patient led decision	22(16%)	18(18%)	4(12%)	14(24%)
Future treatments/worries discussion with doctor				
Very well	78(56%)	49(50%)	20(61%)	20(34%)

MA10.12 Patient-Centered Communication and Knowledge and Preparedness in Treatment Decision-Making Among People with Lung Cancer

K. Doughtie, E.E. Fortune, M.C. Saxton, M.F. Miller, Cancer Support Community, Washington/DC/USA

Introduction: The management of lung cancer requires increasingly complex decision making by healthcare professionals and patients, particularly in the era of biomarker-driven therapeutic strategies. As a result, lung cancer healthcare professionals' ability to successfully provide patient-centered communication (PCC) is required for shared decision making that considers patient values and priorities. The aim of the present study was to examine the impact of PCC among people with lung cancer on knowledge and preparedness in treatment decision-making.

Methods: Participants in Cancer Support Community's Cancer Experience Registry self-reported sociodemographic information and clinical history, rated their level of knowledge about cancer treatment options and preparedness to make treatment decisions, and completed the Patient Centered Communication short form (6 items; α=0.88), which assesses PCC in six core domains: exchanging information, making decisions, fostering healing relationships, enabling patient self-management, managing uncertainty, and responding to emotions. We included select sociodemographic and clinical variables based on conceptual relevance to PCC and treatment decision-making. Due to a negatively skewed distribution, PCC was dichotomized using a median split (median=4). We fit three logistic regression models: (1) sociodemographic and clinical history variables predicting higher PCC (0=lower median, ≤4; 1=upper median, >4), (2) PCC predicting greater perceived knowledge about treatment options (0=Not at all-Somewhat; 1=Quite a bit-Very much), and (3) PCC predicting greater preparedness to make cancer treatment decisions (0=Not at all-Somewhat; 1=Quite a bit-Very much). The latter two models also included sociodemographic variables and clinical history.

Results: The sample consisted of 177 individuals with lung cancer (71% women; 84% non-Hispanic White; 52% college degree; 37% income ≥$40K; 31% metastatic). Mean age was 65 years (range: 30-92, SD=12); median time since diagnosis was 6 years (IQR: 3-9). 39% reported Quite a bit to Very much knowledge of treatment options, and 45% felt Quite a bit to Very much prepared to make treatment decisions. Bivariate analysis showed a significant relationship between PCC and gender (t=2.25, p=.03; PCC levels lower among women), knowledge about treatment options (r=.33, p<.001), and feeling prepared to make treatment decisions (r=.44, p<.001). In multivariable analysis, higher PCC was associated with greater knowledge about treatment options (OR=3.28; 95% CI=1.51, 7.12; n=151) and greater preparedness to make treatment decisions (OR=4.10; 95% CI=1.90, 8.84; n=151), after adjusting for sociodemographic and clinical history variables. In addition, higher income (≥$40K) was associated with greater knowledge (OR=3.14; 95% CI=1.25, 7.90) and older age (years) was associated with greater preparedness (OR=1.04; 95% CI=1.00, 1.07).

Conclusions: PCC was a significant predictor of greater knowledge and preparedness in treatment decision-making among people with lung cancer, even when including sociodemographic and clinical characteristics in the models. As supported by these findings, successful patient-provider communication influences treatment decisions among people with lung cancer. These findings suggest that providers can positively influence decision-making knowledge and preparedness of patients with lung cancer through improving communication. Continued research is needed to identify the elements of effective communication between clinicians and patients and families.

MA10.13 TIME TOX Lung: Retrospectively Quantifying the Time Toxicity of Lung Cancer Clinical Trials

A. Herrmann, L. Bazhenova, S. Jain, University of California San Diego, La Jolla/CA/USA

Introduction: It is estimated that only 3-6% of US adults with cancer will participate in clinical trials, with study complexity and time burden ranking among fundamental barriers to enrollment. The increasing complexity of clinical trials has recently led to several NCI initiatives focused on decreasing operational burden. The concept of "time toxicity," (TT) a quantitative metric of patient-level time cost, has been proposed in the clinical setting, however, is not well defined in clinical trials. The purpose of this study is to develop and retrospectively apply a standardized time metric to lung cancer clinical trials, evaluate TT across study phases, and characterize evolution over time.

Methods: Protocols from 26 trials associated with FDA approvals of 14 oral targeted lung cancer therapies were obtained from public sources. Using each protocol's schedule of events, study-mandated procedures were assigned "Time Toxicity Units" (TTUs) based on standard time dedicated to those procedures in our institution (1TTU=30min). TTUs for each procedure were multiplied by their frequency and then summed for screening through cycle 5 to determine a trial's Total Time Toxicity (TTT). Descriptive statistics were used to summarize time burdens by publication year and study phase. Median TTT was compared for studies published 2005-2014 and 2015-2024 to assess change over time. Two sample Mann-Whitney U Tests were used for non-parametric comparisons.

Results: Publications spanned 2005-2024, including 5 Phase I, 9 Phase II, and 12 Phase III studies. There were 7 studies (1 Ph I, 0 Ph II, 6 Ph III) with associated publications between 2005-2014 and 19 (4 Ph I, 9 Ph II, 6 Ph III) with associated publications between 2015-2024. Median TTT was 80 (range 60-127.2), 86.2 (51.7-141.5), and 73.3 (34-109.3) TTUs for Ph I-III studies, respectively. Among studies published 2005-2014, median TTT was 40.3 (34-109.3) compared to 86.2 (40.7-141.5) for those published 2015-2024 (p=0.056). Exclusion of Phase I studies did not change the numerical median difference, however weakened the trend (p=0.173).

Conclusions: Clinical trials require considerable time investment from patients. In this study, TT was observed to increase over time, with a non-significant trend toward greater time burden in Phase I-III studies published 2015-2024 compared to 2005-2014. This study demonstrates the feasibility of applying a TT metric to trial protocols using the schedule of events. We now aim to prospectively validate this reportable metric, which can then be employed as a mechanism to both inform patients of TT and encourage streamlined protocol development.

MA11.03 First-Line Treatment of Locally Advanced or Metastatic Pulmonary Lymphoepithelioma-likecarcinoma: A Multicenter, Single-Arm, Phase II Trial

C. Zhou[1,2,3,4,5], X. Lin[1,2,3,4,5], S. Li[1,2,3,4,5], N. Sun[1], [1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]National Center for Respiratory Medicine, Guangzhou/CN ,[3]National Clinical Research Center for Respiratory Disease, Guangzhou/CN ,[4]State Key Laboratory of Respiratory Disease, Guangzhou/CN ,[5]Guangzhou Institute of Respiratory Health, Guangzhou/CN

Introduction: Pulmonary lymphoepithelioma-like carcinoma (PLELC) is a distinct subtype of non-small cell lung cancer, associated with Epstein-Barr virus (EBV) infection and a unique immune environment. Thus we aimed to investigate the efficacy and safety of sintilimab plus gemcitabine and carboplatin in untreated locally advanced/metastatic PLELC.

Methods: This multicenter, single-arm, phase II study enrolled PLELC patients from April 2020 and November 2021. Eligible patients had a histologic diagnosis of locally advanced/metastatic PLELC without any prior systemic treatment. Patients received four cycles of sintilimab plus gemcitabine and carboplatin, followed by maintenance treatment with sintilimab. Primary endpoints were objective response rate (ORR) and safety. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and disease control rate (DCR). Association between biomarkers and PFS was exploratorily analyzed

Results: A total of 30 patients were enrolled. At a median follow-up of 31.2 months (95%CI,28.4-36.7), the ORR was 73.3% (95%CI, 54.1-87.7), and the DCR was 100% (95%CI, 88.4-100). The median PFS was 14.0 months (95% CI, 12.2-20.7). The median OS was not reached, but it was predicted to be 36.1 months (95% CI, 25.7-46.6) based on the Gaussian distribution model. Twenty-one (70%) patients experienced ≥ grade 3 treatment-related adverse events, of which neutropenia (n=12, 40%), anemia (n=4, 13.3%), thrombocytopenia (n=2, 6.7%), decreased white blood cell count (n=3, 10%) were the most common. Exploratory analysis revealed that a higher T-cell-inflamed gene-expression profile (GEP) score was independently associated with longer PFS (HR=0.22, 95%CI, 0.07-0.67, p=0.004). The dynamic analysis of plasma EBV DNA load showed a significant decline when the best response was achieved after treatment (p=0.006) and an increase along with PD (p=0.006) in all evaluable patients.

Conclusions: Sintilimab combined with gemcitabine and carboplatin demonstrates promising efficacy and acceptable safety in patients with advanced PLELC as first-line treatment.

MA11.04 First-in-Class PD-1/IL-2 Bispecific Antibody IBI363 In Patients with Advanced Non-Small Cell Lung Cancer in a Phase I Study

J. Zhou[1], N. Xu[1], J. Shan[1], Y. Wang[1], W. Fang[1], H. Wang[2], Y. Pan[3], Y. Chen[4], X. Liang[5], Q. Chu[6], J. Cui[7], Y. Sun[8], J. Fang[9], X. Liu[10], N. Li[11], S. Long[12], Y. Chen[12], L. Zhao[13], H. Wang[12], T. Liang[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN ,[2]Hunan Cancer Hospital, Changsha/CN ,[3]Anhui Provincial Hospital, Hefei/CN ,[4]Fujian Cancer Hospital, Fuzhou/CN ,[5]Hubei Cancer Hospital, Wuhan/CN ,[6]TONGJI HOSPITAL AFFILIATED TO TONGJI MEDICAL COLLEGE HUST, Wuhan/CN ,[7]The first hospital of Jilin University, Changchun/CN ,[8]Shandong First Medical University Affiliated Cancer Hospital/Shandong Cancer Hospital/Shandong Cancer Prevention and Treatment Research Institute, Jinan/CN ,[9]Peking University Cancer Hospital, Beijing/CN ,[10]The Fifth Medical Center of PLA General Hospital, Beijing/CN ,[11]Cancer Hospital Chinese Academy of Medical Sciences, Beijing/CN ,[12]Innovent Biologics (Suzhou) Co., Ltd., Shanghai/CN ,[13]Innovent Biologics (Suzhou) Co., Ltd., Beijing/CN

Introduction: IBI363 is a first-in-class PD-1/IL-2α-bias bispecific antibody fusion protein to block PD-1 checkpoint and rejuvenate exhausted tumor-specific T cells by cis-activating α-bias IL-2. It has great potential to address the unmet clinical need of patients (pts) with immunotherapy (IO)-resistant and cold tumors. Here, we report the initial safety and efficacy results from a phase I, multicenter, first-in-human study of IBI363 in pts with advanced non-small cell lung cancer (NSCLC).

Methods: Eligible pts with advanced NSCLC who failed or were intolerant of standard therapy were enrolled and received IBI363 intravenously at dose levels of 2/10/300/600 ug/kg every week (QW), 0.3/0.6/1 mg/kg every two weeks (Q2W) or 1.5/2/3 mg/kg every three weeks (Q3W). Endpoints included safety, objective response rate (ORR), disease control rate (DCR), duration of response (DoR) and progression-free survival (PFS) by investigator per RECIST v1.1. Data cut-off date for this analysis was Mar 21, 2024.

Results: A total of 89 pts were enrolled (median age: 60.0 years, males: 83.1%, ECOG PS 1: 74.2%, prior treatment lines ≥2: 79.8%), including 5 pts at 0.6 mg/kw Q2W cohort, 51 pts at 1 mg/kg Q2W, 11 pts at 1.5 mg/kg Q3W, 3 pts at 2 mg/kg Q3W, and 12 pts at 3 mg/kg Q3W. Median duration of IBI363 exposure was 8.4 weeks (range: 2.0-41.9); 25 pts (28.1 %) were still on treatment as of data cutoff date. Treatment-related adverse events (TRAEs) occurred in 78 pts (any grade: 87.6%, grade ≥3: 19.1%). Most common TRAEs (incidence ≥20%) were arthralgia (any grade: 37.1%, grade ≥3: 1.1%), anemia (any grade: 30.3%, grade ≥3: 2.2%), and rash (any grade: 21.3%, grade ≥3: 1.1%). TRAEs led to treatment discontinuation and death in 4 (4.5%) and 1 (1.1%) pts, respectively. As of data cutoff, 79 pts (EGFR-mutant: 8 pts) were treated at dose levels ≥0.3 mg/kg and had ≥1 post-baseline tumor assessment. For these pts, ORR was 24.1% (95% CI: 15.1-35.0) and DCR was 68.4% (95% CI: 56.9-78.4); of the 7 efficacy-evaluable pts at 3 mg/kg Q3W cohort, 6 achieved partial response (ORR: 85.7%). Among them, 74 pts were previously IO-treated and they had an ORR of 24.3% (95% CI: 15.1-35.7) and DCR of 68.9% (95% CI: 57.1-79.2). In pts with squamous NSCLC (n = 37, previously IO-treated: 36 pts, EGFR positive by immunohistochemistry: 1 pt), ORR and DCR were 35.1% (95%CI: 20.2-52.5) and 75.7% (95%CI: 58.8-88.2), respectively; median PFS was 5.5 months (95% CI: 4.0-NC) with 16 (43.2%) PFS events.

Conclusions: IBI363 was well tolerated with encouraging efficacy observed in pts with advanced NSCLC including those previously IO-treated pts.

Introduction: The phase 3 CheckMate 227 study demonstrated significant overall survival (OS) benefit with nivolumab (NIVO) + ipilimumab (IPI) vs chemotherapy in patients with advanced non-small cell lung cancer (NSCLC) and tumor programmed death ligand 1 (PD-L1) expression ≥1%.1 CheckMate 227 CHESS (China ExtenSion Study) was a China-specific extension of the CheckMate 227 Part 1A study comparing NIVO+IPI vs chemotherapy in treatment-naive Chinese patients with advanced NSCLC and PD-L1 ≥1%. The aim of this bridging study was to evaluate the consistency in OS benefit (defined as retaining ≥50% risk reduction) compared with CheckMate 227 Part 1A.

Methods: In this open-label study, adult treatment-naive patients with stage IV/recurrent NSCLC, PD-L1 ≥1%, ECOG performance status 0-1, and no known EGFR/ALK alterations were randomized 1:1 to NIVO 3 mg/kg Q2W + IPI 1 mg/kg Q6W ≤24 months or platinum-doublet chemotherapy Q3W ≤4 cycles. Patients were stratified by histology, sex, and PD-L1 expression (≥50% vs <50%). The primary endpoint was OS. Secondary endpoints were progression-free survival and objective response rate per blinded independent central review. Exploratory endpoints included safety and tolerability assessments and patient-reported outcomes. Analysis time was based on a minimum study duration of 30 months. Changes in the treatment landscape for NSCLC led to a reduction in sample size, and, as a bridging study, it was not statistically powered; however, the number of randomized patients was sufficient to provide ≥80% probability to show consistency of OS benefit with CheckMate 227 Part 1A (OS hazard ratio [HR] <0.895).

Results: Overall, 253 patients were randomized; 126 to receive NIVO+IPI and 127 to receive chemotherapy. Baseline characteristics were balanced between treatment arms. Most patients were male (85%); median age was 62.0 (range, 29-77) years. Median OS was 20.99 months with NIVO+IPI vs 15.11 months with chemotherapy (HR, 0.85, meeting the criterion for showing consistent OS benefit; Table). Median time to deterioration in symptoms per the Lung Cancer Symptom Score average symptom burden index was not reached (NR) with NIVO+IPI vs 22.6 months (95% CI, 11.5-NR) with chemotherapy (HR, 0.52 [95% CI, 0.30-0.90]). Similar rates of any-grade treatment-related adverse events (TRAEs) were observed in both treatment groups (NIVO+IPI, 88.9%; chemotherapy, 92.7%). Fewer grade 3/4 TRAEs occurred with NIVO+IPI vs chemotherapy (35.7% vs 48.8%).

Conclusions: Chinese patients with advanced NSCLC and tumor PD-L1 ≥1% receiving first-line NIVO+IPI vs chemotherapy had consistent OS outcomes compared with the CheckMate 227 global study, with no new safety signals.

C. Radiotherapy Center Cluj, Cluj/RO ,[13]Instituto do Câncer do Estado de São Paulo, São Paulo/BR ,[14]Integrated Health and Social Services Centres, Montérégie Centre, Greenfield Park/QC/CA ,[15]Merck & Co., Inc., Rahway/NJ/USA ,[16]Seoul National University Hospital, Seoul/KR

Introduction: Pembrolizumab plus pemetrexed and a platinum is a standard-of-care first-line treatment for metastatic NSCLC. Preclinical data show that PARP inhibitors such as olaparib upregulate PD-L1 expression. The randomized, open-label, phase 3 KEYLYNK-006 trial evaluated pembrolizumab plus maintenance olaparib versus pembrolizumab plus maintenance pemetrexed following induction with pembrolizumab plus pemetrexed and a platinum for nonsquamous NSCLC (NCT03976323).

Methods: Eligible adults with newly diagnosed, previously untreated stage IV nonsquamous NSCLC without targetable EGFR, ALK, or ROS1 aberrations with CR, PR, or SD following induction therapy with 4 Q3W cycles of pembrolizumab 200 mg, pemetrexed 500 mg/m2, and carboplatin AUC 5 mg/mL/min or cisplatin 75 mg/m2 were randomized 1:1 to olaparib 300 mg BID or pemetrexed 500 mg/m2 Q3W, both given with ≤31 cycles of pembrolizumab 200 mg Q3W. Randomization was stratified by ECOG PS (0 vs 1), PD-L1 TPS (<50% vs ≥50%), and response at randomization (CR/PR vs SD). Dual primary end points were PFS (RECIST v1.1 by blinded, independent central review) and OS. Per the prespecified analysis plan, testing was complete at interim analysis 2 (IA2) for PFS and final analysis for OS.

Results: Of the 1003 participants who received induction therapy with pembrolizumab, pemetrexed, and a platinum, 672 (67.0%) were randomized to pembrolizumab plus maintenance olaparib (olaparib arm; n=337) or pembrolizumab plus maintenance pemetrexed (pemetrexed arm; n=335). At randomization, 56.7% of participants had CR or PR and 43.3% had SD. Median time from randomization to the final analysis cutoff date of February 7, 2024, was 3.3 years (range, 2.3-4.3). At IA2 (data cutoff, May 18, 2022), median (95% CI) PFS was 7.1 months (5.6-8.7) in the olaparib arm versus 8.3 months (6.9-11.5) in pemetrexed arm (HR, 1.12; 95% CI, 0.92-1.36; P=0.87). At final analysis, median (95% CI) OS was 20.7 months (18.0-24.8) in the olaparib arm and 23.0 months (19.0-26.4) in the pemetrexed arm (HR, 1.04; 95% CI, 0.87-1.25; P=0.66). At final analysis, grade 3-5 treatment-related AEs occurred in 26.1% in the olaparib arm versus 30.1% in the pemetrexed arm; treatment-related AEs led to death in 0.3% versus 0.3% and discontinuation of ≥1 drug in 13.9% versus 22.6%.

Conclusions: Pembrolizumab plus maintenance olaparib did not improve PFS or OS compared with pembrolizumab plus maintenance pemetrexed in participants who had CR, PR, or SD following induction therapy with pembrolizumab, pemetrexed, and a platinum as first-line therapy for stage IV nonsquamous NSCLC without targetable genetic alterations. There were no new safety signals.

TUESDAY, SEPTEMBER 10, 2024 - 13:30 - 14:45

MA11.08 Preliminary Efficacy and Safety of SHR-1701 Plus Fluzoparib as Maintenance Therapy for Patients with Advanced Lung Squamous Cell Carcinoma

Y. Zhang[1], L. Zeng[1], W. Jiang[1], L. Liu[1], Y. Xiong[1], L. Tian[2], C. Zhao[2], N. Yang[1], [1]Hunan Cancer Hospital, Changsha/CN ,[2]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai/CN

Introduction: Lung squamous cell carcinoma (LUSC) is associated with high mortality. Even with the treatment of PD-(L)1 inhibitors, the survival for advanced LUSC patients is relatively limited. SHR-1701 is a new bifunctional fusion protein composed of a monoclonal antibody against PD-L1 fused with the extracellular domain of TGF-β receptor II. Poly-ADP-ribose polymerase inhibitor (PARPi) has the potential to enhance the response to immunotherapy by promoting neoantigen release, increasing tumor mutational burden, and enhancing PD-L1 expression. Fluzoparib is a PARPi that has shown synergy with immunotherapy. This single-arm, phase 2 study aimed to evaluate the efficacy and safety of SHR-1701 plus fluzoparib as first line maintenance therapy for patients with advanced LUSC.

Methods: Previously untreated patients with stage IV LUSC were enrolled to receive SHR-1701 (30 mg/kg, administered intravenously q3w) and investigator's choice of platinum-based chemotherapy. Patients without disease progression after 4 cycles of treatment would receive SHR-1701 and fluzoparib (100 mg, administered orally bid) until progression or unacceptable toxicity. The primary endpoint was progression-free survival (PFS) per RECIST v1.1 by investigator. Secondary endpoints included objective response rate (ORR), PFS rate at 6 months, disease control rate (DCR), overall survival (OS), and safety.

Results: Between Feb 2023 and Feb 2024, a total of 23 patients were enrolled and received SHR-1701 and chemotherapy.11 patients had received fluzoparib. The median number of treatment cycles of fluzoparib was 5 (range: 1-13). The median age was 65 years and 91.3% were male. 21 (91.3%) patients had stage IV disease, 3 (13.0%) patients had brain metastasis, 4 (17.4%) patients had liver metastasis. 16 pts had at least one post-treatment tumor assessment. 15 pts achieved a partial response (10 pts confirmed), and 1 pt had stable disease as best response. The unconfirmed ORR was 93.75%. The confirmed ORR was 62.5% and DCR was 100%. The median PFS was 8.7 months. Treatment-related adverse events (TRAEs) occurred in 16 (69.6%) patients. 4 (17.4%) pts experienced grade≥3 TRAEs. The most common grade≥3 TRAEs included anaemia, alanine aminotransferase increased and neutrophil count decreased. No unexpected adverse events were reported.

Conclusions: SHR-1701 plus fluzoparib demonstrated encouraging clinical activity with manageable safety profile as first line maintenance therapy for patients with advanced LUSC. The results warranted further investigation.

MA11.09 Phase II Trial of Atezolizumab Plus Cobimetinib in PD-(L)1 Inhibitor Resistant NSCLC: NCI ETCTN Study 10166

A. Saltos[1], R. Hall[2], M. Tan[3], C. Kim[3], A. Saxena[4], K. He[5], H. Mamdani[6], T.W. Lycan[7], L. Villaruz[8], M. Khalil[9], R. Aljumaily[10], T. Tanvetyanon[1], R.D. Gentzler[2], B. Ma[4], D. Ozisik[3], J.A. Murray[11], S.V. Liu[3], [1]Moffitt Cancer Center, Tampa/FL/USA ,[2]University of Virginia Comprehensive Cancer Center, Charlottesville/VA/USA ,[3]Georgetown University, Washington/DC/USA ,[4]Weill Cornell Medicine, New York/NY/USA ,[5]Ohio State University Comprehensive Cancer Center, Columbus/OH/USA ,[6]Karmanos Cancer Institute, Detroit/MI/USA ,[7]Wake Forest University School of Medicine, Winston-Salem/NC/USA ,[8]University of Pittsburgh Medical Center, Pittsburgh/PA/USA ,[9]University of Alabama at Birmingham, Birmingham/AL/USA ,[10]OU Health Stephenson Cancer Center, Oklahoma City/OK/USA ,[11]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore/MD/USA

Introduction: Immunotherapy with a PD-(L)1 inhibitor alone or in combination is the current first-line standard for patients with advanced NSCLC without an actionable genomic alteration. Novel treatment options are needed for patients resistant to these therapies, particularly those with primary resistance. MEK inhibition in preclinical models enhances tumoral T-cell infiltration and favorably alters the immune microenvironment. We report primary results from a two-cohort, single arm phase II study of atezolizumab (anti-PD-L1) plus cobimetinib (MEK inhibitor) in patients with PD-(L)1 inhibitor resistant or refractory NSCLC (ETCTN NCI# 10166, NCT03600701).

Methods: Eligible patients had advanced NSCLC with primary resistance to PD-(L)1 inhibition defined as lack of partial or complete response and progression within 6 months of starting anti-PD(L)1 therapy. There were no PD-L1 expression criteria. Given the potential for transient response from MEK inhibition in a KRAS mutant NSCLC, patients were assigned to either cohort 1 (KRAS mutant NSCLC) or cohort 2 (KRAS wild type NSCLC). Patients received atezolizumab 1680 mg intravenously on day 1 and cobimetinib 60 mg by mouth daily on days 1-21 in 28-day cycles until progression, loss of benefit, or unacceptable toxicity. Each cohort had a Simon two-stage design where one response would be needed to expand accrual from 9 patients to 24 patients. Paired research biopsies were required at baseline and during week 3 of cycle 1 for correlative studies including assessment of changes in T-cell infiltration in response to therapy.

Results: Overall, 48 patients enrolled from 10 sites received at least one dose of study therapy (24 in each cohort); median age was 65 years (range 27-88). In cohort 1 (KRAS mutant), the response rate (RR) was 10% (2/20 evaluable patients) with response durations of 5.7 and 23.6 months. In cohort 2 (KRAS wild type), the RR was 10% (2/20 evaluable patients) with response durations of 16.7 and 8.4+ months. Overall, the median PFS was 3.4 months; median PFS was 4.8 months in cohort 1 (KRAS mutant) and 2.0 months in cohort 2 (KRAS wild type). The median OS was 29.6 months with a median OS of 8.2 months in cohort 1 (KRAS mutant) and the median has not been reached in cohort 2 (KRAS wild type). Two patients remain on therapy in cohort 2 without progression. Grade 3-4 treatment related adverse events were seen in 45.8% of patients with no grade 5 related adverse events; 8 patients (16.7%) discontinued therapy due to adverse events. Analyses of paired biopsies is ongoing.

Conclusions: Though durable responses were noted in both KRAS mutant and wild type cohorts, the combination of atezolizumab plus cobimetinib displayed minimal clinical activity in PD-(L)1 resistant NSCLC.

MA11.11 Benmelstobart, a PD-L1 Mab, Plus Anlotinib in EGFR+ Advanced NSCLC Patients Failed to Prior EGFR TKI Therapies:Phase II Results Update

M. Shi[1], P. Chen[2], L. Cui[3], Y. Yao[4], J. Wang[5], T. Zhou[6], [1]Jiangsu Cancer Hospital, Nanjing, Jiangsu Province/CN ,[2]YanCheng NO.[1] People's Hospital, YanCheng/CN ,[3]Zhangqiu People's Hospital, Zhangqiu/CN ,[4]Affiliated Hospital of Xuzhou Medical University, Xuzhou/CN ,[5]Hanzhong [3201] Hospital, Hanzhong/CN ,[6]Changzhou Cancer Hospital, Changzhou/CN

Introduction: Platinum-based chemotherapy is the standard therapy for the patients with EGFR+ advanced NSCLC failed to prior EGFR TKI therapies. However, the IMpower151 study analyses shows Atezolizumab (PD-L1) plus bevacizumab and chemotherapy did not show a significantly survival benefit (mOS 20.7 months in ABCP group) in EGFR TKI treated NSCLC. The effect of immunotherapy in EGFR-TKI resistant population is uncertain. Benmelstobart plus Anlotinib had demonstrated encouraging PFS and favorable safety profile in the same population in previously reported phase II Results (Meiqi Shi, et al, 2023 WCLC MA15.11). Here, we update the latest efficacy and safety data of the phase II study in 2024.

Methods: This ongoing phase I/II, open-lable trial(ChiCTR1900026273) enrolled patients aged 16-75 years old with pathologically confirmed metastatic or advanced EGFR+ NSCLC who failed to prior EGFR TKI therapies. Pts with previous received platinum-based chemotherapy were excluded. Participants in phase II study were given intravenous Benmelstobart (1200mg, q3w) and oral anlotinib (12mg/d, 2 weeks on/1 week off) until progression or unacceptable toxicity. The primary endpoint is progression free survival (PFS). Secondary endpoints were objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety.

Results: As of 10 March 2024 (data cut-off), a total of 55 patients (median age 64.0 years, female 69.1%), received at least one dose of anlotinib and Benmelstobart in phase II. The median follow-up time was 22.80 months. Among all, 14 achieved confirmed PR, 34 achieved SD, the ORR was 25.5%(14/55)and the DCR was 87.3% (49/55). The median PFS was 8.97 months(95% CI 6.28, 11.76), 6-month PFS rate was 69.7% and 9-month PFS rate was 49.0%. The median OS was 28.9 months(95% CI 19.12, NE), 24-month OS rate was 59.6%. Overall, Benmelstobart and anlotinib was well tolerated. Treatment-related adverse events (TRAEs) of grade 3-4 were observed in 15 (27.3%) of the 55 patients. The most common TRAEs were hypertension(47.3% , 26/55), hand-foot syndrome(38.2%, 21/55), proteinuria(27.3% , 15/55) and cough(27.3% ,15/55). 15pts had previous covid-19 infection.

Conclusions: The chemo-free combination of Benmelstobart plus anlotinib has shown incredible anti-tumor efficacy, mOS over 2 years (mOS 28.9 months), and well tolerance in this study, which will support further development in this field.

MA11.12 A Phase Ib Study of TQB2618 (Anti-TIM-3) in Combination with Penpulimab and Chemotherapy in Patients with Non-Small Cell Lung Cancer

L. Wu[1], G. Lin[2], B. Li[3], Y. Fang[4], Y. Wang[5], S. Cang[6], X. Li[7], X. Li[8], R. Wang[8], Q. Chu[9], Q. Yu[10], R. Ning[10], Z. Gui[11], Z. Zhou[11], [1]Hunan Cancer Hospital, Changsha/CN ,[2]Fujian Cancer Hospital, Fuzhou/CN ,[3]Guilin Medical College Second Affiliated Hospital, Guilin/CN ,[4]Sir Run Run Shaw Hospital Zhejiang University School Of Medicine, Hangzhou/CN ,[5]West China Hospital of Sichuan University, Chengdu/CN ,[6]People's Hospital of Henan Province, Zhengzhou/CN ,[7]The First Affiliated Hospital of Zhengzhou University, Zhengzhou/CN ,[8]Affiliated Zhongshan Hospital Of dalian University, DaLian/CN ,[9]Tongji Hospital affiliated to Tongji Medical College of Huazhong University of Science, Wuhan/CN ,[10]Guangxi Medical University Affiliated Cancer Hospital, Nanning/CN ,[11]Chia Tai Tianqing Pharmaceutical Group Co., Ltd., NanJing/CN

Introduction: T-cell immunoglobulin and mucin-domaincontaining molecule-3(TIM-3) can be co-expressed with PD-1 on exhausted T-cells and may be upregulated in tumors refractory to anti-PD-1 therapy.TIM-3 upregulation on PD-1 positive tumor infiltrating lymphocytes is associated with reduced proliferation and secretion of cytokines important for T cell-mediated anti-tumor activity.Concurrent TIM-3 and PD-1 blockade is more effective at reducing tumor growth than blocking anti-PD-1 only.TQB2618,a humanized IgG4 mAb targeting TIM-3,activates immune cell function and induces significant anti-tumor activity when combined with anti-PD-1 agents.It is unknown how effective TIM-3 combined with PD-1 and chemotherapy is in human.The main purpose of our study was to explore the feasibility of this combination.

Methods: This is an open-label, multicenter, phase Ib study.Inclusion criteria included: age between 18-75 years, pathologically confirmed diagnosis of advanced/metastatic NSCLC(squamous or non-squamous),absence of EGFR, ALK or ROS-1 mutations.Study was divided into two parts: dose-escalation and cohort expansion(cohort A-C).All patients(pts) in cohort A were PD-L1 TPS≥1% and received TQB2618 (1200/1500mg i.v.), Penpulimab (200mg i.v.) Q3W.Pts in cohort B were all squamous and were treated with TQB2618(1500mg i.v.),penpulimab(200mg i.v.), paclitaxel(175mg/m2 i.v.), carboplatin(AUC 5) Q3W. Pts in cohort C, also with squamous,were received TQB2618(1200mg i.v.),penpulimab(200mg i.v.),carboplatin(AUC5) Q3W and albumin abound paclitaxel(100 mg/m2 i.v.) Q1W.TQB2618 and penpulimab treatment will continue until disease progression,unacceptable toxicity,pts withdrawal,investigator's decision,or death. Paclitaxel and carboplatin treatment will continue for 4 cycles or until unacceptable toxicity or disease progression.The primary endpoint is investigator-assessed confirmed objective response rate(ORR) and 6-months progression-free survival(PFS) rate(RECIST v1.1).

Results: As of Feb 29, 2024, 93 pts had been treated in the cohort extension.36 pts were enrolled in cohort A (TQB2618 1200mg[n=20], 1500mg[n=16] with penpulimab) ,21 pts in cohort B and 36 pts in cohort C. 50% of the pts enrolled in Cohort A were squamous,and 44.44% had PD-L1≥50%. 35 pts were evaluated for efficacy,ORR was 39.4%, disease control rate(DCR) was 71.4%. ORR in pts with low PD-L1 expression was 31.6% (6/19) ,and 50.00% (7/14) for PD-L1≥50%. In cohort B and C,52.4% and 55.6% of pts PD-L1-negative,respectively. 17 pts in cohort B had efficacy evaluation,compared with 35 in cohort C. The ORR for two cohorts was 71.2% and DCR was 92.3%. Objective responses occurred in 19 pts in Cohort B and C with PD-L1<1%(ORR was 70.4%), when 18 pts with PD-L1≥1% received partial response(ORR was 75.0%). Moreover, we found that Cohort C had better overall efficacy relative to Cohort B. In cohort C, pts with PD-L1<1% had an ORR more than 73%. TEAEs occurred in 91.7%, 95.2%, 97.2% of pts in cohort A-C, respectively. TEAEs were common but primarily low-grade events in cohort A. Grade≥3 TEAEs(≥10%) were neutropenia(49.1%), leukopenia(29.8%) and anemia(21.1%) in cohort B and C.Serious adverse events(SAEs) related to study treatment(≥5%) was infectious pneumonia(5.6%) in cohort A,and neutropenia(10.5%), leukopenia(8.8%), infectious pneumonia(5.3%), anemia(5.3%) in cohort B and C.

Conclusions: TQB2618 plus Penpulimab was well tolerated and showed preliminary signs of antitumor activity,especially in pts with low PD-L1 expression. In combination with chemotherapy,the efficacy of albumin abound paclitaxel over paclitaxel,regardless of PD-L1 status.

MA11.13 Peripheral T-Cell Receptor Repertoire Differentiates a Typical Progression in Non-Small Cell Lung Cancer Patients Treated with Immunotherapy

J. Han, Y. Lin, W. Li, Beijing Tiantan Hospital, Capital Medical University., Beijing/CN

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment landscape for non-small cell lung cancer (NSCLC) patients. However, the response to immunotherapies can vary from that of standard chemotherapeutic drugs or therapeutic strategies, and accurately determining treatment response can be challenging. This study aimed to identify biomarkers capable of distinguishing between different response patterns in NSCLC patients treated with ICI.

Methods: We performed radiological evaluations on NSCLC patients treated with ICI, with at least two computed tomography (CT) scans prior to treatment and one CT scan during treatment. Tumor growth rate (TGR) was calculated as per the RECIST version 1.1 guidelines, and hyperprogressive disease (HPD) was defined as a ΔTGR greater than 50%. Blood mononuclear cells were sorted using flow cytometry to isolate PD-1+CD8+ and PD-1+CD4+ T cells.

Results: Our study included 51 NSCLC patients, with 11 responders (21.6%), 13 stable disease (25.5%), and 25 progressors (49.0%) at the initial radiological evaluation. Six patients were diagnosed with HPD, and three of the 25 progressors showed pseudoprogression during subsequent treatment. T-cell receptor (TCR) clonality changes ranged from 2.17 to 0.64 in all patients. Among the three types of disease progression, pseudoprogression was associated with a higher diversity of PD-1+CD8+ T cells (P = 0.030), while HPD patients exhibited the highest PD-1+CD4+ TCR diversity (P=0.013).Additionally, an increase in IL-17A levels was observed in patients with HPD.

Conclusions: Our findings suggest that the TCR repertoire of peripheral PD-1+CD8+ and PD-1+CD4+ T cells has the potential to differentiate atypical progression patterns in NSCLC patients treated with ICI. Regular monitoring of TCR changes during ICI therapy could serve as a valuable biomarker for predicting long-term treatment response.

Introduction: Osimertinib, a third-generation, CNS-active EGFR-TKI, is the preferred first-line treatment for EGFR-mutated (EGFRm) advanced NSCLC; however, most patients will develop progressive disease (PD) due to treatment resistance. The Phase III, open-label, randomized FLAURA2 study (NCT04035486) demonstrated a significant PFS benefit with first-line osimertinib + platinum-pemetrexed chemotherapy (osi+CTx) versus osimertinib monotherapy (osi) in patients with EGFRm advanced NSCLC. Preliminary results from a prespecified, exploratory analysis of acquired resistance mechanisms to osimertinib ± chemotherapy were presented previously. We report updated analyses further investigating resistance mechanisms in FLAURA2.

Methods: Patients ≥18 years with untreated EGFRm (Ex19del/L858R) advanced NSCLC were randomized 1:1 to receive osi+CTx or osi. Paired plasma ctDNA samples were collected at baseline and PD and/or treatment discontinuation up to 06Sep2023; samples were analyzed using NGS (Guardant Health, GuardantOMNITM). Tumor tissue was collected at screening for central EGFRm testing and exploratory NGS (Foundation Medicine, FoundationOne®CDx). Clinical outcomes were investigator-assessed (RECIST v1.1).

Results: Of 557 patients randomized to treatment (osi+CTx, n=279; osi, n=278), 181 matched baseline and PD plasma samples were evaluable for analysis, (osi+CTx, n=76; osi, n=105). Of these, 167 had EGFRm ctDNA detected at baseline (osi+CTx, n=68; osi, n=99). Resistance mechanisms were similar across arms, with no novel mechanisms detected. The most common acquired resistance mutations were C797S mutation in the osi arm and MET amplification in both arms (Table). There was no substantial change in tumor mutational burden between baseline and PD for either arm. At time of analysis, 141 baseline tissue samples were available for NGS (osi+CTx, n=72; osi, n=69); 41/72 and 38/69 had TP53 alterations detected, and 31/72 and 31/69 were TP53 wild-type, in the osi+CTx and osi arms, respectively. PFS Kaplan-Meier curves showed a separation in favor of patients with wild-type TP53 versus those with TP53 alterations at baseline, regardless of treatment: osi+CTx, HR not calculated (NC; as <20 events across arms); osi, HR 0.48 (95% CI 0.23, 1.0). Across treatment arms, PFS Kaplan-Meier curves showed a separation in favor of osi+CTx versus osi, irrespective of baseline TP53 status: wild-type TP53, HR NC; TP53 altered, HR 0.57 (95% CI 0.29, 1.12).

Conclusions: Although the plasma analysis set remains enriched for patients with early progression, these more mature data show acquired resistance mechanisms remain similar across treatment arms. Preliminary baseline tissue analyses suggest TP53 alterations to be a prognostic factor; the benefit of osi+CTx versus osi was similar in patients with or without TP53 alterations.

Introduction: Osimertinib is a third-generation, central nervous system (CNS)-active, EGFR-tyrosine kinase inhibitor with demonstrated efficacy in EGFR-mutated NSCLC and is the preferred first-line treatment for EGFR-mutated advanced NSCLC. In the Phase III FLAURA2 study (NCT04035486), osimertinib plus platinum-pemetrexed chemotherapy significantly improved progression-free survival (PFS) versus osimertinib monotherapy as first-line treatment of EGFR-mutated advanced NSCLC (investigator-assessed median PFS [mPFS] 25.5 vs 16.7 months, respectively; HR 0.62, 95% CI 0.49, 0.79; p<0.0001) and is now a recommended treatment option in this setting. To understand the impact of baseline tumor burden (characterized by the number of metastatic anatomical locations and extent of distant metastases at study entry) on outcomes, we assessed PFS in these patient subgroups from FLAURA2.

Methods: Patients were randomized 1:1 to receive osimertinib plus platinum-based chemotherapy, or osimertinib monotherapy until progression or a discontinuation criterion was met. Primary endpoint was investigator-assessed PFS per RECIST v1.1. Post-hoc analyses of PFS (by investigator assessment) were performed in baseline tumor burden subgroups characterized by the number of metastatic anatomical locations (<3 [defined as low] vs ≥3 [high]; patients with ≥1 metastatic lesion in an anatomical location were counted once within the specified metastatic anatomical location) and extent of distant metastases (intra-thoracic [M1a, low] vs extra-thoracic [M1b/M1c, high]; classified according to Version 8 of the IASLC Staging Manual in Thoracic Oncology). Data cut-off: 03 April 2023.

Results: 557 patients were randomized to osimertinib plus chemotherapy (n=279) or osimertinib monotherapy (n=278). The proportion of patients in the baseline tumor burden subgroups was similar across treatment arms (osimertinib plus chemotherapy/osimertinib monotherapy): <3 metastatic anatomical locations, 46/39%; ≥3 metastatic anatomical locations, 54/61%; M1a, 24/25%; M1b and M1c, 71/72%. Among patients with <3 metastatic anatomical locations, mPFS (95% CI) was 27.9 months (24.7, not calculable [NC]) with osimertinib + chemotherapy versus 30.5 months (16.6, NC) with osimertinib; PFS HR 0.75 (95% CI 0.51, 1.11). In those patients with ≥3 metastatic anatomical locations, mPFS (95% CI) was 24.9 months (21.9, 27.6) with osimertinib + chemotherapy versus 16.4 months (13.6, 19.2) with osimertinib; PFS HR 0.57 (95% CI 0.43, 0.77). For patients with intra-thoracic metastases, mPFS (95% CI) was 26.0 months (21.9, NC) versus NC (16.7, NC; PFS HR 0.97 [95% CI 0.59, 1.60]), and for those with extra-thoracic metastases, mPFS (95% CI) was 25.1 months (22.2, NC) versus 16.4 months (13.6, 19.4; PFS HR 0.54 [95% CI 0.41, 0.71]) in the osimertinib + chemotherapy versus osimertinib arms, respectively. Additional data on factors associated with a poor prognosis, including presence of liver and/or CNS metastases, will be presented.

Conclusions: Patients with characteristics associated with high tumor burden at baseline had a clinically meaningful PFS benefit with osimertinib plus chemotherapy compared with osimertinib monotherapy, further supporting the clinical utility of this combination and helping clinical decision making in patients with EGFR-mutated advanced NSCLC.

Introduction: Amivantamab is an EGFR-MET bispecific antibody with immune cell-directing activity. In PAPILLON (NCT04538664), amivantamab plus carboplatin-pemetrexed (amivantamab-chemotherapy) demonstrated significantly longer progression-free survival (PFS) versus chemotherapy (hazard ratio [HR], 0.395 [95% confidence interval [CI], 0.30-0.53]; P<0.0001). Amivantamab-chemotherapy is approved for first-line treatment of advanced non-small cell lung cancer (NSCLC) with EGFR Exon 20 insertions (Ex20ins). TP53 co-mutations and detectable circulating tumor DNA (ctDNA) are linked to poor prognoses. We evaluated treatment outcomes among patients from PAPILLON by biomarker subgroups.

Methods: 308 patients were randomized to receive amivantamab-chemotherapy (n=153) or chemotherapy (n=155). Blood samples, collected at screening and Cycle 3 Day 1 (C3D1), were analyzed for ctDNA using Guardant360 CDx (global/ex-China sites). Clearance of Ex20ins ctDNA was assessed at C3D1. Site of insertion was analyzed using Guardant360 CDx (plasma; global/ex-China sites) or AmoyDx LC10 next-generation sequencing panel (tissue; China sites). PFS, objective response rate (ORR), and duration of response (DoR) were assessed.

Results: Of 206 patients with analyzable ctDNA data at baseline, pathogenic alterations were detected in 178 (86%) patients; 154 had matched samples at C3D1. TP53 co-mutations were detected in 104/178 (58%) patients.

PFS was significantly longer for amivantamab-chemotherapy versus chemotherapy among patients with detectable baseline ctDNA (median, 11.1 vs 5.8 months; HR, 0.38 [95% CI, 0.26-0.55]; P<0.0001). At C3D1, 69% of patients in the amivantamab-chemotherapy arm cleared Ex20ins ctDNA versus 45% in the chemotherapy arm. PFS was approximately twice as long for amivantamab-chemotherapy versus chemotherapy with clearance (median, 12.2 vs 6.8 months; HR, 0.26 [95% CI, 0.13-0.50]; P<0.0001) and without clearance (median, 9.8 vs 4.8 months; HR, 0.55 [95% CI, 0.27-1.13]).

Amivantamab-chemotherapy significantly prolonged PFS versus chemotherapy in patients with TP53 co-mutations (median, 11.1 vs 5.6 months; HR, 0.29 [95% CI, 0.17-0.47]; P<0.0001) and wild-type TP53 (median, 11.3 vs 8.5 months; HR, 0.45 [95% CI, 0.25-0.82]; P=0.008). Significant improvements in ORR were seen with amivantamab-chemotherapy versus chemotherapy in patients with TP53 co-mutations (80% vs 53%; P=0.006) and wild-type TP53 (74% vs 49%; P=0.029). Amivantamab-chemotherapy prolonged DoR versus chemotherapy in patients with TP53 co-mutations (median, 9.8 vs 4.3 months) and wild-type TP53 (median, 8.2 vs 4.6 months).

Of 238 patients with site of insertion data, 197 (83%) insertions were in the near loop, 30 (13%) in the far loop, and 11 (5%) in the helical region. Amivantamab-chemotherapy prolonged PFS versus chemotherapy in the near loop (median, 11.3 vs 5.8 months; HR, 0.40 [95 % CI, 0.28-0.58]; P<0.0001) and far loop regions (median, 9.4 vs 4.1 months; HR, 0.19 [95% CI, 0.06-0.69]; P=0.005). Despite few patients with insertions in the helical region, amivantamab-chemotherapy demonstrated numerically longer PFS versus chemotherapy (median, 11.1 vs 9.1 months; HR, 0.55 [95% CI, 0.1-3.1]). ORR and DoR across Ex20ins sites favored amivantamab-chemotherapy.

Conclusions: Amivantamab-chemotherapy demonstrated superior outcomes versus chemotherapy in patients with and without biomarkers of high-risk disease. Consistent benefit favoring amivantamab-chemotherapy was seen across all Ex20ins sites. Amivantamab-chemotherapy is the first-line, standard of care for Ex20ins advanced NSCLC.

Keywords: NSCLC, TP53 co-mutations, Ex20ins

Introduction: Amivantamab is an epidermal growth factor receptor (EGFR)-MET bispecific antibody with immune cell-directing activity. Lazertinib is a highly selective, CNS-penetrant, EGFR tyrosine kinase inhibitor (EGFR-TKI). In MARIPOSA (NCT04487080), amivantamab plus lazertinib (amivantamab-lazertinib) significantly prolonged progression-free survival (PFS) vs osimertinib (hazard ratio [HR], 0.70; P<0.001) in patients with treatment-naïve, EGFR-mutant advanced non-small cell lung cancer (NSCLC; Cho Ann Oncol 2023;34:S1306;LBA14). We evaluated time to symptomatic progression (TTSP) and patient-reported outcomes (PROs) from MARIPOSA.

Methods: Analyses included the 429 patients randomized to receive amivantamab-lazertinib and the 429 to osimertinib. TTSP was defined as time from randomization to onset of new/worsening lung cancer symptoms requiring change in anticancer therapy, another clinical intervention, or death, whichever occurred first. PROs were measured using EORTC-QLQ-C30 and NSCLC-SAQ; all P-values are nominal. The threshold for a meaningful improvement was a 10-point increase on EORTC-QLQ-C30 functioning scales.

Results: At a median follow-up of 22.0 months, amivantamab-lazertinib demonstrated a significant improvement in TTSP versus osimertinib (HR, 0.72; 95% confidence interval, 0.57-0.91; P=0.005).

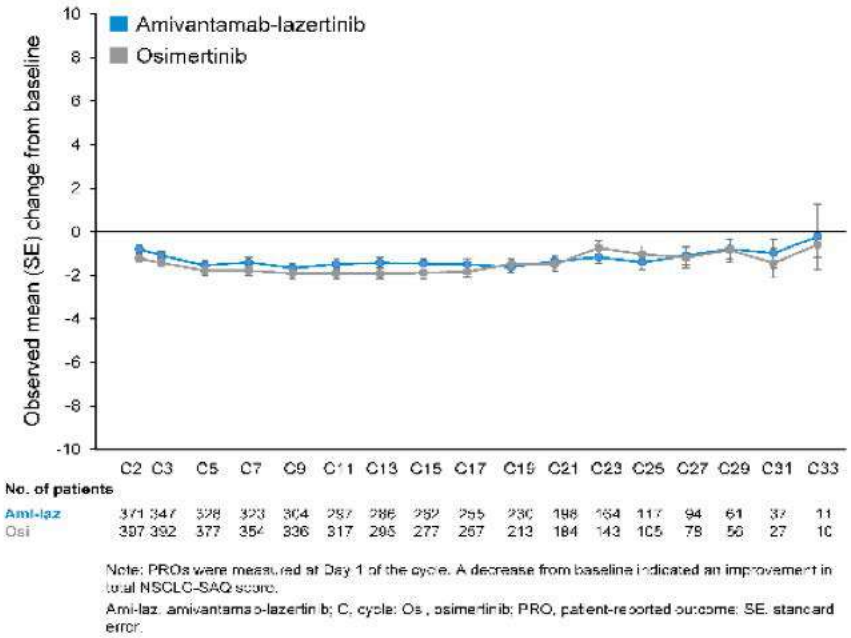
As median treatment duration was 18.5 months for amivantamab-lazertinib versus 18 months for osimertinib, PROs at 18 months are reported to evaluate the long term impact of treatment on quality of life. Based on the EORTC-QLQ-C30 functioning scales at 18 months, the percentage of randomized patients on treatment with improved or stable functioning relative to baseline in the amivantamab-lazertinib versus osimertinib arms was significantly higher for emotional functioning (38% versus 31%; P<0.05) and cognitive functioning (38% versus 31%; P<0.05). For other functioning scales, no statistically significant differences between amivantamab-lazertinib and osimertinib were observed. Functioning was maintained over time in both treatment arms as most changes over time were less than the defined threshold for clinically meaningful differences.

At 18 months, no statistical differences were observed between the amivantamab-lazertinib and osimertinib arms for the absence of key symptoms from the EORTC-QLQ-C30 including dyspnea (34% versus 31%), pain (27% versus 26%), and fatigue (15% versus 16%). There were no significant differences in symptoms between arms based on the NSCLC-SAQ (Figure).

Conclusions: For patients with treatment-naïve, EGFR-mutant advanced NSCLC, amivantamab-lazertinib significantly delayed symptomatic progression versus osimertinib indicating greater control of disease and related symptoms, while maintaining functioning as observed by PRO scales. PROs were comparable across treatment arms at the 18-month landmark, and treatment did not lead to meaningful decrements in patient quality of life.

Keywords: Amivantamab, EGFR TKI, NSCLC

Figure – Total NSCLC-SAQ Score Change from Baseline



Note: PROs were measured at Day 1 of the cycle. A decrease from baseline indicated an improvement in total NSCLC-SAQ score.

Ami-laz, amivantamab-lazertinib; C, cycle; Osi, osimertinib; PRO, patient-reported outcome; SE, standard error.

Introduction: Amivantamab is an EGFR-MET bispecific antibody with immune cell-directing activity. Lazertinib is a CNS-penetrant, thirdgeneration EGFR tyrosine kinase inhibitor. Amivantamab-lazertinib demonstrated efficacy in treatment-naïve and refractory EGFR-mutated advanced non-small cell lung cancer (NSCLC). Intravenous amivantamab has an infusion-related reaction (IRR) incidence of ~67%, typically at first infusion (Park Ann Oncol 2021;32[suppl_5]:S981). This prospective study evaluated prophylactic strategies to reduce the incidence of IRRs.

Methods: The global SKIPPirr study (NCT05663866) enrolled patients with EGFR-mutated (Ex19del or L858R) advanced NSCLC after disease progression on sequential osimertinib and platinum-based chemotherapy. All patients received oral lazertinib and intravenous amivantamab. A Simon's 2-stage design was used to evaluate prophylactic approaches in 4 cohorts (Figure 1): 4-mg oral dexamethasone twice daily (BID) on C1D-1, 8-mg oral dexamethasone BID on C1D-2, C1D-1, and 1 hour prior to infusion on C1D1, 10-mg oral montelukast once daily from C1D-4 to C1D1, and 25-mg subcutaneous methotrexate as a single dose at some point between C1D-7 and C1D-3.

Results: As of February 7, 2024, 48 patients were enrolled. Median age was 64.5 years, 69% were female, and 60% were Asian, with a median of 3 prior therapy lines. The 4-mg dexamethasone and methotrexate cohorts did not pass stage 1 (5/6 patients each with IRR). The montelukast cohort passed stage 1 (3/6 patients with IRR) but not stage 2 (10/15 patients with IRR). The 8-mg dexamethasone cohort proceeded to expansion stage after stages 1 and 2 (2/6 and 6/16 patients with IRR, respectively). At the time of data cutoff (7-Feb-2024), 4 additional patients were enrolled in the expansion stage. Of 20 patients with available efficacy data, 7 experienced IRRs on C1D1.

Among 21 patients with available safety data, most common IRR-related symptoms were hypotension and nausea (both 29%). No patient discontinued amivantamab-lazertinib due to IRRs. Efficacy and safety profiles of amivantamab-lazertinib were consistent with prior reports and will be shared at the meeting.

As of April 1, 2024, an additional 20 patients have been enrolled in the expansion stage. Preliminary estimates from the fully enrolled cohort (n=40) showed 10 IRRs for an incidence rate of 25% on C1D1; further details will be reported at the meeting.

Conclusions: Prophylaxis with 8-mg oral dexamethasone resulted in a meaningful reduction in IRR incidence from historical data and is an effective strategy to reduce IRRs.

Introduction: Brain metastases are present in up to 30% of patients with human epidermal growth factor receptor 2 (HER2) mutation-positive (m+) non-small cell lung cancer (NSCLC) at diagnosis and are particularly common in patients with the HER2 ex20ins YVMA mutation. Zongertinib, a novel HER2-specific tyrosine kinase inhibitor, binds selectively and covalently to the HER2 tyrosine kinase domain while sparing wild-type epidermal growth factor receptor. Beamion LUNG-1 (NCT04886804), a Phase Ia/Ib, first-in-human, open-label trial, is evaluating the safety and efficacy of zongertinib in patients with HER2 aberration-positive solid tumors (Phase Ia) and HER2m+ NSCLC (Phase Ib). Here, we present data from Phase Ia, including patients with brain metastases at baseline.

Methods: Phase Ia enrolled patients with confirmed HER2 aberration-positive (gene mutations, rearrangements, amplification, or overexpression) advanced/unresectable/metastatic solid tumors, refractory to/unsuitable for standard treatment. Patients with asymptomatic brain metastases were eligible. Patients received escalating doses of oral zongertinib twice-daily (BID; ≥15 mg) or once-daily (QD; ≥60 mg), guided by a Bayesian model with overdose control. Brain lesion objective response (according to RANO-BM) and objective response in other lesions (according to RECIST v1.1) was assessed.

Results: At data cut-off (January 29, 2024), 83 patients in Phase Ia have received zongertinib, including 19 patients with brain metastases at baseline. In all treated patients, the median duration of treatment was 4.2 months (range 0-24); treatment was ongoing in 38 patients (46%) at data cut-off. Treatment-related adverse events (TRAEs) were reported in 63 patients (76%), including grade ≥3 TRAEs in 7 patients (8%). The most common TRAEs (any/grade ≥3) included diarrhea (42%/1%), rash (12%/0%), and decreased appetite (10%/0%). Thirty-four patients (41%) had serious adverse events (SAEs), including 2 patients (2%) with treatment-related SAEs. In 74 evaluable patients, the confirmed objective response rate (ORR) across all dose levels was 35%, with a disease control rate (DCR) of 85%. The median duration of response was 12.7 months. Median progression-free survival (PFS) was 8.0 months and 8.3 months with zongertinib BID and QD, respectively. In 41 evaluable patients with NSCLC, the ORR and DCR were 44% and 93%, respectively. The median duration of response was 15.8 months. Median PFS was 13.8 months and 12.3 months with zongertinib BID and QD, respectively. All 19 patients with brain metastases at baseline had lung cancer (NSCLC: 16 patients; unspecified cancer of the lung: 3 patients). Of these patients, 15 (79%) had TRAEs, including 5 (26%) with grade ≥3. The most common TRAEs (any/grade ≥3) included diarrhea (42%/0%), increased alanine aminotransferase (ALT; 26%/16%), and increased aspartate aminotransferase (AST; 21%/5%). SAEs were reported in 13 patients (68%), including 1 patient (5%) with treatment-related SAEs (grade 3 increased ALT and AST). Of the 17 evaluable patients with brain metastases, the ORR per RECIST v1.1 (without confirmation) and DCR was 53% and 94%, respectively.

Conclusions: Zongertinib demonstrated manageable safety and promising efficacy in patients with HER2 aberration-positive solid tumors, including in those with brain metastases at baseline. Updated data will be presented, including Phase Ia RANO-BM data and Phase Ib data.

Introduction: The unmet therapeutic need exists in EGFR-mutated non-small-cell lung cancer (NSCLC) with MET-driven acquired resistance. We evaluated the efficacy and safety of Vebreltinib, a potent and highly selective c-MET inhibitor, plus PLB1004, an oral, potent, irreversible, and selective EGFR tyrosine kinase inhibitor (TKI), in NSCLC patients with EGFR mutation-positive, MET amplified or MET overexpression.

Methods: We conducted a multicenter, open-label, phase Ib/II study, phase Ib study included dose escalation and expansion phases. we enrolled Chinese patients with EGFRm locally advanced or metastatic NSCLC with MET amplification or MET overexpression, whose disease progressed following prior EGFR-TKI treatment. In the dose-escalation phase, patients received oral Vebreltinib(100mg/150mg/200 mg) BID plus PLB1004 (80/160 mg) once daily. In the expansion phase, patients were treated at three escalating dose levels of Vebreltinib and PLB1004 to identify a recommended phase II dose (RP2D). The primary objective of the dose escalation phase was to determine the maximum tolerated dose (MTD) for Vebreltinib plus PLB1004 and safety. In the dose expansion phase, the primary objective was objective response rate (ORR), and its secondary objectives included disease control rate (DCR), duration of response (DoR), progression-free survival (PFS) and overall survival (OS). Here, we present preliminary data of the study with a data cutoff date of February 29, 2024. This study is registered with ClinicalTrials.gov, NCT06343064.

Results: Between June 5, 2023, and Feb 19, 2024, in phase Ib, 44 patients received Vebreltinib 100mg plus PLB1004 160mg (n=15), Vebreltinib 150mg plus PLB1004 160mg (n=13), Vebreltinib 200mg plus PLB1004 80mg (n=3), or Vebreltinib 150mg plus PLB1004 80mg (n=13) and were included in the safety analysis. Among 44 patients, 36.4% of patients had brain metastases, and 86.4% of patients received third-generation EGFR-TKI, respectively. No patients experienced dose-limiting toxicities, and the maximum tolerated dose of Vebreltinib with PLB1004 was not reached. Objective responses occurred across all Vebreltinib and PLB1004 dose levels tested, with partial response (PR) observed in 19/32 (59.4%) response-evaluable patients. PRs were seen in 7/12(58.3%), 6/13(46.2%), 2/3(66.7%), 4/4(100%) response-evaluable patients at the dose of Vebreltinib 100mg plus PLB1004 160mg, Vebreltinib 150mg plus PLB1004 160mg, Vebreltinib 200mg plus PLB1004 80mg and Vebreltinib 150mg plus PLB1004 80mg, respectively. Among patients with brain metastases, ORR was observed in 75.0% (9/12) (95% confidence interval [CI], 42.8 to 94.5). The ORR was 58.6% (17/29) (95% CI, 38.9 to 76.5) in patients who received prior third-generation EGFR-TKI. Treatment-related adverse events occurred in 41 patients (93.2%) with 18.2% of grade ≥3. The most common TRAEs were rash in 19 (43.2%; Grade ≥3, 1 [2.3%]) and paronychia in 18 (40.9%; Grade ≥3, 0[0.0%]) patients. Vebreltinib dose was reduced in 2 (4.5%) and PLB1004 in eight (18.2%) patients. No patients discontinued treatment due to TRAEs.

Conclusions: Vebreltinib plus PLB1004 showed promising antitumor activity and a manageable safety profile in patients with EGFRm NSCLC with MET amplification or MET overexpression who have experienced disease progression after prior EGFR-TKI therapy, especially in those bearing brain metastases and treated with third-generation EGFR-TKI.

MA13.03 Impact of a Tobacco Endgame Intervention on Lung Cancer Mortality in 185 Countries: A Population Birth Cohort Simulation Study

J. Rey Brandariz[1], H. Rumgay[2], O. Ayo-Yusuf[3], R. Edwards[4], F. Islami[5], S. Liu[6], M. Pérez-Ríos[1], P.C. Rodrigues Pinto Corrêa[7], A. Ruano-Ravina[1], I. Soerjomataram[2], [1]University of Santiago de Compostela, Santiago de Compostela/ES ,[2]International Agency for Research on Cancer, Lyon/FR ,[3]University of Pretoria, Petroria/ZA ,[4]University of Otago, Wellington/NZ ,[5]American Cancer Society, Atlanta/GA/USA ,[6]Chinese Center for Disease Control and Prevention, Beijing/CN ,[7]Universidade Federal de Ouro Petro, Ouro Preto/BR

Introduction: In 2019, tobacco use accounted for almost 70% of lung cancer deaths globally. To reduce mortality rates, it is crucial to implement tobacco control interventions aimed at decreasing tobacco use in the population such as the tobacco-free generation. The aim of this study was to estimate the impact of eliminating tobacco consumption (i.e tobacco-free generation) on lung cancer mortality among people born between January 1, 2006 and December 31, 2010 in 185 countries.

Methods: To assess the impact of eliminating tobacco use on lung cancer mortality, the following steps were taken: 1-Lung cancer mortality or incidence data was used to calculate predicted lung cancer rates by age and sex up to 2040-2044. 2-Based on the predicted rates, lung cancer mortality rates were calculated for the birth cohort of 2006-2010 in 185 countries. 3-The number of avoidable lung cancer deaths and the population impact fraction (i.e. proportion of lung cancer deaths that would be avoided) in the birth cohort up to 2095 were calculated. The results are presented in absolute numbers, proportions and age-standardized rates (ASR) by region and the four World Bank income groups (Figure-1).

Results: Eliminating tobacco consumption would prevent 1.2 million deaths (40.2%) from lung cancer in 185 countries. In men, 844,200 deaths (45.8%) and in women 342,400 deaths (30.9%) would be avoided. The highest number of deaths in men that could be prevented would be in Central and Eastern Europe, specifically 48,900 deaths (74.3%). Among women, the region with the highest potential for preventing deaths is Western Europe, where 56,200 deaths (77.7%) could be avoided. In terms of ASRs, the regions with the highest ASRs for prevented lung cancer deaths in men are Eastern Asia and Eastern Europe, with 18.6 and 18.4 prevented deaths per 100,000 population, respectively. In women, the highest ASRs are observed in Western Europe and Southern Europe, with 13.8 and 10.8 prevented deaths per 100,000 population, respectively. In both men and women, high-income countries would prevent the highest number of lung cancer deaths. Specifically, in men, 201,900 deaths (56.7%) would be prevented, and in women, 212,300 deaths (66.0%) would be prevented.

Conclusions: The implementation of the tobacco-free generation alongside other tobacco control measures could substantially reduce lung cancer mortality worldwide. The greatest impact of this intervention would be in more developed regions, such as Europe, North America, Australia, and New Zealand, which have experienced an earlier onset of the tobacco epidemic.

Keywords: tobacco, lung cancer, tobacco-free generation

MA13.04 A Comparison of Ever vs Never Smoking Surgically Treated Lung Cancer Patients

S.J. Tuminello, A. Kaufman, A. Wolf, D-S. Lee, A. Hakami-kermani, D. Nicastri, E. Taioli, R. Flores, Icahn School of Medicine at Mount Sinai, New York City/NY/USA

Introduction: Lung cancer is the leading cause of cancer-related mortality. While smoking substantially increases the risk of lung cancer, cancer in non-smokers is commonly seen and the proportion has increased over time. There are likely substantial clinical and molecular differences in smoking vs non-smoking related lung cancers, however, early-stage non-smoking cancers have been underrepresented in prior studies, as screening is mostly limited to those with smoking histories. We report here demographic, clinical and molecular factors associated with non-smoking lung cancers treated surgically at a diverse New York City health system, as well as differences in surgical outcomes based on smoking status.

Methods: The Department of Thoracic Surgery Prospectively Maintained Database (DTS) contains data on all surgical cases at the Icahn School of Medicine at Mount Sinai between 2012 and 2022. Demographics, pre-operative assessment, details of the surgical procedure, tumor features, and surgical outcomes are recorded. Factors associated with ever vs never smoking were assessed using Pearson test for normal and categorical variables and the Spearman test continuous non-normal variables. Investigated outcomes of surgery were adverse post-operative events, additional surgery for recurrence or secondary primary cancers, and long-term survival, assessed using logistic regression.

Results: Of the 1,832 surgically-treated patients, smoking history was reported for 1,767 patients, among which were 420 (24%) never smokers vs 1,347 (76%) ever smokers. Compared with the ever smokers, never smoking patients were younger ($p<0.001$), female ($p<0.001$), Hispanic ($p<0.001$), privately insured ($p<0.001$), and were more likely to have had their surgery after 2015 ($p=0.022$). Never smokers appeared to be healthier at the time of surgery, with never-smoking patients having a better average % predicted FEV1 (90.7% vs 84.7%, $p<0.001$) and fewer comorbidities (hypertension: 44% vs 58%, $p<0.001$; coronary artery disease: 8% vs 18%, $p<0.001$; no difference in diabetes). Tumors of never smokers were of similar size to ever smokers ($p=0.803$), but were more likely to be located in the upper lobe ($p<0.0001$) and to have had nodal metastasis ($p=0.020$), indicative of more advanced clinical stage. Of the 929 patients with a molecular test, never smokers had more EGFR mutations (57% vs 15%, $p<0.001$), and fewer KRAS and P53 mutations (16% vs 43%, $p<0.001$ & 25% vs 38%, $p=0.004$, respectively). There was not a statically significant difference observed in ALK mutations ($p=0.787$). Never and ever smoker had similar likelihoods of surgery type (pneumonectomy, lobectomy, or wedge resection, $p=0.110$) and pre-surgical treatments (chemotherapy or immunotherapy, radiation, $p=0.200$). While odds of post-operative events and additional surgery for recurrence or second primary cancer were comparable between never vs ever smoking lung cancer patients, of the 1,377 patients for whom long-term survival was known, odds of death was lower for never smokers, even after adjustment for confounding (ORadj [odds ratio]: 0.65; 95% CI [confidence interval]: 0.40-1.02).

Conclusions: Never vs ever smokers with surgically resectable lung cancers differ in clinically meaningful ways. Nevertheless, surgery for never-smokers is effective, and if screening can be implemented for high-risk never smokers, this could help to reduce the burden of lung cancer mortality.

MA13.05 The Impact of Tobacco Control on Lung Cancer Mortality Across 48 Countries

M.T. Warkentin, Y. Ruan, A. Tremblay, D.R. Brenner, University of Calgary, Calgary/AB/CA

Introduction: Lung cancer is the leading cause of cancer-related mortality globally. The widespread success of tobacco control policy and smoking cessation campaigns have led to drastic reductions in tobacco consumption and lung cancer mortality rates that peaked decades ago in many countries. However, it is currently not known how many more lung cancer deaths would have occurred if not for the substantial progress made in lung cancer control.

Methods: We obtained age-specific population counts and lung cancer mortality rates by sex and country from 1950 to 2019 (from 48 countries) from the World Health Organization's Global Cancer Observatory. To identify peak lung cancer mortality for each country, we estimated age-standardized mortality rates (ASMR), standardized to the World Health Organization (WHO 2000-2025) Standard Population. Peak mortality was defined as the maximum ASMR (based on a five-year rolling average), separately for each country and sex. For every year in the period following peak mortality, the expected number of lung cancer deaths was estimated using the peak-year age-specific mortality rates and age-specific population counts for the index year. The total number of avoided deaths was estimated as the difference between the expected and observed number of lung cancer deaths in that period (Figure 2).

Results: Lung cancer mortality rates have peaked for males in all countries but have yet to reach their peak for 11 out of 37 (30%) countries for females. In total, there have been 3.10 million avoided lung cancer deaths since mortality rates peaked for many countries (2.95 million for males, 0.15 million for females). Across all countries, 21.5% and 4.3% of expected lung cancer mortality has been avoided since mortality rates peaked for males and females, respectively. Sixteen countries have reduced lung cancer mortality by more than 25% for males, while only two countries have achieved this feat for females. There has been a statistically significant reduction in lung cancer deaths for 46 out of 48 (96%) countries for males, but only 17 out of 37 (46%) countries for females.

Conclusions: This study highlights the considerable progress made in reducing premature lung cancer mortality due to cancer control initiatives. There has been a substantial number of lung cancer deaths avoided since mortality rates peaked for many countries, though the reduction in mortality has not been observed in all countries or equally for males and females.

Keywords: Avoided deaths, Tobacco control, Lung cancer mortality

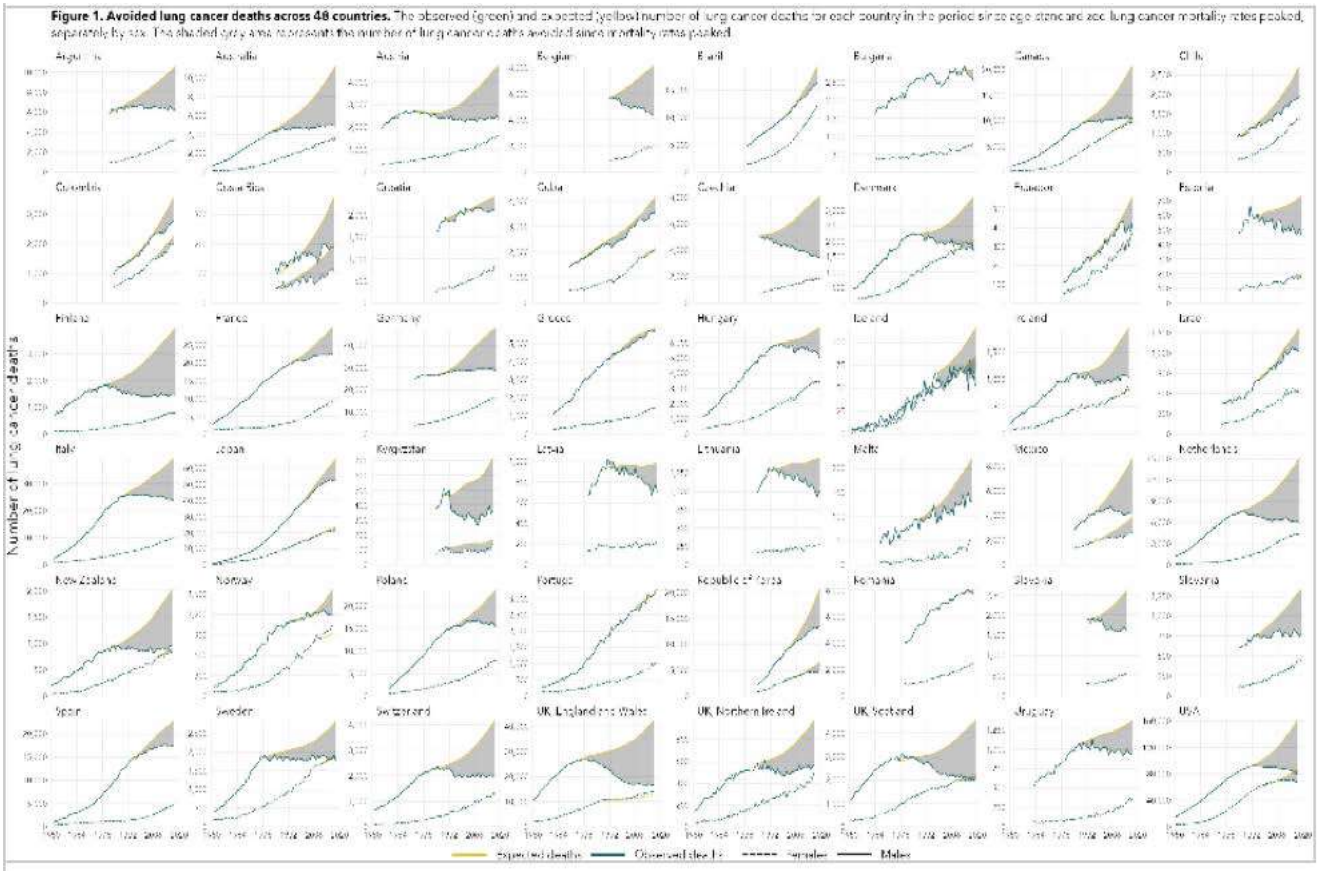

Figure 1. Avoided lung cancer deaths across 48 countries. The observed (green) and expected (yellow) number of lung cancer deaths for each country in the period since age-standardized lung cancer mortality rates peaked, separately by sex. The shaded grey area represents the number of lung cancer deaths avoided since mortality rates peaked.

MA13.07 Practical Implementation of Outdoor Air Pollution Exposure Measurement for Lung Cancer Risk Assessment

C. Durney[1], Y. Chen[1], K. White[2], M. Brauer[2], S. Atkar-Khattra[1], R. Myers[1,2], R. Meza[1,2], S. Lam[1,2], [1]British Columbia Cancer Research Institute, Vancouver/BC/CA ,[2]The University of British Columbia, Vancouver/BC/CA

Introduction: In 2013, the International Agency for Research on Cancer (IARC) classified outdoor air pollution and one of its major components, particulate matter PM2.5, as carcinogenic to humans (Group 1) and causes of lung cancer. Air pollution is the major cause of lung cancer in people who have never smoked tobacco. Previous lung cancer risk prediction models using clinical-demographic risk factors have modest performance. None have incorporated air pollution as a lung cancer risk factor because quantifying long-term exposure to PM2.5 has proven time consuming and difficult to be completed at a point-of-care visit. The purpose of our study is to develop an interactive, real time, PM2.5 assessment tool to measure long-term PM2.5 exposures over several decades that can be readily integrated into a lung cancer risk prediction tool.

Methods: We introduce a novel web-based tool designed to efficiently collect detailed residential histories and covariate information from participants to estimate outdoor exposure to PM2.5. This tool integrates the use of an interactive map to pinpoint, as close as possible, the residential location. To assess PM2.5 exposure, we geocode each residential address and analyze high-resolution concentration estimates from satellite data, chemical transport models, and ground measurements within roughly ~10 x 10 km areas corresponding to the time the individual lives at a given address. From the annual PM2.5 exposure data since 1990 when accurate information became available, cumulative or timed exposure to PM2.5 is estimated in real-time.

Results: The interactive tool is shown in Figure 1A. This tool was implemented in a cohort of lung cancer cases (N=899) to measure PM2.5 exposure during a 20-year window. A sample patient (never smoker) with a varied residential history in North America and Asia (Figure 1B) was analyzed against this cohort for comparison. It takes approximately 30 seconds to enter a known address and 45 seconds to use a map assisted address. An average patient can be completed in under 5 minutes.

Conclusions: Our interactive, web-based air pollution exposure tool can be efficiently applied to generate estimates of long-term PM2.5 exposure information for lung cancer risk assessment. The tool will be very useful for development of an accurate lung cancer risk prediction tool for people who have never smoked that incorporates the carcinogenic effects of air pollution exposure.

MA13.09 A World Map of Air Pollution and EGFR Prevalence

G. Villacampa[1], D.S. Tan[2], O. Arrieta[3], L. Rojas[4], A. Cardona[4], [1]Vall d´Hebron Institute of Oncology, Barcelona/ES ,[2]NationalCancer Centre Singapore (NCCS) and Duke-NUS Medical School, Singapore/SG ,[3]Instituto Nacional de Cancerología (INCan), Mexico City/MX ,[4]Luis Carlos Sarmiento Angulo Cancer Treatment and Research Center – CTIC, Bogota/CO

Introduction: Contamination of air by fine particulate matter (PM2.5), represents an unresolved global environmental health problem. It is responsible for 6.7 million premature deaths worldwide in 2019. Currently, lung cancer (LC) in non-smokers ranks among the 10th most common causes of cancer death. Substantial epidemiological evidence supports a causal link between air pollution (AP) and LC incidence and mortality. Long-term exposure to fine particulate AP has genotoxic and mutagenic effects, which may increase LC risk through inflammatory injury, reactive oxygen species production, and oxidative DNA damage. This risk increases with increasing exposure to PM2.5. A recent study hypothesized that increasing PM2.5 levels exposure was linearly associated with increased risk of EGFR-mutant LC. Considering this background, we analyzed the association between the mean PM2.5 levels from 2000-2020 and the EGFR-mutant prevalence reported worldwide

Methods: To estimate the strength of the association between both variables, we fitted linear regression models weighted by the total number of non-small cell lung cancers (NSCLC). Adjusted R2 values were calculated (the closer the adjusted R2 to 1, the stronger the association). A total of sixty-nine countries had data available for both variables

Results: Overall, the association between PM2.5 levels and EGFR-mutant prevalence was moderate-weak (R2= 0.34). Indeed, when we stratified the analysis according to the different areas worldwide (European, Asia, and Latin-American countries), the association became weaker (R2 < 0.15 in all comparisons). Although there were countries with high air pollution and high EGFR-mutant lung cancer prevalence (China: PM2.5 level of 46.9 and 45.7% EGFR-mutant prevalence), this association was not always observed

Conclusions: Discrepancies between PM2.5 level and EGFR-mutant lung cancer prevalence worldwide could be explained by different access to LC genomic profiling, potential over or underestimation of EGFR-mutant prevalence in some countries as population tested was over-selected, patients tested in some countries are not those more exposed to the AP (PM2.5 level may not be homogenous in all areas of one specific country), this prevalence includes all patients with LC, regardless of the smoking pattern, and alternative contributory factors to pathogenesis of never smoker lung cancer (genomic background and ancestry). All these factors should be considered as potential limitations to directly relate AP PM2.5 to the development of EGFR-mutated LC.

MA13.11 Glucagon-Like Peptide 1 Receptor Agonists Associated with Reduced Risk of Lung Cancer in Type 2 Diabetes Mellitus

T. Tabernacki[1], L. Wang[1], D. Kaelber[2], R. Xu[1], N.A. Berger[1], [1]Case Western Reserve University School of Medicine, Cleveland/OH/USA ,[2]The MetroHealth System, Cleveland/OH/USA

Introduction: Lung cancer (LC) is the second most common cancer in the US and the foremost cause of cancer mortality in the U.S. Insulin therapy, a mainstay strategy for glycemic control in Type 2 Diabetes Mellitus (T2DM), has been implicated in elevating LC risk. The impact of non-insulin antidiabetic agents on LC risk, particularly GLP-1 receptor agonists (GLP-1RAs) is incompletely understood and has not been compared to insulin therapy. We conducted a nationwide retrospective cohort study to evaluate LC risk among T2DM patients treated with seven non-insulin antidiabetic agents in comparison to insulin therapy.

Methods: Utilizing the TriNetX platform, we accessed deidentified electronic health records from 105.9 million patients, across diverse U.S. demographics. The study population comprised 1,040,341 patients with T2DM prescribed antidiabetics between 2005-2019, excluding those with prior antidiabetic use or LC diagnoses. Hazard ratios and 95% confidence intervals for LC risk were calculated comparing users of 7 non-insulin antidiabetics against insulin. Propensity score matching on key LC risk factors was performed to address known confounding factors.

Results: All non-insulin antidiabetics except alpha-glucosidase inhibitors were associated with significantly decreased LC risk versus insulin, with GLP-1RAs offering the most significant decrease (HR: 0.489, 95% CI: 0.408, 0.586). Sub-group analyses revealed GLP-1RAs significantly lowered LC risk across all LC histological types. Risk reduction was significant among Black and White patients, with consistent findings across genders and smoking status.

Conclusions: Our findings suggest that non-insulin antidiabetics, especially GLP-1RAs, are associated with significantly reduced risk of lung cancer after accounting for key confounders. The findings highlight an important consideration for the management of T2D, especially for those patients at an elevated risk of developing lung cancer.

MA13.12 Prevalence of Pathogenic or Likely Pathogenic Germline Variants in Cancer Predisposition Genes in Selected Lung Adenocarcinoma Patients

O. Arrieta[1], E. Caballé-Pérez[1], N. Hernández-Pedro[1], E. Romero-Nuñez[1], J. Lucio-Lozada[1], C. Castillo-Ruiz[1], K. Acevedo-Castillo[2], R.M. Álvarez-Gómez[1], C. Molina-Garay[2], M. Jiménez-Olivares[2], K. Carrillo-Sánchez[2], E.C. Mendoza-Caamal[2], A.F. Cardona[3], J. Remon[4], C. Alaez-Verson[2], [1]Instituto Nacional de Cancerología, Mexico City/MX ,[2]Instituto Nacional de Medicina Genómica, Mexico city/MX ,[3]Cancer Treatment and Research Center, Bogotá/CO ,[4]Gustave Roussy Cancer Campus, Villejuif/FR

Introduction: Pathogenic or likely pathogenic germline variants (PGVs) in cancer predisposition genes may play a role in lung cancer (LC) susceptibility. However, determining an eligible population for genetic testing remains uncertain. This study aimed to assess the prevalence of PGVs in a selected cohort of individuals with lung adenocarcinoma.

Methods: A cross-sectional cohort study was conducted to assess the PGVs rate in lung adenocarcinoma patients with a family history of LC, young-onset presentation, history of never/light smoking, or actionable genomic alterations (AGAs). Sequencing was performed using Sophia Hereditary Cancer Solution panel F, including 144 cancer predisposition genes. Variants classified as pathogenic or likely pathogenic were included for further analysis.

Results: Of 201 patients, 43 (21.4%) exhibited PGVs, among which 64.5% were DNA damage repair genes, and 86.1% were clinically actionable. The main PGVs were in ATM (9.3%), TP53 (6.9%), BRCA2 (6.9%), and CHEK2 (6.9%) genes. PGVs were associated with male sex (adjusted odds ratio [aOR] 2.46, 95% CI 1.15-5.32, p=0.021), along with a trend toward association with AGAs (aOR 6.04, 95% CI 0.77-49.74, p=0.094).

Conclusions: In this study, a high PGVs prevalence was identified based on our selection criteria, which represents an effective strategy to identify candidates for germline genomic testing, potential screening strategies in close relatives, and personalized therapeutic modalities. Our results warrant further exploration in other populations to confirm them.

MA14.03 Breathing Dangers: Unraveling Particulate Matter and Asbestos-Associated Lung Cancer Trends in the Top Ten Most Populous Countries.

C.T. Jani[1], D. Morgenstern-Kaplan[2], S. Kareff[3], G. Hanbury[4], A.S. Salazar[2], H. Singh[5], E. Rodriguez[3], G. Lopes[3], [1]University of Miami, Sylvester Comprehensive Cancer Center, Doral/FL/USA ,[2]University of Miami, Miami/FL/USA ,[3]University of Miami, Sylvester Comprehensive Cancer Center, MIAMI/FL/USA ,[4]Imperial College of london, London/GB ,[5]Medical College of Wisconsin, Milwaukee/WI/USA

Introduction: Amid evolving tobacco policies and escalating air pollution levels, the landscape of lung cancer etiology has experienced significant shifts. This study aims to examine the dynamic trends in air pollution and asbestos-associated Tracheal, Bronchial, and Lung Cancer (TBLC) mortality across top ten most populous countries globally.

Methods: We utilized Global Burden of Disease database to extract overall and risk factor-associated Age Standardized Mortality Rate (ASMR) for TBLC from 1990-2019 for top ten most populous countries (2023 census). For risk factors, we included Asbestos and Particulate matter air pollution, including ambient air matter pollution (PM) and household air pollution from solid fuels (household). Data was reported per 100,0000 population. Estimated Annual Percentage Change (EAPC) were calculated using JoinPoint Trend analysis for overall and gender-based trends.

Results: The global TBLC mortality decreased by 8%, with reductions in asbestos-associated (25%) and particulate matter pollution (15%) associated TBLC ASMR. However, there was a 25% increase in PM and a 62% decrease in the household-associated TBLC ASMR. In recent years, there has been an increase in PM-associated TBLC ASMR observed in 7/10 countries for males and 6/10 countries for females, with Bangladesh experiencing the highest rise for both genders (EAPC males: 8.2, females: 4.2). Pakistan showed the highest overall increase (226%), while China had the highest ASMR in 2019 (8.8), contrasting with a significant decline in the USA (-68%) despite its highest ASMR in 1990 (4.5). However, the USA has shown a modest recent increase since 2017 (EAPC 0.1). In household air pollution, all countries demonstrated a decline. Analysis of asbestos trends showed the highest increase in Indonesia (262%). Despite a decline in the USA's ASMR from 8.91 (1990) to 6.0 (2019), it remained 2x higher than the global average, recording the highest amongst all ten countries. While males consistently exhibited higher ASMR, females experienced a slower decline across most risk factors, accompanied by a concerning increase in recent years.

Conclusions: Our analysis highlights alarming increases in ambient particulate matter pollution globally and in several countries, including a recent uptick in the USA. Recognizing the association of different particulate matter with lung cancer, there's an urgent need for effective policies addressing air pollution and associated health risks. Additionally, trends in asbestos-related mortality, particularly in the USA, underscore the critical necessity for stricter asbestos bans to mitigate its detrimental health impacts. Urgent gender-specific interventions are needed to curb the recent increase in female mortality.

TUESDAY, SEPTEMBER 10, 2024 - 13:30 - 14:45

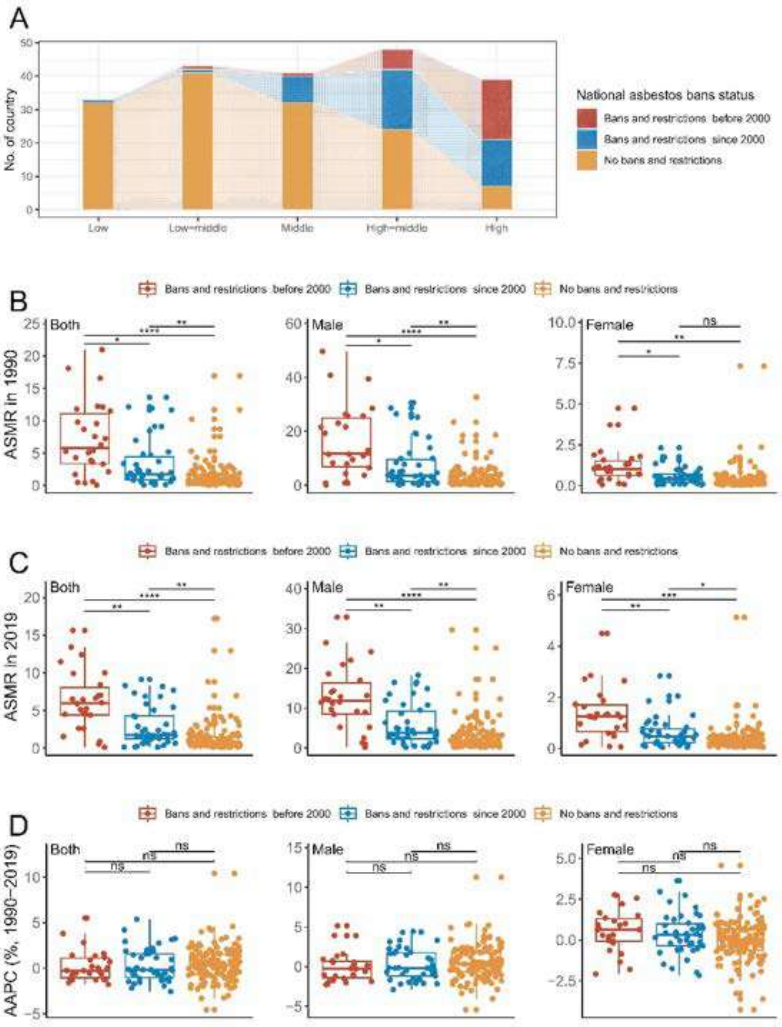
MA14.04 Global Burden and Trends of Asbestos-Related Thoracic Cancers & Their Associations with National Asbestos Ban Status: A Cross-Sectional Study

W-Z. Li[1], H. Liang[1], W. Wang[1], J. Liu[1], S. Lv[2], X. Gui[3], W. Liang[1], J. He[1], [1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai/CN ,[3]The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing/CN

Introduction: Asbestos-related thoracic cancers (ARTCs), comprising asbestos-related lung cancer (ARLC) and mesothelioma, constitute the majority of asbestos exposure fatalities. This study evaluates the global burden and trends of ARTCs and investigates their association with national asbestos ban status.

Methods: Utilizing data from the Global Burden of Diseases Study 2019, we estimated the age-standardized mortality rates (ASMRs) for ARTCs and analyzed their temporal trends from 1990 to 2019, stratified by sex, location, and socio-demographic index (SDI) quintile. We investigated the association between the burden or trends of ARTCs and the national asbestos ban status. The evolving trends of the past three decades and the projections for the next two decades were scrutinized using Decomposition analysis and the Bayesian age-period-cohort model, respectively.

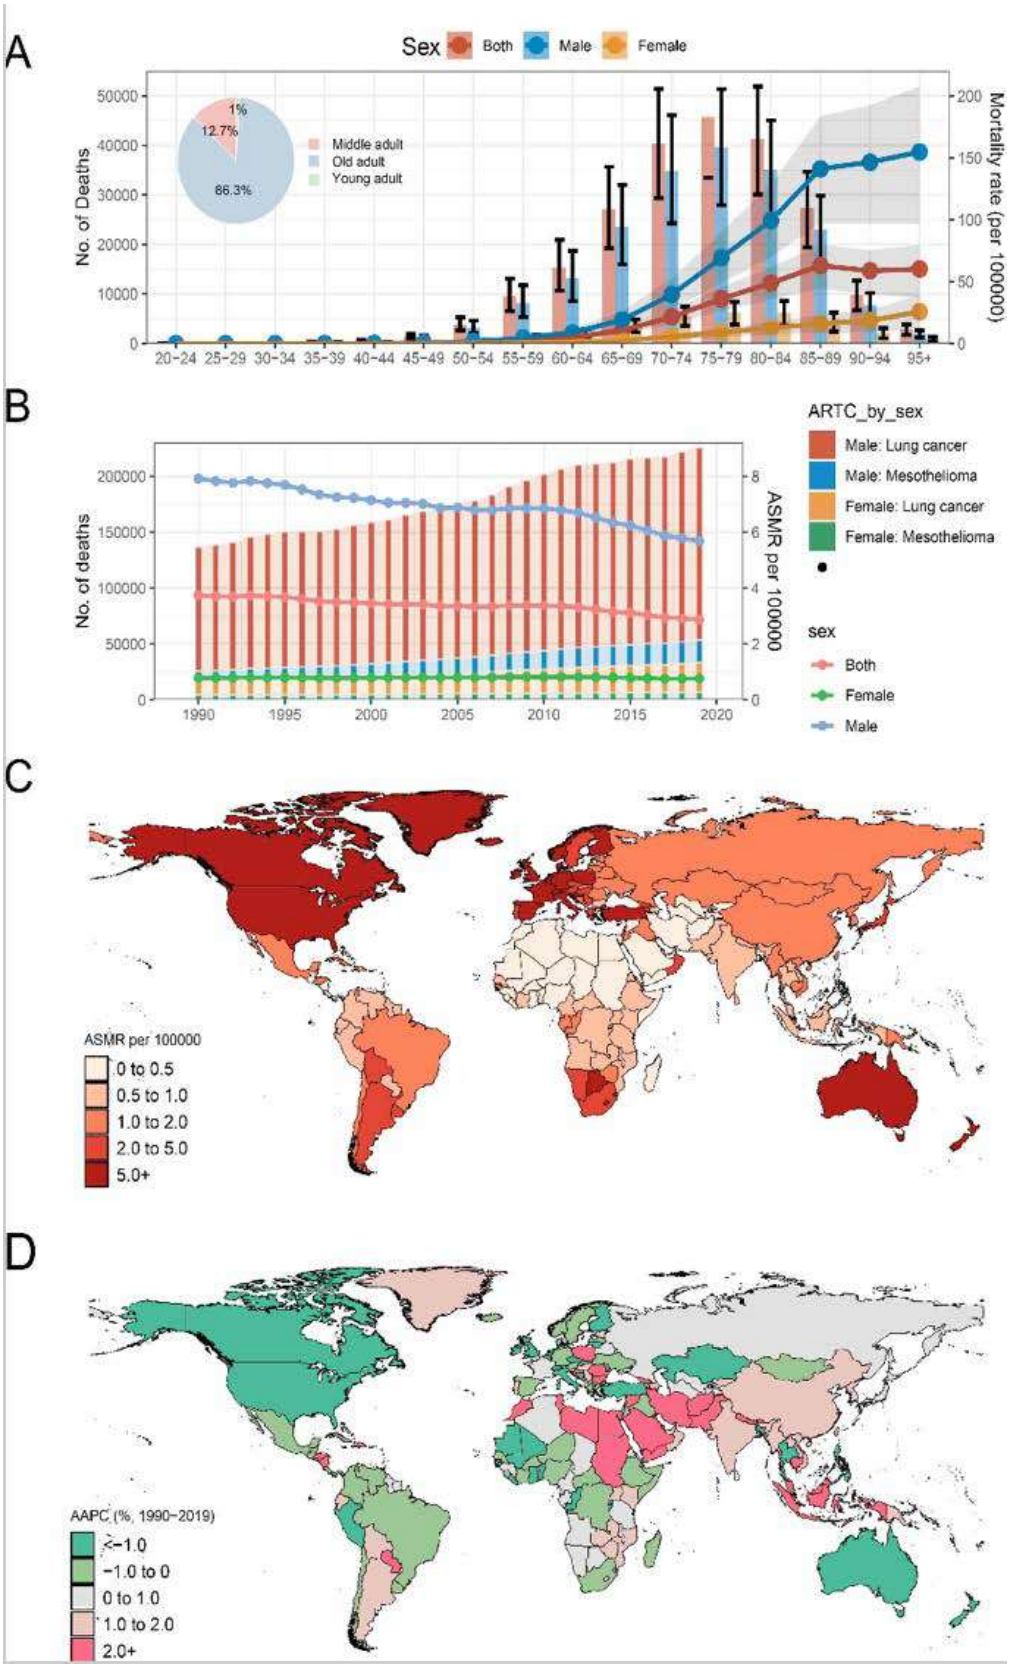
Results: In 2019, ARTCs resulted in an estimated 225,523 deaths and an ASMR of 2.9 per 100,000, with higher burden among males, older adults, and high SDI countries (Figure 1A-C). From 1990 to 2019, there was a global decrease in the ASMR for ARTCs (AAPC: -1.0 [95% CI -1.1 to -0.8], P<0.001), notably in ARLC cases, males, and higher SDI quintiles, whereas increases were noted in lower SDI quintiles (Figure 1D).



Despite a steady decline in ASMR over three decades and expectations of this trend continuing, the total number of ARTCs deaths is rising, probably driven by population growth and aging.

Conclusions: Our findings highlight notable geodemographic disparities in ARTCs burden and trends. Although national asbestos bans are associated with a historically and presently higher ARTCs burden, this correlation does not extend to trends over the study period.

Keywords: Asbestos, Lung cancer, Mesothelioma



The portion of asbestos bans showed a significantly increasing trend from the low- to high-SDI quantiles (P<0.001; Figure 2A). National asbestos bans correlate with higher ARTC burdens historically and currently, yet they don't influence the ASMR trend over the period (Figure 2B-D).

MA14.06 Cost-effectiveness Analysis of Entrectinib in the First-Line Treatment of ROS1+ Locally Advanced or Metastatic NSCLC in China

W. Chen[1], B. Liao[1], Y. Xia[2], H. He[2], S. Lu[3], [1]Fudan University School of Public Health, Shanghai/CN ,[2]Shanghai Roche Pharmaceutical Ltd., Shanghai/CN ,[3]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Lung cancer, predominantly non-small cell lung cancer (NSCLC), causes a heavy global disease burden, with high incidence and mortality rates. ROS1+ NSCLC accounted for approximately 1%-2% of cases. Compared to crizotinib, entrectinib has demonstrated favorable intracranial efficacy in the ROS1 NSCLC and has been approved in China. The study aimed to examine the cost-effectiveness of entrectinib versus crizotinib in the Chinese setting.

Methods: This study included Asian patients with ROS1+ NSCLC from three clinical trials of entrectinib (STARTRK-1/NCT02097810, STARTRK-2/NCT02568267, and ALKA-372-001/EudraCT 2012-000148-88; data cutoff: 02 August 2021) and one clinical trial of crizotinib (OxOnc/NCT01945021). The entrectinib group comprised 52 patients as a study subgroup, while crizotinib as a control group comprised 127 patients. A partitioned survival model was adapted to China clinical practice. Proportion of patients within each health state were based on the progression-free survival (PFS) and overall survival (OS) curves, estimated by parametric extrapolation of observed data from the pooled entrectinib trials. Due to the lack of head-to-head studies, a matching-adjusted indirect comparison (MAIC) was conducted previously, with the crizotinib group as the control and the entrectinib group matched for demographic characteristics to ensure that baseline characteristics were as similar as possible between the two groups. The matched baseline characteristics included gender, age, race, smoking history, ECOG scores, histologic classifications, extent of disease, CNS metastases, and prior therapeutic regimens. The utility values of different health states were retrieved from the clinical trial results and adjusted according to age. The drug cost was calculated according to the local prices in China, dose per week and medication intensity in clinical trials. The drug management cost and the cost to treat brain metastases and side effects was estimated from clinician survey. Finally, the health outcomes and total medical costs of two treatment regimens based on the above partitioned survival model were measured to evaluate the cost-effectiveness of entrectinib versus crizotinib with the discount rate of 5%.

Results: Compared to crizotinib, entrectinib first-line treatment of ROS1+ locally advanced or metastatic NSCLC yielded an additional 1.02 quality-adjusted life years (QALYs) at an increased total treatment cost of CNY48,482 (USD6,735). The incremental cost-effectiveness ratio (ICER) was CNY47,408 (USD6,586) per QALY obtained, equivalent to 0.55 times of GDP per capita in 2022. The probability sensitivity analysis indicated that at a willingness-to-pay threshold of 3 times GDP per capita, most data points fall below the threshold line, suggesting that entrectinib is more cost-effective than crizotinib. The cost-effectiveness acceptability curve showed that at the three times GDP threshold, there is an 80% probability that entrectinib treatment is cost-effective compared to the crizotinib.

Conclusions: Entrectinib can improve patient health outcomes and is more cost-effective than crizotinib in the Chinese ROS1+ NSCLC population.

Keywords: Entrectinib, Crizotinib, Cost-effectiveness analysis

MA14.07 Access Disparities to Lung Cancer Radiotherapy Across Brazil: An Observational Analysis

A.G. Gouveia[1,2,3], D. Del Rosso[2], G.A. Viani[4], T. Tsakiridis[2,3], M.T.M. Starling[5], A.A. Rosa[6], M.S. Castilho[7], G.N. Marta[8], C.F. de Sousa[9], H.A. Carvalho[10], A.A. Jacinto[11], E.F. Rauber[12], F.Y. Moraes[13], [1]Latin American Cooperative Oncology Group, Porto Alegre/BR ,[2]McMaster University, Hamilton, Ontario, Canada, Hamilton/ON/CA ,[3]Juravinski Cancer Centre, Hamilton/ON/CA ,[4]University of São Paulo (FMRP-USP), Ribeirao Preto, SP/BR ,[5]London Health Sciences Centre, London/ON/CA ,[6]Oncoclinicas Salvador and Hospital Santa Izabel, Salvador, BA/BR ,[7]Felicio Rocho Hospital,, Belo Horizonte, MG/BR ,[8]Sírio Libanes Hospital, Sao Paulo, SP/BR ,[9]Johns Hopkins Bloomberg School of Public Health, Baltimore/MD/USA ,[10]Universidade of Sao Paulo, Clinics Hospital,, Sao Paulo, SP/BR ,[11]Barretos Cancer Hospital, Barretos, SP/BR ,[12]Oncoclinicas Rio de Janeiro, Rio de Janeiro, RJ/BR ,[13]Queen's University, Kingston/ON/CA

Introduction: In Brazil, the equitable distribution of healthcare resources remains a challenge, particularly for high-complexity treatments like lung cancer radiotherapy. This observational study aims to evaluate the disparities in access to lung cancer radiotherapy across Brazil, specifically focusing on the distances patients must travel for treatment. Analyzing official data from 2019 to 2022, it seeks to quantify the geographical barriers impacting individuals needing radiotherapy.

Methods: Official data from 2019 to 2022 were collected from Brazil's national Outpatient Procedure Authorization (APAC) system in .dbc format and processed using Python. The dataset encompassed variables such as procedure type and year, patient demographics (including gender and race), residential city, treatment location (by state and region), and instances where treatment was received in a city different from the patient's residence. Distances to treatment centers were calculated using the Haversine formula, expressed in kilometers. This dataset was then integrated into a Power BI database for enhanced analysis. The official annual lung cancer case estimates were juxtaposed with the volume of radiotherapy procedures over the same timeframe to ascertain the utilization rate of radiotherapy. Statistical analysis employed the two-sided Student's t-test and 1-way ANOVA, setting significance at $p < 0.05$.

Results: Among the 13,184 lung radiotherapy procedures, we examined the distance information from 7,904 treatments that required traveling beyond the patient's city of residence. We did not consider the 5,280 treatments within the resident's town in the distance analysis. The national average distance traveled for radiotherapy access was 111.45 kilometers, with non-significant yearly variation ($p=0.719$). Notable regional disparities emerged, with average travel distances reaching 469.76 kilometers in the North, 239.60 kilometers in the Midwest, 152.90 kilometers in the Northeast, 78.24 kilometers in the Southeast, and 63.66 kilometers in the South ($p < 0.001$). At the state level, the disparity widened, ranging from 48.76 kilometers in Santa Catarina (South) to 1,354.54 kilometers in Roraima (extreme North) ($p < 0.001$). Racial disparities in travel distance were also evident; white patients traveled an average of 98.49 kilometers, whereas non-white patients traveled 120.67 kilometers ($p = 0.007$). Gender did not significantly impact travel distance, with females traveling an average of 109.54 kilometers compared to 112.86 kilometers for males ($p = 0.373$). Radiotherapy utilization rates for lung cancer varied regionally: North (12.00%), Northeast (13.49%), Midwest (14.56%), Southeast (14.47%), and South (18.14%), with $p=0.0007$. A higher average travel distance was significantly correlated with a lower radiotherapy utilization rate ($p < 0.05$).

Conclusions: The study uncovers significant geographical and racial disparities in access to lung radiotherapy in Brazil, especially affecting residents of less developed areas and non-white patients. The overall low rates of radiotherapy utilization for lung cancer across regions underscore the urgent need for strategic enhancements in healthcare infrastructure and the accessibility of lung cancer treatment services. The findings can contribute to policy discussions and healthcare planning to mitigate these barriers and enhance cancer care delivery across the nation.

MA14.08 Revolutionizing Survival: The Real-World Impact of High-Cost Therapies on Advanced NSCLC

R. Ruizi,[2], K. Roque[1],[3], M. Galvez-Nino[1], H. Vallejos[4], J.M. Araujo[5], M. Olivera Hurtado De Mendoza[1], N. Valdiviezo[1], O. Coanqui[1], M.W. Castro-Mollo[1], M. Calderon[1], L. Mas[1], [1]Instituto Nacional de Enfermedades Neoplasicas, Lima/PE, [2]Universidad Peruana Cayetano Heredia, Lima/PE, [3]Nine of July University (UNINOVE), Sao Paulo/BR, [4]Hospital de Clinicas, La Paz/BO, [5]Auna, Lima/PE

Introduction: The advent of targeted therapy and immunotherapy has radically improved outcomes for advanced NSCLC, yet access hurdles persist due to medication costs. Propensity score analysis (PS) aids in assessing treatment effects in real-world settings. This study evaluates the impact of high-cost drugs on the overall survival (OS) among patients in a public Peruvian institution.

Methods: Retrospective observational study conducted at INEN from 2014 to 2022, including NSCLC patients who underwent systemic treatment for advanced disease at some point in their evolution. Patients were divided into 3 cohorts according to their access to high-cost drugs; A) patients who did not have access to targeted therapy or immunotherapy at all; B) patients who had access only to erlotinib and, C) patients who had access to osimertinib, alectinib or immunotherapy. Patients from cohort B and C may have received chemotherapy in other line of treatment and patients who received erlotinib followed by osimertinib were allocated to cohort C. OS was calculated from the start of systemic therapy for advanced disease until death, with living subjects censored at their last follow-up. To further assess the impact of these drugs vs chemotherapy we conducted a PS analysis using the nearest-neighbor matching method considering covariates likely to influence OS, including sex and smoking status; as well as age, ECOG, brain metastases (BM) and burden of disease at the initiation of systemic therapy for advanced disease.

Results: FIve-hundred patients were included: cohort A, 294; B, 118 and; C, 88. For the whole population, median age was 59, with 58.2% females, 4% had family history of lung cancer, 19.8% were former/current smokers, 22% were exposed to indoor wood smoke, 34% presented with ECOG PS≥2, and 86.4% had adenocarcinoma histology. At diagnosis 90.4% were at stage IV, 18% had oligometastases and, 25.3% had BM. Erlotinib, alectinib and pembrolizumab were used as 1L in 70.34%, 75% and 92% of patients, respectively. Osimertinib was only used after erlotinib in T790M+ cases, mostly in 2L (63.64%). Median OS (mOS) since the initiation of systemic treatment was 7.36m (6.38-8.71) for cohort A; 21.76m (18.74 - 27.12) for cohort B and 27.16m (19.00 - 50.66) for cohort C ($p < 0.001$). Within the latter, mOS was 46.52m for osimertinib, NR for alectinib and 16.08m for pembrolizumab. PS-adjusted Kaplan-Meier curves showed that the mOS for patients treated with any high-cost drug versus those who only received chemotherapy was 21.04 (16.90 - 31.0) vs 9.17m (6.77- 12.3). For EGFR-driven disease, the mOS for patients who received EGFR-TKI vs those who only received chemotherapy was 25.78 vs 6.67m ($p<0.001$). Due to the limited number of matches, analyzing ALK-driven disease was unfeasible. For driver-negative disease, mOS for patients treated with immunotherapy vs those who only received chemotherapy was 15.9 vs 10.7mp<0.001).

Conclusions: Access to standard-of-care drugs remains a challenge for Latin American NSCLC patients, affecting the choice of initial treatment. Our real-world data affirms that incorporating these high-cost medications significantly improves survival rates, thus, it is imperative to strive for expanding access to these treatments.

MA14.09 Disparities in Outcomes of Hospitalized Unhoused Patients with Lung Cancer

F. Khan, L. Khokhlov, Trihealth Good Samaritan Hospital, Cincinnati/OH/USA

Introduction: Lung cancer is a leading cause of cancer-related mortality worldwide, with outcomes significantly influenced by socioeconomic status, access to healthcare, and comorbid conditions. Unhoused individuals represent one of the most vulnerable populations affected by lung cancer, facing unique challenges that may worsen their health outcomes. This study aims to explore the disparities in clinical outcomes among hospitalized unhoused patients diagnosed with lung cancer. Understanding these disparities is crucial for highlighting the need for targeted interventions to improve care and outcomes for this marginalized population.

Methods: This study identified all hospitalized adults aged ≥18 with a lung cancer diagnosis in the 2017-2020 National Inpatient Sample. The primary endpoint was inpatient mortality, with secondary endpoints including cardiac arrest, intubation, length of stay, and total hospital charges. Multivariable logistic regression analysis was utilized to estimate clinical outcomes, with a significance threshold of $P<0.05$.

Results: The analysis included 1,615,135 hospitalizations for lung cancer, with 6,634 (0.4%) involving unhoused patients. A significantly higher proportion of unhoused patients were male (78.5%) and younger (mean age 61) compared to their housed counterparts (50.9% male, mean age 69). The racial composition also differed, with higher percentages of Black (23.8% vs. 12.2%) and Hispanic (6% vs. 4.5%) individuals among unhoused patients. Notably, unhoused patients exhibited higher rates of nicotine and alcohol use. Significant disparities in the prevalence of comorbidities such as anemia, diabetes mellitus, hypertension, systolic heart failure, and chronic obstructive pulmonary disease were observed, indicating poorer health status among the unhoused. Unhoused patients experienced longer hospital stays and incurred higher total charges compared to housed patients. Despite these challenges, the rates of cardiac arrest and intubation were comparable between the two groups. Interestingly, a higher rate of in-hospital mortality was observed in the housed population compared to homeless patients.

Conclusions: Unhoused individuals face not only higher rates of comorbidities and substance use but also longer hospital stays and increased healthcare costs. Despite these challenges, the comparable rates of intubations suggest that unhoused patients do receive critical care when hospitalized. However, the overall higher mortality rate among housed patients may reflect differences in access to palliative care services and end-of-life care. These findings call for a concerted effort to address the specific needs of unhoused individuals with lung cancer, aiming to improve their access to comprehensive care and ultimately, their clinical outcomes.

MA14.11 Duration of Intervals in the Care-Seeking Pathway of Lung Cancer in Nepal - Unraveling the Delays from Symptom Onset to Treatment Initiation

S. Pandey[1], B.D. Paudel[2], B. Acharya[1], S.C. Acharya[1], A. Karn[1], S. Poudyal[1], P. Thapa[1], J. Gurung[1], R. Shilpakar[1], [1]National Academy of Medical Sciences, Kathmandu/NP ,[2]KIST Medical College and Teaching Hospital, Lalitpur/NP

Introduction: Nepal is a Lower Middle Income Country in South Asia. According to Global Cancer Statistics (2022), lung cancer is the commonest malignancy in Nepal and is the leading cause of cancer mortality. Over two-thirds of Nepal's lung cancer patients present at an advanced stage. Delays in the timely diagnosis and treatment of lung cancer limits opportunities for curative treatment and can cause adverse outcomes.

OBJECTIVES: The objective of this study was to determine the expected interval (in days) from first symptom onset to first healthcare visit (access interval), first health care visit to diagnosis (diagnostic interval) and diagnosis to treatment (treatment interval) as per the World Health Organization Guide to Cancer Early Diagnosis 2017 and to identify the reasons for delay.

Methods: A cross-sectional study was conducted at Bir Hospital, Nepal. Fifty-eight patients diagnosed as primary lung malignancy between July 2022 to December 2022 were enrolled and interviewed with a standardized questionnaire. The access, diagnostic and treatment intervals were calculated in days (Figure 1). The patients were inquired about the possible reasons for delay. Frequencies/percentages and mean/median were calculated for categorical and quantitative variables respectively.

Results: The mean age was 64.0 ± 11.1 years (Range 27-80 years). Male to female ratio was 1.6:1. Cough (44.0%) and chest pain (15.5%) were the most common initial symptoms, while hemoptysis (31.0%) and dyspnea (22.4%) were the commonest symptoms for seeking healthcare attention. The majority of patients had stage IV disease (60.3%) followed by stage III (37.8%). Squamous cell carcinoma was the commonest histology (46.5%), followed by adenocarcinoma (36.2%). None of the patients visited an oncologist as their first point of healthcare contact, 74.1% visited a trained medical professional, whereas the remaining 25.9% visited an informal healthcare provider. The common reasons for access delay was misinterpretation of initial symptoms (41.3%) and financial difficulties. Reasons for diagnostic delay include being treated for other diseases (36.2%), long waiting time for investigation and lack of timely referral. Reasons for treatment delay include treatment with alternative medicines and fear of adverse effects of cancer treatment.

Conclusions: Our study shows that there is significant delays in the access and diagnostic interval of patients with lung cancer. In order to reduce delays in the care-seeking pathway of lung cancer, we need to focus on developing awareness programs for the general population and encourage medical professionals to rule out lung cancer in patients with high index of clinical suspicion.

Introduction: Advances in therapeutic options have increased the number of survivors patients with lung cancer. They may suffer from cancer treatment-related effects, including exacerbation of sexual dysfunction (SD), a condition that affects their quality of life and is under-recognized. Our aim was to describe the frequency, severity, and factors associated with SD in a cohort of Ibero-American patients.

Methods: Prospective, analytical, observational, multicenter study. Clinical and demographic variables were collected between July 2023 and February 2024. Sexual function was assessed with a validated questionnaire for each gender. Descriptive analysis, measures of differences in categorical variables by chi2 ($\chi 2$) and logistic regression analysis were performed.

Results: 448 patients from 24 hospitals were included. Of these, 277(61.83%) were male and 365(81.48%) had metastatic disease. 284(63.39%) reported occurrence of SD after starting anticancer treatment and 396(88.39%) considered it important to be evaluated for this condition.398(88.84%) were on active treatment, 47(10.93%) reported improvement of SD after discontinuation of therapy, but 275(63.95%) had never discontinued treatment. Population characteristics in Table 1. Statistically significant associations for global SD were female gender OR 3.53 (95% IC 1.88-6.6) p 0.001, smoking history OR 1.77 (95% IC 1.01-4.01) p 0.04 and obesity OR 1.7 (95% IC 1.01-3.16) p 0.05. Differences by gender and risk factors for SD are shown in Table 2.

MA14 GLOBAL PERSPECTIVES OF LUNG CANCER ACROSS THE CARE CONTINUUM
TUESDAY, SEPTEMBER 10, 2024 - 13:30 - 14:45

MA14.13 Analysis of Lung Cancer-Specific Patient-Reported Outcome Measures (PROMs): Results from the PRO4All Project

A. Servetto[1], F. Malandrini[2], M. Meregaglia[2], A.A. Valsecchi[3], C. Bennati[4], F. Giovanardi[5], C. Pinto[5], M. Di Maio[3], O. Ciani[2], [1]University of Naples Federico II, Naples/IT ,[2]SDA Bocconi School of Management, MIlan/IT ,[3]University of Turin, Turin/IT ,[4]Ausl Romagna, Ravenna/IT ,[5]Azienda Unità Sanitaria Locale-IRCCS, Reggio Emilia/IT

Introduction: Assessment of Quality of Life (QoL) should be included among endpoints in oncology clinical trials. However, a plethora of distinct patient-reported outcome measures (PROMs) eligible for adoption in clinical trials exists. Therefore, we aimed to establish a lung cancer-specific comprehensive list of PROMs developed for clinical trials, investigating their unique properties and characteristics.

Methods: As part of the PRO4All project, we explored the following resources to identify lung cancer-specific PROMs: facit.org; eortc.org; eprovide.mapi-trust.org; ema.europa.eu (European Public Assessment Reports); published reviews. For each identified PROM, we collected information about name, type of questionnaire (self-reported, observer-reported or caregiver's report), recall period, number of items and presence of minimum clinically important difference (MCID) reference in literature. Finally, each item of various questionnaires was assigned to a specific list of predefined 38 outcome domains.

Results: We identified 386 PROMs in oncology clinical trials. Among them, 17/386 (4.4%) were lung cancer-specific. The sources were eprovide, facit.org, eortc.org or published reviews in 8 (47.1%), 6 (35.5%), 2 (11.8%) and 1 (5.8%) cases, respectively. Five (n=5/17, 29.4%) were variants of other questionnaires. The recall period was "last week", "today" or "treatment related" in 10 (58.8%), 2 (11.8%) and 2 (11.8%) cases, respectively. In 3 PROMs (17.6%), the recall period was not specified. All questionnaires were self-reported, none of them was observer-reported (e.g., by family members or caregivers). The median number of items for each PROM was 9 (range 4-38). We identified a total of 231 items. The most represented domains were: i) Respiratory, thoracic and mediastinal outcomes (n= 53 items); ii) General outcomes (n=39); iii) Emotional functioning/wellbeing (n=30); iv) Social functioning (n=28). Of note, only 4 (n=4/231, 0.2%) items, reported in 4 different questionnaires, were assigned to "Global QoL" domain. As a consequence, 13/17 (76.5%) PROMs did not include items regarding the Global QoL domain. Finally, an MCID reference was identified only for 4/17 (23.5%) questionnaires.

Conclusions: Our study led to the establishment of a detailed archive of available lung cancer-specific PROMs. Analysis of distinctive features and characteristics of the various instruments might help scientists and clinicians to select the most appropriate PROM for different research and clinical settings, as well as to develop more homogeneous and standardized methodologies to assess PROs in patients with lung cancer.

Introduction: Lung cancer has a high risk of recurrence after curative treatment, but patient outcomes may be improved if recurrences are detected at an early stage. Therefore, post-treatment surveillance with scheduled computed tomography (CT) for early detection and treatment of relapses is broadly recommended. The purpose of the SUPE_R trial is to assess if surveillance with [^{18}F]Fluorodeoxyglucose positron emission tomography ([^{18}F]FDG PET)/CT can improve recurrence detection, thereby increasing the proportion of recurrences that can be treated with curative intent.

Methods: This national, multi-center randomized controlled trial involved 750 patients who completed definitive therapy for stage IA-IIIC non-small cell lung cancer, recruited from most major hospitals in Denmark, from February 2019 to November 2021. Participants were randomized (1:1) into two groups: the control group, receiving a contrast-enhanced (ce)CT scan every three months (the current standard of care in Denmark), and the PET group, alternating between ceCT and contrast-enhanced [^{18}F]FDG PET/CT scans at three-month intervals. Both groups followed the assigned follow-up schedule for two years or until recurrence was detected.

Results: 373 patients were randomized to the PET group and 377 patients to the control group. Baseline characteristics were comparable across both groups (Table 1). Recurrence was observed in 83 patients (22%) in the PET group and 75 (20%) in the control group (p = 0.43). There was no significant difference in the proportion of recurrences treated with curative intent, with 46% in the PET group and 47% in the control group (p = 0.85). More recurrences were detected outside of scheduled surveillance in the control group compared to the PET group (23% vs 11%, p = 0.045). The 2-year disease-free survival rate was 74.6% (95% CI 71.4-78%) for all patients, with no difference between groups. A secondary, per-protocol analysis confirmed these results. There were fewer reported adverse events from biopsy procedures to diagnose recurrence in the control group, but the difference was not significant (incidence rate ratio = 0.76, 95% CI 0.57-1.01, p = 0.06).

Conclusions: These findings indicate that [^{18}F]FDG PET/CT, despite its increased sensitivity, may not offer a substantial advantage in the early detection of recurrence over standard CT. The impact of [^{18}F]FDG PET/CT on patient quality of life, cost-effectiveness and the role of liquid biopsies in this context remains to be analyzed and will be addressed in future publications. The SUPE_R trial is registered on Clinicaltrials.gov (NCT03740126).

MA15.04 MRD Predicts Clinical Outcomes of Patients with Early-Stage EGFR-Mutant NSCLC: A Post-Hoc Biomarker Analyses of EVIDENCE

F. Zhou[1], J. Zhang[2], F. Li[2], L. Ding[3], C. Zhou[1], [1]Shanghai East Hospital, Tongji University School of Medicine, Shanghai/CN ,[2]Genecast Biotechnology Co., Ltd, Wuxi/CN ,[3]Betta Pharmaceuticals, Hangzhou/CN

Introduction: EVIDENCE was a randomized, open-label, phase 3 trial that compared icotinib versus chemotherapy as adjuvant treatment for stage II-IIIA, resected EGFR-mutant NSCLC, demonstrating significantly improved DFS with adjuvant icotinib in this patient population. Here, we reported the preliminary post-hoc biomarker analyses of EVIDENCE, to investigate the value of ctDNA-based molecular residual disease (MRD) detection in adjuvant setting among patients with early-stage EGFR-mutant NSCLC.

Methods: A total of 179 patients were included in the biomarker-evaluable population (BEP), consisting of 108 in icotinib arm and 71 in chemotherapy arm. The ctDNA detection was based on a tumor-informed assay (MinerVa Prime) in which SNV, indel and fusion variants detected in tumor tissues using a whole exome panel supplemented with frequent lung cancer fusion genomic regions (WES-lc) were ranked and the top 50 variants per patient were selected in designing of customized panels and tracked in patient postoperative plasma samples to determine the MRD status during and after adjuvant therapy. The ctDNA status was estimated using a statistical model, where a significant difference from the intra-sample background ($p < 0.01$) is considered positive. The MinerVa Prime assay had been analytically validated to possess a specificity of 99.67% and a limit of detection (LoD) of 0.0025% at 30ng of input DNA.

Results: In the BEP, adjuvant icotinib significantly improved DFS compared with chemotherapy (HR 0.4, 95% CI 0.2-0.6). A total of 1432 blood samples from 179 patients were successfully profiled at different time points for further sequencing. In the landmark time point analysis, the positive landmark ctDNA detection rate was 28.6% in chemotherapy arm and 27.8% in icotinib arm, respectively. Patients with detectable MRD at landmark or longitudinal time points had worse DFS than those with undetectable MRD (landmark: HR 4.2, 95% 2.4-7.2, $p < 0.001$; longitudinal: HR 6.1, 95% 3.1-11.2, $p < 0.001$) (Fig 1). Similar results were observed in patients with stage II or stage III diseases or in patients treated with adjuvant icotinib or chemotherapy. Patients with early ctDNA response (landmark detectable MRD transformed to undetectable in first on-therapy time point) had better DFS than those with persistent detectable MRD. The sensitivity for longitudinal MRD for predicting the recurrence was 81.1% and the median lead time for patients with recurrence was 5.6 months.

Conclusions: The current post-hoc biomarker analyses from a phase 3 study highlight the role of MRD in adjuvant setting among patients with stage II-IIIA, completely resected EGFR-mutant NSCLC.

MA15.05 Follow-Up Update of Molecular Residual Disease in Localized Non-Small Cell Lung Cancer

J-T. Zhang[1], X. Gao[2], S-Y. Liu[1], Z. Jiao[2], S. Dong[1], Y. Pan[1], Q. Zhou[1], W-Z. Zhong[1], X-N. Yang[1], X. Yi[2], Y-L. Wu[1], [1]Guangdong Provincial People's Hospital, Guangdong Lung Cancer Institute, Guangzhou/CN ,[2]Geneplus-Beijing Institute, Beijing/CN

Introduction: The concept of molecular residual disease (MRD) in solid tumors is progressively gaining traction. Here, we present the updated follow-up from our prior study involving 261 patients with stage I-III non-small cell lung cancer (NSCLC), highlighting the negative predictive value of longitudinal MRD, which was determined to be 96.8%. We aim to validate our previous findings and clarify the clinical application of MRD for NSCLC.

Methods: As of December 31, 2023, the median follow-up for this cohort reached 34.6 months. An additional 296 follow-up blood samples (collected every 3-6 months post-surgery) were obtained for ctDNA-MRD testing, bringing the total number of follow-up blood samples to 1209. Longitudinal time points were defined as intervals of every 3-6 months since the landmark detection. The predictive value and sensitivity of longitudinal MRD were evaluated across various stages and recurrence patterns.

Results: In all, 77 cases (29.5%) recurred at the latest follow-up, with median disease-free survival 18.6 months. 83.1% of them had detectable MRD signals before recurrence, with a median lead time of 5.2 months (95%CI: 3.9-8.9 months). Overall, 190 patients (n=190/261, 72.8%) remained longitudinal undetectable MRD after surgery, and 177 of them kept disease-free, resulting in a negative predictive value of 93.2%. In contrast, 13 patients experienced recurrence while having longitudinal undetectable MRD, potentially influenced by two main clinical and non-clinical factors: brain-only metastases (n=7) and absence of blood samples within six months prior to recurrence (n=4).

Conclusions: With the support of updated follow-up, we strengthen the argument that longitudinal undetectable MRD could serve as a robust indicator for identifying those localized NSCLC patients are cured postoperatively.

MA15.07 Preliminary Analysis of Adjuvant Chemotherapy with Atezolizumab in Stage I-III Resected NSCLC and Clearance of ctDNA

R. Maniar[1], E. Shum[2], N.A. Mohindra[3], D.H. Owen[4], P.C. Ma[5], M. Haigentz, Jr[6], R.D. Hall[7], S.A. Rajguru[8], J. Grindheim[9], K. Schulze[9], N.H. Hanna[1], [1]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis/IN/USA ,[2]New York University Perlmutter Cancer Center, New York/NY/USA ,[3]Northwestern University Robert H. Lurie Comprehensive Cancer Center, Chicago/IL/USA ,[4]The Ohio State University James Comprehensive Cancer Center, Columbus/OH/USA ,[5]Penn State Cancer Institute, Hershey/PA/USA ,[6]Rutgers Cancer Institute of New Jersey, Robert Wood Johnson Medical School, New Brunswick/NJ/USA ,[7]University of Virginia Comprehensive Cancer Center, Charlottesville/VA/USA ,[8]University of Wisconsin Carbone Cancer Center, Madison/WI/USA ,[9]Genentech, Inc., South San Francisco/CA/USA

Introduction: The use of adjuvant immune checkpoint blockade (aICB) has demonstrated benefit in patients with early-stage, resectable non-small cell lung cancer (NSCLC) positive for PD-L1 expression. Unanswered questions remain regarding which patients derive benefit from aICB including patients with PD-L1 negative tumors and optimal duration of treatment. The use of circulating tumor DNA (ctDNA), as a measurement of minimal residual disease has been increasingly employed to monitor disease status outside of standard radiographic surveillance and has the potential to inform treatment decision-making and personalize treatment duration, although there is considerable variability in assay methodology and sensitivity.

Methods: We conducted a single-arm, multicenter, phase II trial of adjuvant cisplatin-based chemotherapy with concomitant atezolizumab every 3 weeks for 4 cycles followed by up to 13 additional cycles of atezolizumab alone for patients with resected Stage IB (tumors ≥4cm) - III NSCLC (8th ed) (NCT04367311). ctDNA was collected prior to initiating adjuvant therapy, at 3 months, 6 months, 9 months, and 30-days post completion of the study or every 3 months for 1 year after initiating treatment, for early discontinuation. The AVENIO Oncology Surveillance Test, a tumor-informed, germline-normalized panel-based assay was utilized with ctDNA-positivity (ctDNA+) defined as a detected index ≤0.1. The primary aim of the study was to estimate the percentage of ctDNA+ patients after surgery who had clearance following 4 cycles of adjuvant chemotherapy with atezolizumab plus up to 13 additional cycles of atezolizumab. The study enrollment closed in December 2023.

Results: At the time of this analysis, 59 patients were enrolled in the study with evaluable baseline ctDNA results available for 47 patients. Of the evaluable cohort, 0 (0%), 3 (6%), 20 (43%), 23 (49%), and 1 (2%) patients had Stage IB, IIA, IIB, IIIA and IIIB disease, respectively. 30 (64%) patients were non-squamous while 12 (26%) had squamous histology. 3 (6%) patients had adenosquamous and 2 (4%) patients had NSCLC NOS. PD-L1 expression included PD-L1 <1% (14 patients [30%]), 1-49% (17 patients [36%]) and ≥50% (14 patients [30%]). 2 patients (4%) had unknown PD-L1 expression. Based on the presence of variants identified on the ctDNA panel, 15 (32%) patients had ctDNA positivity at the baseline timepoint after surgical resection. Results from additional analyses, including 6-month disease-free survival and longitudinal on-treatment ctDNA clearance after 3 months will be available on all patients at the time of reporting updated results.

Conclusions: This preliminary analysis shows a substantial portion of patients are ctDNA positive after undergoing curative-intent surgical resection for early-stage NSCLC. Ongoing analysis has the potential to identify patients who obtain benefit from adjuvant systemic therapies and characterize ctDNA kinetics through the course of treatment.

MA15.08 Ultrasensitive Blood Test for Early Lung Cancer: Integrating Fragmentomics and Mutational Signatures in cfDNA

J. He[1,2], H. Wang[1,2], Y. Feng[1,2], J. Li[1,2], P. Chen[1,2], X. Zheng[1,2], W. Fu[1,2], C. Li[1,2], S. Tang[3], H. Bao[3], M. Wu[3], S. Chang[3], D. Zhu[3], S. Yang[3], Y. Shao[3,4], R. Yin[5,6,7], W. Liang[1,2], [1]the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]China State Key Laboratory of Respiratory Disease & National Clinical Research Centre for Respiratory Disease, Guangzhou/CN ,[3]Nanjing Geneseeq Technology Inc., Nanjing/CN ,[4]Nanjing Medical University, Nanjing/CN ,[5]Jiangsu Key Laboratory of Molecular and Translational Cancer Research, Jiangsu/CN ,[6]Jiangsu Key Lab of Cancer Biomarkers, Prevention and Treatment, Nanjing/CN ,[7]Nanjing Medical University Affiliated Cancer Hospital & Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research, Nanjing/CN

Introduction: Effective detection of lung cancer in the general population is critical to improve treatment outcomes and increase the 5-year survival rate. Despite the utility of Low Dose Computed Tomography (LDCT) as the standard screening method, its limitations in broad population applications necessitate the development of more accessible and sensitive detection strategies.

Methods: We explored the multi-omic profiles of circulating tumor DNA (ctDNA) and cell-free DNA (cfDNA) to distinguish between malignant lung cancer patients and non-cancer subjects using a blood-based assay. Employing whole-genome sequencing to characterize cfDNA, we developed a machine learning model based on integrated fragmentomic and mutational signatures (as shown in Figure1). This research encompassed two independent cohorts totaling 1,600 lung cancer patients and an equivalent number of control participants. These cohorts were subsequently divided into training and validation groups.

Results: The developed model demonstrated robust diagnostic performance, evidenced by an area under the curve (AUC) of 95.59% within the training cohort and 95.74% in the validation cohort (ad shown in Figure2). Remarkably, it maintained high efficacy across different cancer stages and histologies. External validation further substantiated the model's utility, achieving 85.9% sensitivity and 94.8% specificity in distinguishing cancer from non-cancer cases. Comparative analyses revealed that our ctDNA assay surpassed both LDCT and a previously established method in simulated population screenings, highlighting its superior diagnostic accuracy.

Conclusions: The developed ctDNA assay represents a groundbreaking advancement in the early detection of lung cancer, showcasing unparalleled sensitivity and specificity. Its ability to efficiently differentiate between cancerous and non-cancerous states in a non-invasive manner suggests a significant potential to complement existing LDCT screening protocols, thereby enhancing early detection rates and potentially improving survival outcomes in lung cancer patients.

Introduction: LCMC3 (NCT02927301) was a Phase II, open-label, single-arm study in patients with resectable NSCLC that met its primary endpoint, with a 20% major pathological response (MPR) rate after neoadjuvant atezolizumab. We report final disease-free survival (DFS) and overall survival (OS) and their association with ctDNA status and clearance.

Methods: Patients who had resectable stage IB-IIIA or select IIIB NSCLC (AJCC, 8th edition), were ≥18 years of age, and had ECOG PS 0-1 received neoadjuvant atezolizumab 1200 mg IV every 3 weeks for 2 cycles, followed by surgery. Adjuvant chemotherapy, radiotherapy and/or adjuvant atezolizumab could then be given to patients without progression per investigator decision. The efficacy population included patients with a complete resection, MPR assessment, and without known EGFR/ALK alterations. ctDNA was collected at baseline, post-neoadjuvant atezolizumab and post-surgery. ctDNA was measured using the tissue-informed AVENIO Oncology Surveillance Test, with ctDNA-positive (ctDNA+) defined as ctDNA detection index ≤0.1. The adjuvant atezolizumab safety analysis population comprised patients who received ≥1 dose of adjuvant atezolizumab.

Results: Of 181 enrolled patients with NSCLC, 137 (76%) composed the efficacy population, of whom 53 (29%) received adjuvant atezolizumab. As of October 13, 2023, median follow-up was 3.1 years (range, 0.2-4.9). The median DFS and OS were not reached and 4-year DFS and OS rates were 70% and 82%, respectively. For patients with stage I/II vs III disease, neither DFS nor OS were statistically different. DFS rates were higher in patients with MPR vs no MPR (4-year, 86% vs 67%; P=0.047) and those receiving adjuvant atezolizumab vs no adjuvant atezolizumab (3-year, 83% vs 64%; P=0.023; Table). Patients with post-surgery ctDNA-negative (ctDNA−) vs ctDNA+ status had improved DFS (HR, 0.29; 95% CI: 0.12, 0.75; P=0.006; n=75). Comparing patients with post-surgery clearance vs no clearance, DFS (HR, 0.25; 95% CI: 0.08, 0.78; P=0.010) and OS (HR, 0.26; 95% CI: 0.07, 0.99; P=0.034; n=53; Table) were both improved. Treatment-related adverse events (TRAEs) in patients receiving adjuvant atezolizumab (n=57) occurred in 65%, with TRAEs leading to adjuvant atezolizumab discontinuation occurring in 18%.

Conclusions: At final analysis, having MPR and receiving adjuvant atezolizumab continued to be associated with DFS benefit. The clinical and survival outcomes for stage III disease were similar to stage I/II. Post-surgery ctDNA clearance was associated with longer OS. Additionally, longer DFS was seen with post-surgery ctDNA− status and clearance. These data suggest that MPR, ctDNA status, and ctDNA clearance may serve as biomarkers for risk stratification.

MA15.11 Neoadjuvant Sintilimab plus Chemotherapy in EGFR-mutant NSCLC Followed by adjuvant Osimertinib or Observation: A Phase II CTONG2104 Trial

C. Zhang[1], B-y. Jiang[1], L-x. Yan[2], Z-y. Chen[1], C. Lv[1], Y-s. Li[1], S. Dong[1], R-q. Liao[1], X-n. Yang[1], Q. Zhou[1], Y-L. Wu[1], W-z. Zhong[1], [1]Guangdong Lung Cancer Institute, Guangzhou/CN ,[2]Guangdong Provincial People's Hospital, Guangzhou/CN

Introduction: Neoadjuvant immunotherapy plus chemotherapy in EGFR-mutant NSCLC remained poorly explored and how it influenced subsequent use of EGFR-TKIs during disease progression or adjuvant setting was unclear. Herein, we report the prespecified analysis of a phase 2 prospective trial (NCT05244213).

Methods: This is an open-label, phase 2 prospective trial with Simon's two-stage design. 35 patients with stage IIB-IIIB (N2) and EGFR mutation including non-sensitive mutations were enrolled, and up to 3 cycles sintilimab plus chemotherapy would be provided followed by surgery and observation for stage I cohort or adjuvant osimertinib for stage II cohort.

Results: As of July 15, 2024, 35 patients had been consecutively enrolled, with 33 completing neoadjuvant treatment and surgery, while the others did not undergo surgery. Common treatment-related adverse events (TRAEs) included alopecia, nausea, and paresthesia, with 17.1% of patients experiencing grade 3-4 granulocytopenia. The confirmed ORR was 60.0% (21/35), with one patient showing PD. Among patients who received neoadjuvant immunochemotherapy, the MPR and pCR rates were 34.3% (12/35) and 11.4% (4/35), respectively. Baseline PD-L1 expression did not correlate with MPR status (p=0.57), but patients without a smoking history exhibited higher MPR rate (p=0.005). With a median follow-up of 14.4 months for the two-stage cohorts, 9 out of 35 (25.7%) patients experienced disease relapse/progression. The median event-free survival (EFS) was 21.1 months, with 12- and 18-month EFS rates of 90.7% and 71.9%, respectively. Despite that no significant difference in EFS based on pathological response status, patients who achieved pCR showed a favorable trend in EFS. No OS events were observed in this study. The ORR for all patients with relapsed/progressive disease who were subsequently treated with EGFR-TKIs was 100%, with one patient achieving CR. The safety profile for patients treated with subsequent EGFR-TKIs or adjuvant osimertinib after neoadjuvant immunochemotherapy was well tolerated. Common TRAEs included diarrhea, rash, and mouth ulcers. In the stage II cohort treated with adjuvant osimertinib, 4 (23.5%) patients experienced grade 3-4 ALT/AST elevation, while no grade 3-4 TRAEs were observed in patients from the stage I cohort treated with osimertinib after disease relapse.

Conclusions: Neoadjuvant sintilimab plus chemotherapy could be an optional treatment modality in selected EGFR-mutant NSCLC without adding severe toxicity to adjuvant or subsequent EGFR-TKIs. Long-term follow-up was warranted to further clarify the role of additional neoadjuvant immunochemotherapy in EGFR-mutant NSCLC.

MA15.12 Aumolertinib as Adjuvant Therapy in Resectable I-III EGFR-Mutant NSCLC : Also Effective in Patients with High-Risk Relapse Factors

J. Yao[1], W. Song[2], R. Wang[1], S. Gu[1], Q. Zhang[1], J.L. Zou[1], C.H. Zhong[1], R.C. Qu[1], L. Chen[1], [1]Jilin Province People's Hospital, Changchun/CN ,[2]Health Management Centre, The First Clinical Hospital of Jilin University/CN

Introduction: Early NSCLC patients(pts) with high-risk relapse factors such as micropapillary/solid tumor/complex glandular component (MP/S/CGC), spread through air space (STAS), visceral pleural invasion (VPI) and vascular invasion (VI) tend to have a poor prognosis. Our study aimed to investigate the efficacy of aumolertinib as adjuvant therapy for stage I-III EGFR-mutant NSCLC undergoing R0 resection, and the impact of high-risk relapse factors on the clinical benefit.

Methods: We enrolled EGFR-mutant NSCLC pts who underwent radical surgery and received a daily dose of aumolertinib 110 mg. The adjuvant duration was 36 months, if tolerable. The results of gene detection and immunohistochemistry were also recorded. We evaluated the disease-free survival (DFS), safety and efficacy of aumolertinib in pts with high-risk relapse factors.

Results: This study analyzed 113 cases of pathologically confirmed adenocarcinoma, EGFR positive mutation (19Del or L858R), and stage I-III NSCLC pts from August 2021 to December 2023. At the data cutoff, 91 pts (80.5%) have been followed up for ≥ 6 months, 21 pts (18.6%) have been followed up for ≥ 18 months. The 1-year DFS rate is 100%, while the 2-year DFS rate is 94.1%. Among them, 44 pts had at least one high-risk relapse factor,including 29 patients with MP/S/CGC (65.9%), 9 patients with STAS (20.5%), 20 patients with VPI (45.5 %), and 5 patients with VI (11.4%). 33 pts (75%) were followed up for ≥ 6 months, 26 pts (59%) were followed up for ≥ 12 months. Median follow-up time was 12.5 months. At 12 months, 100% pts were alive and disease-free. Based on adjuvant targeted therapy, there was no significant difference in postoperative recurrence between the population with the high-risk relapse factors and the overall population in one year. During the treatment, 24 pts (21.2%) had treatment-related adverse events (TRAEs) of any grade, such as mild rash and diarrhea. No grade≥3 adverse events occurred. No pts withdrew from therapy due to adverse drug reactions.

Conclusions: This study suggested that aumolertinib had good efficacy and a tolerable safety profile as adjuvant therapy in resectable EGFR-mutant NSCLC,specially in patients with high-risk relapse factors. Our study is still ongoing to expand the cohort of pts with high-risk pathologic factors and extend the follow-up period to determine longer-term outcomes.

MA15.13 Furmonertinib as Adjuvant Therapy for Completely Resected Stage IA with High-Risk Factors and IB NSCLC Patients with EGFR Mutations

R. Geng[1], Y. Chen[1], J. Miao[2], H. Liu[1], Y. Qin[1], Z. Han[1], S. Li[1], Y. Guan[2], H. Wu[3], Y. Zhao[2], Y. Wang[1], [1]Peking Union Medical College Hospital, Beijing/CN ,[2]Beijing Chao-Yang Hospital, Beijing/CN ,[3]Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/CN

Introduction: Furmonertinib (AST2818) is a highly brain-penetrant, third-generation EGFR tyrosine kinase inhibitor (TKI), which has been approved for the first-line treatment of patients with 19Del or L858R mutations and treatment of patients with T790M mutations whose disease has progressed on or after EGFR TKI therapy. A retrospective analysis has indicated good efficacy and safety of furmonertinib as adjuvant therapy for completely resected stage IA2 to IIIB NSCLC patients with EGFR mutations (19Del, L858R, G719A and Ex20ins), but there are no prospective evidence of furmonertinib as adjuvant therapy for completely resected NSCLC. Here we firstly report the efficacy and safety of furmonertinib as adjuvant therapy for completely resected stage IA with high-risk factors and IB NSCLC patients with EGFR mutations in a prospective, multi-center, single-arm study (NCT05445310).

Methods: In this prospective, multi-center, single-arm, phase II study, 114 patients will be enrolled, completely resected stage IA with high-risk factors and stage IB NSCLC patients with EGFR mutations (19Del, L858R and uncommon mutations except for Ex20ins) will receive furmonertinib 80mg orally once daily for 3 years. Staging is determined according to the eighth edition of the Cancer Staging Manual of the AJCC. The primary endpoint is the disease-free survival (DFS) rate at 3 years. The secondary endpoints are median DFS, overall survival (OS) rate at 3 years, median OS, and safety. The exploratory endpoints are the changes of molecular residual disease (MRD) and the relations between the efficacy and MRD status.

Results: From August 2022 to March 2024, there were 32 completely resected NSCLC patients enrolled. The median follow-up was 311.5 days, baseline characteristics were as follows, the median age was 60 years (range: 44-70), male 43.8%, stage IA 56.3% (IA1 3.1%, IA2 34.4%, IA3 18.8%), all stage IA patients had at least one high-risk factor, the high-risk factors mainly included micropapillary (55.6%), solid component (33.3%) and spread through air spaces (33.3%), EGFR mutations were 19Del (25.0%), L858R (65.6%), G719A (3.1%) and L861Q (6.3%). At data cut-off March 20.2024, all patients continued to receive furmonertinib and no disease recurrence. There were 12 postoperative patients successfully detected by MRD assay, all the patients' MRD were negative. No grade 3 or higher treatment related adverse events (TRAEs) occurred. The most common TRAEs (≥10%) were skin chapping 25.0%, rash 21.9%, and oral ulcer 18.8%. Dose interruption due to TRAE was reported in one patient. There was no incidence of dose reductions, treatment discontinuation or deaths due to TRAEs.

Conclusions: Furmonertinib 80mg orally once daily has shown potential efficacy and excellent safety as adjuvant therapy for completely resected stage IA with high-risk factors and IB NSCLC patients with EGFR mutations. Patients were well tolerated and the TRAEs were consistent with previous studies.

MA16.03 Survival Outcomes in Single Versus Double Immune Checkpoint Inhibitor in Advanced Non-Small Cell Lung Cancer: A Meta-Analysis

B. Ponvilawan[1], H. Mahadevia[1], A. Khan[1], J. Subramanian[2], D. Bansal[3], [1]University of Missouri-Kansas City, Kansas City/MO/USA ,[2]Inova Schar Cancer Institute, Fairfax/VA/USA ,[3]St. Luke's Cancer Institute, Kansas City/MO/USA

Introduction: Immune checkpoint inhibitors (ICI) with or without chemotherapy (CMT) are the initial standard of care in patients with advanced non-small cell lung cancer (NSCLC) without actionable mutations. This meta-analysis was conducted to evaluate the survival benefit of ICIs based on the number of ICIs used in the first-line regimen.

Methods: Articles with search terms related to ICI and NSCLC were evaluated from Medline, Embase, and CENTRAL databases. Eligible studies must be randomized controlled studies of patients with advanced NSCLC in the first-line setting. At least one arm must receive ICI with or without CMT, and the other must receive CMT alone. Hazard ratios (HR) for overall survival (OS) and progression-free survival (PFS), along with their 95% confidence intervals (CI), were collected and pooled using the generic-inverse variance method. Subgroup analyses were performed based on the number of ICIs used (single vs double).

Results: In total, 21 studies were included in the meta-analysis. OS and PFS in patients with negative PD-L1 were similar for single versus double for squamous (pooled HR for OS 0.82; 95%CI 0.71-0.96 and 0.72; 95%CI 0.57-0.91, and PFS 0.63; 95CI 0.53-0.75 and 0.60; 95%CI 0.42-0.86, respectively) and nonsquamous (pooled HR for OS 0.82; 95%CI 0.74-0.91 and 0.72; 95%CI 0.61-0.86, and PFS 0.70; 95%CI 0.62-0.78 and 0.76; 95%CI 0.62-0.94, respectively) histological subtypes. Similarly, no survival outcome distinctions based on the number of ICI in the regimen were noted in the positive PD-L1 subgroup in both histological subtypes (Figure 1A-B). OS and PFS benefits also did not differ based on any KRAS, KRAS G12C, or STK11 mutations. However, patients with KEAP1 mutation had improved OS and PFS with double ICI (pooled HR for OS 0.41; 95%CI 0.25-0.67 and PFS 0.48; 95%CI 0.26-0.88) but not single ICI (pooled HR for OS 0.84; 95%CI 0.58-1.22 and PFS 0.97; 95%CI 0.72-1.32) (Figure 1C).

Conclusions: Double ICI did not confer improved survival outcomes compared to single ICI for advanced non-small cell lung cancer based on PD-L1 status, histological subtype, or KRAS and STK11 mutations. However, patients with KEAP1 mutations may benefit from double ICI therapy.

MA16.04 Radiomic Biomarkers Predict Response to Immunotherapy Rechallenge in Recurrent NSCLC after Chemoradiation and Durvalumab

L. Delasos[1], M. Khorrami[2], M. Zokaei Nikoo[1], P.D. Patil[3], M.A. Shapiro[1], K.A. Hassan[1], J. Stevenson[1], A.A. Adjei[1], A. Madabhushi[2], N.A. Pennell[1], [1]Cleveland Clinic Taussig Cancer Center, CLEVELAND/OH/USA ,[2]Wallace H. Coulter Department of Biomedical Engineering at Georgia Tech and Emory University, Atlanta/GA/USA ,[3]Nuvance Health Medical Oncology, Poughkeepsie/NY/USA

Introduction: Over 50% of patients with unresectable stage III non-small cell lung cancer (NSCLC) experience recurrence within two years of receiving chemoradiation (CRT) and consolidative durvalumab. Our prior study revealed a median progression-free survival (mPFS) of 6.1 months in those rechallenged with pembrolizumab-based regimens, suggesting suboptimal responses with IO for recurrent NSCLC (rNSCLC). However, PFS varied widely (0.2 to 36.8 months) without discernible differences in patient characteristics or biomarkers (e.g., PD-L1 expression, KRAS mutation status, etc.), indicating that a subset of patients with rNSCLC derive benefit from pembrolizumab. We therefore sought to identify radiomic biomarkers derived from CT images at the time of recurrence that are capable of predicting response to IO rechallenge.

Methods: In this retrospective study at the Cleveland Clinic Foundation, 45 cases of rNSCLC with measurable lung lesions on CT scans were analyzed. All patients were treated with CRT and durvalumab prior to disease recurrence and subsequently received pembrolizumab ± chemotherapy. CT images at the time of recurrence were scrutinized for radiomic signatures predicting response to IO rechallenge. Based on PFS, patients were categorized as “responders” (PFS ≥ 6 months) or “non-responders” (PFS < 6 months). Utilizing 860 texture features, a linear discriminant analysis classifier (LDA) predicted response through 100 iterations of threefold cross-validation, with performance assessed using the area under the curve (AUC). A LASSO Cox regression model, for PFS prediction, derived a multivariate radiomic signature, providing risk scores to categorize patients as high or low risk based on the median.

Results: The mRMR method identified the top five predictive intra/peritumoral radiomic features. An LDA classifier, utilizing these features, effectively discriminated between responders and non-responders (AUC 0.87). The radiomic risk score was determined by applying a linear combination of the five most significant features selected through the LASSO method, each assigned corresponding coefficients. Employing a multivariate Cox proportional hazards model that incorporates clinicopathologic variables (including age, sex, race, smoking history, pack-year, and tumor histologic subtype) along with radiomic features, the radiomics signature demonstrated a significant association with PFS (HR: 4.5; 95% CI: 2.84-6.7; P = 0.003).

Conclusions: Textural features extracted from both within and outside malignant nodules on CT images of individuals with rNSCLC, who previously received concurrent CRT and consolidative durvalumab, proved to be predictive of PFS and responses to pembrolizumab ± chemotherapy. Radiomic biomarkers may play a key role in identifying a subset of patients with rNSCLC who would derive benefit from IO rechallenge while sparing others from unnecessary toxicity. Further validation of these quantitative image-based biomarkers in multiple, independent, multi-institutional cohorts is essential.

MA16.05 PIEZO1+ Caner-associated Fibroblasts Shape an Inert Microenvironment to Suppress Anticancer Immunity in Non-Small Cell Lung Cancer

M. Zhou[1], J. Jiang[1], K. Cai[1], S-C. Ma[2], [1]Southern Medical University, Guangzhou/CN ,[2]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou/CN

Introduction: Immune checkpoint inhibitors (ICIs) have shown significant improvements over chemotherapy in non-small cell lung cancer (NSCLC). However, cancer-associated fibroblasts (CAFs) can lead to immunotherapy resistance, and PIEZO1 is highly expressed in CAFs. Therefore, we aim to explore the impact of PIEZO1+ CAFs on the antitumor immunity in NSCLC.

Methods: Transcriptomic data were utilized to analyze the prognostic effect of PIEZO1 in NSCLC, followed by pathway enrichment and immune infiltration analysis to explore downstream signalings. Spatial and cellular distribution of PIEZO1 in NSCLC microenvironment was investigated using single-cell and spatial transcriptomics data. The interaction between PIEZO1 and cytotoxic lymphocyte activity was analyzed to explore its immunoregulatory effect. An immunotherapy clinical cohort was collected to explore the relationship between PIEZO1 and ICI response.

Results: High PIEZO1 expression yielded poor prognosis in NSCLC, regardless of overall survival and disease-free survival. PIEZO1-related genes were significantly enriched in extracellular matrix remodeling and collagen biosynthesis pathways. Tumors with higher PIEZO1 expression yielded more CAF infiltration compared with PIEZO-low counterparts. Single-cell profiling of NSCLC revealed co-expression between PIEZO1 and CAF-secreting protein FAP. Spatial transcriptomics data suggested that PIEZO1 and FAP were co-localized in the fibrous components of NSCLC microenvironment (Fig 1). The infiltration of CD8+ T cells was significantly reduced in PIEZO1-high tumors, accompanied by an increase of regulatory T cells. Interaction analysis between PIEZO1 and cytotoxic lymphocyte activity indicated that the antitumor effect of cytotoxic lymphocytes was dependent on PIEZO1 expression. Survival analysis of the ICI cohort demonstrated significantly shorter overall survival in PIEZO1-high patients compared to those with low expression (Fig 2).

Conclusions: In NSCLC, PIEZO1+ CAFs shaped an inert microenvironment by potentially reversing the antitumor effect of cytotoxic lymphocytes, thereby inducing poor prognosis and immunotherapy resistance in NSCLC. Interventions targeting PIEZO1+ CAFs may represent a new strategy to enhance ICI efficacy in NSCLC.

MA16.07 A First in Human (FIH), Phase 1 Open Label, Dose Escalation and Expansion Study of CTM103, a LNP MRNA Encoding an IL2Rß? Selective Il-2v, As Monotherapy and in Combination with Pembrolizumab, in Patients with Advanced Solid Tumors

C. Kong[1], J. Zhang[1], L. Sun[1], Q. Xuan[1], H. Huang[2], K. Wang[1], [1]The Fourth Affiliated Hospital of Zhejiang University School of Medicine, Zhejiang University, Yiwu/CN ,[2]iLeukon Therapeutics, San Diego/CA/USA

Introduction: CTM103 is an LNP mRNA encoding an IL2R$\beta\gamma$ selective IL-2v derivative fused with Human Serum Album. Preclinically, the novel LNP mRNA platform allowed expression and therefore extended plasma half-life of IL2v in animal models, which is not achieved with other protein-based IL-2 drugs. CTM103 stimulated significant and sustained expansion of CD8 T cells for more than three weeks, with minimal expansion of regulatory T cells. Moreover, CTM103 demonstrated superior efficacy than IL-2 based drugs in multiple cancer models and has an excellent safety profile in rodents and non-human primates. Therefore, the novel design of CTM103 has the potential to fully unleash the antitumor effects of the IL-2 pathway while mitigating unwanted toxicity.

Methods: This first-in-human, open label phase 1 study evaluates the safety, tolerability, and initial efficacy of CTM103 with or without pembrolizumab in patients with advanced solid tumors. The design includes two portions of the study: Parts A, CTM103 monotherapy in which patients receive intravenous CTM103 once every 3 weeks (Q3W) and Part B in which patients receive CTM103 in combination with pembrolizumab (200 mg on day 1), both intravenous Q3W. Both portions of the study consist of 3+3 escalation cohorts to define maximum tolerated dose (MTD). If response signal is observed in a given dose cohort, additional 10-20 patients will be enrolled in the expansion portion of the study to further evaluate the safety and efficacy. The trial is ongoing and data as of 7/24/2024 is presented in this abstract.

Results: In Part A, 9 patients in three dose cohorts received CTM103. All patients demonstrated high and prolonged plasma level of IL-2, and remarkable elevation of CD8 T cells (upto 5 folds) and NK cells (upto 25 folds), which can last through the 3-week-period until next injection. No dose-limiting toxicities (DLT) were observed. In Part B, 13 patients in two dose cohorts were enrolled, 10 of which are treatment naïve PDL1+ advanced NSCLC. All patients showed increased CD8 T cells (upto 12 folds) and NK cells (upto 22 folds), and most AEs were at grade 1-2, and were all transient and recovered in less than 7 days. At the cut-off date, 8 of the 10 PD1 treatment naïve PDL1+ NSCLC patients in Part B reached at least the 1st tumor evaluation time-point, 6 of which were evaluated to be PR, and the other 2 were SD. ORR is 75%.

Conclusions: CTM103 was generally well tolerated at the current dose level, which already demonstrated high and prolonged plasma level of IL-2, and robust immune stimulatory activity in promoting CD8 T cells and NK cells proliferation.

Introduction: NCT04495153 is an open-label, phase 2 clinical trial of CAN-2409+valacyclovir in combination with continued ICI treatment in patients with non-resectable, stage III/IV NSCLC following an inadequate response to anti-PD-(L)1 treatment. Here, we explore the impact of the specific site of injection of CAN-2409 on overall survival (OS) and immunological biomarkers.

Methods: Patients were enrolled in 2 cohorts (C) depending on disease status at enrolment. C1: patients with stable disease despite ICI treatment, and C2: patients with progressive disease despite ICI treatment. Two doses of CAN-2409 (5x10^11vp) were injected 5-7w apart via bronchoscopic or percutaneous injections into lung tumor (LT), lymph nodes (LN), or peripheral metastases (PM), each followed by valacyclovir.

Results: As of 16Jan2024, 73 patients were treated (safety population: ≥1 dose of CAN-2409) and 44 were evaluable per protocol (received 2 doses of CAN-2409+valacyclovir and 12-week CT scan). 18 patients received both injections into LT, 13 LN, 8 PM, and 5 in combination of different lesions (LT and LN). Lesions were mainly injected via bronchoscopy (>60%). There were no significant differences between grade 3 events by site of injection; most common TRAEs (≥5%) were fatigue and pyrexia. Median OS (mOS) for C1 (n=5) was not reached (mFU 15.2mos; 4 patients were still alive at follow-up); mOS for C2 was 20.6 months (mFU 19.2mos). The proportion of patients surviving through 12, 14, or 18 months was not significantly different when comparing patients injected into LT versus LN. However, survival was significantly shorter in patients injected into PM compared to combined LT and LN injected patients (P = 0.029 and P = 0.04 for 12 and 14 months, respectively). Importantly, none of the patients injected into PM developed a partial RECIST response; the number of patients with progressive disease was higher in this subgroup compared to patients injected into LN or LT. CyTOF analysis revealed that LN injections were associated with a greater increase in exhausted B cells, CD8+ Tim3+ T cells, and CD4+ PDL1+ T cells after the first CAN-2409 injection compared to LT injections (p=0.024, p=0.002, and p=0.027, respectively). LT injections were associated with an increase in CD69+ Naïve CD4+ T cells, Tim3+ Central Memory CD4+ T cells, and CD11C+ Naïve CD4+ T cells (p=0.001, p=0.023, and p=0.040, respectively after second injection), whereas LN injections were associated with a decrease in these cell populations. LT injections elicited an increase in plasma levels of granzyme H and CCL20, which were significantly greater than changes observed after LN injections (p=0.046 and p=0.039). Due to limited biospecimen availability, PM specimens were excluded from the analysis.

Conclusions: CAN-2409 can be safely delivered intratumorally into LT, LN, and PM in patients with NSCLC. Injection into LT and/or LN is associated with improved survival compared to injection into PM. Administration of CAN-2409 into LT and/or LN is associated with systemic immune activation.

Introduction: The landscape of limited disease small cell lung cancer (LD-SCLC) management has changed little over 30 years. The standard of care treatment remains platinum-doublet chemotherapy with radiation concurrently or sequentially as the standard of care since the early 1990s. Some patients also receive prophylactic cranial radiation subsequently. This treatment pattern may change in the coming months as outcomes of phase 3 randomized clinical trials combining chemotherapy and immunotherapy with radiation in LD-SCLC are reported.

Methods: We analyzed data from the international lung cancer consortium (ILCCO) across 20 sites in Europe, North America, and Asia. This analysis included 1,503 patients who were diagnosed with LD-SCLC between 1990 and 2020 who had complete clinicodemographic data available (e.g., age, sex, smoking status, education level, ethnicity and stage). A subset also had cardiometabolic/respiratory co-morbidity data. Cox regression models were generated evaluating potential prognostic variables on overall survival (OS). Median follow-up time was measured in years using the reverse Kaplan-Meier method.

Results: The consortium harmonized patient data from 12 North American, 6 European and 2 Asian studies. The median age was 65 years (interquartile range: 58-72), 54% were male, 96% were ever-smokers, 88% were White, 6% Asian, 45% had a cardiometabolic comorbidity in which 13% had diabetes, 41% had a respiratory comorbidity, including 26% with COPD. The median follow-up of this mature dataset was 11.4 years and median OS was 19.0 months (95% CI: 17.3, 20.6). OS probabilities at 1, 2, and 4 years are provided in Table 1. In univariable analyses, men (HR=1.14, 95% CI: 1.02, 1.27), low education (HR 1.27, 1.07, 1.51), 70+ years old (HR 1.66, 1.48, 1.87), or European (HR 1.24, 1.07, 1.43), were associated with inferior prognosis (p <0.05). In multivariable analysis, poorer OS was associated for male sex, HR=1.18 (1.03, 1.34; p=0.019) and older age revealed a HR per 10 y -increase of 1.33 (1.23-1.44; p<0.001). In contrast, the year of diagnosis was not associated with median OS or survival probabilities.

Conclusions: When compared to historical data, 2-year survival was reported as 44% (radiation given once or twice daily; Turrisi A.T, et al NEJM 1999), which is similar to all time periods in our 30-year international dataset, with expectedly high comorbidity rates. There has not been a significant change in outcome in over 3 decades. Our real-world outcome data in LD-SCLC will be important to compare with the control-arm outcomes of upcoming immunotherapy studies such as ADRIATIC.

Introduction: There is a paucity of relevant PRO data reported for patients with small-cell lung cancer (SCLC), particularly in the limited-stage (LS) setting. In the double-blind, phase 3 ADRIATIC study (NCT03703297), consolidation durvalumab after concurrent chemoradiotherapy (cCRT) significantly improved the dual primary endpoints of overall survival and progression-free survival versus placebo in patients with LS-SCLC. Durvalumab was well tolerated, with no new safety signals observed. Here we report results from the secondary PRO endpoints.

Methods: Eligible patients had stage I–III LS-SCLC (stage I/II inoperable), WHO performance status 0/1, and had not progressed after cCRT. Patients (N=530) were randomized 1-42 days after cCRT to durvalumab 1500mg or placebo Q4W until investigator-determined disease progression, intolerable toxicity, or a maximum of 24 months. Secondary endpoints included change in symptoms, functioning and global health status/quality of life (GHS/QoL) using European Organisation for Research and Treatment of Cancer QLQ-C30 and QLQ-LC13 electronic questionnaires. Change from baseline for prespecified key subscales was examined using mixed-effect model repeat measurement analysis. Time to deterioration (TTD) and improvement rates (for prespecified key subscales and other subscales) were analyzed using stratified Cox proportional hazards models and logistic regression, respectively. A score change of ≥10 from baseline was considered clinically meaningful.

Results: Compliance with QLQ-C30/LC13 questionnaires was 79.7-82.2% at baseline and remained >70% through Week 16 in both durvalumab (n=264) and placebo (n=266) arms. Mean baseline scores were comparable between the two arms. In both arms, mean changes from baseline in prespecified key subscales averaged over 24 months were small and not clinically meaningful for any subscale. For prespecified key subscales (Table) and other subscales (QLQ-C30: emotional, cognitive and social functioning, pain, nausea/vomiting, dyspnea, insomnia, constipation, diarrhea; QLQ-LC13: hemoptysis, arm/shoulder pain, other pain, sore mouth, dysphagia, peripheral neuropathy, alopecia), there were no between-arm differences in TTD except for arm/shoulder pain (LC13), which was delayed with durvalumab versus placebo (median 25.7 versus 9.1 months [hazard ratio 0.70; 95% CI 0.51-0.94]). Similar improvement rates were reported in both arms for prespecified key subscales (Table) and other subscales; the only difference observed was for chest pain (LC13; 67.3% versus 47.8% for durvalumab versus placebo [odds ratio 2.28; 95% CI 1.08-4.95]).

Conclusions: In ADRIATIC, treatment with durvalumab for up to 2 years improved survival outcomes versus placebo without a clinically meaningful impact on PROs for GHS/QoL, functioning or symptoms, further supporting consolidation durvalumab as a new standard of care in LS-SCLC.

MA17.05 Longitudinal MRD Monitoring Enhances Prognosis Prediction in 105 Patients with Limited-Stage SCLC Receiving Concurrent Chemoradiotherapy

Y. Yang[1], J. Zhao[1], Y. Wu[1], T. Zhang[1], J. Wang[1], L. Deng[1], M. Zhu[2], X. Zhao[2], Q. Ou[2], Y. Shao[2], L. Wang[3], N. Bi[1], [1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing/CN ,[2]Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing/CN ,[3]National Cancer Center/ National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, Guangdong/CN

Introduction: Limited-stage small-cell lung cancer (LS-SCLC) accounts for approximately one third of newly diagnosed small-cell lung cancer cases. Chemoradiotherapy with/without following prophylactic cranial irradiation (PCI) serves as the standard of care for unresectable LS-SCLC, and poor clinical outcomes underscore an urgent need to develop noninvasive biomarkers for prognostic prediction. Given few studies systematically investigating circulating tumor DNA (ctDNA) applicability in LS-SCLC, our prospective study aims to evaluate the prognostic value of minimal residual disease (MRD) through ctDNA monitoring.

Methods: Patients with unresectable LS-SCLC who received 1-2 cycles of chemotherapy followed by concurrent chemoradiotherapy were prospectively enrolled. Plasma ctDNA samples were collected at multiple time points, including the baseline, after 1-2 cycles of induction chemotherapy and before thoracic radiotherapy (pre-RT), within one month after completing thoracic RT (post-RT), and on the last day of PCI (post-PCI). The MRD status integrating single nucleotide variants, copy number alterations, and fusions was identified by a next-generation sequencing panel covering 139 lung cancer-relevant genes with an average sequencing depth of approximately 30000×. Kaplan-Meier curves and log-rank tests were performed in survival analyses, with hazard ratios (HRs) and 95 % confidence intervals (CIs) estimated by Cox proportional hazards models.

Results: A total of 105 eligible patients were consecutively enrolled between June 2018 and December 2022 (median age: 59 [31-74]; male: 81.9%; stage III: 86.7%; smoker: 70.5%; median follow-up: 24.93 months). ctDNA positivity was observed in all baseline samples, and the positivity rate decreased dramatically to 54% after 1-2 cycles of chemotherapy (p=0.002). Patients with positive pre-RT ctDNA status exhibited inferior PFS (median: 14.40 months vs. 42.20 months; HR: 1.81; 95% CI: 1.07-3.05; p=0.03) and OS (median: 29.53 months vs. not reached [NR]; HR: 1.95; 95% CI: 1.02-3.74; p=0.04) to pre-RT ctDNA negative patients. Given that clearance of MRD within one month after thoracic RT was observed in 60% of patients with detectable pre-RT ctDNA, patients were classified into the pre-RT ctDNA negative (N=48), post-RT MRD clearance (N=21), or post-RT MRD sustained subgroup (N=14). Superior PFS (median: 16.53 months vs.9.70 months; HR: 0.37; 95% CI: 0.17-0.82; p=0.01) was observed in the post-RT MRD clearance subgroup in comparison to the post-RT MRD sustained subgroup, with similar result obtained in OS (median: NR vs. 22.77 months; HR: 0.26; 95% CI: 0.09-0.76; p=0.01). In contrast, no significant differences in PFS and OS were observed between the pre-RT ctDNA negative and the post-RT MRD clearance subgroups. It should be noted that of 46 MRD negative patients at post-RT, only 2 patients regained MRD positivity at the post-PCI time point confirmed disease progression soon, with 2.47 and 2.65 months preceding radiographic progression respectively, demonstrating higher recurrence risks than post-PCI MRD negative patients (log-rank p<0.001).

Conclusions: This is the first prospective study to evaluate ctDNA MRD systematically in a large LS-SCLC cohort receiving chemoradiotherapy. ctDNA-derived MRD can identify LS-SCLC with a high disease progression risk at concurrent chemoradiotherapy initiation or through longitudinal monitoring. Moreover, MRD status after PCI is useful to detect recurrence prior to radiological assessment.

MA17.07 Durvalumab Plus Anlotinib Versus Durvalumab as Maintenance Treatment in ES-SCLC (DURABLE): A Randomized, Phase 2 Trial

Department of Medical Oncology, Shanxi Province Cancer Hospital/Shanxi Hospital Affiliated to Cancer Hospital, Taiyuan/CN ,[8]Department of Thoracic Oncology, Sichuan Cancer Hospital, Chengdu/CN

Introduction: The phase 3 CASPIAN trial established durvalumab plus chemotherapy as first-line standard of care for extensive-stage small-cell lung cancer (ES-SCLC) patients. However, approaches that can boost long-term survival are still needed. Antiangiogenic therapy has the potential to alleviate immunosuppression and showed synergetic effect with immune check-point inhibitors (ICIs). Anlotinib is an oral novel anti-vascular agent, and recent study have showed that adding anlotinib into ICIs plus chemotherapy could improve patients outcomes compare with chemotherapy alone. In the DURABLE study, we aimed to assess the efficacy and safety of durvalumab plus anlotinib versus durvalumab alone as maintenance treatment for ES-SCLC patients.

Methods: This randomized, open-label, phase 2 trial was done at 5 sites in China. Eligible patients were adults (aged 18-75) ES-SCLC patients with ECOG PS 0-1. Patients with no disease progression after 4 cycles of first-line durvalumab plus platinum-etoposide were randomized to durvalumab (1500 mg, q4w) plus anlotinib (12 mg, 1-14 days, q3w) or durvalumab alone (1500 mg, q4w) until disease progression or unacceptable toxicity. The primary endpoint was PFS (from maintenance); secondary endpoints included overall survival (OS), PFS (from first dose of treatment) and safety.

Results: From December 2021 to September 2023, 66 patients were randomized to durvalumab plus anlotinib arm (n=34) or durvalumab alone arm (n=32). Baseline demographics were generally well balanced between treatment arms. At data cut-off (1st March. 2024), the median follow-up was 15.1months (range 6.8-26.9). Durvalumab plus anlotinib significantly improved PFS compared with durvalumab alone (median PFS [from maintenance]: 5.3 vs 1.9 months, HR=0.66 [80% CI: 0.46, 0.95],median PFS [from first dose of treatment]: 8.4 vs 5.6 months, HR=0.67 [80% CI: 0.46, 0.97]). Median OS for durvalumab plus anlotinib arm and durvalumab alone arm was not reached vs 12.9 months, HR 0.56 [80% CI: 0.34, 0.91]),12-month OS rates were 63.3% vs. 57.5%. Grade≥ 3 treatment-emergent adverse events (TEAEs) occurred in 17.6% patients in the durvalumab plus anlotinib arm vs.12.5% in the durvalumab alone arm, with the most common grade ≥ 3 TEAEs being hematological toxicity in both arms. TEAE leading to treatment discontinuation occurred in 2.9% patients vs. 3.1%. 17 patients remained on treatment. Further assessment is ongoing.

Conclusions: Durvalumab in combination with anlotinib as maintenance therapy demonstrated significant PFS benefit (about 3 months) and trend of improved OS compared with durvalumab alone in in ES-SCLC patients not progressed from durvalumab plus platinum-etoposide. No new safety signal was observed. Further investigation is warranted.

Introduction: Tifcemalimab (JS004 or TAB004) is a humanized IgG4 monoclonal antibody with a hinge mutation (S228P) that binds BTLA and blocks its interaction with its ligand HVEM. In an I/II study (NCT05000684) as we previously reported at 2023 ASCO Annual Meeting, tifcemalimab in combination with toripalimab (anti-PD-1) showed preliminary anti-tumor activities with a manageable safety profile in refractory extensive stage small cell lung cancer (ES-SCLC). Here, we report the updated efficacy and safety results from the intent-to-treatment population.

Methods: Patients with pathologically confirmed ES-SCLC and refractory to prior systemic therapies were enrolled. Eligible patients received 200mg tifcemalimab and 240mg toripalimab intravenously once every three weeks until disease progression, intolerable toxicity or up to 2 years of treatment. Primary endpoints included safety and objective response rate (ORR) evaluated by investigator per RECIST v1.1.

Results: From 8/27/2021 to 1/13/2023, a total of 43 patients with ES-SCLC were enrolled. As of March 14, 2024, the median follow-up duration was 11.17 months. The median age was 59.0 (range 38-75) years, and 34 (79.1%) were males. Nineteen (44.2%) patients had received ≥2 lines of prior therapies. By the data cut-off date, 39 (90.7%) patients experienced treatment-emergent adverse events (TEAEs); 17 (39.5%) experienced grade >=3 TEAEs. The most common TEAEs included anemia (25.6%), blood creatine phosphokinase increase (25.6%), alanine aminotransferase increase (23.3%), COVID-19 (23.3%), hyperglycemia (23.3%), hyponatremia (20.9%), and hypothyroidism (20.9%). Eleven (25.6%) patients experienced TEAEs led to interruption of study drugs and no TEAEs led to discontinuation of study drugs were reported. Eighteen (41.9%) patients experienced immune related AE (irAEs), and 4 (9.3%) experienced CTCAE grade >=3 irAEs. Among 43 patients, 40 were efficacy evaluable, the ORR was 32.6%, the disease control rate (DCR) was 51.2%. The duration of response was 5.7 (95%CI 2.0, 14.6) months. The median progression free survival was 2.8 (95% CI 1.4, 4.4) months, the median overall survival was 12.3 (95% CI 7.8, 15.7) months. The preliminary biomarker analysis of available tumor tissue suggested that higher ORR and DCR were observed among patients with PD-L1 or HVEM positive expression. Further biomarker analysis will be updated.

Conclusions: Tifcemalimab in combination with toripalimab showed promising antitumor activity with manageable toxicity in patients with refractory ES-SCLC. Further clinical evaluation of this combination treatment in SCLC is warranted.

MA17.09 Efficacy and Safety of Tislelizumab Plus Anlotinib and 2-Cycle Irinotecan as Second-Line Treatment for ES-Small Cell Lung Cancer(ESTAIL)

X. Chen, H. Zhang, W. Li, Y. Qu, X. Qu, R. Zhou, H. Hong, Y. Zhu, X. Chai, L. Liu, Y. Li, Oncology department ,Guangdong Hospital of Traditional Chinese Medicine, Guangzhou/CN

Introduction: Second-line treatment for ES-SCLC is mainly chemotherapy, but the efficacy needs to be improved. In recent years, immune checkpoint inhibitors and anti-angiogenic drugs have become important treatments for ES-SCLC. Herein, we hypothesis that Tislelizumab (Tis) combined with Anlotinib (Anlo) and 2-cycle Irinotecan can improve efficacy and tolerability in second-line treatment for ES-SCLC.

Methods: This is a single-arm, Phase II study (NCT05027100). Pts failed to first-line treatment with EP or EC or PD-L1 inhibitor +EP/EC are permitted. Pts are treated with Tis plus Anlo and Irinotecan for up to 2cycles, followed by Tis plus Anlo maintenance therapy. Primary endpoint was objective response rate, and second endpoints included PFS, OS, DOR, DCR and safety. The planned sample size was 32 with a historical control of 16%, an expected value of 35%, a one-sided α of 0.05, and a power of 80%, One Arm Binomial design.

Results: Between July 27,2021 and November 29,2023,32 patients were enrolled. Fifteen pts (46.9%) had stable brain metastases. There were 23 pts received first-line EP/EC treatment and 9 pts received PD-L1 inhibitor +EP/EC. As of March 1 ,2024, the median follow-up was 9.6 months. Among the 32 patients in the efficacy analysis set, the ORR was 50%, which met the primary endpoint, median DOR was 5.72 months. The median PFS was 7.1months and 6m-PFS rate was53.2% (95%CI:28.9%-72.6%). The subgroup analysis of median PFS according to first-line EP/EC or PD-L1 inhibitor +EP/EC were 8.4 months and 3 months, 6m-PFS rate were 63.5% (95%CI:33.1%-83%) and 22.2% (95%CI:0.9%-61.8%). The median overall survival was 7.5 months, The subgroup analysis of median OS according to first-line EP/EC or PD-L1+EP/EC were 9.0months and 5.6months,respectively .The median OS2 from first-line to data cutoff was 17.2months and 1y-OS2 rate was 63.9% (95%CI:42.9%-78.9%).The subgroup analysis of 1y-OS2 rate according to first-line EP/EC or PD-L1+EP/EC were 67.6% (95%CI:43.7%-83.1%) and 47.4% (95%CI:7.8%-82.3%),respectively. The overall safety was manageable, Grade 3 or higher treatment related AEs and immune-related AEs occurred in 8 patients (8/32, 25%) and 3patients (3/32, 9.3%), respectively. The most frequently reported grade 3 or higher TRAEs were hyperglycemia,thrombocytopenia and Neutropenia.

Conclusions: Tislelizumab combined with Anlotinib and 2-cycle Irinotecan as second-line Treatment for ES-SCLC demonstrated promising efficacy and safety, especially pts who failed to first-line treatment of PD-L1 inhibitor +EP/EC could benefit from it.

MA17.11 NOTCH1 Expression Is Associated with Overall Survival in Small Cell Lung Cancer Patients Treated with Atezolizumab in IMpower133

Y.S. Kim[1], B. Nabet[2], H. Chen[3], A. Chiappori[4], M. Velez[5], D. Shames[2], N. Roper[1], [1]National Cancer Institute, Bethesda/MD/USA ,[2]Genentech, San Francisco/CA/USA, [3]Washington University, St. Louis/MO/USA, [4]Moffitt Cancer Center, Tampa/FL/USA, [5]University of Rochester, Rochester/NY/USA

Introduction: Small cell lung cancer (SCLC) resists response to immune checkpoint blockade (ICB) and predictive biomarkers to guide ICB treatment in the SCLC clinic are lacking. We hypothesized major Notch pathway genes may correlate with survival with first-line ICB treated SCLC patients based on our prior work linking Notch signaling with ICB efficacy in relapsed SCLC (Roper et al. Nature Communications 2021).

Methods: We analyzed expression of major Notch signaling genes NOTCH1, NOTCH2, REST, and HES1 in relation to overall survival (OS) in the phase 3 IMpower133 extensive-stage SCLC clinical trial in which first-line atezolizumab (atezo) plus etoposide and platinum (EP) significantly improved OS (HR 0.70, 95% CI, 0.54-0.91, P = 0.007) compared to placebo (pbo) plus EP. Analysis was performed using recently defined transcriptional subsets (Nabet et al. Cancer Cell 2024): SCLC-N (NEUROD1) (31%, n=85/271), SCLC-A (ASCL1)+SCLC-I-NE (Inflamed, neuroendocrine) (47%, n=127/271), and SCLC-I-nNE (Inflamed, non-neuroendocrine) (22%, n=59/271). High and low expression were defined as greater than or equal to median or less than median expression, respectively, within each subset. Cleaved NOTCH1 (Val1744) antibody was used for immunohistochemistry (IHC).

Results: Within the SCLC-A+SCLC-I-NE subset, high NOTCH1 expression was strongly associated with OS with atezo compared to pbo (HR 0.39, 95% CI, 0.22 to 0.69; P=0.0012) whereas low NOTCH1 expression was not (HR 1.21, 95% CI, 0.67-2.18, P=0.536). Comparing treatment arms, atezo favored high NOTCH1 expression (HR 0.51; 95% CI, 0.29 to 0.88; P=0.02), while pbo favored low NOTCH1 expression (HR 2.04; 95% CI, 1.13 to 3.67; P=0.02). Within the SCLC-N subset, high NOTCH1 expression was also associated with OS with atezo compared to pbo (HR 0.44; 95% CI, 0.21-0.92; P=0.024), but low NOTCH1 expression was not (HR 0.79; 95% CI, 0.40-1.55; P=0.49). There was no difference in OS between atezo and pbo based on NOTCH2, REST, and HES1 expression. Active NOTCH1 signaling by IHC was evident across subsets in 29% (n=56/193) of SCLC tissues.

Conclusions: High NOTCH1 expression is associated with longer OS with the addition of ICB to EP in the major subsets of SCLC whereas low NOTCH1 expression is not. Our results implicate NOTCH1 as a potential predictive biomarker for ICB in SCLC.

MA17.12 Delineating the Mechanism of Resistance to Targeted Therapy via Cellular Transdifferentiation

P. Gopal, M. Abazeed, Northwestern University, Chicago/IL/USA

Introduction: Patients with oncogene-directed targetable mutations (i.e., EGFR) experience better outcomes in non-small cell lung cancers (NSCLC). Most tumors treated with targeted therapies ultimately relapse. Repeat biopsies of relapsing tumors have identified a phenomenon, referred to as cellular transdifferentiation. A subset of NSCLC tumors, lung adenocarcinomas (LUADs) upon treatment with targeted therapy, transdifferentiate into small cell lung cancer (t-SCLC). As more selective and potent targeted therapies for LUAD enter the clinic, including anti-Ras therapies, this phenomenon takes on even greater significance. Survival after neuroendocrine transdifferentiation is poor since targeted therapies are not effective against high-grade neuroendocrine tumors. However, the mechanisms of transdifferentiation from one cancer type to another remain very poorly understood.

Methods: We have combined patient derived xenografts (PDX) and PDX-derived ex vivo lines with multi-omic characterization, high-content image-based morphometry and fluorescence tracking, and single-cell barcode tracing to better understand the process of lung tumor transdifferentiation.

Results: We have developed a first-of-its-kind t-SCLC model that reconstitutes in real-time (in ex vivo culture) LUAD to SCLC transdifferentiation. Genomic and transcriptomic analyses of our NSCLC PDX collection identified multiple tumors with mutations in TP53 and RB1, two genes that are biallelically altered in virtually all de novo SCLCs. PDX sample CBX336 and CBX282 have been identified as having mutations in both TP53 and RB1, in addition to expressing the KRASG12C oncogene. Upon treatment with Sotorasib, tumors initially demonstrated slow tumor growth. This was followed by a dramatic increase in the growth trajectory after prolonged drug exposure. We characterized the resultant resistant tumors and showed that they contained expression of canonical markers of the neuroendocrine lineage, including NEUROD1. We show that in CBX336 the t-SCLC that emerges has high levels of NEUROD1 expression. Immunohistochemical (IHC) characterization revealed evidence of histological transformation to a NeuroD1-expressing SCLC. Our experimental (fluorescence tracking) and computational data suggest a synchronized procession toward transdifferentiation with the upregulation of the neuroendocrine transcription factor NEUROD1.Our experimental and computational data suggest a highly coordinated procession toward transdifferentiation with the parallel upregulation of the neuroendocrine transcription factor NEUROD1 across numerous epithelial cellular clones.

Conclusions: We have developed a new experimental system and framework for the study of lung t-SCLC at the single-cell level. Ongoing work includes the integration of new resources to study lineage reprogramming, the regulation of transdifferentiation by the cancer genome, and advancing new therapeutic strategies that combat plasticity by deploying unique drug combinatorial strategies.

MA17.13 DLL3-targeted CAR-T Therapy of Small Cell Lung Cancer Utilizing Circular RNA

J. Cai[1], M. Sun[2], M. Qiu[1,3,4], [1]Peking University Peoples' Hospital, Beijing/CN ,[2]The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou/CN ,[3]Peking University People's Hospital, Beijing/CN ,[4]Peking University, Beijing/CN

Introduction: The survival of small cell lung cancer (SCLC) is discouraging, necessitating the development of novel targets and effective therapeutic approaches. Delta-Like Ligand 3 (DLL3) represents a promising target for the treatment of SCLC, with ongoing vigorous therapeutic strategies. Here, we report DLL3-targeted CAR-T therapy constructed by circular RNA (circRNA), yielding promising therapeutic results of treating SCLC.

Methods: Circular RNAs (circRNAs) are covalently closed single-stranded RNAs that are resistant to exonuclease-mediated degradation. Compared with linear mRNA, circular RNA is more stable and efficient as translate templates, thus circRNA has been considered as "the next generation" of mRNA. By splicing CVB3 IRES into 2 parts, we developed a new Group I permuted intron-exon (PIE) self-splicing system (named NeoAna) for in vitro circRNA synthesis. Thus, circRNA transcripts encoding the DLL3-targeted CAR structure were synthesized with the NeoAna platform. By employing electroporation, DLL3-targeted CAR-T cells were constructed directly using T cells from healthy volunteers.

Results: We have previously reported a highly efficient TREM1/DAP12-based novel multiple-chain CAR structure. In current study, we successfully synthesized and validated the feasibility of circRNA encoding DLL3-targeted CAR. Through comparative comparison with messenger RNA (mRNA), we observed distinct advantages of circRNA, particularly in terms of stability and sustained DLL3 CAR expression. Moreover, we fine-tuned the electroporation conditions and RNA dosage, achieving a CAR-T positivity rate of approximately 47%. Subsequent in vitro co-culture experiments revealed the potent cytotoxicity of CAR-T cells against SCLC cells, with ELISA and RT-PCR analyses providing further validation. Lastly, using mice subcutaneous, orthotopic, and metastatic models, we demonstrated the efficacy of circRNA-based CAR-T therapy in SCLC tumor eradication, significantly extending survival.

Conclusions: Leveraging electroporation and circRNA, we have effectively engineered DLL3-targeted CAR-T cells with effective cytotoxicity against SCLC. This research offers a promising avenue for advancing SCLC therapeutics.

MA18.03 Participant Eligibility for Lung Cancer Screening in Australia: An Analysis of Proposed Criteria

C. Kumarasamy[1], K. Betts[1], R. Norman[1], A. McWilliams[2], E. Stone[3], D.C-L. Lam[4], R. Manser[5], P. Fogarty[6], H. Marshall[7], S. Lam[8], M.C. Tammemägi[9], K.M. Fong[7], S. Atkar-Khattra[8], F. Brims[1], [1]Curtin University, Perth/AU ,[2]Fiona Stanley Hospital, Nedlands/AU ,[3]St Vincent's Hospital Sydney, Sydney/AU ,[4]The University of Hong Kong, Hong Kong SAR/CN ,[5]Royal Melbourne Hospital, Melbourne/AU ,[6]Epworth Internal Medicine Clinical Institute, Melbourne/AU ,[7]The Prince Charles Hospital, Brisbane/AU ,[8]BC Cancer, Vancouver/BC/CA ,[9]Brock University, St Catharines/ON/CA

Introduction: Eligibility for the proposed Australian National Lung Cancer Screening Program (NLCSP) is based around categorical smoking and tobacco exposure recommendations from the Medical Services Advisory Committee (MSAC). Canadian provinces have adopted screening using PLCOm2012 risk model, with UK adopting a combination of the PLCOm2012 and LLPv2 risk models. The aim of this study was to investigate the proportion of International Lung Screening Trial (ILST) participants who could have been eligible, and lung cancers that would have been detected, by the MSAC criteria in an Australian NLCSP setting.

Methods: All individuals between 50-80 years of age, who underwent baseline eligibility assessment under the ILST were included (regardless of screening enrolment). This included participants from Canada, Australia and Hong Kong. Eligibility under MSAC criteria (aged 50-70 years; ≥30 pack-years, ≤10 years since cessation) were compared against USPSTF2021 (aged 50-80 years, ≥20 pack-years, ≤15 years since cessation) criteria and the PLCOm2012 and LLPv2 risk models at ≥1.51%, 6 year-risk and ≥2.5%, 5-year risk thresholds, respectively.

Results: A total of 9,725 participants were included (of which 4,053 were eventually enrolled in ILST). The cohort was 48% (n=4,670) female, with the majority having quit smoking (61.7%, n=5,997). The median (IQR) age was 63 (59-69) years, with a mean smoking duration and quit time of 34.9 and 17.2 years, respectively. 173 lung cancers were detected in total.

Regarding eligibility, the USPSTF2021 criteria selected the largest proportion of participants (59%, n=5,761), followed by PLCOm2012 (54%, n=5,223) and LLPv2 (49%, n=4,759), with MSAC criteria selecting the least (37%, n=3,612; see Figure 1).

For detected lung cancers, the PLCOm2012 model identified the largest proportion (92%, n=159), while MSAC criteria identified half the cases (52%, n=90). The USPSTF2021 and the LLPv2 identified 83% (n=143) and 78% (n=134) of lung cancers, respectively.

The MSAC criteria demonstrated poor sensitivity (0.52, 95%CI 0.44-0.60), when compared to USPSTF2021 (0.83, 95%CI 0.76-0.88) criteria, and LLPv2 (0.77, 95%CI 0.7-0.83) and PLCOm2012 (0.92, 95%CI 0.87-0.96) risk models, at selected thresholds.

Conclusions: Compared to other selection criteria and risk-prediction models for assessment of lung cancer screening eligibility, the proposed MSAC criteria lacks sensitivity. Under MSAC criteria fewer individuals are eligible and fewer lung cancers would be detected. Continuing evaluation of MSAC optimal selection criteria for the Australian NLCSP will be required after establishment in 2025.

MA18.04 Evaluating Early-Stage Lung Cancer Survival Based on Age and Morbidity to Inform the Upper Age Limit for Screening

M.T. Warkentin[1], E. Vakil[1], E.L.R. Bedard[2], W.Y. Cheung[1], D.R. Brenner[1], A. Tremblay[1], [1]University of Calgary, Calgary/AB/CA ,[2]University of Alberta, Edmonton/AB/CA

Introduction: Lung cancer is the leading cause of cancer-related mortality globally. Older individuals have an elevated lung cancer risk, but those with significant comorbidities also have greater competing risks for mortality. This could preclude curative treatment options and reduce the survival benefits of screening. The objective of this study was to inform the upper age limit for lung cancer screening by assessing early-stage lung cancer survival based on comorbidities and fitness for surgery.

Methods: We used the Alberta Cancer Registry (ACR) to identify all lung cancers diagnosed in Alberta, Canada between 2010 and 2020. Only early stage (I or II) lung cancers were included. We defined five age groups based on the following categories: <70, 70-74, 75-79, 80-84, and 85+. Overall survival was based on the time from the date of lung cancer diagnosis until the date of death (any cause) or a censoring date based on the last known date of follow-up. We estimated overall survival using the Kaplan-Meier method. We present the five-year overall survival with 95% confidence intervals (CI) for each age group and sex and stratified by Charlson Comorbidity Index and receipt of surgery.

Results: There were 6,401 patients with early-stage lung cancers (71% stage I, 29% stage II) in the ACR between 2010 and 2020, of which 43% and 57% were among males and females, respectively. For females, the five-year survival was 54.7% (CI: 50.6-58.8), 47.2% (CI: 42.7-51.7) and 33.7% (CI: 28.4-38.9) for ages 70-74, 75-79, and 80-84, respectively. For males, five-year survival was 47.7% (CI: 43.1-52.3), 38.0% (CI:33.2-42.8), and 24.2% (CI: 19.2-29.3) for ages 70-74, 75-79 and 80-84, respectively. Across all age groups, the five-year survival was higher for those with fewer comorbidities and who received surgery as part of their treatment strategy (Figure 1). Five-year survival for males and females ages 75-79 and 80-84 was still high and may suggest that lung cancer screening among selected individuals in these age groups may confer substantial survival benefit.

Conclusions: Some older age patients have reasonable survival and may still benefit from screening despite being ineligible according to most guidelines. Application of upper age limits to lung cancer screening should consider comorbidity and fitness for surgery since these can significantly influence the survival benefit derived from early detection. The criticisms of risk-based approaches for preferentially selecting older individuals for screening may only be warranted among those with significant comorbidities that would limit their survival benefit.

MA18.05 Effectiveness of NELSON vs PLCOm2012 Lung Cancer Screening Eligibility Criteria: Final Analysis of the Prospective German HANSE Study

J. Vogel-Claussen[1], B. Bollmann[1], K. May[2], S. Stiebeler[3], S. Dettmer[1], A. Faron[3], A. Kuhlmann[4], G. Schmid-Bindert[5], R. Kaaks[6], J. Barkhausen[2], S. Bohnet[2], M. Reck[7], [1]Hannover Medical School, Hannover/DE ,[2]UNIVERSITÄTSKLINIKUM Schleswig-Holstein Campus Lübeck, Lübeck/DE ,[3]Radiologische Allianz GbR, Grosshansdorf/DE ,[4]Universitätsmedizin Halle, Hannover/DE ,[5]Medizinische Fakultät Mannheim, Universität Heidelberg, Mannheim/DE ,[6]Deutsches Krebsforschungszentrum, Heidelberg/DE, [7]Lungeenclinic Grosshansdorf, Grosshansdorf/DE

Introduction: Lung cancer is a major health problem. CT lung screening can reduce lung cancer mortality through early diagnosis. Retrospective analyses and one prospective trial using the USPSTF2013 criteria suggest that identifying individuals for screening by accurate prediction models is more efficient than using categorical age-smoking criteria. This study prospectively compared the effectiveness of the Netherlands Leuvens Longkanker Screenings Onderzoek (NELSON) and PLCOm2012 model eligibility criteria.

Methods: In this prospective northern German cohort study (HANSE), participants, aged 55-79 years, who were current or former smokers and who met either NELSON risk criteria (smoking quit time ≤10 years, >15 cigarettes/day for >25 years or >10 cigarettes/day for >30 years) or a PLCOm2012 risk threshold of at least 1.58% within 6 years of screening, were recruited from 3 certified lung cancer sites (Hannover, Grosshansdorf, Lübeck) and received baseline and one year follow-up low-dose CT screening (Rofo. 2022 Dec;194(12):1333-1345). Main outcome was the comparison of the positive predictive values (PPV) for lung cancers detected in PLCO m2012-selected vs. NELSON-selected high-risk groups. For testing the null hypothesis of equal PPVs for lung cancer detected in PLCOm2012-selected versus NELSON-selected individuals, the weighted generalized score statistic by Kosinski was used (ClinicalTrials.gov, NCT04913155).

Results: The cancer detection rate of participants with lung cancer was significantly higher using the >1.58 % at 6 years of PLCOm2012 risk score compared to the NELSON inclusion criteria (108 [97.3%] of 111 individuals vs 85 [76.6%] individuals; p<0.0001). When the sample was supplemented with the low risk population, who did not meet the high-risk criteria and consented to participate in the HANSE study (n=7463), the calculated lung cancer detection rates (sensitivity) of the NELSON criteria and the PLCOm2012 threshold of >1.58% at 6 years were 60.7 % and 77.1%, respectively. Accordingly, the HANSE study showed a 19.4% relative increase of the PPV for screen detected lung cancers in the PLCOm2012-selected group (PPV=108/4167 [2.59%] compared to the NELSON-selected group (PPV=85/3916 [2.17%], p=0.004). After adjusting the PLCOm2012 risk score cutoff to > 1.68 % at 6 years to achieve equal sized groups the specificity values were not significantly different (69.4% vs 69.6%, p=0.68), while sensitivity remained significantly higher (106/109, [97.3%]) and PPV even increased to 106/ 3916 (2.71%, relative difference 24.7%) in the PLCOm2012 risk vs the NELSON criteria group. Cumulative estimated life expectancies from baseline for those subsequently diagnosed with lung cancer were higher in those who had PLCOm2012 risk of > 1.68 % at 6 years than in individuals who were NELSON-positive (1650.3 years vs 1405.5 years; difference 244.8 years, p=0.021). Despite no differences in the PLCOm2012 score (p=0.44), a significant higher rate of lung cancer was detected in females (2.63%) vs. males (1.78%, p=0.04) in the high-risk HANSE cohort.

Conclusions: PLCOm2012 is reliable and more efficient than the NELSON criteria for selecting individuals to be enrolled into a lung cancer-screening program and should be used for identifying high-risk individuals based on the results of the HANSE Study. Further research adjusting risk scores for gender should be considered.

MA18.07 Missing Variables and the Utility of Lung Cancer and Lung Nodule Risk Calculators

W. Liao[1], A.T. Matthews[2], J.U. Goss[1], T.U. Qureshi[1], S.U. Peppers[1], A.U. Harris[1], A.U. Porter[1], K.U. Dortch[1], C. Fehnel[1], K. Tonkin[3], M.A. Ray[4], A. Mehrotra[3], S. Ely[5], M.P. Smeltzer[4], R.U. Osarogiagbon[1], [1]Baptist Cancer Center, Memphis/TN/USA ,[2]Baptist Memorial Health Care, Memphis/TN/USA ,[3]Baptist Memorial Hospital, Memphis/TN/USA ,[4]University of Memphis, Memphis/TN/USA ,[5]George Washington University, Washington/DC/USA

Introduction: Early lung cancer detection depends on screening healthy high-risk individuals, and assessing the malignancy probability of lung nodules (LNs). Validated risk calculators help identify candidates for lung cancer screening (LCS), and triage individuals with LNs. We evaluated variables required in three LCS, and two LN malignancy risk calculators, to assess the feasibility of using natural language searches to automate their use.

Methods: We analyzed a prospective observational LCS and incidental LN program (P) database abstracted from routinely generated clinical records. Using information at initial enrollment, we evaluated the availability of component variables for three LCS risk calculators- PLCOm2012, Lung Cancer Death Risk Assessment Tool (LCDRAT), and the Bach model- and two LN malignancy risk calculators- the Brock University and Solitary Pulmonary Nodule Malignancy Risk (Herder) models. The three LCS risk calculators were examined in all LCS patients and LNP enrollees age-eligible for LCS; the two LN risk calculators were examined in all LNP enrollees and LCS patients with Lung-RADS 2 - 4 (indicating presence of a lung lesion).

Results: From 2015 to 2023, 13,823 and 29,712 persons were enrolled into LCS and LNP. Among the LCS cohort, 8,576 (62%) had a Lung-RADS score of 2 or greater; 20,507 (69%) of LNP enrollees met age criteria for LCS. Overall, 1,328 (9.61%), 1,325 (9.59%), and 3,926 (28.4%) of LCS enrollees had all variables needed for the PLCOm2012, LCDRAT and Bach models, respectively; 137 (0.46%) and 1,491 (5.02%) of LNP enrollees had all variables needed for the Brock and Herder models, respectively. Missing information on education and family history of lung cancer impaired use of the PLCOm2012 and LCDRAT; the Bach Model suffered less than 10% missing data. Missing data on nodule attenuation (85%) and edge characteristics (93%) impaired use of the Brock and Herder models. Among the LNP cohort age-eligible for LCS, 2,414 (11.77%), 2,414 (11.77%) and 10792 (52.63%) had all the variables needed to use the PLCOm2012, LCDRAT and Bach models, respectively; among the LCS cohort with Lung-RADS 2-4, 949 (11.07%) and 1,636 (19.08%) had all the variables needed to use the Brock and Herder models, respectively (Table).

Conclusions: Although validated risk calculators can be useful in triaging patients into risk-based pathways of care, they require variables not routinely provided during care delivery, limiting their practical utility. Key nodule descriptors were most frequently missing from radiology reports, likely preventing the automation of their use for natural language processing algorithms.

MA18 NEW PARADIGMS IN LUNG CANCER SCREENING
TUESDAY, SEPTEMBER 10, 2024 - 15:00 - 16:15

MA18.08 Risk and Timing of Second Primary Lung Cancer Among Young Women with a History of Breast Cancer in the United States

A. Potter[1], P. Senthil[1], D. Srinivasan[1], C. Haridas[1], L. Martin[2], C-F.J. Yang[1], [1]Massachusetts General Hospital, Boston/MA/USA ,[2]University of Virginia, School of Medicine, Charlottesville/VA/USA

Introduction: Young women with a history of breast cancer may benefit from lung cancer screening, despite not meeting requisite age or smoking pack-year eligibility criteria. However, the risk of lung cancer diagnosed among young women with a history of breast cancer has never been studied. Our objective was to evaluate the incidence, timing, and predictors of lung cancer diagnosed among young women with a history of breast cancer.

Methods: Women aged <50 years diagnosed with breast cancer from 2000-2018 in the Surveillance Epidemiology End Results database were identified for analysis. The incidence of primary lung cancer among women in the study cohort was compared to the incidence of primary lung cancer among an age, sex, race, and calendar year-matched cohort in the general U.S. population using standardized incidence ratios. Patterns in the time from breast cancer diagnosis to lung cancer diagnosis were examined. Fine-Gray competing risks regression was used to identify predictors of an increased risk of primary lung cancer among young women in the study cohort. Five-year survival after lung cancer diagnosis was examined by stage using the Kaplan-Meier method.

Results: From 2000-2018, 891 women aged <50 diagnosed with breast cancer developed lung cancer. The incidence of lung cancer among young women with a prior breast cancer diagnosis, compared to young women in the general population, was significantly elevated for 5 years after breast cancer diagnosis (Figure). The median time from breast cancer to lung cancer diagnosis was 6.58 (IQR: 2.83-11.0) years. Of lung cancers diagnosed, the stage distribution was 27% stage I, 7% stage II, 23% stage III, and 43% stage IV. There were disparities in the stage of lung cancer diagnosed, and 55% of Black women were diagnosed with stage IV disease compared to 42% of White women. Predictors of increased risk of lung cancer included older age and patients living in rural compared to urban regions. Five-year survival from the date of diagnosis of stage I, II, III, and IV lung cancer was 77%, 61%, 34%, and 9%, respectively.

Conclusions: Young women diagnosed with breast cancer had a significantly increased risk of developing primary lung cancer. Over 40% of lung cancers were diagnosed at stage IV when five-year survival was 9%. These findings suggest the need to explore the possibility of lung cancer screening in this patient population, especially among women whose demographic and tumor characteristics are associated with highest risk of second primary lung cancer.

MA18.09 Comparing Efficient Lung Cancer Screening Strategies for Black and White Americans

S. Skolnick[1], P. Cao[2], J. Jeon[1], R. Meza[3],[4], [1]University of Michigan, Ann Arbor/MI/USA ,[2]MD Anderson Cancer Center, Houston/TX/USA ,[3]BC Cancer Research Institute, Vancouver/BC/CA ,[4]University of British Columbia, Vancouver/BC/CA

Introduction: In 2021, the United States Preventative Services Task Force (USPSTF) updated their lung cancer screening guidelines, in part, to address documented disparities in eligibility. Black individuals are proportionally less eligible for screening compared to their White counterparts, despite having higher lung cancer risk. It is thus critical to assess the relative effectiveness of current and alternative lung screening strategies for Black individuals using race-specific data and analyses.

Methods: We used a well-validated microsimulation model of the natural history of lung cancer, CISNET MichiganLung, to evaluate screening strategies by race and identify and compare optimal strategies for the US Black and White populations. The CISNET MichiganLung model was originally developed for the whole US population, so it was adapted to the Black and White sub-populations. For both populations, we evaluated a range of screening scenarios with varying factors such as age at start and stop of screening and pack-year history. We then assessed life years gained, lung cancer deaths averted, screening harms, such as false positive screens and overdiagnosis, and identified efficient screening scenarios for Black and White Americans. Efficient scenarios were those that had the highest life years gained and/or lung cancer deaths averted for a given number of screens.

Results: Overall, efficient screening strategies for Black Americans were less restrictive (lower starting age and fewer packyears required) compared to those for White Americans. The 2021 USPSTF guidelines were found to be efficient for both populations, but the 2013 recommendations were efficient only for White Americans. Regardless, current and previous USPSTF screening recommendations appear to be substantially more beneficial for White than for Black Americans.

Conclusions: Our results suggest that screening strategies that are efficient for Black Americans are different from those for White Americans. Race-specific guidelines might be needed with a lower packyear threshold for eligibility for Black individuals.

MA18.11 The Evolution of the Lung Screening Network: Uniting to Strengthen Community and Share Best Practices Among Navigators

L. Dowling[1], D. Wojcik[1,2], J. Aversano[1,3], S. Moffat[1,4], A. Lally[1,5], [1]Lung Screening Network, Chicago/IL/USA ,[2]Northwestern Memorial Hospital, Chicago/IL/USA ,[3]Endeavor Health, Arlington Heights/IL/USA ,[4]Advocate Health, Libertyville/IL/USA ,[5]Rush University System for Health, Chicago/IL/USA

Introduction: Lung cancer is the leading cancer of cancer mortality accounting for about 20% of cancer deaths1. The United States Preventive Services Task Force3 and Centers for Medicare and Medicaid Services2 approved coverage of lung cancer screening (LCS) following the National Lung Cancer Screening Trial, which demonstrated that LCS reduces lung cancer mortality3. Following these approvals, healthcare organizations began to develop LCS programs with navigators assuming these roles without formal education or training on LCS. A LCS navigator from Chicago, Illinois observed that in healthcare institutions, a single navigator was responsible for coordination of all care and education in this new position. She recognized an opportunity to locally collaborate and network which prompted the convening of an October 2019 in-person meeting of navigators to discuss their respective LCS programs. At that initial meeting, navigators working for competing healthcare organizations voiced the need to share and learn from each other. From there, the Lung Screening Network (LSN) was founded. Its mission was to create a consortium of professionals involved in LCS to strengthen individual programs and bring greater awareness to the emerging discipline of LCS.

Methods: Broad use of virtual platforms during the Covid-19 pandemic allowed for the first virtual LSN meeting in late 2020. The LSN has since continued to meet virtually every other month. A steering committee comprised of five navigators with over 30 years combined screening experience was established to lead the LSN. The committee meets at least twice per month focusing on delivering relevant best practices and educational content at every LSN meeting.

Results: Growth: LSN Member Volumes by Year: 2019: 27; 2020: 54; 2021: 83; 2022: 106; 2023: 122; LSN Member Geographic Reach: 2019: Illinois, Indiana; 2024: Illinois, Arizona, California, Iowa, Indiana, Kentucky, Michigan, North Carolina, New Jersey, Wisconsin, Georgia, United Kingdom, US Partners with national reach Advocacy and Community: Prior to updated LCS guidelines in 2021, 18 LSN members representing nearly 100,000 LCS exams submitted commentary to CMS endorsing expansion of LCS eligibility criteria. Partnerships: National Lung Cancer Round Table, American College of Radiology, American Lung Association, GO2 Foundation for Lung Cancer Focus on LCS Navigator Needs: LSN members completed a survey in 2023 to understand the LSN audience and to provide meaningful content and support. The results include: 64% from the LSN home state of Illinois. 25% of programs began in 2015 while 21% began in 2020 or later. 70% are nurse navigators, 60% have responsibilities beyond LCS. Members requested further support in retention, communication, and data management.

Conclusions: The LSN adds value to LCS navigators as evidenced by growth, increased advocacy, and the need to address common issues among diverse programs. Currently, the LSN committee volunteers time and uses platforms borrowed from healthcare systems to plan and host meetings. The group continues to evolve with limited infrastructure or monetary support. Future considerations include exploring new opportunities for LSN growth and navigator support.

MA18.12 Innovations in Lung Cancer Screening: Adoption of the Pink and Pearl Campaign

A. Lally, M. Skoczynski, P. Shah, L. Stempel, G. Alex, A. Madrigano, N. Geissen, Rush University Medical Center, Chicago/IL/USA

Introduction: Lung cancer is an often-overlooked women's health concern. According to the American Lung Association, only 8% of adults recognize lung cancer as the #1 cancer killer of women. Lung cancer screening (LCS) is the only approved method for screening patients identified as high risk for lung cancer; however, LCS faces distinctive barriers including complicated eligibility criteria, lack of awareness, and stigma. In the United States roughly 80% of women eligible for mammography complete the recommended screening, while only 7% of people eligible for LCS complete screening. Tennessee's Department of Health launched the first Pink and Pearl Campaign to raise awareness for breast and lung cancer screening, simultaneously. Building upon this initiative, our institution tailored and implemented a similar campaign to identify patients undergoing mammography who might also qualify for LCS. Our campaign's objective is to identify, educate, and facilitate LCS among women already engaged in preventative care mammography.

Methods: Our multidisciplinary team, consisting of thoracic surgeons, primary care providers, radiologists, and breast surgeons, led by a LCS nurse navigator convened to plan and implement Pink and Pearl. Several in-person and virtual patient and provider facing educational events were held during the months of October and November 2023, which respectively coincided with Breast Cancer Awareness Month and Lung Cancer Awareness Month. These events were promoted internally via email, fliers, and posters. A continuous outreach program was developed to directly target women undergoing mammography. An existing screening tool routinely completed at mammogram appointments was modified to identify patients that may be eligible for LCS. Patients identified were contacted by lung screening nurse navigators to facilitate LCS. The navigators assessed LCS eligibility, discussed shared decision-making including tobacco cessation, and facilitated ordering LCS with the patient's primary care provider. Eligibility status, eligible patient follow-up plan, and reason for ineligibility were recorded by the navigators.

Results: 8 total events were hosted during October and November 2023. Format: 6 in person, 2 virtual; Audience: 4 patients, 1 healthcare providers, 3 both. Over a 5-month period, 225 patients were identified to receive outreach by LCS nurse navigators. 65 Not reached, 36 Ineligible for LCS, 124 Eligible for LCS: 56 Already enrolled in a LCS program, 27 Declined LCS, 41 LCS Orders requested.

Conclusions: Utilizing a multidisciplinary approach to target at risk patient populations already engaged in preventive care is an effective method for healthcare institutions to try to increase LCS rates. It is important to consider the complicated and inconsistent guidelines for LCS that will likely contribute to the persistent low uptake of LCS.

MA18.13 Comparison of Sybil with Brock and PLCOm2012 Models Among Screening Participants with Positive and Negative Baseline Screens

R. Meza[1,2], C. Durney[1], Y. Mok[1], S. Atkar-Khattra[1], R. Phellan Aro[3], M.T. Warkentin[4], M. Tammemagi[5], R. Myers[1,2], R.J. Hung[3], S. Lam[1], [1]BC Cancer Research Institute, Vancouver/BC/CA ,[2]University of British Columbia, Vancouver/BC/CA ,[3]Lunenfeld-Tanenbaum Research Institute, Sinai Health, Toronto/ON/CA ,[4]University of Calgary, Calgary/AB/CA ,[5]Brock University, St. Catharines/ON/CA

Introduction: There is growing interest in using artificial intelligence (AI) decision-support tools to enhance lung cancer risk prediction. A deep learning model (Sybil) has been proposed to predict future lung cancer risk for up to six years from a single low-dose computed tomography (LDCT) to personalize lung cancer screening. The ability to accurately stratify screen participants with lower risk who can have their next screening or surveillance CT in 2 to 6 years has significant implications for health care resource utilization, radiation exposure and costs. The purpose of our study is to evaluate the performance of Sybil versus the International Lung Screening Trial (ILST) protocol, where participants with no nodules detected on the first LDCT or with nodules with <1.5% lung cancer probability based on the Brock malignancy score (PanCan model) were triaged to have their next LDCT in 24 months (71% of the entire screened cohort belong to this negative screen category with 0.19% of them diagnosed with lung cancer within 24 months).

Methods: Baseline LDCTs from the ILST Vancouver (N=2121) and the Pan-Canadian Early Detection of Lung Cancer Study (PanCan, N=2192) were analyzed with Sybil. The performance of Sybil was compared with the PLCOm2012 lung cancer risk prediction model for individuals with no nodules or with nodules <1.5% Brock lung cancer probability (termed here as negative screens). We also compare the performance of Sybil versus the Brock model in participants with lung nodules with lung cancer probability greater than 1.5%. Model performance was assessed using the area under (AUC) the receiver-operating-characteristic (ROC) curve.

Results: Among patients with negative screens, PLCOm2012 performed better with AUCs of 0.760 in ILST versus 0.59 for Sybil (Figure 1). The Brock model and Sybil had similar performance in patients with lung nodules with malignancy risk >1.5%. The AUCs were 0.786 and 0.796 for Brock and Sybil respectively. Similar results were obtained when the comparisons were performed using the PanCan dataset (AUCs 0.633 in PanCan, 0.560 for Sybil in the negative screens; 0.753 in PanCan versus 0.743 in Sybil for scans with nodule malignancy risk scores >1.5%). The performance of all models improved after recalibration with additional smoking covariates.

Conclusions: The performance of AI tools needs to be compared with existing lung cancer risk prediction tools using cohorts with adequate follow-up and known outcomes before prospective evaluation in clinical settings.

MA19.03 SMARCA4 Controls State Plasticity in SCLC Through Regulation of Neuroendocrine Transcription Factors and REST Splicing

E. Redin[1], H. Sridhar[1], Y. Zhan[2], B. Pereira Mello[1], H. Zhong[1], P. Manoj[1], I. Linkov[3], J. Qiu[4], R.P. Koche[2], E. de Stanchina[4], A. Quintanal-Villalonga[1], C.M. Rudin[1,5], [1]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]Center for Epigenetics Research, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[3]Precision Pathology Center, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[4]Antitumor Assessment Core, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[5]Weill Cornell Medicine Graduate School of Medical Sciences, New York/NY/USA

Introduction: Small Cell Lung Cancer (SCLC) accounts for 15% of all lung cancer cases and is classified into transcriptional subtypes with distinct degrees of neuroendocrine (NE) differentiation. The majority (~75%) of SCLC tumors, including those of the SCLC-A (ASCL1+) and -N (NEUROD1+) subtypes, exhibit a high-NE profile. Recent evidence supports plasticity among subtypes with a bias toward adoption of low-NE states during disease progression or upon acquired chemotherapy resistance. Notably, the regulators involved in SCLC subtype switching have not been fully defined. Pharmacologically tractable targets to constrain subtype plasticity in SCLC could have substantial clinical utility. Here, we evaluated the role of SMARCA4, the catalytic subunit of the SWI/SNF complex, in tumor plasticity and as a therapeutic target in SCLC.

Methods: SMARCA4 expression levels were assessed at the CCLE and public patient databases. ATACseq and RNAseq experiments were performed in SCLC cells after treatment with FHD-286, a SMARCA4/2 dual ATPase inhibitor. DNA binding profile of SMARCA4 was characterized by ChIPseq in high-NE SCLC Patient Derived Xenografts (PDXs). Combination of FHD-286 and afatinib was tested in vitro and in a set of chemo-resistant SCLC PDXs in vivo.

Results: SMARCA4 expression positively correlates with NE genes in both SCLC cell lines and patient databases. Pharmacological inhibition of SMARCA4 with FHD-286 induces the loss of NE features and downregulates neuroendocrine and neuronal signaling pathways while activating non-NE factors. Mechanistically, SMARCA4 binds to the promoter of the NE-lineage transcription factors ASCL1 and NEUROD1, and to other NE genes, including SYP, FOXA1, FOXA2, INSM1, CHGA and DLL3. Enrichment analysis of high-confidence SMARCA4 targets, identified by integrating ChIPseq and RNAseq data, revealed neuron related pathways among the top GO Biological processes regulated by SMARCA4 in SCLC. Additionally, ATAC-seq experiments showed that SMARCA4 inactivation alters chromatin accessibility, predominantly at enhancer regions, to suppress NE programs. In parallel, SMARCA4 also controls REST, a known suppressor of the NE phenotype. We found that the RNA splicing factor of REST, SRRM4, is only expressed in tumor types with both high SMARCA4 and NE/neuronal features. Interestingly, SMARCA4 binds to the transcription starting site of SRRM4 and promotes the splicing of REST into the inactive neuron-specific isoform, REST4, to sustain the NE state in SCLC. Furthermore, SMARCA4 inhibition with FHD-286 inhibits the proliferation of SCLC NE cells at nanomolar doses (median IC50=90). Pharmacological inhibition of SMARCA4 drives the activation of ERBB and Neuroregulin-1 (NRG1) pathways by upregulating the expression of ERBB family members and subsequent downstream targets ERK and AKT. FHD-286 in combination with the pan-ERBB inhibitor, afatinib, demonstrates strong synergy in SCLC cell lines and induces greater cell death relative to single agent treatments. Dual targeting of SMARCA4 and ERBBs also exhibits a potent anti-tumor effect on chemo-resistant SCLC PDXs.

Conclusions: In summary we provide evidence for a critical role of SMARCA4 as a key regulator of the NE phenotype, as well as a potential therapeutic target for the treatment of SCLC.

MA19.04 Teriflunomide in Vitro or Leflunomide in Vivo Treatment Increases the Efficacy of Lurbinectedin in SCLC

T. Mirzapoiazova, L. Tseng, I. Mambetsariev, H. Li, B. Armstrong, S. Singhal, P. Kulkarni, R. Salgia, City of Hope National Medical Center, Duarte/CA/USA

Introduction: Inhibition of transcription is one of the strategies for targeting SCLC. Lurbinectedin is a selective inhibitor of RNA pol II, which is commonly hyperactivated in SCLC. Lurbinectedin has shown promise in treating SCLC patients after failure to first-line systemic therapy (Dumoulin et. al, 2022). Nevertheless, the 5-year survival rate remains around 6% (Koinis et. al, 2016). Previous studies have shown that Teriflunomide and Leflunomide have potent anticancer effects on human bladder cancer and NSCLC cells (Cheng et. Al, 2020; Jiang et. Al, 2018). We hypothesized that treatment with Leflunomide or a combination of Teriflunomide and Lurbinectedin can be a novel therapeutic approach to treat SCLC.

Methods: SBC3 and H446 SCLC cells were used for spheroid formation. LDH assay was used to detect drug cytotoxicity effect. Immunoblotting was performed to evaluate drug-induced cellular damage. Mitochondrial dysfunction of the spheroids was assessed by MitoSOX and ATP assays. Immunofluorescent staining and confocal microscopy were used to quantify spheroid mitochondria. RNA-seq analysis of spheroids was performed after Teriflunomide/Lurbinectedin treatment. Xenograft study was performed to test therapeutic efficacy of the Leflunomide/Lurbinectedin combination.

Results: Treatment of SBC3 spheroids with Teriflunomide/Lurbinectedin low-dose combination synergistically inhibited spheroid viability. The combination of Teriflunomide/Lurbinectedin inhibited RNA pol II activity and increased the levels of proteins related to DNA damage and replication stress. The expression of MDM2, p21, and E2F1 proteins, which are regulators of p53 and cell cycle associated cyclins, was downregulated upon combination treatment. Combination treatment also induced an increase of mitochondrial superoxide and decreased ATP production. Moreover, the combination treatment significantly decreased the level of round mitochondria and was associated with inhibition of mitochondrial fission DRP1 protein. RNA-seq results indicated a robust effect of combination treatment on critical cancer pathways in the SCLC spheroid model. Finally, the efficacy of Teriflunomide/Lurbinectedin combination was tested in SBC3 mouse xenograft model. While Leflunomide and Lurbinectedin alone inhibited tumor growth by 22 and 39%, respectively the Teriflunomide/Lurbinectedin combination acted synergistically and significantly reduced tumor growth by 83% compared to the untreated control.

Conclusions: Collectively, our data suggest combinations of Lurbinectedin with Teriflunomide or Leflunomide are a potential therapeutic approach to suppress SCLC progression. These novel results pave the way for clinical trials in the future to validate these treatment strategies in patients with SCLC.

MA19.05 Dynamic Immune Profile of Peripheral Blood Predicts Immunotherapy Efficacy and Prognosis in Small Cell Lung Cancer

L. Wu, J. Wang, B. Chen, X. Pu, J. Li, Y. Xu, L. Xu, Y. Kong, F. Xu, K. Li, Q. Wang, L. Liu, Hunan Cancer Hospital, Changsha/CN

Introduction: The immune profile of peripheral blood can provide abundant data on efficacy and prognosis, which is expected to provide more biomarkers and related mechanisms for exploring tumour treatment. However, the lack of biomarkers that can accurately predict efficacy and prognosis in immunotherapy for extensive small cell lung cancer(ES-SCLC) is an urgent problem.

Methods: In this study, 81 dynamic peripheral blood samples (baseline, after two cycles of treatment[C2], and progressive disease) were collected from ES-SCLC patients who received first-line immunotherapy combined with chemotherapy (n=20) and chemotherapy alone (n=7). The following proteins were performed on peripheral blood mononuclear cells cytometry by time of flight (CyTOF): CD45, CD3, CD4, CD8, CD25, CD127, CD45RA, CD45RO, CCR7, TCR$_{\gamma\delta}$, CD19, CD66b, CD14, CD56, CD16, CD11c, CD123, HLA-DR, CD38, CD57, CXCR3, CCR6, CCR4, CXCR5, CD95/Fas, LAG-3, Tim-3, CTLA-4, PD-L1, PD-1, CD278/ICOS, and TIGIT. Peripheral blood immune cells from ES-SCLC patients were finely typed, and the activation/depletion status and immune checkpoint expression levels of different immune cells were detected. We further explored the dynamic immune profile of peripheral blood that could predict the efficacy and prognosis of SCLC immunotherapy in combination with efficacy assessment and survival indicators.

Results: In the immunotherapy group, a high percentage of senescent CD4+TEM/CD4+TEM at baseline (P=0.0206) was significantly associated with longer PFS. A high percentage of $\gamma\delta$T cells (P<0.0001) and high expression of TIGIT on CD4+T cells (P=0.021) at baseline were significantly associated with shorter PFS. In contrast, in the chemotherapy group, the above peripheral blood immune profiles were not predictors of PFS with chemotherapy. In addition, dynamic changes in immune checkpoint showed that CTLA-4 and ICOS expression in total cells at disease progression was significantly higher compared with C2 in the immunotherapy group. In contrast, no such dynamic changes were observed in the chemotherapy group, suggesting that elevated CTLA-4 and ICOS expression may be related to immunotherapy resistance.A high percentage of CD8+TEM/T cells at baseline (P=0.003) and C2 (P=0.024) and a high percentage of DCs at baseline (P=0.006) were significantly negatively correlated with OS only in the immunotherapy group. PD-1 (B cells, P=0.031; NK, P=0.008; cDCs, P=0.026; pDCs, P=0.030; Early NK, P=0.007; Late NK, P=0.008; CD4+TCM, P=0.009; Naive CD4+T, P=0.014) and TIGIT (NK, P=0.037; Late NK, P=0.028) expression was significantly negatively correlated with OS in several cell subsets.

Conclusions: In SCLC peripheral blood immune cell subsets, a high percentage of senescent CD4+TEM cells and a low percentage of $\gamma\delta$T cells suggested better immunotherapy efficacy, while a high percentage of CD8+TEM cells and DC cells suggested poorer immunotherapy prognosis. Elevated expression of CTLA-4 and ICOS was associated with immunotherapy resistance. High expression of TIGIT and PD-1 was associated with a worse immunotherapy prognosis.

MA19.07 Targeting USP22 Suppressed Carcinogenesis and Enhanced Immune Response in KRAS-Induced Lung Cancer

K. Zhang, C. Ouyang, J. Wang, W. Li, W. Tsark, C. Marconett, D. Raz, City of Hope National Medical Center, Duarte/CA/USA

Introduction: Ubiquitin-specific peptidase 22 (USP22), a putative cancer stem cell biomarker, primarily controls key epigenetic modifications by catalyzing the removal of the mono-ubiquitin moiety from histone H2B to control gene expression. It also stabilizes proteins or regulates activities of those critical cancer drivers including SIRT1, cMyc, and CCND1, inhibits many p53 host-protective functions. Overexpression of USP22 is frequently found in various human cancers and is strongly associated with aggressive cancer growth, metastasis, recurrence, and resistance to treatment. Notably, recent studies have further revealed that USP22 stabilizes programmed-death ligand-1 (PD-L1) in cancer cells and Foxp3 in T regulatory cells (Tregs), which substantially contribute to immunosuppression in the tumor microenvironment (TME). Therefore, USP22 is also a promising target for cancer immunotherapy. In addition, mutant Kras upregulates PD-L1 in lung cancer, Kras-induced inflammation and immunosuppression play a critical role in cancer progression.

Methods: A transgenic mouse model with conditional knockout of USP22, Kras-G12D mutation, and p53 loss (USP22-Ko) was created and compared to mice bearing Kras G12D mutation and p53 loss alone (Kp) to characterize the impact of USP22 depletion on the carcinogenesis and immune response in lung adenocarcinoma. Tumor volume was assessed via micro-CT scanning. The immune infiltration in TME was displayed by immunohistochemistry and multiple immunofluorescence (mIF) analysis of immune cell specific markers of T cells and microphages. Modulated signaling pathways and immune landscape by USP22-Ko were examined by RNAseq, Spatial transcriptomics analysis, and validated by immunofluorescence and Western-blot analysis. The response of USP22-Ko lung cancer to anti-PD-L1 therapy was assessed by in vivo therapeutic experiment and was compared to treatment in Kp mice.

Results: USP22-Ko drastically suppressed the in vivo growth and progression of lung cancers and significantly prolonged the survival of cancer-bearing mice compared with Kp mice. Morphological and immunohistochemistry analysis demonstrated that USP22-Ko was associated with better differentiation, enhanced T cell immune infiltration, and decreased FOXP3+ Tregs and PD-L1 expression in mouse lung adenocarcinomas compared with Kp mice. Importantly, RNAseq and gene set enrichment analysis indicated that USP22-Ko significantly inhibited Kras signaling pathway and enhanced p53 signaling pathway, suggesting that targeting USP22 may attenuate oncogenic Kras potential and partially rescue p53 tumor suppressor function. Furthermore, Spatial transcriptomics analysis and mIF analysis demonstrated that USP22-Ko dramatically decreased macrophage cells infiltration, suppressed TGF-beta 1 signaling pathway in TME of lung adenocarcinoma compared to Kp mice. In addition, USP22-Ko potentially enhanced the therapeutic efficacy of anti-PD-1 immune checkpoint blockade on mouse lung adenocarcinoma, indicating targeting USP22 may improve immunosuppression in TME, enhance sensitivity to immunotherapy, and exerts synergistic anticancer effects.

Conclusions: Intrinsic USP22 in cancer is critical for carcinogenesis and immunosuppressive TME in Kras-mutant lung cancer; and targeting USP22 will suppress cancer progression, partially break immunosuppression in TME, and sensitize Kras-mutant lung cancer to anti-PD-L1 therapy.

MA19.08 Transcriptomic Features of Circulating CX3CR1+CD8+ Temra Cells as a Predictor of Chemo-Immunotherapy Response in NSCLC Patients

J. Wu[1], X. Xu[2], H. Si[1], Y. Li[2], L. Xu[1], Y. She[1], X. Hu[2], C. Chen[1], Y. Dong[3], [1]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN ,[2]Abiosciences, Beijing/CN ,[3]Shanghai Pulmonary Hospital, No. [507], Yangpu District, Shanghai, China, Shanghai/CN

Introduction: Our previously study (Zheng L et al. Science. 2021) on pan-cancer single-cell landscape of tumor-infiltrating T cells revealed that circulating CX3CR1+CD8+ Temra Cells harbored tumor-specific TCRs and had the highest mobility between blood and tumor microenvironment in most cancer types. Here, we further explore the transcriptomic features of CX3CR1+CD8+ Temra cells for predicting the efficacy of chemoimmunotherapy in NSCLC.

Methods: We conducted 12 single-cell RNA and TCRs sequencing for 6 paired tumor and peripheral blood samples from NSCLC patients treated with neoadjuvant chemo-immunotherapy (3 Pathological complete response vs 3 Non-pathological response). After annotating CD8+ T cell subsets, we validated whether CX3CR1+CD8+ Temra cells in peripheral blood following chemoimmunotherapy exhibit tumor-specific TCRs. Subsequently, we integrated three published datasets along with our own peripheral blood single-cell transcriptomic data of CX3CR1+CD8+ Temra cells to construct a machine learning model (logistic regression model) for predicting the efficacy of chemo-immunotherapy. Patients identified as responders if they achieved PR or CR on the first radiological assessment. Others (PD and SD) were classified as non-responders in the machine learning model. Finally, we prospectively established a multi-centers cohort with metastatic NSCLC patients treated with first line chemo-immunotherapy from April to December 2023 (NCT 06054152). The collected peripheral blood samples were subjected to fluorescence-activated cell sorting (CD45+CD8+CX3CR1+) followed by Bulk-RNA sequencing.

Results: CX3CR1+CD8+ Temra cells exhibit high expansion (ASCL2, KLF2, KLF3, ZEB2, TBX21), migration (CXCR2, CXCR1) and strong effector molecule (GZMB) and significantly enrich in patients acquired pathological complete response. In the three training datasets (Sade-Feldman M, et al. Cell. 2018, Zhang Y, et al. Cancer Cell. 2021, Liu B, et al. Nat Cancer. 2022.), the accuracy of logistic regression-based machine learning model is 94.7% to 100% in a total of 38 patients. Specifically, 88 transcriptomic features were identified in our model, such as CD9, COPE, SFRP4t and so on. Furthermore, we prospectively collected 131 samples from NSCLC patients and conducted the Bulk-RNA sequencing for sorted CX3CR1+CD8+ Temra cells. Finally, we used this cohort as the validated dataset for the machine learning model. Importantly, the overall accuracy is 81.3% with 81.8% recall rate. Due to the relatively short follow-up period (Median follow-up time: 7.8 months), we are currently unable to conduct prognostic stratification analysis.

Conclusions: Overall, our study highlights the potential utility of transcriptomic Features of circulating CX3CR1+CD8+ Temra cells as a blood-based biomarker for chemo-immunotherapy and a marker to identify frequent circulating tumor-infiltrating lymphocyte repertoires.

MA19.10 The Tracerx 421 Cohort Provides Insights to Key Pathological Features of Lung Squamous Cell Cancer

A. Cheung[1], D.A. Moore[1], T. Karasaki[1], C. Puttick[1], K. Grigoriadis[1], K.S.S. Enfield[1], A.M. Frankell[1], N. McGranahan[1], M. Jamal-Hanjani[1], C. Swanton[1], [1]Francis Crick Institute, London/GB

Introduction: Lung squamous cell carcinoma (LUSC) can present pathologically with diverse histomorphologies, principally reflecting the presence or absence of keratinization, but also reflecting other histological features. The biological basis for these variations in morphology are poorly understood. TRACERx is a multi-centre prospective observational cohort study that examines cancer evolution in non-small cell carcinoma from diagnosis to treatment. We sought to understand the genomic and evolutionary events that govern keratinization and invasiveness in LUSC within the TRACERx cohort.

Methods: By performing multi-region whole exome sequencing in 136 patients diagnosed with LUSC from the TRACERx 421 cohort, encompassing 498 tumoural regions, we examined the genomic and transcriptomic events that underlie keratinization and subclonal evolution in LUSC. Geneset enrichment analyses were performed to examine the signaling pathways associated with tumour keratinization and invasiveness. Paired primary and metastasis samples were studied to estimate the timing of metastasis divergence. The pathological and genomic features were compared for survival differences in LUSC patients.

Results: LUSC is characterized by an abundance of truncal chromosomal events across the genome. High clonal tumour mutation burden and neoantigen load is a feature of non-keratinized LUSC compared to keratinized LUSC. In a subset of keratinized LUSC where ancestor/descendent-like relationships were identified between regional samples, transition from keratinized to non-keratinized histology was frequently observed and this is associated with an increase in loss of heterozygosity events. The diverse pathological manifestations in LUSC are associated with distinct transcriptomic profiles with invasive features being associated with epithelial-mesenchymal transition and stromal breakdown-related genesets. Early metastatic divergent tumours, defined as metastatic clones diverged before the last clonal sweep within the primary tumour, dominated the cohort, suggesting that metastasis may frequently occur in LUSC before the primary tumour become clinically detectable in the imaging studies. Clinically, the interplay between keratinization, tumour budding, and the reduction in tumour infiltrating lymphocytes in LUSC may influence the patient outcome.

Conclusions: Taken together, LUSC keratinization and specific features of invasiveness are associated with distinct genomic and transcriptomic features. These data highlight the potential clinical relevance of such findings and the impact of regional histological features within those tumours demonstrating morphological heterogeneity.

MA19.11 In Vivo CRISPR/Cas9 Library Screening for Target Genes of SCLC Brain Metastasis

C. Chong[1], M. Wang[1], X. Zhai[1], G. Che[1], Y. Wang[2], [1]West China Hospital, Sichuan University, Chengdu/CN ,[2]Sichuan University, Chengdu/CN

Introduction: Immunotherapy has come of age for lung cancers, especially lung squamous cancer (LUSC) which is lack of targeted therapies. However, the efficacy of immunotherapy needs improvement, given its frequent primary and adaptive resistance.

Methods: A new strategy to generate LUSC models in mice was developed with genetically engineered lung organoids, followed with orthotopic transplant into the lung of C57B/l6 recipient mice. Histopathological assays were performed to validate these models for LUSC. Then, tumor organoids were developed from these mouse models for genome wide CRISPR/cas9 library screening. Once the sgRNA library was introduced into the tumor organoids, they were transplanted into secondary C57B/l6 recipient mice or nude mice as a control and treated with anti-PD1 antibodies. When the recipients were succumbed to the disease, tumors were harvested and the relative enrichments and depletions of sgRNAs were detected by high throughput sequencing, comparing the tumors from the C57B/l6 mice to those from the nude mice. The candidate target genes are under validation and their potential molecular mechanisms will be investigated.

Results: A serial of LUSC mouse models with different genetic drivers were established. Histopathological analyses showed that these models represented the features of human disease. Tumor organoids were successfully developed from these models and serial transplantation confirmed that these organoids remained the characteristics of the original models. A sgRNA library of 120,000 sgRNAs targeting all the coding genes of the whole genome was introduced into the organoids. Dozens of hits for ICI sensitizers were revealed by high throughput sequencing.

Conclusions: The new models would be of value for translational studies on LUSC. And the genome wide CRISPR/cas9 library screening would identify new therapeutic targets to co-operate with immunotherapy.

MA19.12 Identification of Novel Therapeutic Targets for SOX2 Driven Lung Squamous Cell Carcinoma

R. Navab, M-S. Tsao, B. Raught, N. Moghal, Princess Margaret Cancer Centre, Toronto/ON/CA

Introduction: Lung cancer is the leading cause of cancer mortality in Canada (25% of all deaths, Canadian Cancer Statistics, 2019) and the world. The predominant forms are adeno (50%), squamous cell (LUSC) (25%), and small cell (15%) carcinomas. Two-thirds of LUSC patients are diagnosed at advanced, nonresectable stages. The major driver mechanism of LUSC involves amplification of 3q26-28, with the SOX2 transcription factor being a key player in this amplicon, along with one of its partners, TP63. Many LUSC models have lost SOX2 and TP63 expression, making it challenging to study clinically relevant mechanisms of SOX2-mediated pathogenesis.

Methods: To better model clinical LUSC pathogenesis, we generated the MGH7 LUSC cell line and 4 long-term LUSC organoid models (XDO's) from patient and PDX tumors. These models have been characterized for mRNA expression using RNAseq and for SOX2 and TP63 expression by IHC. They were also validated to be dependent on SOX2 and TP63 by shRNA knockdown. SOX2-interacting proteins were identified by BioID in MGH7 cells grown under standard 2D culture conditions and the XDO377 organoid model grown in 3D culture. SOX2-interactors were tested for their involvement in LUSC growth through a CRISPR-Cas9 dropout screen in MGH7 cells. SOX2 target genes were also identified in MGH7 cells through shRNA-mediated SOX2 knockdown and RNAseq.

Results: Our 2D and 3D LUSC models were found to not only maintain SOX2 and TP63 expression, as observed in clinical tumors, but to also show growth dependency on these transcription factors. SOX2 BioID identified 443 and 479 SOX2-interactors in MGH7 and XDO377 organoid cells, respectively. Overall, 60% of the SOX2-interactors were common to both models. However, among many classes of well-defined transcriptional regulators (eg. chromatin remodelers, chromatin modifiers, coactivators, corepressors), the overlap was >80%. 319/443 (73%) of the SOX2-interactors identified in MGH7 cells promoted growth of these cells, as revealed in the CRISPR-Cas9 dropout screen. Many of the SOX2-interactors that promote MGH7 growth are not annotated as common essential genes in the DepMap, supporting cancer-specific functions. Experiments are currently underway to validate the non-common essential SOX2-interactors found to be hits in the CRISPR screen, and to determine how they may impact SOX2 function, and whether their function can be generalized across multiple SOX2-expressing LUSC models.

Conclusions: Compared to 2D cell culture, organoid culture may increase the likelihood that LUSC cancer cells cultured from patient tumors retain SOX2 and TP63 expression and growth dependency. However, if established to maintain SOX2 and TP63 expression, even some 2D LUSC cell lines may be equally good to 3D models, as evidenced by highly similar SOX2-interactomes. A number of SOX2-interactors that are not common essential genes promote growth of LUSC cancer models, supporting the notion that they could be good surrogate therapeutic targets for SOX2 to develop new treatment strategies for LUSC.

P1.01A.01 The INHERIT Study - Investigating Hereditary Risk in Thoracic Cancers (NCT05587439)

J. LoPiccolo[1], V.G. Williamson[1], D.R. Koeller[1], D.R. Haradon[1], A. Harper[2], V. Kotait[2], E. Izzo[2], A. Ciupek[3], B. Addario[4], J.C. King[5], R. Erwin[2], C.A. Granville[3], J.E. Garber[1], P.A. Jänne[1], [1]Dana Farber Cancer Institute, Boston/MA/USA ,[2]Addario Lung Cancer Medical Institute, San Carlos/CA/USA ,[3]GO[2] for Lung Cancer, Washington/DC/USA ,[4]GO[2] for Lung Cancer, San Carlos/CA/USA ,[5]IASLC, Denver/CO/USA

Introduction: The contribution of inherited susceptibility to lung cancer is not well understood, particularly among those without significant tobacco exposure. Studies of germline/inherited susceptibility to lung cancer and identification of pathogenic germline mutations associated with lung cancer risk may increase understanding of potential genetic modifiers of somatic alterations in lung cancer oncogenes. Indeed, germline EGFR mutations have been identified as one cause of familial lung cancer, and previous research has outlined a syndrome of familial EGFR-mutant lung cancer predisposition across multiple unrelated kindreds (Oxnard GR, et. al., JCO, 2023). The INHERIT (Investigating Hereditary Risk In Thoracic Cancers) study (NCT05587439) aims to ascertain genetic contributors to lung tumorigenesis and establish a repository for clinicopathologic information and biologic specimens from individuals with inherited lung cancer predisposition.

Methods: INHERIT will create a data and specimen repository and follow patients with potential germline risk over time. Eligible patients fall into one of three cohorts: 1) Individuals with personal or family history of lung cancer who carry or are at high risk of carrying an EGFR T790M or other EGFR germline variant identified in blood or saliva, including via somatic single or multi-gene panel testing (MGPT), 2) Individuals with personal or family history of lung cancer who carry or are at high risk of carrying non-EGFR germline variants (e.g., HER2, TP53, ATM, BRCA1/2, CHEK2, PTEN, YAP1, and others that will be identified) that may contribute to inherited lung cancer risk, identified in blood or saliva, including via somatic single MGPT, and 3) individuals with lung cancer or family history of lung cancer who are not known to carry a pathogenic germline variant and with one of the following: more than one first-degree relative diagnosed with lung cancer, multi-generational family history of lung cancer, or personal history of multiple primary lung cancers or other neoplasms. Eligible participants are asked to complete study questionnaires to obtain lung cancer history, other medical history, social history, occupational and environmental exposure history, and detailed family history of cancer. All participants provide a research blood specimen, either at clinical centers or via remote collection using mobile phlebotomy, for whole-genome and RNA sequencing, as well as banking of serum, along with optional clinical germline multi-gene panel testing (MGPT) through a commercial laboratory. Participants with positive MGPT results (pathogenic/likely pathogenic variants) are offered genetic education and counseling and cascade testing for family members. Computed tomography (CT)-based screening will be performed in EGFR T790M carriers, who represent the largest and ideal population for screening and follow up, to better determine risk of lung cancer and age of disease onset. A multi-pronged recruitment and enrollment method is utilized to increase diversity of participants including locally at partnered clinical sites, remotely as referred by local clinical contacts, and self-referral via an IRB-approved study website (www.inheritstudy.org) with consent and enrollment by centralized study staff and remote blood collection via mobile phlebotomy. Data and specimens will be utilized primarily to create an ongoing data and specimen repository for future IRB-approved research.

P1.01A.02 Monitoring Inflammatory Response Secondary to Air Pollution Exposure Through Volatile Organic Compounds

R.L. Myers[1], A. Smolinska[2], C. Bartolomeu[3], F. Ricciardi[2], B. O'Brien[2], S. Thompson[2], M. Allsworth[2], B. Boyle[2], C. Carlsten[4], S. Lam[1], [1]BC Cancer, Vancouver/BC/CA ,[2]Owlstone, Cambridge/GB ,[3]BC Cancer Research Institute, Vancouver/BC/CA ,[4]Vancouver Coastal Health, Vancouver/BC/CA

Introduction: Outdoor air pollution, specifically particulate matter less than 2.5 µg/m3 (PM2.5) is known as a Group 1 carcinogen and a significant contributor to lung cancer and respiratory disease world-wide. It elevates the risk of mortality due to conditions like heart disease, stroke, and is the 5th ranking mortality risk factor as of 2015. Inflammation in the lungs is a common response to pollutants, releasing volatile organic compounds (VOCs) in breath, which can potentially serve as non-invasive markers for assessing inflammation. The aim of this study is to examine the changes over 24 hours in exhaled breath compounds and blood after an acute exposure 300µg/m3 of PM2.5.

Methods: The study uses a randomized controlled double-blind crossover design. Twenty non-smoking, healthy individuals underwent 2 separate exposures in the UBC Air Pollution Exposure Lab booth. Sessions were 4 weeks apart and consisted of diesel exhaust (DE) diluted to 300g/m3 of PM2.5 or to filtered air (FA; sham), exposures demonstrated to be indistinguishable to participants. Breath samples were analyzed using gas chromatography coupled with high-resolution mass spectrometry (Breath Biopsy®) at various time points: before exposure, immediately after, and at 0.5, 1,3, 6-, and 24-hours post-exposure. The samples were compared to blank samples to identify VOCs originating from breath rather than ambient air. Blood samples were collected at baseline, 1h 3h and 24h post exposure. Both untargeted and targeted analyses of inflammation-related VOC compounds were analyzed. Blood was analyzed via Mesoscale™, CRP, TNFµ and 8-isoprostane. Data analysis included univariate analysis using linear mixed models and multivariate techniques such as principal component analysis and ANOVA simultaneous component analysis (ASCA).

Results: ASCA revealed a significant effect of exposure type (DE vs FA, $p < 0.01$) and a significant interaction ($p < 0.05$) between post-exposure time and exposure type. Compounds related to inflammation, such as hexadecane and butanal increased significantly in the breath of individuals exposed to PM2.5 in DE vs FA. However, all samples collected 24 hours post-exposure resembled baseline samples, indicating that the observed changes post-exposure diminished within 24 hours, which corresponded with the blood panels.

Conclusions: This study demonstrates that a distinct multi-VOC profile is detectable in breath from individuals exposed to air pollution, inflammatory response was confirmed via blood panels. These findings suggest that VOCs in exhaled breath may offer a non-invasive means to detect acute airway inflammation, providing valuable insights into detecting, monitoring and treating respiratory disease (and potentially downstream effects) secondary to air pollution.

P1.01A.03 Can-Prevent-Lung Trial-Canakinumab for the Prevention of Lung Cancer: Updated Interim Clinical and Biomarker Analysis

J.J. Zhang, M. Salehjahromi, S. Heeke, M. Godoy, H. Tran, M. Antonoff, B. Carter, E. Ostrin, X. Le, C. Gay, M. Vailati Negrao, L. Byers, C. Lu, G. Blumenschein, D. Rice, G. Walsh, R. Rajaram, S. Lin, W. Hofstetter, R. Mehran, A. Vaporciyan, S. Moghaddam, J.J. Lee, J. Wu, J. Heymach, MD
Anderson Cancer Center, Houston/TX/USA

Introduction: Preclinical work has demonstrated anti-interleukin-1beta (IL-1B) can delay the progression of precancers into invasive lung adenocarcinomas. Canakinumab, a humanized anti-ILB antibody has been reported to decrease lung cancer incidence by ~70% in CANTOS trial. Can-Prevent-Lung is single arm Phase II trial aiming to test whether canakinumab can increase regression rate of persistent high-risk lung nodules and prevent lung cancer.

Methods: Patients with persistent high-risk pulmonary nodules (at least 2 CT scans 3 months apart showing no evidence of regression; predicted risk exceeding 10% according to the Brock model for those without personal history of lung cancer or exceeding 5% for those with localized lung cancer who complete standard-of-care therapy) are eligible to receive canakinumab 200mg subcutaneously every 3 weeks for up to 8 doses. CT scans are scheduled after 2 doses, 4 doses, and 8 doses. Therapeutic response are evaluated using modified RECIST criteria (mRECIST), which assess both solid and ground-glass opacity components as well as 3D volumetric analysis. A control group of patients identified through propensity matching is analyzed in a similar manner. Peripheral blood T cell receptor (TCR) sequencing, cytokine profiling, and plasma cell-free DNA (cfDNA) methylation profiling, are conducted at various time points, including baseline before treatment initiation, 3 weeks and 6 months after the first dose of treatment.

Results: At the updated analysis, 15 patients have completed treatment and safety follow-up. Canakinumab has been well tolerated, with no toxicities of Grade 3 or higher. The most common toxicity was Grade 2 neutropenia (n=4) with no active infections. According to mRECIST criteria, 11 patients demonstrated shrinkage of lung nodules, with the best response being a reduction of -27%, while 13 patients exhibited a slower growth trajectory following canakinumab treatment compared to before treatment initiation. In 3D volumetric analysis, the treatment group showed volume shrinkage, with a median growth rate of -6.7% per year, in contrast to a growth rate of +14.8% per year observed in the control group. Additionally, compared to the control group, lesions in the treatment group tended to have a significantly smaller number of cells (P=0.024), lower degree of intra-lesion spatial heterogeneity (P=0.049), and lower average CT density (P<0.001). Interestingly, the concentration of cfDNA negatively correlated with treatment response, and distinct methylation patterns were associated with the diagnosis of lung cancer in longitudinal analysis. T-cell receptor (TCR) profiling and peripheral blood cytokine profiling are currently ongoing.

Conclusions: Canakinumab has exhibited a favorable safety profile and promising efficacy in the treatment of patients with high-risk lung nodules. Methylation changes in ctDNA may offer valuable insight for lung cancer interception trials. Can-Prevent-Lung trial has been amended to administer canakinumab at a dosage of 300mg subcutaneously every 3 months for up to 4 doses to mitigate the risk of neutropenia and reduce patient travel requirements in the interception setting.

Keywords: Prevention, Precancer, canakinumab

P1.01A RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL - CLINICAL TRIALS IN PROGRESS
SUNDAY, SEPTEMBER 8, 2024 - 12:00 - 14:00

P1.01A.04 Point-of-care Nicotine Replacement for the Treatment of Nicotine Addiction in a Provincial Cancer System

R.L. Myers[1], C. Colby[2], M. Crosby[3], B. Freeman[3], C. Bartolomeu[4], S. Lam[1], F. Feldman[1], [1]BC Cancer, Vancouver/BC/CA ,[2]BC Cancer, Abbotsford/BC/CA ,[3]BC Cancer, Prince George/BC/CA ,[4]BC Cancer Research Institute, Vancouver/BC/CA

Introduction: Smoking Cessation at the time of a cancer diagnosis is an integral part of cancer treatment. In 2014 the Surgeon General's Report (SGR) concluded that cessation at diagnosis was associated with reductions in; cancer-specific mortality, overall mortality, cancer recurrence and improved treatment response. The 2020 SGR concluded that cessation exacts a 40% reduction in mortality, improving well-being, is cost-effective and is a vital part of cancer treatment. In 2022, IASLC issued a position statement on tobacco cessation after a cancer diagnosis, outlining the importance of screening and treating all cancer patients at the time of a cancer diagnosis. Comprehensive tobacco cessation pathways are required at all cancer institutions, starting with screening for use and providing evidence-based cessation support. Despite the initiation of these programs, cessation rates remain low, indicating novel ideas to break the status quo are required. We describe a point-of-care nicotine replacement pilot program nested within a larger cessation program.

Methods: BC Cancer initiated an Ask, Advise, Refer (AAR) tobacco cessation program at 6 sites across British Columbia, Canada, where all cancer patients presenting for their first visit are screened for tobacco use and offered treatment specific advice on cessation and an opt-out referral to a telephone quit line and provincial nicotine replacement program (NRP). The NRP supplies 3 months of nicotine replacement therapy (NRT) at no cost to the patient. Adoption, reach and effectiveness indicators were recorded from 2019 to 2024. Based on low quit rates, a pilot point-of-care NRT program was initiated at a single center, where patients who were still smoking would leave the cancer clinic, after their first visit, with a NRT (patch) applied to the arm and a 7-day supply of dual NRT therapy (patch and gum), and referral to NRP. Given the challenging geographic area, patients that were reviewed virtually had dual NRT shipped to their home.

Results: Between 2019-2021, 45,348 patients presented for cancer treatment throughout all 6 sites. 11,832 of these patients were screened for tobacco use, identifying 1,974 (17%) current tobacco users; 46% female, and 67% Caucasian. 1102 (56%) were offered a referral to the telephone quit line and the NRP, 580 (53%) accepted. Of these, 223 (38%) quit, attempted to quit or reduced tobacco consumption. The point-of-care NRP pilot was initiated in Oct 2023, a total of 21 patients (48% female, median 30 pk-yrs (min 9.75, max 90) have received NRT at point-of-care, 76% received dual NRT, 71% accepted referral to a telephone quit-line. Eight patients were remotely located, with an average distance of 463 km from the nearest centre. The average cost of shipping NRT was $25.14. Quit rates will be recorded at 6 and 12 months.

Conclusions: Tobacco cessation is an integral part of cancer treatment but is often overlooked. Broader access to effective and novel methods of screening and treatment is required, particularly for those in rural/remote communities. We describe a novel point-of-care pathway to service all patients, including those in rural/remote communities who generally experience decreased access to in-person care.

P1.01B.01 Derivation and Validation of Nomogram to Predict Outcomes of Patients with Simultaneous Multiple Primary Lung Cancer

Y. Liu[1], L. Wang[1], Q. Sun[1], R. Qi[1], B. Liu[1], X. Qian[1], Y. zhang[2], H. Niu[3], R. Li[4], [1]Nanjing Drum Tower Hospital, Nanjing/CN ,[2]West China Hospital, Chengdu/CN ,[3]Nanjing University of Chinese Medicine, Nanjing/CN ,[4]Nanjing Medical University, Nanjing /CN

Introduction: Simultaneous multiple primary lung cancers (sMPLC) are detected increasingly nowadays, but there is no reliable tool for the assessment of long-term survival probability. This study aimed to develop a nomogram estimating the probability of the overall survival for patients with sMPLC undergoing resection.

Methods: This retrospective study enrolled 447 patients with sMPLC from two centers between June 2010 and April 2023. All patients were randomly divided in a 3:1 ratio to generate training and validation cohorts. The least absolute shrinkage and selection operator regression analysis and Multivariable Cox regression analysis were utilized to identify risk factors for overall survival. Based on the factors, a nomogram for predicting overall survival was constructed. Areas under the receiver operating characteristic curves (AUC), calibration plots and decision curve analysis (DCA) were used to evaluate the efficiency of the nomogram in both the training and validation cohorts.

Results: The training cohort included 335 patients, and the validation cohort included 112 patients, with a total of 43 (9.6%) patients experiencing all-cause death. Age, pathological pattern, pleural invasion, neutrophile granulocyte, and nature of lesions were used to build the nomogram. The AUC values of the nomogram were 0.910, 0.902, 0.871 and 0.860 for the 1-, 2-, 3-, and 4-year overall survival in the training cohort, and 0.892, 0.894, 0.895 and 0.873 in the validation cohort, respectively. The calibration curves for probability of overall survival showed optimal agreement between the prediction by nomogram and the actual observation, and the DCA indicated that the constructed nomogram conferred high clinical net benefit.

Conclusions: This nomogram can accurately predict the probability of overall survival for patients with sMPLC.

P1.01B.02 The Genomic Landscape of Lung Cancer in Never-Smokers from the Women's Health Initiative

S. Moorthi[1], A. Paguirigan[1], P. Itagi[1], M. Ko[1], M. Pettinger[1], A.C.H. Hoge[1], A. Nag[2], N.A. Patel[2], F. Wu[1], C. Sather[1], K.M. Levine[1], M.P. Fitzgibbon[1], A.R. Thorner[2], G.L. Anderson[1], G. Ha[1], A.H. Berger[1], [1]Fred Hutchinson Cancer Center, Seattle/WA/USA ,[2]Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Therapies targeting driver oncogenes such as EGFR have transformed the clinical management of lung cancer, which has contributed to the decline in mortality rates. However, much of our understanding of lung cancer stems from studies involving individuals with a history of smoking. Despite smoking being the primary risk factor, a substantial proportion of lung cancer cases occur in never-smokers, particularly affecting women. The rising incidence of lung cancer in never-smokers mirrors both global shifts in smoking habits and an increase in never-smoker lung cancer cases. Lung cancer in never-smokers presents distinct clinical and genetic features compared to smoker-associated lung cancer. In this study, we explore the genetic landscape of lung cancer in never-smoker women enrolled in the Women's Health Initiative and explore the impact of smoking history, sex, and age.

Methods: We conducted whole exome and/or whole genome sequencing on tumor and/or matched normal DNA samples obtained from participants of the Women's Health Initiative who developed lung cancer. The analysis encompassed samples from 73 women, enabling the genomic profiling of never-smoker lung cancer cases. Bioinformatic analyses were performed to identify somatic mutations, mutational signatures, copy number alterations, and fusion events. Furthermore, we corroborate the novel genetic findings with data from the TCGA, MSK, and GENIE cohorts.

Results: Never-smokers exhibit a significant enrichment in EGFR indel mutations compared to heavy smokers. Intriguingly, among never-smokers, those diagnosed at a younger age (under 50 years) displayed a significant enrichment in EGFR indel mutations compared to their older counterparts (aged 50 years or more). In contrast, heavy smokers demonstrated a heightened prevalence of KRAS G12C mutations, whereas never-smokers showcased diverse occurrences of other G12 amino acid changes. Moreover, mutations in MGA were notably prevalent among smokers, particularly in individuals diagnosed at an older age. Conversely, MET mutations were found to be enriched in never-smokers, as well as in individuals diagnosed later in life. Analysis of somatic mutation signatures unveiled DNA repair defects in a subset of tumors, although no attributable germline predisposition variants were identified. Interestingly, the absence of ALK, RET, and ROS1 fusions in the WHI cohort can be partially attributed to the older age at diagnosis and the early tumor stage within this group. Lastly, it's worth noting that there was no discernible difference in aneuploidy based on smoking

Conclusions: Our analysis revealed a unique mutational spectrum of EGFR and KRAS variants in never-smoker lung cancer cases, with implications for both targeted and immunotherapeutic interventions. We found that chromosomal fusions involving ALK, RET, and ROS1 were absent, suggesting lower rates of fusion oncogenes in older female never-smokers. Contrary to expectations, distinct copy number subtypes previously associated with never-smoker lung cancer were observed across tumors from both smokers and never-smokers, indicating that aneuploidy and somatic copy number alterations are general features of lung cancer independent of smoking status.

P1.01B.03 Risk Factors Associated with Venous Thromboembolism in Advanced ALK Rearranged Non-Small Cell Lung Cancer

C. Kamali, S. Ekman, Karolinska Institutet, Stockholm/SE

Introduction: Non-small cell lung cancer (NSCLC) patients are at an elevated risk of venous thromboembolism (VTE), which is associated with poor prognosis. The incidence of VTE in patients with anaplastic lymphoma kinase (ALK) rearrangements is reported to be three to five times higher, suggesting a potential benefit from prophylactic anticoagulant therapy. This study aimed to identify clinical and molecular factors associated with an increased risk of VTE in patients with advanced ALK-positive NSCLC.

Methods: A retrospective study was conducted involving patients with advanced ALK-positive NSCLC treated at Karolinska University Hospital between January 2009 and December 2021. ALK rearrangements were assessed using immunohistochemistry (IHC) or fluorescence in situ hybridization (FISH), while EML4-ALK fusion variants were detected by reverse-transcriptase-polymerase-chain-reaction (RT-PCR). Patients diagnosed after 2015 were analyzed by Next-generation sequencing (NGS). VTE events were recorded from 90 days before the histological cancer diagnosis until death or the end of follow-up.

Results: Ninety-eight advanced ALK-positive NSCLC patients were enrolled, among whom 36 developed VTE. The location of the VTE was pulmonary in 23 cases (63.9%) and 17 (47.2%) occurring beyond 6 months from treatment initiation. Re-thrombosis was observed in 6 patients (16.7%). The median time from diagnosis to the first clot was 170.0 days. Median overall survival (mOS) was 25.0 months (95% CI: 17.5, 32.5) for VTE-positive patients and 76.0 months (95% CI: 51.7, 100.3) for VTE-negative patients. Logistic multivariable regression analysis revealed that the presence of adrenal metastasis (OR, 3.35; 95% CI: 1.42, 7.91), BMI ≥35 kg/m2 (OR: 11.7; 95% CI: 2.42, 57.0), Leukocyte count >11x10^9/L (OR, 5.44; 95% CI: 2.40, 12.3) and Hemoglobin <10g/dL (OR, 6.38; 95% CI: 1.93, 21.1) significantly increased VTE risk, while Albumin ≥3.5 g/dL lowered the odds (OR, 0.36; 95% CI: 0.15-0.89).

Conclusions: Patients with ALK-positive NSCLC, particularly those with adrenal metastasis, BMI ≥35 kg/m^2, leukocyte count >11x10^9/L, or hemoglobin <10g/dL, face an elevated risk of VTE. Prophylactic anticoagulation may benefit these patients due to their increased susceptibility to cancer-related thrombosis. However, further studies are needed to validate these findings before considering clinical implementation.

P1.01B.04 A Highly Unmet Need: Patterns of Lung Cancer Screening in Head and Neck Cancer Survivors Preceding a Lung Cancer Diagnosis

C. Olazagasti[1], S. Malik[2], D.C. Qu[2], G. Stoel[2], J. Noy[2], E. Rodriguez[3], G. Lopes[4], [1]Sylvester: Sylvester Comprehensive Cancer Center, Miami/FL/USA ,[2]University of Miami Miller School of Medicine, Miami/FL/USA ,[3]Sylvester Comprehensive Cancer Center, Coral Gables/FL/USA ,[4]Sylvester Comprehensive Cancer Center, miami/FL/USA

Introduction: One fourth of head and neck cancer (HNC) survivors die from a second malignancy, and lung cancer (LC) is responsible for over half of the cases. HNC survivors with a smoking history have a 2.5 times higher incidence of LC than the average population. Contrary to most tumor types, there is no standard long-term image surveillance recommended for HNC survivors. However, NCCN does recommend annual low dose CT (LDCT) for LCS in HNC survivors with a ≥ 20-pack year (py) smoking history. Yet, the rates of LCS implementation in HNC survivors are unknown. We aimed to understand the patterns of LCS eligibility and implementation in HNC survivors preceding a LC diagnosis.

Methods: We performed a single institution study at the University of Miami including all subjects with a history of HNC and LC seen from 2018-2022. Demographic information including age, sex at birth, race/ethnicity was included. Smoking history, LC staging, LCS eligibility, and mortality status were collected. A descriptive analysis was performed.

Results: We reviewed the charts of 51 patients with HNC preceding a LC diagnosis, 16 were female and 35 men. 49 patients self-identified as White and 2 as Black race. 22 patients self-identified as Hispanic, 28 as non-Hispanic, and 1 as unknown or another ethnicity. As depicted in Table 1, most patients (61%) had a ≥ 30 py. history of smoking and up to 65% fulfilled LCS eligibility criteria. However, only 3.9% of patients underwent LCS following the HNC and preceding LC diagnosis. The majority of patients (29%) had stage IV at LC diagnosis. The average LC diagnosis following HNC was 4.04 years.

Conclusions: Despite the high incidence of second primary LC in HNC survivors, our study showed that LCS in eligible HNC survivors remains critically underutilized. Only 3.9% of the patients from our cohort underwent LCS following their HNC diagnosis despite most having a heavy tobacco history and fulfilling LCS criteria. The LCS rates for eligible Americans are suboptimal at 6%, however, our study shows that these rates could be disproportionately worse for HNC survivors. In our study, patients were diagnosed with LC an average of 4 years after HNC diagnosis. Enforcing and implementing LCS in HNC survivors could help overcome the high rates of late-stage diagnosis and potentially improve mortality rates in HNC survivors. Therefore, it is imperative to conduct prospective studies to better understand the barriers and promote LCS in this high-risk population.

Introduction: KBP[i] is a Real-World French prospective study on Lung Cancer (LC) conducted in non-academic public hospitals (NPH) every ten years since 2000. Herein, we report the three-year survival (3-yS) rate in NSCLC among the 2020 cohort and the comparisons with the 2000 and 2010 cohorts.

[i] Debieuvre D et al. Two-year lung cancer survival between 2000 to 2020: Results from 3 French nationwide cohorts. JCO 41, 8542-8542(2023). DOI:10.1200/JCO.2023.41.16_suppl.8542

Methods: Collection of all consecutive diagnosed LC, all stage, and all histology, between 01/01 and 12/31 in NPH pulmonology or oncology units in 2000, 2010 and 2020 with the same methodology. A Scientific Committee controlled inclusion exhaustivity and quality in each center. The vital status was collected at different follow-up times. Survival rates were calculated using the Kaplan-Meier method.

Results: 8,999 patients were included in 82 centers in 2020, 7847 with NSCLC, including 7824 with vital status known. The 3-yS rate for patients with NSCLC was 34.6% [33.4 - 35.8], the median overall survival was 17.4 [16.5 - 18.3] months. Compared to 2000, survival improved significantly (+17.7%) (Table 1). Adenocarcinoma was the histological type whose prognosis has improved the most (+ 20.4%).

Factors associated with 3-yS were sex, age, ECOG Performans Status (PS), TNM stage. The 3-yS for women (F) was 41.4% [39.4 - 43.5] compared to men (M) 31.0% [29.6 - 32.4] in 2020, significantly increased over 20 years: + 22.5% for F and + 14.4% for M. In 2020, as expected, the 3-yS decreased with age from 40.1% [35.1 - 45.8] for patients <50 y-o to 16.4% [14.0 - 19.2] for patients > 80 y-o. PS was associated with the 3-yS rate of 43.0% [41.6 - 44.5] for patients with PS 0-1,11.2% [9.4 - 13.3] for PS 2 and 4.7% [3.2 - 6.9] for PS3-4. TNM stage was still determining for 3-yS, from 80.9% [78.2 - 83.6] for stage I to 18.3 [17.1-19.6] for stage IV.

Conclusions: These results showed the impressive improvement in the survival rate of NSCLC in real life conditions with new strategies and therapies. Expanding KBP 2020 follow-up provided us with longer-term overall survival data with a benefit that appears to be maintained.

Keywords: 3-year survival, non-small cell lung cancer

NSCLC survival	Months	2000 N=4669	2010 N=6083	2020 N=7824*
	1	90.7 [89.9 - 91.6]	90.9 [90.1 - 91.6]	92.7 [92.1 - 93.3]
	3	76.0 [74.7 - 77.2]	76.8 [75.8 - 77.9]	80.4 [79.5 - 81.3]
	12	41.1 [39.7 - 42.6]	44.3 [43.1 - 45.6]	57.6 [56.6 - 58.8]
	24	23.2 [22.0 - 24.5]	27.7 [26.6 - 28.9]	43.6 [42.5 - 44.7]
	36	16.9 [15.9 - 18.1]	21.0 [20.0 - 22.1]	34.6 [33.4 - 35.8]
	Median survival time (months)	9.0 [8.5 - 9.4]	10.0 [9.5 - 10.3]	17.4 [16.5 - 18.3]

**7824 patients with vital status captured at least once during the follow-up. Preliminary results with 1923 missing dataat Month 36 - Update will be available for the congress*

Conclusions: These results showed the impressive improvement in the survival rate of NSCLC in real life conditions with new strategies and therapies. Expanding KBP 2020 follow-up provided us with longer-term overall survival data with a benefit that appears to be maintained.

P1.01C.01 Effectiveness of Health Education on Adolescent Tobacco Use Intention: Cluster RCT in Ibadan, Nigeria

O.F. Fagbule[1], M.E. Osuh[1], F.B. Lawal[1], O. Ibiyemi[1], B. Faseru[2], [1]University of Ibadan, Ibadan/NG ,[2]University of Kansas School of Medicine, Kansas/KS/USA

Introduction: Most adults who use tobacco start during adolescence. Curbing the initiation of tobacco use among adolescents has the potential to significantly diminish its prevalence. Notably, the intention to use tobacco serves as a proximal factor that reliably predicts actual tobacco uptake. Given the well-established addictive nature of tobacco and the associated challenges in cessation, directing prevention efforts toward non-tobacco users with an intention to use tobacco holds greater promise for successful intervention. Hence, this study aimed to assess the effect of a Health Belief Model (HBM) based health education program on school-going adolescents' intention to use tobacco in Ibadan, Nigeria.

Methods: In this cluster randomized controlled trial of in-school adolescents in Ibadan, Nigeria, we estimated a total sample size of 720 participants across eight schools. Using a two-stage cluster sampling, approximately 90 students were selected from each school, with schools randomized into either the intervention (4 schools) or control (4 schools) groups. The intervention comprised two sessions of expert-led tobacco-related lectures, the placement of classroom posters, and the distribution of customized notebooks containing key anti-tobacco messages. (Figure 1)In contrast, the control group received lectures focusing on oral hygiene practices. A modified and validated Global Youth Tobacco Survey questionnaire was used to collect sociodemographic information and intention to use tobacco (yes/no) at baseline and six months post-intervention (endline). Intention-to-treat analysis was employed. Binary logistic regression modeling was conducted to assess intervention effectiveness while controlling for potential confounding.

Results: The participants' mean (±SD) age was 14.7 (±1.2) years. About half of the participants were from private schools (50.1%) and males (50.6%). No differences in the baseline characteristics between the two groups (p>0.05). At baseline, the prevalence of intention to use tobacco was 13.6% in both groups. In the intervention group, this prevalence decreased to 8.9% at the endline, while it increased to 14.4% in the control group (p=0.020). After adjusting for age, gender, and school type (public vs private), the odds of improvement (no intention at endline) in the intervention group were 1.7 times higher than the control group (aOR: 1.71; 95%CI: 1.07-2.74).

Conclusions: The HBM-based behavioral change intervention notably reduced the participant's intention to use tobacco six months post-intervention, affirming the effectiveness of targeted health education grounded in the HBM. These findings emphasize the importance of sustained, contextually relevant health education in broader tobacco control initiatives for diverse populations.

P1.01C.02 Tobacco Control and Smoking Cessation-related Content in Oncology Meetings: A Scoping Review

S. Choi[1], A. Alghabban[1], J. Do[1], W. Boateng[1], D. Chen[1], R.S. Huang[1], M. Khan[1], N.K. Quartey[1], S. Raman[1], M.E. Giuliani[1], W.K. Evans[2], L. Eng[1], [1]Princess Margaret Cancer Centre, Toronto/ON/CA ,[2]McMaster University, Hamilton/ON/CA

Introduction: Tobacco is a known risk factor for the development of cancer, and patients with cancer who continue to smoke have poorer outcomes. Despite the importance of tobacco control and smoking cessation in cancer care, it remains unclear how much tobacco control and smoking cessation content are included in major oncology meetings. The purpose of this project is to evaluate how much tobacco control and smoking cessation-related content is presented at major oncology meetings.

Methods: We performed a scoping review for tobacco control and smoking cessation-related content using online programmes, proceeding files, and abstract books from January 2018 to July 2023 for 12 major international oncology meetings representing different disciplines and disease sites. Eligible abstracts and education sessions included content evaluating the impact of tobacco on cancer risk, tobacco use on cancer outcomes, and/or smoking cessation in cancer care. Content was excluded if tobacco use was solely evaluated as a co-variate or if the content did not have a primary focus on tobacco control or smoking cessation. Descriptive statistics helped to characterize frequencies and trends over time.

Results: A total of 5168 tobacco control and smoking cessation-related content was identified using our search criteria; 389 abstracts and 114 educational sessions met the inclusion criteria. Between 2018 and 2023, meetings from the World Cancer Congress (mean: 1.66 ± 3.06%), the World Conference on Lung Cancer (mean: 1.52 ± 0.59%), and the Multidisciplinary Head and Neck Cancers Symposium (mean: 0.72 ± 1.03%) had the highest percentages of tobacco-related abstracts presented with a consistent trend over the 5-year period. The World Cancer Congress (mean: 4.08 ± 1.30%) and the World Conference on Lung Cancer (mean: 3.94 ± 1.63%) had the highest percentages of tobacco-related educational sessions and were the only meetings that primarily presented tobacco-related educational sessions throughout every meeting across the 5 years. Among the included abstracts, 37% focused on tobacco and cancer risk, 37% focused on smoking cessation, and 26% focused on the impact of tobacco on cancer outcomes. Slightly less than half (43%) of the abstracts were focused on clinical/epidemiological research, followed by quality improvement/health services research (35%), basic science/translational research (20%), and review studies (2%). Most first author abstract presenters were from North America (56%), Asia (20%) and Europe (17%).

Conclusions: Despite the importance of tobacco control in cancer, tobacco control or smoking cessation-focused abstracts and educational content are limited at major oncology meetings. The organizers of cancer meetings need to be encouraged to include educational sessions focused on tobacco control and smoking cessation, and to explore new strategies to attract submissions on these topics, particularly from underrepresented regions of the world.

P1.01C.03 The Influence of Smoking on Morbidity and Early Mortality after Anatomical Lung Resections for Stage I-IIIA NSCLC

K. Grapatsas[1], F. Doerr[2], F. Oezkan[2], N. Baldes[2], D. Theegarten[2], K. Darwiche[2], W. Eberhardt[2], T. Gauler[3], M. Stuschke[3], H. Hautzel[3], K. Herrmann[3], C. Taube[2], M. Forsting[3], M. Schuler[3], S. Bölükbas[1], [1]University Medical Center Essen-Ruhrlandklinik, Essen/DE ,[2]University Medical Center Essen, Ruhrlandklinik, Essen/DE ,[3]University Medical Center Essen, Essen/DE

Introduction: Smoking status before an operation is associated with increased postoperative morbidity and mortality. The aim of this study is to investigate the impact of smoking status on patients undergoing anatomical lung resection for NSCLC with stage I-IIIA.

Methods: This retrospective single-center study included patients who underwent anatomical resection for NSCLC in postoperative stages I-IIIA between 2016 and 2022 at the West German Cancer Center. Smoking status was divided into three categories: never smokers, past smokers (patients who had quit smoking at least twelve months before surgery), and current smokers (patients who smoked up to one week before surgery). Early mortality was defined as death from any cause within 30 days after the operation.

Results: The study included 1093 patients. Histology showed IA1 stage in 8.8% of patients, IA2 in 15.1%, IA3 in 8.2%, IB in 16.7%, IIA in 7.0%, IIB in 22.8%, and IIIA in 21.5%. Never smokers were mostly detected in stage I (50.4% vs 54.6% vs 46.5%, p=0.01). Bilobectomy was performed in 4.3% of cases, lobectomy in 83%, pneumonectomy in 6.2%, and segmentectomy in 6.5%. Neo-adjuvant therapy was performed in 22.8% of patients. Of the study patients, 36% were current smokers, 53.2% were past smokers, and 10.9% were never smokers. More male patients were past smokers (52.9% vs. 22.7% vs. 62.6%, $p < 0.01$). Past smokers had more cardiovascular comorbidities and ECOG status >1 ($p = 0.01$). Current smokers were more likely to have liver disease (8.1%, $p = 0.01$), previous malignancies (30.1%, $p < 0.01$), and COPD of any stage (36.6%, $p < 0.01$). There was no statistical significance between the three groups regarding obesity, arterial hypertension, chronic kidney disease, stomach comorbidities, or the extent of lung resection ($p > 0.05$). More VATS resections were performed in never smokers (56.3%, $p < 0.01$). Past smokers had more complications diagnosed (30.5% vs. 22.7% vs. 34.3%, $p = 0.04$). Current smokers showed a higher incidence of persistent air leak after the operation (13.0% vs. 1.7% vs. 12.0%, $p < 0.01$) and postoperative atelectasis requiring bronchoscopy intervention (2.8% vs. 0.0% vs. 0.7%, $p < 0.01$). There was no statistical significance between the groups concerning ARDS, pneumonia, postoperative empyema, cardiac failure, renal failure, postoperative re-intubation and ventilation, and unexpected admission to the ICU ($p > 0.05$). Current smokers did not show an increased early mortality compared to the other two groups (1.0% vs. 3.4% vs. 1.0%, p=0.20).

Conclusions: Despite advances in medical technology and surgical techniques, postoperative morbidity remains higher for smokers. Both past and current smokers exhibited significant differences in the frequency of postoperative complications compared to never smokers. However, smoking status did not appear to influence early postoperative mortality.

Rankin[1], [1]University of Melbourne, Melbourne/AU ,[2]Flinders University, Adelaide/AU ,[3]University of Queensland Thoracic Research Centre and Department of Thoracic Medicine, The Prince Charles Hospital, Brisbane/AU ,[4]St. Vincent's Hospital Sydney, Sydney/AU ,[5]UNSW Sydney, Sydney/AU ,[6]Consumer Panel, Thoracic Oncology Group of Australasia, Melbourne/AU ,[7]Consumer Member, TROG Cancer Research, Newcastle/AU ,[8]The University of Newcastle, Newcastle/AU ,[9]Hunter Medical Research Institute, Newcastle/AU ,[10]The University of Queensland, Brisbane/AU ,[11]University of Wollongong, Wollongong/AU ,[12]The Daffodil Centre, a joint venture between Cancer Council NSW and The University of Sydney, Sydney/AU ,[13]Fiona Stanley Hospital, Perth/AU ,[14]University of Western Australia, Perth/AU ,[15]Sir Charles Gairdner Hospital, Perth/AU ,[16]Curtin University, Perth/AU ,[17]St. John of God Subiaco Hospital, Perth/AU ,[18]PC[4] Community Advisory Group, Primary Care Collaborative Cancer Clinical Trials Group, Melbourne/AU

Introduction: International clinical practice guidelines recommend the integration of smoking cessation interventions in low-dose computed tomography lung cancer screening (LCS). In LCS programs, smoking cessation interventions have demonstrated cost-effectiveness, and have favourable outcomes for LCS participants who smoke, including high sustained quit rates. There is emerging evidence on the optimum strategies to integrate cessation interventions into LCS programs, but little data specific to the Australian setting, where a targeted National LCS Program (NLCSP) will commence in 2025. To inform policy and program development, we sought national expert stakeholders' views on factors that would enhance feasibility and acceptability of cessation interventions in NLCSP implementation.

Methods: In July 2023, a full-day, in-person consensus workshop was conducted. Varied recruitment strategies, including cancer advocacy/professional organisations, our existing networks, and snowball sampling, were used to invite stakeholders. The priority setting process was guided by modified Nominal Group Technique methodology. In small-group activities, stakeholders identified facilitators/barriers of smoking cessation interventions in assigned LCS delivery models (e.g., mobile screening, primary care-led), and potential cessation interventions for implementation throughout the LCS screening and assessment pathway. Each group generated priorities across defined categories (e.g., 'delivery', 'equity'), before individual online voting to shortlist priorities, and refinement of priorities through whole-group discussion. Workshop notes and audio recordings were interpreted through a deductive rapid qualitative analysis.

Results: Stakeholders (N=38) were from all Australian states and territories, and broad disciplines including tobacco control, respiratory medicine, cancer policy, and community advocacy. The 12 shortlisted priorities represented both short- and long-term considerations, aligned with policy-level to consumer-driven actions (Figure 1). Foremost was development of a strategy to design and deliver smoking cessation training packages with professional disciplines involved in NLCSP delivery (priority 1), reflecting concerns about existing workforce capacity. Stakeholders strongly endorsed smoking cessation interventions co-designed for priority population groups (2), an embedded cessation-specific evaluation framework (3), and cessation messaging featuring participant testimonials to avoid exacerbating stigma (4). An overarching 'equity' principle (c.f. standalone priority) was suggested to support "participant-centric" program design and delivery.

Conclusions: These priority-based, pre-implementation recommendations emphasise equity-focused approaches to embedding cessation and capitalising on existing resources, including authentic priority population engagement. Considering a broad range of implementation determinants, these findings provide foundational evidence to improve LCS program planning. Based on multidisciplinary expert consensus and a comprehensive methodological approach to elicit and determine priorities, this study provides a framework from which to detail short- and long-term LCS delivery approaches.

P1.01C.05 Potential Impact of Tobacco Control Policies in Preventing Incident Lung Cancers in the Eastern Mediterranean Region

S. Nemati[1], M. Sheikh[1], P. Fattahi[2], N. Taheri[2], M. Vand Rajabpour[2], [1]International Agency for Research on Cancer, Lyon/FR ,[2]Cancer Institute of Iran, Tehran/IR

Introduction: Lung cancer is the second leading cause of cancer deaths in the Eastern Mediterranean Region (EMR). While an estimated 85% of lung cancer deaths are attributable to tobacco smoking, tobacco control policies have still not been well-implemented in most EMR countries. To investigate the impact of the highest level of implementation of tobacco control policies on preventing incident lung cancer cases between 2025 to 2050 in the EMR countries.

Methods: We extracted information on the level of anti-tobacco policy implementation and calculated the cigarette affordability index (percentage of GDP per capita required to purchase 2000 cigarettes) for 16 EMR countries using publicly available data sources. Anti-tobacco policy implementation was measured by the World Health Organization (WHO) introduced the MPOWER measures score (range: 7-34) that constitutes monitoring tobacco use and prevention policies (4 score); protecting people from tobacco smoke (5 score); offering help to quit tobacco use (5 score); warning about the dangers of tobacco (5 score), Anti-tobacco mass media (5 score); enforcing bans on tobacco advertising, promotion, and sponsorship (5 score); and raising taxes on tobacco (5 score). First, we used Linear Fixed-effect regression models to investigate the associations between changes in MPOWER scores, cigarette affordability index, and alterations in tobacco prevalence over the past decade in each EMR country. Then, for each EMR country, we calculated the population attributable fraction (PAF) and number of incident lung cancer cases that would be attributable to tobacco smoking between 2025 and 2050 using their current tobacco smoking prevalence, WHO-estimated number of incident lung cancer cases in 2025, WHO-estimated annual percentage change in lung cancer incidence rates, population growth rate, and tobacco-related lung cancer risk estimate from the latest meta-analysis. Finally, for each country, we assessed the separate and combined effects of the highest level of MPOWER implementation, and a 10% increase in the affordability index, on their tobacco prevalence. To estimate the number of preventable lung cancer cases, the PAF of tobacco smoking under each scenario was calculated and subtracted from the PAF under the current prevalence scenario.

Results: Between 2025-2050, we estimate that 38,381,600 new lung cancer cases will occur among men, and 11,923,098 among women. We estimated that the highest implementation of the MPOWER measures could potentially prevent 574,828 lung cancer cases in men (1.5% of the total) and 366,761 in women (3.0%). Increasing the cigarette affordability index by 10% is estimated to prevent 475,995, and 342,004 new lung cancer cases in men (1.2%) and women (2.8%), respectively. A simultaneous application of both strategies could prevent a total of 886,949 cases in men and 549,361 in women in the EMR by 2050. The greatest impact is estimated for Iran (prevention of 518,494 new cases), Pakistan (prevention of 509,944), and Morocco (prevention of 140,606).

Conclusions: Our analysis shows that the implementation of robust tobacco control policies at the population level, encompassing the comprehensive enforcement of WHO-introduced MPOWER measures along with increasing the cigarette affordability index, may significantly decrease lung cancer incidence over the upcoming 25 years in the EMR countries.

P1.02A.01 ADAR1 Regulates Tumorigenesis and Stem Cell Properties in Non-Small Cell Lung Carcinoma

B.A. Jacobson, S. Tao, A. Sehgal, R. Khadilkar, R.A. Kratzke, M. Patel, H. Saveraid, K. Lan, J. Lan, A. Dolezal, University of Minnesota, Minneapolis/MN/USA

Introduction: RNA editing gene, ADAR1, has been implicated as an important regulatory node in many cancers including NSCLC. ADAR1 regulates gene expression by editing RNA post-transcriptionally but also inhibits type I interferon response. In melanoma and colorectal cancer, ADAR1 loss has been shown to enhance therapy with immune checkpoint inhibitors in murine syngeneic models in a process that is dependent on tumor-derived IFN-β. In NSCLC, ADAR1 loss has been shown to lead to marked cytotoxicity of exogenous IFNβ in some cells, however, the effect of ADAR1 loss in vivo has been less well documented. We previously showed that ADAR1 loss in murine LM2 NSCLC cells led to near complete loss of tumorigenicity in syngeneic immune competent cells as well as athymic mice suggesting that the mechanism was not dependent of the presence of T cells. Here, we add to our work by studying the effects of ADAR1 loss on tumorigenicity of human NSCLC cells. Based on our previous work, we hypothesized that the mechanism maybe related to lung cancer stemness.

Methods: ADAR1 was knocked out using CRISPR/Cas9 in human NSCLC cell lines, H2009 and A549. We previously confirmed that CRISPR/Cas9 gene editing resulted in loss of ADAR1 expression by Western Blot and PCR. Wild-type (WT) and ADAR1 knockout (ADAR-KO) cells were assayed for cell proliferation using CCK-8 assay. N=5 mice were injected with 1x106 cells on bilateral flanks (WT cells on left and ADAR-KO cells on right). Subsequent tumors were measured and mice were sacked when tumors reached 2000mm3 in volume. Also, the stem cell properties between WT and ADAR-KO (ALDH expression) were assessed by Western blot. Cells were treated with gemcitabine and cytotoxicity was compared between WT and KO cells in vitro.

Results: ADAR-KO cell lines grew in cell culture at the same rate as WT cells for H2009 and A549 cells over 72 hours. Morphologically, cells appeared similar under light microscopy. When grown in nude mice, WT cells formed tumors in 100% of the mice injected for both A549 and H2009. None of the ADAR1 KO cells formed tumors. In A549 cells, ALDH1A1 expression, a cancer stem cell marker, was completely lost in ADAR-1 KO cells compared to WT cells. H2009 cells do not express ALDH1A1 and will be evaluated by Aldefluor assay. A549 and H2009 KO cells were not more sensitive than WT cells to chemotherapy with gemcitabine in vitro.

Conclusions: ADAR1 loss in human NSCLC cells abrogates tumorigenicity. ADAR1 loss markedly decreases ALDH1A1 expression suggesting that ADAR1 is important in maintaining cancer stem cell phenotype. Further work will be done to evaluate the effect of ADAR-KO on cancer stemness (Aldefluor assay and tumor sphere formation). The mechanisms by which ADAR1 maintains the cancer stem cell phenotype will be further explored by evaluating the contributions on alteration of IFN signaling versus A to I RNA editing.

P1.02B.01 Mirnome Functional Profiling of Non-Small Cell Lung Cancer Identified New Mechanisms of PD-L1 Regulation

R. Cuttano, M.K. Afanga, V. Melocchi, E. Dama, M. Bizzarri, C. Carbonelli, P. Graziano, F. Bianchi, IRCCS Casa Sollievo Della Sofferenza, San Giovanni Rotondo/IT

Introduction: The use of immune checkpoint blockade (ICI), such as anti-PD-(L)-1 antibodies, has emerged as an effective treatment for both locally-advanced and advanced NSCLC. PD-L1 expression in cancer cells is regulated by a plethora of genetic and epigenetic mechanisms including genomic alterations, aberrant oncogenic and inflammatory pathways, post-transcriptional regulators (e.g., miRNA) and post-translational modification (e.g., ubiquitination, phosphorylation, glycosylation, palmitoylation). All these molecular processes contribute to dynamic and spatially heterogenous PD-L1 expression profile in lung cancer samples, which complicates PD-L1 pathological assessment thus limiting diagnostic accuracy. Interestingly, the 3' UTR of PD-L1 gene is disrupted in several tumor types, leading to a stabilized form of PD-L1 and high expression (i.e., with TPS≥ 50%). The 3' UTR of genes can be bound by microRNAs, small non-coding RNA that function as post- transcriptional regulators of gene expression, which induce mRNA degradation and translational repression.

Methods: By integrating miRNome and transcriptome profiling obtained from treatment-naïve (Stage IIIA) NSCLC mediastinal lymph node metastases and experimental lung cancer models, with high-throughput functional miRNA profiling using human miRNA lentiviral library (shMIMIC), we explored the role of miRNA in regulating PD-L1 expression and response to ICI treatment.

Results: Originally, we found that a signature of 16 miRNAs (aka LN-signature) can identify treatment naïve (Stage IIIA) NSCLC mediastinal lymphnodal metastases which develop resistance to induction chemotherapy (ICT). Importantly, LN-signature low-expressing tumors were characterized by a higher expression of PD-L1 as well as of enrichment of IFN stimulated genes (IFNG), which is a prerequisite to response to ICI treatment. Interestingly, LN-signature includes miR-455-5p, which we found to directly regulate PD-L1 expression and response to NACT. Next, we performed shMIMICs functional screening and identified the landscape of miRNAs enriched/depleted in PD-L1high vs. PD-L1low NSCLC. Since PD-L1 is mostly regulated by the IFNγ; signaling pathway, we identified also which miRNAs were modulated by IFNγ; signaling and involved in PD-L1 regulation. Such findings were then validated in cohorts of NSCLC patients (pre- and post-treatment by ICI) that we analyzed by combined miRNA-seq and RNA-seq profiling.

Conclusions: Our findings revealed a substantial role of miRNAs intertwined with other transcriptional signatures, in the regulation of PD-L1 expression and response to ICI therapy. Therefore, the heterogeneous tumor expression of PD-L1 can be explained, at least in part, by the modulation of the expression of such miRNAs functionally linked to PD-L1 and modulated by the IFNγ; signaling pathway. We anticipate that our findings will pave the way for the development of more accurate predictive biomarkers for ICI response.

P1.02B.02 Role of Chromosome 3 Aneuploidy in Basal Cell Differentiation and Lung Squamous Cell Carcinoma Initiation

J.J. Castellano, M. Saavedra Bagdonas, A. Saqi, A. Taylor, Columbia University, New York/NY/USA

Introduction: Lung cancer remains the most commonly diagnosed cancer type and the leading cause of cancer-related death in the United States. In the lung squamous cell carcinoma (LUSC) subtype, basal cells are considered to be the cell of origin with few identified driver mutations to date. However, chromosome or chromosome arm imbalance (aneuploidy) is present since the early development of LUSC. Alterations affecting chromosome 3 are extremely common in LUSC, where in stage I 80% and 60% of the cases (TCGA data) show loss of chromosome arm 3p and gain of chromosome arm 3q, respectively. These findings suggest a possible role for aneuploidy in tumor initiation.

Methods: To study the relationship between aneuploidy and LUSC development, our lab genetically engineered immortalized human lung epithelial cells to harbor either chromosome 3p deletion (3pDel) or chromosome 3q gain (3qGain) using CRISPR. We then induced differentiation in wild type (WT) and aneuploid clones grown in organoids and characterized phenotypes at the histological, morphological and gene expression level.

Results: Using RNAseq and immunofluorescence, we validated the basal-like gene expression pattern in our cells, with the expression of the canonical basal cell markers TP63 and KRT5. Interestingly, aneuploid cells showed an increased proliferative gene expression signature. After differentiation induction in 3D culture using Pneumacult media, both WT and aneuploid organoids showed squamous morphologies with noticeable genotype-related differences. WT organoids showed well-structured basal layers populated with epithelial-shaped cells, whereas aneuploid organoids presented unorganized basal layers with stretched cells. Additionally, WT organoids developed inner structures with high cellularity and hollowing areas. In contrast, 3qGain organoids showed squamous carcinoma features such as the accumulation of keratin pearls. Then, we assessed the differentiation grade of the organoids. At the mRNA level, canonical differentiation markers SCGB1A1 and MUC5B expression was induced in all genotypes; however, these were only detectable in WT organoids at the protein level. While both WT and 3qGain organoids successfully upregulated KRT23 expression upon differentiation, 3pDel organoids did not. In both WT and 3qGain organoids, KRT14 expression was detectable at late differentiation time points. In WT organoids this expression was traceable to KRT14Low/KRT5High epithelial-shaped cells located in the basal layer of the organoids. In contrast, in 3qGain organoids, these cells showed to be KRT14High/KRT5Low with flattened morphologies located at the organoid's basal layer. Furthermore, gene expression analysis revealed increased expression of proliferation markers (AURKB, TOP2A, KI67) in 3qGain organoids, while 3pDel organoids showed increased expression of NOTCH and TGFB.

Conclusions: Our results show aneuploidy genotype-specific features upon basal cells differentiation in 3D. Furthermore, these results suggest that aneuploidy can impair the differentiation of basal cells in the lung, possibly contributing to the early steps of LUSC development. Future scRNAseq experiments will help to uncover the specific mechanisms disrupted by aneuploidy during these process.

P1.02C.01 Intrinsic STING of CD8+T Cells Regulates Self-Metabolic Reprogramming and Improves Anti-Tumor Effects

Q. Xu[1], X. Hua[1], B. Li[2], B. Jiang[2], R. Xu[3], T. Lv[4], Y. Song[1], [1]Southeast University, Nanjing/CN ,[2]Nanjing University of Traditional Chinese Medicine, Nanjing/CN ,[3]University of Nottingham, Nottingham/GB ,[4]Nanjing University, Nanjing, Jiangsu province/CN

Introduction: Many preclinical studies have demonstrated that STING agonists have effective anti-tumor effects, but their adverse effects prevent practical use. Previous research by our team has demonstrated that STING has a more significant anti-tumor role in host immune cells than tumor cells, and the level of STING mRNA is associated with the outcome of immunotherapy in non-small cell lung cancer. Although STING is necessary for CD8+T cells to exert immunological activity, its effect on CD8+T cells is debatable. Therefore, we will concentrate on the particular roles of STING in CD8+T cells.

Methods: We used in vitro and in vivo models to confirm the influence of STING on CD8+T cell function. We examined the impact of STING on CD8+T cell metabolic function using RNA-seq, Seahorse, flow, electron microscopy, and other techniques. STING knockout mice were used to study the effect of competitive inhibition of glycolytic products during immunotherapy. In addition, we collected peripheral blood immune cells from 30 immunotherapy patients to examine the correlation between immune cell glycolysis levels and immunotherapy efficacy.

Results: RNA-seq showed significant changes in signaling pathways such as glycolysis/glycogen synthesis, oxidative phosphorylation, tricarboxylic acid cycle, and one carbon unit in STING-/- CD8+T cells. In vitro experiments revealed that the inactivation of the STING gene reduced the number of mitochondria, altered the choice of metabolic pathways, and impaired the anti-tumor ability. Flow results showed that the mean fluorescence intensity of mitochondria in STING-/- CD8+T decreased. Seahorse experiment showed that STING-/- CD8+T glycolysis was enhanced, and oxidative phosphorylation was decreased. Meanwhile, the content of lactic acid in the culture supernatant of STING-/- CD8+ T increased dramatically, the high level of lactic acid further inhibited the proliferation of CD8+ T and the secretion of IFN-γ. Competitive inhibition of the glycolysis process or lactic acid formation can save the function of STING-/- CD8+ T cells and the secretion of IFN-γ, save the immunotherapy effect of STING-/- mice. This provides a new therapeutic idea for patients with low STING expression and poor immunotherapy response. In the peripheral blood immune cells of immunotherapy patients, we observed a negative correlation between the mRNA levels of glycolysis-associated molecules and STING. Additionally, we found a correlation between the levels of glycolysis-associated molecules in immune cells and immunotherapy efficacy outcomes.

Conclusions: Our study is the first to explore the effect of STING on the metabolic process in CD8+ T cells. Intervening in the metabolic process of STING-deficient CD8+ T can save the efficacy of immunotherapy.

P1.02C.02 NIR-II Mediates Cancer Nanocomposite Vaccines for Lymph Node Targeted Delivery and Enhanced Immunotherapy

H. Zhou[1], Y. Huang[2], B. Xu[3], H. Hou[2], L. Yao[1], Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]School of Medicine, South China University of Technology, Guangzhou/CN ,[3]School of Biomedical Sciences and Engineering, South China University of Technology, Guangzhou/CN

Introduction: Lung cancer, with its high morbidity and mortality rates, stands as a formidable challenge in the realm of oncology. While immunotherapy has shown initial promise, its efficiency leaves room for improvement, underscoring the pressing need for precise diagnostic and effective treatment strategies. Cancer vaccines, an emerging modality for solid tumors, hold great promise for future tumor treatments, but their systemic administration often results in adverse side effects. Nanovaccines, leveraging nanotechnology to effectively deliver tumor antigens and adjuvants, activate antigen-presenting cells, and induce specific anti-tumor immune responses, present a unique solution to these challenges. In this context, we propose a straightforward approach for in situ programming of lung cancer using a lymph node-targeting nanovaccine.

Methods: Initially, we synthesized non-toxic PSS-modified gold nanorods (Au-PSS), along with the amphiphilic polymer mPEG-PHEP and cationic liposome DOTAP nanoparticles, which encapsulate the immune adjuvant R848 (VNPR848). Following this, we conducted a comprehensive characterization of these nanoparticles, which revealed vaccine-like effects at the cellular level and lymph node targeting capabilities of the nanovaccine at the animal level. Furthermore, in animal models, we observed the nanovaccine's efficacy in distal models, lung metastasis, and postoperative recurrence. These findings collectively validated the potent therapeutic impact of this nanovaccine.

Results: Under near-infrared II light irradiation, antigens were released by orthotopic tumor cells via gold nanorods and captured by VNPR848, which has promoted the synergistic transport of antigen and R848 to lymph nodes and then had a significant therapeutic effect on distant tumors (Fig. 1a). This procedure resulted in a notable maturation rate of DCs at 46.9% within the Au(+)/VNPR848 group (Fig. 1b) and facilitated the activation of primary T cells, leading to the generation of tumor-specific CD8+ T cells. These combined effects not only completely inhibited the growth of distant tumors but also curtailed lung metastasis and postoperative recurrence, thereby inducing a long-term immune memory effect.

Conclusions: In our research, we have strategically designed two distinct nano-vaccine systems, each with unique functionalities. These systems effectively amalgamate the processes of in situ tumor antigen production, antigen capture by nanoparticles, and co-delivery of these antigens and immune adjuvants to lymph nodes. This approach engenders a potent anti-tumor response, stimulates systemic immunity, and fosters long-term immune memory. Our findings pave the way for a novel strategy in constructing in situ cancer vaccines.

P1.02C.03 A Novel IL-15 Superagonist SHR-1501 Promotes Immune Response in Lung Cancer via Modulating Tumor Microenvironment

q. zhang, shanghai pulmonary hospital, shanghai/CN

Introduction: Interleukin-15 (IL-15) is a pleiotropic cytokine and identified as a promising agent to be used in caner immunotherapy. Now, we developed a novel IL-15 super-agonist, SHR-1501, a pharmacological grade IL-15/IL-15Rα complex fused to an IgG1 Fc, in which structure exhibits prolonged the half-life in vivo and increased biological activity of IL-15. In this study, we investigated the anti-tumor effects of the newly developed IL-15RA, SHR-1501, both alone and in combination with PD-1 monoclonal antibody (mAb), in two murine lung cancer models. And this is the first study conducted to examine the alteration of the TME and the immune response induced by SHR-1501.

Methods: We investigated its antitumor effects of SHR-1501 by intra-tumoral injection in two lung cell-delivered murine lung cancer models: Lewis lung cancer (LLC) and Kras G12D, p53-/- (KP) lung cancer cell models. We administered SHR-1501 through intratumoral injection (5/15μg) and collect tumor, spleen, and peripheral blood samples for analysis. We use flow cytometry analysis, single-cell sequencing and IHC staining to examine the alteration of tumor microenvironment (TME) and flow cytometry analysis for peripheral immune system.

Results: We found that the administration of SHR-1501 alone at the dose of 5 or 15μg can significantly inhibit tumor growth in both mice models. And the higher dose had shown more effective anti-tumor effects with no significant toxicities. We found an enhanced infiltration of CD8+ T cells, effector CD8+ T lymphocytes, and natural killer (NK) cells in the TME. Additionally, there was a significant increase in the proportion of CD8+ T cells and effector CD8+ T cells in the spleen and peripheral blood samples of mice, and the proportion of NK cells in the peripheral immune system showed a significant early elevation upon SHR-1501 administration (day 7). The results of single-cell sequencing also demonstrated that SHR-1501 can regulate cell populations such as macrophages within the TME, leading to a shift towards a more favorable anti-tumor immune response. We further explored the synergistic anti-tumor immune efficacy of SHR-1501 in combination with PD-1 mAb. Using a subcutaneous tumor model of mouse lung cancer, SHR-1501 was injected into the tumor (15μg, once) and PD-1 mAb was injected intraperitoneally (200μg/each, 6 times). We found that in the combination treatment group, the inhibition of tumor volume growth was most significant and the tumor volume was the smallest. Survival analysis also showed that the combination group had the longest survival period, and the mice did not exhibit obvious drug toxicity. These results indicate that SHR-1501 has a synergistic anti-tumor immune effect with PD-1 mAb. In addition, by establishing a bilateral tumor mouse model, we observed an obscopal effect induced by SHR-1501.

Conclusions: The novel IL-15 superagonist, SHR-1501, has a strong anti-tumor effects in lung cancer cell mouse models, and the combination of SHR-1501 with PD-1 mAb had shown a potent synergistic anti-tumor effect. The findings from this study can provide evidence and experimental basis to support further clinical trial.

P1.02D.01 Exosome PAICS Enhances Radioresistance in NSCLC by Mitigating Radiation-Induced DNA Damage and Facilitating Immune Evasion

X. Gong, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Radioresistance in NSCLC is not solely a consequence of tumor cell adaptation but also involves significant alterations within the tumor microenvironment, including changes in immune cell dynamics. Tumor-derived exosomes play a critical role in this adaptive resistance, influencing not just the tumor cells but also the immune cells. Unraveling the molecular mechanisms of exosome-mediated radioresistance is crucial for identifying novel targets that can sensitize tumors to radiotherapy and serve as predictive markers for treatment response.

Methods: Colony formation assay, wound healing assay and immunofluorescence assay were utilized to assess how exosomes from radioresistant cells influence the radiosensitivity of NSCLC cells. RNA-seq sequencing was performed to identify the functional gene of radioresistant NSCLC cells. We conducted comprehensive in vitro and in vivo studies, including subcutaneous tumor models and flow cytometry, to explore the impact of exosome-delivered functional proteins on NSCLC and the underlying mechanisms.

Results: Our research found that exosomes from radioresistant A549/X cells reduce DNA damage and increase radioresistance in NSCLC cells(Figure1). Specifically, PAICS(Phosphoribosylaminoimidazole carboxylase, phosphoribosylaminoimidazole succinocarboxamide synthetase), significantly upregulated in A549/X and its exosomes, appears to contribute to NSCLC's radioresistance. Silencing PAICS in A549/X cells diminished these effects, suggesting PAICS's role in mitigating radiation damage and inhibiting NSCLC cell migration. This process involved alterations in DNA damage response and immune evasion mechanisms, including changes in H2AX phosphorylation, RAD51 expression, and STING pathway activation. Additionally, animal studies demonstrated that A549/X-derived exosomes decreased radiotherapy's tumor-reducing effects, which was counteracted by using exosomes from PAICS-silenced A549/X cells. Flow cytometry revealed that exosome PAICS promotes an immunosuppressive environment, aiding in tumor immune escape by inhibiting CD4+T cells, CD8+T cells, DC cells infiltration and promoting the polarization of M2-type macrophages.

Conclusions: Our results demonstrate that PAICS, a crucial enzyme in the purine biosynthesis pathway, can be conveyed to recipient NSCLC cells via exosomes. This mechanism may play a significant role in conferring radioresistance in NSCLC.

P1.02D.02 Tumor-Derived Exosomal tsRNA 3' tiRNA-AlaCGC Promotes Immune Tolerance by Inducing Fibroblast Senescence in LUAD

Y. Zhang, G. Zhao, H. Zhang, D. Ge, Zhongshan Hospital, Fudan University, Shanghai/CN

Introduction: The benefit of immunotherapy varies among lung adenocarcinoma(LUAD) patients due to the heterogeneity of the tumor microenvironment(TME). Transporter RNA-derived small RNAs(tsRNAs) are able to influence mRNA stabilization and thus the TME, but their role in immunotherapy resistance in LUAD has not been elucidated.

Methods: The correlation between tsRNA and immunotherapy resistance in the neoadjuvant chemotherapy combined immunotherapy cohort was investigated using high-throughput Arraystar Small RNA microarray. The expression, clinical relevance and biological functions of 3'tiRNA-AlaCGC in LUAD were investigated. By adding 3'tiRNA-AlaCGC mimics and inhibitors, extracting exosomes secreted by tumor cells, and using FISH, flow cytometry, senescence staining, liquid phase cytokine microarrays, and RNA-seq, the role of 3'tiRNA-AlaCGC on immune cells and fibroblasts and the mechanism leading to immune resistance were investigated. Meanwhile, at the animal level, it has been demonstrated that 3'tiRNA-AlaCGC leads to resistance to anti-tumor immunotherapy.

Results: 3'tiRNA-AlaCGC was significantly elevated in the progressive disease(PD) group than partial response(PR) group. It was associated with poor prognosis and decreased CD8+ T cells in multiple other cohorts. Altering intracellular 3'tiRNA-AlaCGC levels in tumor cells did not affect LUAD proliferation, migration or invasive capacity, nor did it affect tumor size in immunodeficient mice. LUAD cells can secrete tsRNA 3'tiRNA-AlaCGC via exosomes. Its overexpression in tumor exosomes did not affect immune cells in the TME, but inhibited the proliferation and migration abilities of fibroblasts and caused an increase in their senescence-associated secretory phenotype(SASP), which promoted their senescence. Mechanistically, 3'tiRNA-AlaCGC decreased the expression of FOXO3, which led to the enrichment of senescence-related pathways, promoted fibroblast senescence, and suppressed the function of CD8+ T cells in the TME. In addition, tsRNA 3'tiRNA-AlaCGC increased the secretion of the immunosuppressive ligand Gal-9 through the TGFβ-Smad pathway, which further suppressed anti-tumor immunity. Animal experiments confirmed that 3'tiRNA-AlaCGC overexpression decreased the level of FOXO3 and increased the expression of Gal-9 in cancer tissues, causing a decrease in CD8+T anti-tumor function and leading to anti-PD-L1 treatment resistance.

Conclusions: LUAD cells can secrete tsRNA 3'tiRNA-AlaCGC through the exosomal pathway to induce fibroblast senescence, which induces a decrease in the anti-tumor capacity of CD8+T cells, leading to anti-PD-L1 immunotherapy resistance and poor prognosis in LUAD. Targeting tsRNA 3'tiRNA-AlaCGC may be a novel strategy for synergistic immunotherapy in LUAD.

P1.03A.01 Identification of Disulfidptosis in ESCC Based on Single-Cell and Bulk RNA-seq Data to Predict Prognosis and Treatment Response

X. Zhang, B. Zheng, M. Chen, Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: Our study aims to identify the molecular subtypes of genes associated with disulfidptosis in ESCC, construct a scoring model to explore the differences in tumor growth behavior and find novel potential therapeutic targets.

Methods: Consensus cluster analysis was performed based on the GSE53625 dataset. The prognostic signature was constructed using univariate, multivariate, and Lasso-Cox regression analysis. The TCGA-ESCC dataset and single-cell RNA-seq data from the GSE160269 dataset was combined with trajectory analysis to analyze the prognostic signature. Additionally, the differences in tumor growth patterns, immune microenvironment, and cellular communication were explored, immunotherapy effects were predicted between high- and low-score groups, and potential therapeutic strategies were investigated to provide ideas for follow-up studies.

Results: We identified two distinct patterns of disulfidptosis expression with significant differences in overall survival. Then, we constructed the prognostic signature of disulfidptosis, and results showed patients with high score had worse prognosis. Univariate and multivariate Cox analysis demonstrated that the constructed prognostic signature was an independent prognostic factor and was validated in an independent validation set. The two subgroups differed in the proportion of immune cell infiltration and related signaling pathways in ESCC. The exploration of immunotherapy data confirmed our prognostic signature also had certain predictive power for immunotherapy. Regarding drug prediction, the results suggested the EGFR inhibitor had a stronger inhibitory effect on the low-score group.

Conclusions: This study provides a new prognostic signature for ESCC, explores new therapeutic targets, and provides new theoretical support for personalized treatment.

P1.03A.02 FBXO32 Promotes EMT and Regulates the Cell Cycle by Targeting PTEN for Proteasomal-Dependent Degradation in LUAD

J. Wu[1], T. Wen[2], A. Marzio[3], D. Song[1], S. Chen[4], C. Yang[1], F. Zhao[1], H. Ren[1], Q. Chen[2], Y. Yang[5], S. Qin[1], [1]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an/CN ,[2]School of Basic Medical Sciences, Xi'an Jiaotong University, Xi'an/CN ,[3]Meyer Cancer Center, Weill Cornell Medical Center, New York/NY/USA ,[4]The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an/CN ,[5]Clinical Research Center for Shaanxi Provincial Radiotherapy, Shaanxi Provincial Cancer Hospital, Xi'an/CN

Introduction: FBXO32, a member of the F-box protein family, is known to play both oncogenic and tumor-suppressive roles in different cancers. However, the functions and the molecular mechanisms regulated by FBXO32 in lung adenocarcinoma (LUAD) remain unclear.

Methods: The expression of FBXO32 and PTEN in LUAD tissues and cells was measured by RT-qPCR, immunohistochemistry and Western blotting. The distribution of cells in the cell cycle was determined via flow cytometry. Transwell and wound-healing assays were performed to analyse the migration and invasion ability of LUAD cells. The expression of related molecular markers was measured by Western blot and immunofluorescence assays. A nude mouse model of tumour metastasis was established to evaluate the effect of FBXO32 on metastasis in vivo. The regulatory mechanisms were validated by coimmunoprecipitation and ubiquitination assays.

Results: FBXO32 is overexpressed in LUAD compared with normal lung tissues, and high expression of FBXO32 correlates with poor prognosis in LUAD patients. Firstly, we observed with a series of functional experiments that FBXO32 alters the cell cycle and promotes the invasion and metastasis of LUAD cells. We further corroborate our findings using in vivo mouse models of metastasis and confirmed that FBXO32 positively regulates LUAD tumor metastasis. Using a proteomic-based approach combined with computational analyses, we found a positive correlation between FBXO32 and the PI3K/AKT/mTOR pathway, and identified PTEN as a FBXO32 interactor. More important, FBXO32 binds PTEN via its C-terminal substrate binding domain and we also validated PTEN as a bona fide FBXO32 substrate. Finally, we demonstrated that FBXO32 promotes EMT and regulates the cell cycle by targeting PTEN for proteasomal-dependent degradation.

Conclusions: In summary, our study highlights the role of FBXO32 in promoting the PI3K/AKT/mTOR pathway via PTEN degradation, thereby fostering lung adenocarcinoma progression.

P1.03B.01 Multi-Omics Profiling Reveals the Genomic Origin and Adeno-Squamous Transdifferentiation Mechanism in Adenosquamous Carcinoma

X. Zheng[1], G. Lin[1], Q. Miao[2], K. Jiang[1], X. Zheng[1], L. Zhang[1], [1]Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou/CN ,[2]Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fozhou/CN

Introduction: Adenosquamous carcinoma (ASC) represents a rare subtype (0.4-4%) of non-small-cell lung cancer (NSCLC), with its multi-omic landscape yet to be fully elucidated. This study aims to explore the genomic origins and molecular mechanisms of adeno-squamous transdifferentiation in lung ASC through comprehensive multi-omics.

Methods: We analyzed 69 samples from 31 lung ASC patients, including 16 FFPE samples with microdissected paired adenocarcinoma (AC) and squamous cell carcinoma (SCC) components, and additionally, incorporated pure Lung Adenocarcinoma (LUAD, n = 51) and pure Squamous Cell Carcinoma (LUSC, n = 28) for comparative analysis. Techniques included whole-exome sequencing, whole-genome methylation profiling, transcriptomics, single-cell RNA sequencing, and spatial transcriptomics.

Results: AC and SCC exhibited similar genomic mutation landscapes, indicating a common genomic origin for AD and SCC. The SCC component in ASC displayed higher homologous recombination repair deficiency (HRD) and a notable 16p13.3 deletion in 31% of ASC transformations. Differential methylation analysis highlighted TP63's lower methylation in SCC, correlating negatively with RNA expression ($P < 0.001$), indicative of methylation-driven regulation. DMR binding motif analysis revealed hypo-methylation in p63, p53, and AP-1 motifs, and hyper-methylation in MKX2-1, FOXA1/2 motifs ($P < 0.05$). The transition from AC to SCC in ASC was marked by upregulated MYC signaling, proliferation, and DNA repair, with EMT changes not methylation-driven. Metabolic pathways were upregulated, and EMT/KRAS pathways downregulated in SCC compared to LUSC. Immune infiltration in LUAD-AC-ASC transformation showed an initial increase and subsequent decrease, transitioning from immune-infiltrated and immune-excluded to immune-desert phenotypes. IL36G of the IL1 family was highly expressed in the SCC component and strongly correlated with the squamous marker P63 (Pearson $r = 0.72$, $P < 0.001$). Single-cell RNA-seq data demonstrated a significant increase in IL36G in squamous cells of lung ASC. In vivo models showed adeno-squamous differentiation in adenocarcinoma cells expressing IL36G.

Conclusions: This study provides a comprehensive multi-omic insight into the complex genomic and epigenomic landscape of ASC, highlighting a shared genomic origin and distinct molecular mechanisms in the adeno-squamous transdifferentiation process. The findings, particularly the role of TP63 methylation and IL36G expression in the SCC component, offer novel insights into the molecular heterogeneity of ASC.

P1.03C.01 A Landscape of the Driver Alterations in 920 Brazilian Lung Cancer Patients.

R. De Oliveira Cavagna[1], F. Escremim de Paula[1], G. Noriz Berardinelli[1], M. Bonatelli[1], I. Santana[1], G. Ramos Teixeira[1,2], B. Garbe Zaniolo[2], J. Mourão Dias[1], F.A. Ferreira da Silva[1], C.E. Baston Silva[1], M. Gondim Borges Guimarães[1], C. Pinto Barone[1], M. Xavier Reis[1], E. Lopes Maia[1], T. Santos de Alencar[1], R. Martins Queiroz Barbosa[1], F.H. de Queiroz[1], I. Marriel Ramos Novais[1], J. Favoreto Neto[3], A.A. Jacinto[1], L. Ferreira[3], G. Severino Bueno[3], R.E. Noleto da Nóbrega Oliveira[1], J.E. Miziara[1], P. de Marchi[4], M.A. Molina-Vila[5], L. Ferro Leal[1,2], R.M. Reis[1,6], [1]Barretos Cancer Hospital, Barretos/BR ,[2]Barretos School of Health Sciences Dr. Paulo Prata – FACISB, Barretos/BR ,[3]Barretos Cancer Hospital, Porto Velho/BR ,[4]Oncoclinicas, Rio de Janeiro/BR ,[5]Pangaea Oncology, Barcelona/ES ,[6]Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga/PT

Introduction: The profile of driver alterations directly impacts the clinical management of lung cancer patients and can significantly change among ethnic groups. The molecular profile in admixed populations, as in Brazil, is poorly understood. We aimed to describe the molecular profile of Brazilian patients with non-small cell lung cancer (NSCLC) using real-world data from a single center in Brazil.

Methods: Driver mutations and fusions in 920 NSCLC patients were assessed by NGS (TruSight Tumor 15) and RNA-based nCounter approaches, respectively. The genetic ancestry was assessed using 46-ancestry-informative markers. Additionally, the molecular profile was associated with patients' clinicopathological and survival features.

Results: Most patients harbored at least one oncogenic alteration (88.4%; n=813/920)(Figure 1). EGFR mutations were associated with females, never-smokers, diagnosed with non-squamous histology, and the presence of metastasis in the nervous system. KRAS mutations were associated with ever-smoker, loss of weight (6-months prior to diagnosis), and adenocarcinoma histology. TP53 mutations were associated with males, ever-smoker, and squamous histology. ALKfusions were associated with younger patients, never-smokers, and adenocarcinoma subtype. Higher African ancestry was associated with TP53 mutations (p=0.002). Patients harboring EGFR mutations showed longer overall survival than wild-type patients (p<0.0001, 36.3 and 14.5 months, respectively). Of note, patients harboring concomitant EGFR and TP53 mutations showed shorter overall survival than patients with only EGFR mutations (p=0.019; 25.7 and 62.0 months, respectively). Similar trends were observed in patients who received TKI treatment, with EGFR-mutant patients harboring TP53 mutations presenting shorter overall survival than patients with only EGFR mutations (p=0.086; 23.4 and 33.1 months, respectively).

Conclusions: Most patients harbor at least one oncogenic alteration. The association of TP53 mutations and African ancestry suggests an influence of genetic ancestry in molecular profile in Brazilian patients. Co-occurrence of TP53 and EGFR mutations suggested an unfavorable prognosis for TKi-treated patients. Our results reinforce the importance of molecular characterization in ethnic admixed NSCLC patients.

P1.03C.02 Different STK11 Mutation Status Defines Various TIME in NSCLC

X. Chen[1], J. Zheng[2], J. Lu[1], W. Liu[1], [1]Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou/CN ,[2]The Second Affiliated Hospital of Fujian Medical University, Department of Radiation Oncology/CN

Introduction: To unveil whether overexpressed- and mutated-STK11 impact survival in NSCLC and to explore whether immune related genes (IRGs) are involved in STK11 mutations.

Methods: 188 NSCLC patients with intact FFPE tissue available for detecting STK11 protein expression were included. After IHC detection of STK11 protein, patients were divided into high STK11High and STK11Low, and survival analysis and COX proportional hazards model were used to compare survival. In addition, the mutation data from the TCGA database was used to categorize the NSCLC population, i.e., STK11Mut and STK11Wt subgroups. The difference in OS between STK11Mut and STK11Wt was compared. Finally, bioinformatics analysis was used to compare the differences in IRGs expression between STK11Mut and STK11Wt populations.

Results: The median follow-up time was 51.0 months (range 3.0 - 120.0 months) for real-life cohort. At the end of follow-up, 64.36% (121/188) of patients experienced recurrence or metastasis. 64.89% (122/188) of patients ended up in cancer-related death. High expression of STK11 was a significant protective factor for NSCLC patients, both in terms of PFS [HR=0.42, 95% CI= (0.29-0.61), P<0.001] and OS [HR=0.36, 95% CI= (0.25, 0.53), P<0.001], which was consistent with the finding in TCGA cohorts [HR=0.76, 95%CI= (0.65, 0.88), P<0.001 HR=0.76, 95%CI= (0.65, 0.88), P<0.001]. In TCGA cohort, STK11 mutation was a significant risk factor for NSCLC in both lung squamous cell carcinoma (LUSC) and lung adenocarcinoma (LUAD) histology in terms of OS [HR=6.81, 95%CI= (2.16, 21.53), P<0.001; HR=1.50, 95%CI= (1.00, 2.26), P=0.051, respectively]. Furthermore, 7 IRGs, namely CALCA, BMP6, S100P, THPO, CGA, PCSK1 and MUC5AC, were found significantly overexpressed in STK11-mutated NSCLC in both LUSC and LUAD histology.

Conclusions: Low STK11 expression at protein level and presence of STK11 mutation were associated with poor prognosis in NSCLC, and mutated STK11 might probably alter the expression IRGs profiling.

P1.03D.01 Efficacy and Biomarker Analysis of Neoadjuvant Toripalimab Plus Chemotherapy in Resectable Stage IIB-IIIB Non-Small Cell Lung Cancer (NSCLC)

B. Liu[1], N. Wu[2], S. Yan[1], E. Zhang[3], L. Xu[3], X. Cheng[3], [1]Peking University Cancer Hospital & Institute, Beijing/CN ,[2]Peking University Cancer Hospital, Beijing/CN ,[3]Genecast Biotechnology Co., Ltd, Wuxi/CN

Introduction: Immune checkpoint inhibitors revolutionized cancer treatment, including NSCLC. Several studies have revealed preliminary efficacy and safety of neoadjuvant chemoimmunotherapy in NSCLC. However, further studies are still necessary to validate its efficacy and safety. Furthermore, while neoadjuvant chemoimmunotherapy exhibits superior efficacy over standard chemotherapy, it does not confer benefits to all patients, as evidenced by on-going trials.

Methods: This was a prospective single-arm, phase II clinical trial conducted at Peking University Cancer Hospital & Institute (NCT04606303). From December 18, 2020 to January 9, 2023, 100 patients with histologically confirmed clinical stage IIB to IIIB NSCLC (stage IIIB, T3-4N2M0 only) received the following drugs intravenously in each 21-day treatment cycle: toripalimab, cis-platinum, pemetrexed for lung adenocarcinoma (LUAD) and albumin-bound paclitaxel for lung squamous cell carcinoma (LUSC) or NSCLC-not identified subtype (NSCLC-other). We conducted targeted methylation panel sequencing and analyzed the methylation profiling for all plasma samples and calculated methylation fragment ratio scores (MFR) and performed whole methylation sequencing (WMS) and assessed chromosomal aneuploidy of featured fragments (CAFF) score.

Results: Among the 100 patients enrolled in this study, 83 (83.0%) patients successfully underwent surgical resection and included in the final efficacy analysis, and R0 resection was achieved in all these patients. Surgical complications occurred in 21 (25.3%) patients. According to postoperative pathological evaluation, 54 (65.1%) patients achieved major pathological response. For MPR patients, both the MFR score and CAFF score significantly reduced from C0 to C1 ($P < 0.001$) and remained low at BS ($P < 0.001$). In contrast, non-MPR patients exhibited a different dynamic pattern. The MFR score similarly reduced at C1 ($P < 0.05$), but it tended to increase at the end of neoadjuvant treatment (BS), showing no significant difference between BS and C0 time points ($P = 0.132$). A similar dynamic pattern was observed for the CAFF score in MPR group. Notably, the CAFF score showed no significant reduction at C1 compared to C0 for non-MPR patients ($P = 0.111$).

Conclusions: We demonstrated the efficacy of neoadjuvant toripalimab combined with chemotherapy and the predictive value of MFR and CAFF score in neoadjuvant chemoimmunotherapy.

Keywords: non small cell lung cancer, neoadjuvant chemoimmunotherapy, biomarker

P1.03D.02 An Enhanced Immunotherapeutic Strategie for NSCLC via in Situ Tumor Nanovaccines and Activation of STING and TLR7/8 Pathways

H. Zhou[1], H. Hou[2], Y. Huang[2], B. Xu[3], S. Wu[1], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]School of Medicine, South China University of Technology, Guangzhou/CN ,[3]School of Biomedical Sciences and Engineering, South China University of Technology, Guangzhou/CN

Introduction: Following surgical treatment, radiotherapy, and chemotherapy, immunotherapy has emerged as a novel and promising therapeutic approach for tumors. Among the various strategies, therapeutic tumor vaccines are gaining attention due to their potential in eradicating tumors and preventing recurrence and metastasis by inducing or amplifying T cell-mediated immune responses. However, the therapeutic efficacy of these vaccines is often limited by the heterogeneity observed both between and within tumors. In contrast, in situ tumor vaccines, which are prepared directly from tumor patients and thus produce whole autologous antigens, present another promising strategy that is gaining momentum in the field.

Methods: In our research, we engineered a multifunctional nanopolymer, termed as PAEMA-PCR848, which is a transformable nanoassembly. This assembly is composed of the photosensitizer PEG-Ce6 (Polyethylene glycol-chlorin-e6), a tumor pH-responsive polymer P-AEMA (Poly(2-azepane ethyl methacrylate)), and the immune adjuvant Resiquimod (R-848). We validated the activation of bone marrow-derived dendritic cells at a cellular level and subsequently investigated the inhibition of distal tumor growth mediated by PAEMA-PCR848 through photodynamic therapy (PDT).

Results: We have successfully prepared and characterized an acid-responsive nanovaccine loaded with agonists of the STING and TLR7/8 pathways. Enhanced Dendritic Cells (DCs) Maturation In vitro studies demonstrated a notable maturation rate of DCs at 38.8±2.0% within the PAEMA-PCR848 group which was significantly superior compared to other groups, indicating that PAEMA-PCR848 efficaciously fosters DC maturation and augments antigen presentation capabilities. In the C57BL/6 mouse model, the PAEMA-PCR848 group demonstrated a significantly higher infiltration ratio of 60.1±5.8% for CD8+ T cells in distant tumors, indicating an enhancement in immunogenicity and antigen presentation, thereby potentially augmenting the efficacy of immunotherapy.

Conclusions: In this research, we have devised a straightforward yet potent approach centered on in situ tumors. This strategy has demonstrated potential in curbing tumor growth, triggering immunogenic cell death, and eliciting a systemic anti-tumor immune response. Furthermore, we aim to extend our investigations to ascertain the therapeutic impact on metastatic and distal tumors.

Keywords: Drug delivery, Immunotherapy, In situ tumor vaccin

P1.03D.03 Artemisinin Enhances Anti-Tumor Immunity by Increasing FGL1 Ubiquitination Degradation via Activating TRIM21 In NSCLC

Y. Zhang[1], P. Zhou[1], D. Ge[1], J. Gu[1], C. Zhang[2], [1]Zhongshan Hospital, Fudan University, Shanghai/CN ,[2]Key Laboratory of Metabolism and Molecular Medicine, Ministry of Education, and Department of Biochemistry and Molecular Biology, School of Basic Medical Sciences, Fudan University, Shanghai/CN

Introduction: In addition to malaria, artemisinin has recently been reported have antitumor effects, but the mechanism in non-small cell lung cancer(NSCLC) remains unclear. Fibrinogen-like protein-1 (FGL1) has been reported an inhibitory ligand for lymphocyte activation gene-3 (LAG3) on T cells.High expression of FGL1 in NSCLC was correlated with poor prognosis in immunotherapy. However, the pathway of endogenous degradation of FGL1 was unknown.

Methods: A subcutaneous tumor model of NSCLC with artemisinin therapy was established in immunodeficient and immunocompetent mice. Immune ligands in the tumor microenvironment(TME) were analyzed at protein and RNA levels to find targets of artemisinin. IP-MS and co-IP were used to search and validate potential ubiquitin ligases of FGL1. The mechanism of ubiquitination degradation of FGL1 by TRIM21 was clarified by constructing mutant proteins and whether it affects tumor progression was clarified using animal models. The molecular mechanism of FGL1 degradation by artemisinin was clarified by RNA-seq and animal experiments. The application prospect of artemisinin combined with immunotherapy was explored in vivo. Clinical cohorts were used to explore the correlation between FGL1 and TRIM21 and its impact on prognosis.

Results: Artemisinin inhibited tumor progression in immunocompetent mice, but not in immunodeficient mice. Artemisinin increased CD8+ T cell proliferation and killing function and inhibited exhausted in the TME. The immunosuppressive ligand FGL1 was significantly downregulated at the protein level, but not at the mRNA level. TRIM21 was identified as a ubiquitin ligase for FGL1. Overexpression of TRIM21 resulted in a shortened half-life and increased ubiquitination levels of FGL1 and vice versa. Clinical cohorts suggested FGL1 and TRIM21 were negatively correlated in NSCLC and their ratio correlated with prognosis. TRIM21 interacted with FGL1 through PRYSPRY domain and catalyzed K27 ubiquitination of FGL1 through RING domain. The ubiquitination sites of human FGL1 were lysine 159 and lysine 278, corresponding to lysine 161 in mouse. Tumors were enlarged after overexpression of FGL1 and could be shrunk after overexpression of TRIM21, but not after mutation of K161. Artemisinin increased the level of TRIM21 through inhibition of the PI3K/AKT pathway which in turn promotes ubiquitination degradation of FGL1. Artemisinin combined with anti-PD-1 immunotherapy in mouse models can better activate the anti-tumor function of CD8+ T cells and improve the efficacy of immunotherapy.

Conclusions: Artemisinin can increase TRIM21 expression, thereby enhancing FGL1 ubiquitination degradation and activating anti-tumor immunity. Artemisinin combined with immunotherapy may improve therapeutic efficacy and provide a new target for immunotherapy in NSCLC.

P1.03D.04 Circulating APOBEC Signature as a Non-Invasive Biomarker Delineating Potential Responder to Neoadjuvant Immunotherapy for IIIA-N2 NSCLC

C. Wu[1], Y. Huang[1], S. Li[1], L. Hou[1], T. Hu[2], T. Sun[2], J. Wang[2], X. Li[2], C. Zhu[2], [1]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN ,[2]Amoy Diagnostics Co., Ltd., Xiamen/CN

Introduction: Circulating tumor DNA offers a non-invasive method to assess tumor genomics. The impact of circulating tumor genomic signatures on the efficacy of neoadjuvant immunotherapy (NAI) for locally advanced NSCLC is largely unexplored. Leveraging a phase II trial of NAI in locally advanced NSCLC (NCT04422392), this study explores the relationship between pre-NAI circulating tumor DNA genomic signatures and NAI therapeutic efficacy.

Methods: A single-arm, phase II trial of Sintilimab with chemotherapy as neoadjuvant treatment for IIIA-N2 NSCLC (NCT04422392) was conducted. Plasma and peripheral blood mononuclear cell (PBMC) were prospectively collected. Genomic DNA from Pre-NAI FFPE biopsies and cell-free DNA were subjected to comprehensive genomic profiling. Signature Multivariate Analysis (SigMA) was used to evaluate mutation signatures (Gulhan DC, et al, Nat Genet. 2019). Tumor microenvironment of pre-and post-NAI tissues was analyzed by RNA-seq.

Results: A higher ctDNA APOBEC signature, closely matching tissue APOBEC (R = 0.61, P < 0.001) (Fig. A), strongly linked to major pathologic response (MPR) (OR = 0.11, P = 0.009) (Fig. B). ctDNA profiling from POPLAR (n=211) and OAK (n=642) showed APOBEC+ status improves progression-free survival (PFS) with immunotherapy (POPLAR HR=0.56, p=0.018; OAK HR=0.77, P=0.031) but not chemotherapy. Immunotherapy also enhanced overall survival (OS) in APOBEC+ patients compared to chemotherapy (POPLAR HR=0.32, p=0.001; OAK HR=0.59, P<0.0001) (Fig. C). APOBEC+ patients showed higher infiltration of B cell (P = 0.051), Mast cell (P = 0.084) and memory CD4+ cells (P = 0.094) in tumor microenvironment (Fig. D). In PBMC, enriched IL6-JAK-STAT3 (FDR = 0.02) and IL2-STAT5 pathways (FDR = 0.045) were revealed (Fig. E). These patients also displayed increased signatures of IFN-γ (P = 0.03), M0-macrphage (P = 0.045), memory B cells (P = 0.087), follicular T cells (P = 0.052) (Fig. D). Conversely, APOBEC- patients had a hypoxia microenvironment featured by elevated HIF-1 signaling (FDR = 0.022), glycolysis (FDR < 0.001) (Fig. E). And higher infiltration of Th17 cell (P = 0.0013), M2-macrophage (P = 0.084) (Fig. D) were also identified in those patients. Correspondingly, microenvironmental remodeling with vast infiltration of various types of pro-inflammatory cells were observed in post-NAI APOBEC+ tissues, especially for increased CD8+ T cells (P = 0.076), B cells (P = 0.05) and NK cells (P = 0.014) (Fig. F).

Conclusions: The circulating APOBEC signature is a novel, non-invasive biomarker for immunotherapy in locally advanced NSCLC patients, indicative of systemic and local immune response changes against tumors.

P1.03D.05 A Novel DNA Repair-Gene Model to Predict Responses to Immunotherapy and Prognosis in Patients with EGFR-Mutant Non-Small Cell Lung Cancer

F. Wang[1,2], X-w. Wei[1], M-y. Yang[1], C. Lu[1], X-r. Yang[1], J-y. Deng[1], Z-h. Chen[1], Q. Zhou[1], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Peking University Shenzhen Hospital, Shenzhen/CN

Introduction: The epidermal growth factor receptor mutant (EGFRm) non-small cell lung cancer (NSCLC) has a unique "cold" immune profile. DNA-damage repair (DDR) genes are closely related to tumorigenesis and the effectiveness of immunotherapy in many tumors. However, the role and mechanism of DDR in the genesis and progression of EGFRm NSCLC remain unclear.

Methods: This study included 101 EGFRm NSCLC samples from The Cancer Genome Atlas (TCGA) dataset and 246 samples from a GSE dataset (external set). Cluster analysis was used to classify DDR subtypes. LASSO regression analysis was used to develop a DDR-based predictive model. The prognostic significance of this model was assessed using Cox regression, Kaplan-Meier, and receiver operating characteristic (ROC) curve analyses. Bioinformatics analysis was performed to investigate the clinicopathological characteristics and immune profiles associated with this model.

Results: We identified two subtypes of EGFRm NSCLC: DDR-activated and DDR-suppressed. The DDR-activated subtype showed more aggressive clinical behavior and poorer prognosis and was more responsive to immunotherapy. A prognostic model for EGFRm NSCLC was constructed using four DDR genes: CAPS, FAM83A, IGLV8-61, and SLC7A5. The derived risk score could serve as an independent prognostic indicator. High- and low-risk patients exhibited distinct clinicopathological characteristics, immune profiles, and responses to immunotherapy. The T-cell inflammation and Tumor Immune Dysfunction and Exclusion (TIDE) scores differed between the high- and low-risk subgroups, with both showing enhanced effectiveness of immunotherapy in the low-risk subgroup. Targeted therapy such as BI.2536, an inhibitor of polo-like kinase 1, could be effective for patients with high-risk EGFRm NSCLC.

Conclusions: This study demonstrated a diversity of DDR genes in EGFRm NSCLC and developed a predictive model using these genes. This model could assist in identifying potential candidates for immunotherapy and in assessing personalized treatment and prognosis of patients with EGFRm NSCLC.

P1.03D.06 Targeting IL-6 And Immune Checkpoint Interactions to Augment the Anti-Tumor Immune Response in Lung Carcinoma

K. Goliwas, S. Sivan, A. Desai, Y-i. Kim, J. Donahue, J. Deshane, University of Alabama at Birmingham, Birmingham/AL/USA

Introduction: The central role of the tumor microenvironment in non-small cell lung cancer (NSCLC) progression is well recognized, with tumor-stromal interactions impacting response to therapeutic intervention. Yet mechanisms to effectively inhibit immune suppression and promote tumor clearance are largely unknown. Interleukin-6 (IL-6) is a critical modulator of immune responses in cancer, mediating accumulation and activation of immune suppressive cells, including myeloid derived suppressor cells (MDSCs) which can hinder the efficiency of immune directed therapy. IL-6 has been shown to induce MDSC recruitment into the tumor microenvironment and upregulate arginase-1 expression and reactive oxygen species production by MDSCs, leading this suppressive cell population to be more efficient in inhibiting anti-tumor immunity. We hypothesize that targeting IL-6 signaling in combination with frontline immune checkpoint directed therapeutics may increase efficacy by altering recruitment and function of immune suppressive cell populations within the lung tumor microenvironment.

Methods: Using an ex vivo perfusion culture platform, remnant tumor tissue specimen from 12 patients were cultured. Matched autologous peripheral blood mononuclear cells (PBMCs) were pre-stained with CFSE, and placed into circulation to track recruitment and retention of immune cells into tumor tissues in a subset of samples (6 tissues). Starting on day 3 of culture, tissues were treated with an immune checkpoint inhibitor (ICI, 10 μg/ml anti-PD-1, Pembrolizumab biosimilar) and an IL-6 receptor inhibitor (5 μg/mL anti-IL6R, Tocilizumab biosimilar) or ICI alone (11 days treatment, 14 days ex vivo culture). Flow cytometry and histologic analyses were performed following intervention.

Results: Tissue specific increases in cell apoptosis are observed in 70% of tissues when combination therapy is compared to ICI alone (average percentage within tissue: 16.4% ± 3% (ICI + anti-IL6R) vs. 14% ± 3% (ICI)). When tumor cell (PanCytokeratin+EpCam+/-) death was assessed using a viability dye, an increase in tumor specific death was observed in 91% of tissues when combination therapy is compared to ICI alone (average percentage within tissue; 15.7% ± 6.3% (ICI + anti-IL6R) vs. 9.8 % ± 4% (ICI), p=0.03). Two populations of MDSCs were assessed, monocytic MDSCs (M-MDSC) constituted about 6% of the total CD45+ immune cell population and granulocytic (G-MDSC) comprised only about 0.4% of the total CD45+ immune cell population in the tissues evaluated. When recruitment of M-MDSC and G-MDSC was measured by evaluation of CFSE+ MDSC populations in the subset of tissues with circulating PBMCs, patient specific decreases in MDSC recruitment were observed with combination therapy. A reduction in recruited (CFSE+) M-MDSCs was seen in 67% of tissues with combination therapy (average percentage within tissue: 7.1% ± 3.1% (ICI + anti-IL6R) vs. 21% ± 6.2% (ICI), p=0.07) and a reduction in recruited (CFSE+) G-MDSCs was seen in 83% of tissues with combination therapy (average percentage within tissue: 49.1% ± 13.2% (ICI + anti-IL6R) vs. 76.3% ± 11.2% (ICI), p=0.03).

Conclusions: This combination strategy may increase long-term therapeutic benefit by reducing immune suppression within the tumor microenvironment. Further understanding of how cell-cell interactions are modulated by this combination strategy and additional characterization of the tumor microenvironment following intervention is critical.

P1.03D.07 Overcoming Immunotherapy Resistance in Non-Small Cell Lung Cancer With a Triple Combination Therapy: Efficacy and Mechanisms

Y. Guo[1], L. Wu[1], X. Xu[1], Y. Zhu[1], J. Feng[2], F. Li[3], Y. Xu[1], [1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]Zhejiang Cancer Hospital, Hangzhou/CN ,[3]School of Basic Medicine, Fudan University, Shanghai/CN

Introduction: Immunotherapy including anti-programmed death receptor-1 (PD-1) antibody is one of the most effective treatments for cancers, but the efficacy of anti-PD-1 antibody in monotherapy for advanced non-small cell lung cancer (NSCLC) patients is only 20%. Hypofractionated radiotherapy and anti- T cell immunoreceptor with immunoglobulin and ITIM domain (TIGIT) antibody are potential therapies in combination with PD-1 therapy for advanced NSCLC patients. Therefore, this study investigated the efficacy and mechanism of hypofractionated radiotherapy in lung combined with anti-PD-1 antibody and anti-TIGIT antibody in the treatment of advanced NSCLC.

Methods: Here, 51 out of 142 NSCLC patients with immunotherapy resistance received hypofractionated radiotherapy for progressive lesions in the lungs. Besides, we investigated the efficacy and safety of 5 patients with locally-advanced NSCLC recieved radiotherapy combined with anti-PD-1 antibody and anti-TIGIT antibody. Primary and distant lung cancer models were established by subcutaneous injection of mouse lung cancer line KP cells into C57BL/6 mice followed by radiation and immunization treatment using anti-PD-1 and anti-TIGIT antibodies. Immune cell infiltration status of mouse tumors was measured by flow cytometry and immunohistochemistry (IHC). RNA sequencing was utilized to explore targeted genes and pathways of the combination treatment of hypofractionated radiation, anti-PD-1 antibody, and anti-TIGIT antibody.

Results: Hypofractionated radiotherapy ameliorates immunotherapy resistance to improve abscopal effects in advanced NSCLC. All patients (5/5, 100%) who received radiotherapy combined with anti-PD-1 antibody and anti-TIGIT antibody achieved partial response. Besides, anti-TIGIT antibody enhances the efficacy of hypofractionated radiotherapy combined with anti-PD-1 antibody in vivo, while hypofractionated radiotherapy facilitates antitumor immune effects activated by anti-PD-1 antibody and anti-TIGIT antibody and promotes tumor-associated macrophage (TAM) infiltration and M1-like polarization as well as promotes abscopal effects. Additionally, the combination treatment of hypofractionated radiation, anti-PD-1 antibody, and anti-TIGIT antibody might exert effects by various of immune-related signaling pathways including leukocyte transendothelial migration and complement and coagulation cascades in NSCLC.

Conclusions: The combination treatment of lung hypofractionated radiation, anti-PD-1 antibody, and anti-TIGIT antibody ameliorates immunotherapy resistance and induces obvious abscopal effects by enhancing antitumor immune effects in advanced NSCLC. These findings provide a novel strategy for treating advanced NSCLC.

P1.03D.08 Padeliporphin VTP Reverts NSCLC Orthotopic Tumors in Animal Models Into Highly Responsive to aPD1 Therapy

D. Kain[1], L. Agemy[1], K. Sasson[1], I. Biton[1], T. Yechezkel[1], A. Scherz[1], [1]The Weizmann Institute of Science, Rehovot/IL

Introduction: The recent administration of immune checkpoint inhibitors (ICI) (aPD-1, aCTLA-4, aPD-L1) as first line treatments, appeared promising. Although patient' survival is lower than expected, it indicates the significance of attenuating the cancer induced antitumor immunity for treatment's success. We hypothesized that complementary activation of the antitumor immunity by vascular targeted photodynamic therapy (VTP) with Padeliporfin (WST11, TOOKAD®) would prolong animal survival. Padeliporfin-VTP is a non-thermal ablation approach approved by the EMA for grade 1 localized prostate cancer and is being evaluated in Phase 3 trial for treatment of upper tract urinary cancer. In multiple animal tumor models Padeliporfin-VTP triggers innate and adoptive antitumor immunities. Concomitantly, in the tumor microenvironment (TME), a significant increase in immune suppressive signals is observed including PD-1, PD-L1 and CTLA-4. We therefore hypothesized that synchronized combination of VTP and clinically approved ICI may markedly increase the therapeutic success. Here we show the results of testing this concept on mice orthotopic model of NSCLC.

Methods: C57BL/6 mice bearing orthotopic LLC-Luc-mCherry were divided into eight treatment groups: Controls, Padeliporfin-VTP, aPD-1, aCTLA-4, aPD-1+aCTLA-4, Padeliporfin-VTP+aPD-1, Padeliporfin-VTP+aCTLA-4 and Padeliporfin-VTP+aPD-1+aCTLA-4. Padeliporfin-VTP using relatively low light dose (60mW/cm2) was performed when the bio-luminescence measured by IVIS, reached 107. Tumor morphology, immune markers, and pathological changes were assessed at different time intervals post VTP. Multiplex immunohistochemistry and Micro CT were performed before, and at different time intervals post treatment. Tumor progression was followed up to 90 days using IVIS and complementary H&E staining

Results: Non-treated tumor bearing mice survived for up to 40 days. Low light dose induced up to 50% tumor necrosis at 3 days post treatment with only 5% animal survival at day 90. No survival was observed in animals treated by aPD1 or aCTLA4. Animals treated with aPD1+ aCTLA4 reached 14% survival at day 90. Thirty-three and 70% of the animals treated by VTP+aPD1 and VTP+aCTLA-4+aPD1, respectively were tumor free at day 90. Micro CT analyses enabled prediction of treatment success already at day 20 post VTP application.

Conclusions: Based on the immune landscape of the LLC tumors, timely synchronization of VTP and clinically used ICI was designed and found effective and safe for treatment of orthotopic NSCLC in mice. Similar exploration in the upcoming Phase 1 clinical trial of Padeliporfin-VTP in patients with peripheral lung cancer is expected to provide guidelines for new treatment protocols combining ICI and VTP.

P1.03D.09 Single Cell RNA Sequencing and Functional Monocyte Stimulation Reveals Phenotypic Predispositions to Developing Lung Cancer in Never Smokers

V. Chin[1,2,3], R.A. McCloy[1], A. Sennabouth[1], D. Neavin[1], H. Arora[1], M. Boyer[4,5], J. Simes[4,5], A. Joshua[2], B. Brown[5], J. Powell[1,3], [1]The Garvan Institute of Medical Research, Sydney/AU ,[2]The Kinghorn Cancer Centre, St Vincent's Hospital Sydney, Sydney/AU ,[3]The University of NSW, Sydney/AU ,[4]Lifehouse, Sydney/AU ,[5]University of Sydney, Sydney/AU

Introduction: There is little research into how never-smoking patients develop lung cancer. 20% of men and >50% of women with lung cancer are never smokers. Recent studies have revealed interleukin1-beta (IL1B) secretion by macrophages in response to exposure to pollution is a key step in the development of lung cancer in never smokers (LCINS). Single nucleotide polymorphisms (SNPs) can alter gene expression in a cell-specific manner. Expression quantitative trait loci (eQTL) analysis measures the effect of SNPs on gene expression. We have developed methods to measure eQTLs at a cellular level which can be applied to inflammatory response genes. We hypothesised that genetic variation in inflammatory response to pollution could contribute to risk of LCINS. Comparing healthy people with patients with LCINS, we aimed to assess eQTLs in inflammatory response genes in immune cells to identify genetic predispositions to LCINS.

Methods: Peripheral circulating immune cells (PBMC) from 17 patients with LCINS were processed for single cell RNA sequencing (cells, n = 50,000). These were compared with 265 age matched, healthy, never-smoking controls (cells, n = 330,000). Cell sub-typing was undertaken using automated methods. PBMCs were analysed using our single cell eQTL methods in inflammatory response genes. Confirmatory tests in circulating monocytes were done in vitro using lipopolysaccharide (LPS) stimulation to measure IL1B and TNFa levels.

Results: 85% of patients had a driver mutation. 23 distinct immune cell subtypes were characterised. Comparing the LCINS and healthy cohort, 294 eQTLs in 77 inflammatory genes from 20 immune cell types were identified. Figure 1 shows eQTLs found in inflammatory genes by cell types. The heatmap shows the effect size (beta) of gene expression seen in the eQTL. The monocyte population had the highest incidence of eQTLs including in IL1B. Functional assays demonstrate varied IL1B responses by monocytes to LPS by genotype.

Conclusions: Individual variation in the IL1B genotype may affect monocyte responses to external stimuli and could be used to identify at-risk individuals for developing LCINS.

Keywords: Never-smoking, Single cell, single nucleotide polymorphism

P1.03D.10 Uncovering the Molecular Pathways Associated with Immunotherapy-Induced Pneumonitis in Non-Small Cell Lung Cancer Patients

X. Lin[1,2,3,4], C. Zhou[1,2,3,4], J. Deng[1,2,3,4], [1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]National Clinical Research Center for Respiratory Disease, Guangzhou/CN ,[3]State Key Laboratory of Respiratory Disease, Guangzhou/CN ,[4]Guangzhou Institute of Respiratory Health, Guangzhou/CN

Introduction: Immune checkpoint inhibitor-related pneumonitis (CIP) is a concerning complication of cancer immunotherapy, especially in non-small cell lung cancer (NSCLC) patients, and can lead to immune-related mortality. Despite the effectiveness of corticosteroids in most cases, 15%-20% of patients exhibit poor responsiveness, and the systemic immunosuppressive effects of corticosteroids may hinder the effectiveness of antitumor therapies. Elucidating the cellular and molecular characterization of the tissues during the occurrence of CIP is crucial for understanding the specific pathogenesis and developing new therapeutic strategies. There is no study of single-cell sequencing of CIP based on tissue samples. In this study, we selected a population of NSCLC patients with the highest number of CIP occurring after treatment with ICI, with the aim of revealing the immune landscape of CIP, and to provide a theoretical basis for future disease diagnosis and targeted interventions.

Methods: We employed a cross-sectional approach to investigate this issue, wherein the experimental group comprised pneumonitis tissues from NSCLC patients who developed CIP after immunotherapy, while the paired non-cancerous adjacent tissues from NSCLC(NSCLC) patients following neoadjuvant therapy. We applied several research tools, single-cell transcriptome sequencing(scRNA-seq)/TCR/BCR was performed to analyze 10 patients/controls and validated our findings with IHC, multiplex immunohistochemistry, and previously published bulk RNA-seq data.

Results: We observed an increase in the proportion of CD8+ T cells and a decrease in the proportion of DC cells in CIP, indicating dysregulation of immune homeostasis during CIP. Furthermore, we confirmed that CD8+ tissue-resident memory T (TRM) cells were the predominant activated subset of T cells in CIP, accompanied by upregulation of the transcription factor STAT1 and substantial release of IFNγ. This phenomenon has also been documented in autoimmune-related skin diseases and Immune Checkpoint inhibitor-colitis. Meanwhile CIP patients expressed macrophage M1 phenotypes, the expression of pro-inflammatory chemokines CCL3 and CCL4 in macrophages was observed to be elevated. as well as high expression of pyroptosis-related genes in macrophages, especially increased expression levels of the pyroptosis-related protein GSDME, which was verified by immunofluorescence and bulk-RNA sequencing data, we guess that nuclear release of pro-inflammatory cytokines and chemokines from macrophages, thereby establishing a positive feedback loop during the process of macrophage pyroptosis may be one of the core links in the development of CIP.

Conclusions: Our findings provide more insights into the immune microenvironment at the single-cell level during the occurrence of CIP in NSCLC patients. Based on these results, we suggest that a significant increase in IFNγ-producing CD8+ TRM cells may be a common pathway for a number of immune-related adverse events. Macrophage pyroptosis may be a key factor contributing to the development of CIP, intervening in the process of CIP by specifically inhibiting key proteins and signals for pyroptosis development is expected to achieve precise prevention and treatment of CIP patients.

P1.03D.11 Association Between Plasminogen Activator Inhibitor-1 & Tolerance Against Anti-PD-1 Antibody in Non-Small Cell Lung Cancer

M. Sumii, T. Masuda, K. Shimoji, K. Yamaguchi, S. Sakamoto, Y. Horimasu, T. Nakashima, H. Iwamoto, H. Hamada, N. Hattori, Hiroshima University Hospital, Hiroshima city/JP

Introduction: Immune checkpoint inhibitors (ICIs) have improved the prognosis of patients with advanced non-small-cell lung cancer (NSCLC). Despite ICI treatment, most of patients with advanced NSCLS cannot be cured due to ICI-tolerant cells (ICI-TCs), survived cancer cells within a tumor after ICI treatment. Eliminating these ICI-TCs would potentially lead to the cure of advanced NSCLC. Our previous research has shown the involvement of plasminogen activator inhibitor-1 (PAI-1) in the tolerance of EGFR-mutated NSCLC cells to osimertinib.

Methods: To examine the role of PAI-1 in tolerance of lung cancer to ICI treatment, and if PAI-1 could serve as a viable therapeutic target to overcome the ICI-tolerance.

Results: In a mouse subcutaneous tumor model using mouse lung adenocarcinoma or squamous cell carcinoma cell line, surviving cancer cells within the tumor seven days after anti-programmed death-1 (PD-1) antibody treatment, were defined as ICI-TCs. PAI-1 and epithelial-mesenchymal transition (EMT)-related gene expression levels were significantly higher in ICI-TCs than those in control cells. Subsequently, to examine the tumor microenvironment seven days after PD-1 antibody treatment, immunohistochemical staining of tumor sections was performed. Immunohistochemical analyses showed higher PD-L1 expression of cancer cells and increased M2 macrophages in the tumor seven days after anti-PD-1 antibody treatment compared to control tumors, alongside a reduction in CD8-positive lymphocytes. Continuous administration of anti-PD-1 antibody led to tumor regrowth after 28 days. In contrast, a combination of anti-PD-1 antibody and a PAI-1 inhibitor, TM5614, resulted in decreased expression of EMT-related genes, PD-L1 expression of cancer cells, and M2 macrophages, alongside increased CD8-positive lymphocytes in tumors. Furthermore, this combination treatment exhibited prolonged inhibition of tumor growth.

Conclusions: This study underscores the involvement of PAI-1 in tolerance of NSCLC to ICI via its association with EMT of cancer cells and alteration of tumor immune-microenvironment. Additionally, PAI-1 may be a potential therapeutic target to overcome tolerance to ICI in NSCLC.

P1.03E.01 Effect of Gut Microbiota and Metabolites on the Efficacy of Immunotherapy Combined with Chemotherapy in Lung Squamous Cell Carcinoma Patients

Y. Xin[1], D. Zang[1], J. Chen[1], X. Han[2], [1]The Second Hospital of Dalian Medical University, DaLian/CN ,[2]The second hospital affiliated to dalian medical university, Dalian/CN

Introduction: The first-line application of immunotherapy combined with chemotherapy in lung squamous cell carcinoma (LUSC) patients has achieved an effective rate of 50-60%. Currently, evidence from preclinical to clinical studies has gradually established that the gut microbiota can regulate anti-tumor immunity and affect the efficacy of cancer immunotherapy. It is worth noting that one of the primary mechanisms by which the gut microbiota regulates anti-tumor immunity is through metabolites, which can diffuse from their initial gut location and influence both local and systemic anti-tumor immune responses.

Methods: We collected 112 fecal samples from patients with LUSC who underwent immunotherapy combined with chemotherapy. The samples were divided into a baseline group comprising samples from patients who had not received any treatment, and a disease control rate (DCR) group consisting of samples from patients who are complete response, partial response or stable disease after immunotherapy combined with chemotherapy. We performed metagenomic and metabolomic sequencing to compare the differences in gut microbiota and metabolites between the two groups of samples.

Results: Among all samples, there were 58 samples in the baseline group and 52 samples in the DCR group. Our analysis revealed significant differences in gut microbiota and metabolites between the two groups of samples. In the metagenomic analysis, it was found that the relative abundance of gut microbiota such as s_Faecalibacterium_prausnitzii (P<0.05), g_Faecalibacterium (P<0.05), g_Eubacterium (P<0.05), f_Eubacteriace (P<0.05), and g_Prevotella (P<0.05) was higher in the DCR group. Metabolomic analysis revealed that metabolites such as Pregnenolone (P<0.05), Cellobiose (P<0.05), Ggstop (P<0.05) and palmitic acid (P<0.05) had higher relative abundances. KEGG metabolic pathway analysis of the differential genes in both groups revealed significant differences in fatty acid biosynthesis and aldosterone synthesis and secretion pathways. Subsequently, we conducted a joint analysis of metagenomics and metabolomics. Random forest analysis showed an AUC > 0.8, indicating a high reliability of the selected gut microbiota and metabolites.

Conclusions: Our findings indicates the abundance of gut microbiota and their metabolites is associated with the efficacy of immunotherapy combined with chemotherapy in patients with LUSC. Gut microbiota and their metabolites may serve as effective targets for predicting the efficacy of immunotherapy combined with chemotherapy for LUSC.

P1.03F.01 Imaging the Nucleolus Using Two-Photon Microscopy to Distinguish Between Tumor Cells and Normal Cells

J. Gao, D. Xie, Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Nucleoli can be used as diagnostic biomarkers, such as their number, which has received considerable attention in pathological testing. Fluorescent molecular probes are important for research and clinical applications to detect the precise location of lesions.

Methods: Here, we used fluorescent nanomaterials (NTFNPs) prepared from phospholipid materials to study the difference in the number of nucleoli between normal and tumor cells labeled by fluorescent probes and used NTFNPs as an example to study the difference in the number of nucleoli between tumor cells and normal cells labeled by two-photon effect in 3D tumor cell models, mouse tissue sections and lung adenocarcinoma patient samples. The staining differences of several nucleolar probes were compared, and the fluorescence recovery ability of NTFNPs in tissues was compared.

Results: Researchers used NTFNPs to label nucleoli to differentiate between normal and tumor cells fluorescently. Tumor cells exhibited irregular, featureless nucleoli compared to the uniform, rounded nucleoli in normal cells. Average nucleolar counts per cell were higher in tumor cells (2.36 for A549 and 2.11 for BEL7402) than in normal cells (1.49 for MRC5 and 1.71 for L02), with significant differences confirmed statistically. TEM also showed more nucleoli in tumor cells, corroborating fluorescence microscopy results. NTFNPs demonstrated two-photon fluorescence properties, enabling deeper tissue penetration and clearer detection. In 3D-printed and mouse models, NTFNPs effectively labeled nucleoli, distinguishing tumors from normal cells. Human patient samples showed an average of 3.45 nucleoli per tumor cell versus 1.62 for normal cells.

Conclusions: In this study, lung cancer cells A549, lung normal cells MRC5, liver cancer cell BEL7402, and liver normal cell L02 were used as examples to distinguish tumor cells from normal cells by fluorescently labeling nucleoli with NTFNPs, and the significant differences in the number of nucleoli between tumor cells and normal cells were counted. NTFNPs have a two-photon/three-photon effect with an optimal excitation wavelength of 900 nm, and NTFNPs labeling could distinguish tumor cells from normal cells in the 3D printed cell model. Significant differences in the number of nucleoli between tumor cells and normal cells were observed in mouse and patient tissues. NTFNPs have excellent fluorescence recovery ability and can be used for long-term observation of labeled cells in animal lung cancer tissue sections. This study focused on the feasibility of applying nucleolar-targeted fluorescent nanoparticles (NTFNPs) in tumor diagnosis and diagnosis and provided a new and rapid diagnostic method for tumor diagnosis.

P1.03F.02 Establishment of EBUS-TBNA Sample Derived Lung Cancer Organoid and Xenograft and Utility for Development of Targeted Therapy

T. Koga[1], H. Ogawa[1], N. Radulovich[2], N-A. Pham[2], M. Li[2], Y. Wang[2], Y. Sata[1], S. Kitazawa[1], Y. Hiraishi[1], T. Ishiwata[1], A. Effat[1], K. Kazlovich[1], F. Yokote[1], T. Yanagihara[1], K. Nakahashi[1], Y. Fujibayashi[1], N. Bernards[1], M-S. Tsao[2], K. Yasufuku[1], [1]Toronto General Hospital, University Health Network, Toronto/ON/CA ,[2]Princess Margaret Cancer Center, University Health Network, Toronto/ON/CA

Introduction: Lung cancer patient-derived organoids (PDO) and patient-derived xenograft (PDX) have been reported as novel preclinical models for translational research. However, many of them were established from resected tumor of early-stage lung cancer, which do not require systemic therapy. Here, we explored the establishment of lung cancer organoids from patients with advanced lung cancer using EBUS-TBNA, which is a method routinely used in to biopsy tumors.

Methods: A total of 81 and 106 lung cancer samples were used to establish PDO and PDX, respectively. We also established xenograft derived organoids (XDOs) using PDX tumors. In organoid establishment, EBUS samples or PDX tumors were digested to single cells using collagenase II. Tumor cells were embedded in matrigel and cultured in M27 organoid culture medium developed at our institute. For PDX establishment, EBUS samples were engrafted subcutaneously in nonobese severe combined immune deficient gamma (NSG) mice. The models passaged more than ten times in organoid and twice in PDX were validated histologically to exclude non-cancer cells contamination. Whole exome sequencing, transcriptome sequencing and pathological assessment were performed on organoid and PDX models. We evaluated the drug sensitivity of PDX and organoids, and compared them with clinical treatment in the matched patients. The drug screening assay was performed using stable organoids to detect the potent drug for each model.

Results: In 71 lung cancer samples, we successfully established six stable lung cancer organoids (8.5%) including three lung adenocarcinoma and three small cell lung cancer. Twenty Stable EBUS-PDXs were generated with a 18.9% (20/106) success rate. Fourteen (70%) stable EBUS-XDOs including five adenocarcinoma, two squamous cell carcinoma, six small cell lung cancer, and one large cell neuroendocrine carcinoma were established from the PDX tumors. We detected a total of four non-cancer cell outgrowths during establishment process: two lymphomas in PDX, one normal airway cell outgrowth in PDO, one mouse cell outgrowth in XDO. Pathological and genetic characteristics were well recapitulated in organoid models. We treated the three matched PDX and XDO models with chemotherapy and observed consistent responses with matching models from individual patient. In the drug sensitivity assay, response heterogeneity was observed in HER2-altered models; an HER2 amplified PDO showed a potent response to HER2 targeted therapies, whereas PDO with HER2exon 20 insertion was resistat. Both PDO and XDO models were feasible for drug screening assay, and response to MEK inhibitor was observed in a XDO model harboring a rare MAP2K point mutation.

Conclusions: We were able to establish lung cancer organoids and PDX models with EBUS samples. These models recapitulated the characteristics of the source tumor samples. Since most EBUS samples are obtained from advanced lung cancers, these preclinical models may be useful for understanding the tumor biology and preclinical drug testing.

P1.03F.03 Utility of Patient-Derived Xenograft and Xenograft-Derived Organoid Models with EGFR Mutation to Study EGFR-TKI Resistance.

T. Koga[1], N-A. Pham[2], J. Rosen[2], Q. Li[2], A. Arivajiagane[2], K. Hueniken[2], S. Khan[2], M. Khalil[2], N. Radulovich[2], F.A. Shepherd[2], K. Yasufuku[1], G. Liu[2], M-S. Tsao[2], [1]Toronto General Hospital, University Health Network, Toronto/ON/CA ,[2]Princess Margaret Cancer Centre, University Health Network, Toronto/ON/CA

Introduction: EGFR driver mutations are the most common druggable alterations in lung adenocarcinoma, however, there are still many outstanding issues including mechanisms of drug tolerance and acquired resistance to osimertinib. Preclinical models that reproduce tumor complexity are needed to understand and develop strategies for overcoming these issues. We have established patient-derived xenografts (PDXs) and their matched xenograft-derived organoids (XDOs) using both treatment naïve and post TKI-resistant lung adenocarcinomas.

Methods: Samples from surgical resection or core needle biopsy were engrafted into non-obese severe combined immune deficient gamma mice, and serially passaged for two or more times to stably establish PDX models. Stable XDO models were generated when they successfully passed for more than 10 times. Whole exome and transcriptome sequencing, and pathological assessment were performed on stable models. Models were evaluated for sensitivity towards EGFR tyrosine kinase inhibitors (TKIs), matched to their patient therapy lines. We performed drug screening on stable XDO models to identify novel therapy for overcoming TKI resistance.

Results: Twenty-two PDX models were established from patients with different EGFR mutation types and therapies, 7(32%) from treatment naïve and 15 (68%) from post EGFR-TKI. These include twelve with exon 19 deletion (55%), nine with exon 21 L858R (41%) and one with exon 19 insertion (4%). Among 15 PDX models derived from post EGFR-TKI tumors, two were after 1st line osimertinib, eight were after 2nd or later line osimertinib, five were treated only with 1G or 2G EGFR-TKIs. In nine PDXs of osimertinib resistant samples, MET amplification was identified in three models, and secondary G719, G724, G796, and C797 EGFR co-mutations were identified in one model each, concurrent with other gene alterations. Thirteen PDX models were evaluated for their sensitivity to one or more EGFR-TKIs in mice, and were categorized to sensitive, stable disease, delay resistant or resistant based on the response patterns. Of the 10 PDX models that could be compared to the treatment response in patients, eight showed consistent response to the same EGFR-TKIs. We successfully established 12 XDO models out of 18 PDXs and screening with 14 drugs has been completed. XDOs were categorized to two sensitive, seven intermediate, and three resistant models to osimertinib. High throughput screening is in progress in osimertinib resistant XDO models to identify potential drug combinations that can overcome EGFR-TKI resistance.

Conclusions: We have successfully established large cohort of EGFR mutant PDX and XDO models that show various sensitivity to EGFR-TKIs. Responses to EGFR-TKIs were generally consistent with the clinical responses in the patients. Models derived from osimertinib resistant tumor replicated the gene alteration that may represent resistant mechanisms. We are investigating the strategy to overcome the osimertinib resistance, taking advantage of the characteristics of models that reproduce the tumor complexity.

P1.03G.01 Lurbinectedin Synergizes with Selinexor by Inhibiting DNA Damage Repair and Enhancing Immune Cell Infiltration in Neuroendocrine Lung Tumors

E. Redin[1], P. Manoj[1], J. Qiu[2], H. Zhong[1], S. Vural[3], Y. Zhan[4], R. Koche[4], N. Socci[3], E. DeStanchina[2], C.M. Rudin[1], A. Quintanal-Villalonga[1], [1]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]Antitumor Assessment Core, Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[3]Bioinformatics Core Facility, Memorial Sloan Kettering Cancer Center, New York, NY, New York/NY/USA ,[4]Center for Epigenetics Research, Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Large cell neuroendocrine carcinomas (LCNECs) and small cell lung cancer (SCLC) tumors, are particularly aggressive lung neuroendocrine carcinomas (lung NECs) with limited clinical therapeutic options. Patients with lung NECs are treated with platinum-based chemotherapy as the first line of treatment, but they promptly develop resistance. Lurbinectedin has been approved by the FDA as a second-line treatment for SCLC due to its efficacy in metastatic chemorelapsed SCLC patients. However, there are still SCLC patients who do not respond to lurbinectedin and those who benefit from it show an ORR of 35.2% with a median duration of response of 5.3 months and a median OS of 9.3 months. Previous work from our group had shown that exportin-1 (XPO1) was a driver of chemoresistance in SCLC and its inhibition with selinexor resentitized to first- and second-line chemotherapies in naïve and chemorelapsed SCLC patients derived xenografts (PDXs), respectively. Importantly, selinexor is an FDA-approved drug for the treatment of relapsed multiple myeloma and is currently undergoing clinical testing in multiple solid tumors.

Methods: We performed synergy assays in vitro and characterized DNA damage/repair pathways by western blotting. Cell cycle and apoptosis were analyzed by flow cytometry. RNAseq was performed in cells treated in vitro. Drug efficacy was studied in SCLC and LCNEC PDXs, and in a SCLC syngeneic mouse model. Tumor microenvironment was characterized by single cell RNAseq.

Results: Selinexor strongly synergized with lurbinectedin in both SCLC and LCNEC cell lines. Mechanistically, this combination altered DNA damage and DNA repair mechanisms by inducing γH2A and decreasing CHK1 and CHK2 protein levels, suggestive of the impairment of DNA response. Additionally, selinexor reduced the expression of MLH, a key regulator of DNA mismatch repair in monotherapy and in combination with lurbinectedin. Consistent with these results, selinexor in combination with lurbinectedin also induced a significant increase in apoptotic cells and promoted cell cycle arrest. Interestingly, dual treatment activated STING and autophagy pathways via mTOR and LC3B-I/II. Pathway analysis of the genes differentially expressed in double treated cells versus untreated SCLC cells, analyzed by RNAseq, revealed very strong enrichment of DNA damage, inflammatory and IFNγ related pathways, suggesting an immunomodulatory role for this therapeutic combination. Accordingly, combination of selinexor with lurbinectedin strongly synergized not only in chemorelapsed SCLC and LCNEC PDXs, but also in a Rb1/Tp53/Rbl2 (RPR) mutant mouse model that was refractory to either lurbinectedin or selinexor alone. Transcriptomic characterization of the RPR model by scRNAseq revealed higher infiltration of immune cells along with increased antigen presentation in tumors treated with lurbinectedin and the combination. Lurbinectedin alone or in combination also enhanced the infiltration of T-cells but most notably promoted a very significant increase in monocyte and macrophage infiltration. These data suggest that lurbinectedin in combination with selinexor exerts a potent antitumor an immunomodulatory effect in lung NECs.

Conclusions: These findings suggest that selinexor combined with lurbinectedin is a promising therapeutic combination in both SCLC and LCNEC. Our study offers a strong preclinical rational for investigating this strategy in patients with lung NECs who fail chemotherapy regimens.

P1.03G.02 Genotyping of RB1 Status Identifies Two Distinct Subtypes in EGFR-Mutant Lung Cancers with SCLC Transformation

J. Huang[1], C. Zhang[1], S-L. Zhang[2], W. Huang[1], J-J. Yang[1], Y-L. Wu[1], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangzhou/CN ,[2]Affiliated Cancer Hospital and Institute of Guangzhou Medical University, Guangzhou/CN

Introduction: Small cell lung cancer (SCLC) transformed from EGFR-mutant non-small cell lung cancers (NSCLC) exhibits significant clinical heterogeneity. However, whether the heterogeneity is attributable to the distinct molecular biology of transformation remains unclear. While patients with lung cancers harboring EGFR/RB1/TP53 mutations are at a high risk for SCLC transformation, precisely identifying individuals who will transform remains a formidable challenge.

Methods: From January 2017 to December 2021, we identified 63 SCLC patients transformed from EGFR-mutant NSCLC and 97 NSCLC patients with concurrent EGFR/RB1/TP53 alterations. The transformed SCLC patients were divided into two subgroups: the EGFR-mutant/RB1-wild subgroup and the EGFR/RB1-mutant subgroup. The EGFR/RB1/TP53-mutant NSCLC patients were categorized based on whether they underwent SCLC transformation. We comprehensively compared clinical profiles, genomic, and transcriptomic signatures across these subgroups.

Results: Time to transformation was significantly extended in the EGFR/RB1-mutant subgroup compared with the EGFR-mutant/RB1-wild subgroup, and RB1 alteration was an independent prognostic factor for SCLC transformation. Pre-transformation analyses revealed that neuroendocrine-related pathways were enriched in the EGFR/RB1-mutant subgroup, while immune-related pathways were upregulated in the EGFR-mutant/RB1-wild subgroup. A substantial increase in PI3K/AKT pathway mutation frequency was observed in the transformed subgroup compared with the untransformed subgroup, whereas this signaling appeared to be suppressed post-transformation in the EGFR-mutant/RB1-wild subgroup. Single-cell RNA sequencing of post-transformation samples further revealed significant differences in cellular cluster distribution and expression patterns of key transcriptional regulators between the EGFR/RB1-mutant subgroup and the EGFR-mutant/RB1-wild subgroup. Additionally, we developed and validated a nomogram model for predicting the risk of transformation in EGFR/RB1/TP53-mutant lung cancers.

Conclusions: The study introduces a novel classification of transformed SCLC from EGFR-mutant NSCLC based on RB1 status, suggesting potentially distinct therapeutic vulnerabilities of the subgroups. The established nomogram model offers a precise predictive tool for assessing the risk of SCLC transformation in patients with concurrent EGFR/RB1/TP53 alterations.

P1.03G.03 Role of SMARCA4, Core SWI/SNF Complex Component, in Small Cell Lung Cancer Development

N. Kirk, University of Virginia School of Medicine, Charlottesville/VA/USA

Introduction: : Small cell lung cancer (SCLC) is a lethal disease that is estimated to result in approximately 30,000 patient deaths annually in the United States. This high mortality is attributed to invariable resistance to current radiation and chemotherapies. SCLC is driven by a large number of loss of function mutations in tumor suppressor genes, including near-universal inactivation of both P53 and RB. The nature of these mutations makes it challenging to target and complicate the development of personalized therapies. Thus, understanding the molecular changes driven by these frequent alterations may help identify actionable targets for intervention strategies. Our research is focused on recurrent mutations in components of the SWI/SNF chromatin modifying complex, which regulates transcription through nucleosome sliding at enhancers and promoters of target genes. Particularly, SMARCA4, the encoding the catalytic component, harbors inactivating mutations in SCLC patient tumors. These observations led us to hypothesize that SMARCA4 acts as a tumor suppressor and its functional loss promotes SCLC development.

Methods: To determine the role of SMARCA4 in SCLC tumorigenesis, we used a combination of in vitro and in vivo models, including genetically engineered mouse models (GEMMs) of SCLC that contained floxed alleles for Smarca4. We employed two separate SCLC GEMMs: mice with an RPR2 (RbΔ/Δ; p53Δ/Δ; Rbl2Δ/Δ) or RPM background (RbΔ/Δ; p53Δ/Δ; MYCT58A). Tumor burden and histology were assessed through H&E staining. Neuroendocrine (NE) differentiation of tumor or lesion was determined using immunohistochemistry. Primary tumor cells were isolated from tumors and examined for proliferative capacity.

Results: Deletion of Smarca4 resulted in decreased tumor development in the lungs of SCLC GEMMs. Cells isolated from SMARCA4-deficient tumors formed significantly fewer colonies in soft agar that those from SMARCA4-wild type tumors. Despite being smaller in size, the SMARCA4-deficient tumors had numerous necrotic areas and lacked expression of NE markers. The SMARCA4-deficient tumor cells also had reduced expression of ASCL1, a well-known NE lineage survival factor. This phenotype of losing NE differentiation, which is typical of late-stage disease, was observed in numerous lines of mouse and human SCLC cells and coincided with loss of various SWI/SNF components. Moreover, lower SMARCA4 expression correlated with lower overall survival in patients.

Conclusions: Our study demonstrated that SMARCA4 is required for SCLC development, suggesting a previously unsuspected role of SMARCA4 in early-stage SCLC tumorigenesis. The mechanism by which SMARCA4 loss results in tumor suppression is not known, but the loss of ASCL1 in the SMARCA4-deficient tumor cells may be an important cause. The recurrent mutations in patient tumors and the spontaneous loss of SMARCA4 expression in SCLC cells suggest that its functional loss is a late-stage event. Given the role of SMARCA4 in NE differentiation, we are testing whether the loss of the chromatin modifier drives tumor heterogeneity in late stages. Integrating both in vitro and in vivo models resulted in unexpected findings that led us to raise previously unrecognized questions about the temporal role of recurrent mutations. Our findings provide novel insight into how we approach current intervention strategies.

P1.03G.04 A Model of Human Small Cell Lung Cancer Metastasis Utilizing Orthotopic Transplantation of Patient-Derived Xenografts

J. Kim[1], S. Pal Chadhouri[1], K. May[1], T. Salisbury[1], C. Suchors[1], B. Freitas[1], S. Hamilton[1], V. Chien[1], L. Girard[1], M.S. Lawrence[2], B.S. Drapkin[1], University of Texas Southwestern, Dallas/TX/USA ,[2]Massachusetts General Hospital, Boston/MA/USA

Introduction: Small Cell Lung Cancer (SCLC) is a deadly and highly metastatic disease. Approximately 70% of patients are found with distant metastasis at diagnosis. Current in vivo models of SCLC include genetically-engineered mouse models and transplant models of human SCLC. The development of patient-derived xenografts (PDXs) has significantly advanced the study of human SCLC. The PDXs are genetically and functionally faithful to their original tumors including their responses to therapy. Most of PDXs are generated and grown in the subcutaneous flank of immunocompromised mice, which do not accurately reflect the microenvironment of SCLC. To date, metastasis of SCLC PDXs has yet to be reported - despite the fact that most of the PDXs are generated from biopsies of metastatic sites or circulating tumor cells. Here, we report on a model of an orthotopic transplantation of SCLC PDXs that metastasize to distant organs in a pattern consistent with human SCLC patients.

Methods: We adapted an orthotopic transplantation method that injects lung cancer cells directly into the lung parenchyma (Jacoby et al., J. Thoracic Oncol, 2010, Wilson et al., Methods Mol Biol, 2022) for our studies. After an incision of the skin was made to reveal the left chest wall of immunocompromised NSG mice, dissociated SCLC PDX cells suspended in 25% growth factor reduced Matrigel were injected through the chest wall and directly into the left lung, with visualization of the injection of tumor cells. Three PDX lines were been tested - one treatment naïve, and two drug-resistant lines - in at least 10 mice per PDX line. Lung tumor growth was followed by magnetic resonance imaging.

Results: All three PDX lines generated a primary left lung tumor and metastases to distant organs including the mediastinal lymph nodes, contralateral right lung, liver, adrenal glands, brain and ovaries. Rates of metastases ranged from 55 - 92% of mice injected with SCLC cells, depending on the PDX line. Mice bearing one particular drug-resistant SCLC PDX line consistently developed hydrocephalus and brain metastases. The primary left lung tumor and metastases expressed the neuroendocrine markers, synaptophysin and NCAM-1. Brain metastases were verified through their expression of TTF-1, a marker of SCLC and lung adenocarcinoma.

Conclusions: We have developed an orthotopic transplantation model of human SCLC that consistently generates metastases and faithfully mirrors the pattern of human SCLC, except for ovarian metastasis. To our knowledge, this is the first lung cancer PDX model that spontaneously metastasizes to distant organs and the first in vivo model of lung cancer that spontaneously metastasizes to the brain. Our model can be utilized to elucidate the biology of metastatic SCLC and as a platform to test therapeutic strategies against metastatic SCLC.

P1.06A.01 Machine Learning Models Discriminate Independent Primaries with Metastatic in Non-Small-Cell Lung Cancer

N. Liu, Y. Wang, Sichuan University, Chengdu/CN

Introduction: The determination of multiple lung cancers (MLCs) as multiple primary lung cancers (MPLCs) or intrapulmonary metastases (IPMs) is the basic for staging and adjuvant treatment decision. Although there are large characteristic differences between MPLCs and IPMs with regards to their development and clinical outcome, the discrimination between MPLCs and IPMs remains challenging. This study sought to identify four indices based whole-exome sequencing (WES), and then employ machine learning algorithms to develop a novel approach to differentiate multiple primaries from metastasis.

Methods: We performed WES on DNA extracted from 152 lung nodules and 5 pleural metastatic nodules from 72 MLCs patients which were obtained from two cancer centers. Based on the somatic mutations, we characterized inter-tumor heterogeneity within MLCs by four indices including entropy, shared mutation number, spearman correlation and trunk mutation number. Patients with known MPLCs (n=36) and IPMs (n=10) were used as training cohort. Three distinct machine learning methods: decision trees (DT), random forests (RF), and gradient boosting decision trees (GBDT) were utilized for generation of differentiation models, which were then applied to undetermined MLCs (n=26).

Results: In training cohort, MPLCs exhibited lower shared mutation number (median, 0 vs. 22, $P < 0.0001$), spearman correlation (median, -0.52 vs. 0.65, $P < 0.0001$) and trunk mutation number (median, 0 vs. 22.5, $P < 0.0001$), and higher entropy (median, 0.67 vs. 0.39, $P < 0.0001$) than IPMs. DT model, RF model and GBDT model employed the four factors and each has a sensitivity of 1, specificity of 1 and accuracy of 1, with the area under curve (AUC) value of 1. Machine learning models discriminated the undetermined MLCs as MPLCs (n=15) and IPMs (n=11). MPLC identified by machine learning models demonstrated fewer shared mutations (median, 1 vs. 26; $P < 0.0001$), a lower Spearman correlation coefficient (median, -0.44 vs. 0.57; $P < 0.0001$), and fewer trunk mutations (median, 0 vs. 35; $P < 0.0001$), but higher entropy (median, 0.68 vs. 0.35; $P < 0.0001$), compared to IPMs. MPLCs also had significantly prolonged DFS comparing to IPMs (Hazard Ratio, 0.25; 95% CI, 0.04 to 1.18; $P = 0.04$).

Conclusions: Machine learning models based on WES enable precise differentiation between independent multiple primary lung cancers and intrapulmonary metastases in NSCLC.

P1.06A.02 Discovery of Morphomolecular Neighbourhoods in Lung Adenocarcinoma Using Self-supervised Learning

K. Rakovic[1,2,3], F. Ballantyne[2], S. Martinelli[2], L. Officer-Jones[2], R. Pennie[2], I. Powley[2], K. Yuan[1,2], J. Le Quesne[1,2,3], N. Poulain[2], C. Ficken[2],
[1]University of Glasgow, Glasgow/GB ,[2]CRUK Scotland Institute, Glasgow/GB ,[3]Queen Elizabeth University Hospital, Glasgow/GB

Introduction: Lung adenocarcinoma (LuAd) is a morphologically heterogenous disease, and this variation in growth pattern underpins the current clinical grading system. Routinely collected diagnostic haematoxylin and eosin (H&E) sections are remarkably information-dense and contain a wealth of data we do not yet fully understand how to utilise. Are there further morphological clues that can help us risk stratify patients with LuAd in the adjuvant setting? How can we quantitatively and reproducibly encode the histological features of a patient's tumour in a scalable fashion? Can we link subsequently identified patterns to targetable biological signatures with therapeutic targets?

Methods: We trained a self-supervised artificial intelligence workflow, histomorphological phenotype learning (HPL), on 4456 whole slide images (WSIs) from 1025 patients from a single centre. Each WSI is broken down into tiles of approximately 400 microns in diameter. The model learns to recognise key morphologies on each tile with no prior annotation required. Tiles with similar appearances are grouped into histomorphological phenotype clusters (HPCs). Each cluster is a recognisable morphological entity, which can be reviewed and interpreted by a pathologist. This allows us to quantitatively express the spectrum of histological variance per patient as a compositional vector, which can be interrogated by statistical models such as logistic regression and Cox proportional hazards. Subsequent to this, we ran our trained model on 23 tissue microarray slides consisting of >2500 cores. We applied a basic immuno-oncology multiplex immunofluorescence Polaris panel to all sections, and a more detailed, high-plex immuno-oncology and fibroblast phenotyping PhenoCycler to a sub-selection.

Results: We discovered 64 HPCs. These accounted for the spectrum of appearances expected, such as classical growth patterns and normal parenchymal elements. Furthermore, we discovered HPCs defined by variant appearances, primary stromal patterns rich in fibroblasts, collagen or with varying quantities of immune cell populations. We constructed survival models using overall survival and recurrence-free survival and end-points and found that the highest risk morphologies were those characterised by morphoeic and discohesive epithelial morphology with dense eosinophilic stroma and abundant fibroblasts. In contrast, those with elastotic stroma and more abundant lymphocytes were associated with more favourable prognosis. For each cluster we obtained fractions of cell lineages and metrics of their spatial distribution to develop HPCs as integrated morpholomolecular neighbourhoods.

Conclusions: We demonstrate methodology which allows us to encode recurrent morphological features as HPCs in LuAd without prior annotations. HPCs serve as immediately hypothesis-generating entities which allow us to pursue clinical and biological questions. We observe that the tumour microenvironment is influential for prognosis and that HPC-led prognostication exceeds the clinical gold-standard. Furthermore, we characterise the cellular composition of our HPCs using spatially resolved proteomic data.

P1.06A.03 Use of Biosimulation to Predict Concomitant Chemotherapy Benefit in NSCLC Patients with EGFR Mutations Being Treated with Osimertinib

C. Aggarwal[1], J.A. Wingrove[2], S. Kapoor[2], S. Khandelwal[2], A. Ambreen[2], Y.S. Ullal[2], A. Ghosh[2], P. Kumari[2], N. Gupta[2], A. Kumar[2], M. Castro[2], T. Patil[3], [1]University of Pennsylvania, Philadelphia/PA/USA ,[2]Cellworks Group, Inc, South San Francisco/CA/USA ,[3]University of Colorado, Denver/CO/USA

Introduction: Targeted therapy has become a standard treatment option in patients with non-small cell lung cancer (NSCLC) carrying EGFR mutations. Although targeted therapy is largely effective, it is imperfect and the addition of chemotherapy may be beneficial, although the additive value of chemotherapy may not be the same in all patients. A mechanistic computational biology model was developed by Cellworks that integrates a patient's tumor-based genomic profile as determined via next-generation sequencing, revealing signaling pathway dysregulation and patient-specific drug response. Model output was used to identify patients who may or may not respond to the addition of chemotherapy to targeted treatment for EGFR mutations.

Methods: Computational biosimulation was performed using a real-world retrospective cohort of 116 advanced NSCLC front-line patients with EGFR mutations receiving osimertinib, obtained from the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine NSCLC clinico-genomic database (FH-FMI CGDB). The de-identified data originated from approximately 280 US cancer clinics (~800 sites of care). Efficacy scores (ES), based on biosimulated composite cell growth in response to disease and therapy, were generated on all patients for both osimertinib and osimertinib + carboplatin + pemetrexed. Chemotherapy-driven improvements in predicted clinical response was assessed, using the upper 95% CI of osimertinib ES as a threshold.

Results: Overall survival (OS) was associated with clinical response (median OS CR > 60, PR=34.1, SD=26.7,PD=15.7 months) as well as ORR (p = 0.017). Efficacy scores for osimertinib were significantly associated with clinical response (mean ES for CR=25.8, PR=19.3, SD=11.3, PD=6.7; ANOVA, p=0.011) and ORR (ttest, p=0.002). The biosimulated addition of chemotherapy to osimertinib led to a higher ES (median increase = 26.8) resulting in an increase in ORR from 75% to a predicted 79%, confirming previous clinical trial results. Although all patients showed response to chemotherapy addition, the benefit was variable. Patients predicted to have greater chemotherapy benefit tended to have deficiencies in DNA repair (DDR) genes such as ATM and SMARCA4, whereas patients predicted to have less benefit tended to have TP53 mutations and copy number gains in EGFR.

Conclusions: In this study, a therapy efficacy score produced through biosimulation was predictive of incremental chemotherapy benefit in a real-world cohort of patients with NSCLC being treated with osimertinib. Future studies will be performed to confirm the hypothesis that biosimulation has utility in deciding which patients receiving osimertinib may benefit from concomitant chemotherapy.

P1.06A.04 Deep Learning-based Whole Slide Image Analysis Predicts PD-L1 Status from H&E-Stained Histopathology Images in Lung Cancer

Y-F. Qi[1], W-Y. Huang[2], J-C. Liang[3], Z-X. Zhou[2], Z-B. Qiu[1,4], C. Zhang[1,4], Y-L. Wu[1,4], W-Z. Zhong[1,4], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Department of Pathology, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[3]School of Software, South China Normal University, Guangzhou/CN ,[4]School of Medicine, South China University of Technology, Guangzhou/CN

Introduction: Immune checkpoint inhibitors (ICIs) have greatly improved the survival of lung cancer patients. Programmed death ligand-1 (PD-L1) status is related to the ICIs benefit. Artificial assessment of PD-L1 scores may lack uniformity between different pathologists. Here, the H&E-stained images were used to predict the PD-L1 status of lung cancer using deep learning techniques.

Methods: A total of 348 H&E-stained whole slide images (WSI) were tiled into 3480 non-overlapping patches of 380x380 pixels. Using the convolutional neural network (CNN) based on the ResNet50 to extract features about the PD-L1 status of each patch. Then we employ the attention mechanism to summarize the scores of 10 patches to train the PD-L1 status prediction model. The model has an output score between 0 and 1. A score ≥ 0.5 predicts a positive PD-L1 status (TPS ≥1%), and a score < 0.5 predicts a negative PD-L1 status for this HE-stained WSI (TPS <1%).

Results: The 348 patients were randomly split into the training set (N = 279) and the testing set (N = 69) (8:2). 94.83% of lung cancers were stained by the 22C3 clone. 12.93% of patients had high PD-L1 expression, and 44.83% had negative PD-L1. And the study included lung cancer at stages I to IV. Among them, stage III (48.55%) accounted for the largest proportion. Adenocarcinoma was the most common pathological type (83.48%). The AUC of the training set was 0.88 (0.84-0.92). In the testing set, the AUC was 0.75 (0.63-0.87), the sensitivity was 71.05% (27/38), and the positive predictive value (PPV) was 79.41% (27/34).

Conclusions: This study highlights the potential of utilizing deep learning techniques on H&E-stained WSIs to identify lung cancer patients who could benefit from ICIs.

P1.06A.05 Assessing Pathologic Response to Neoadjuvant Chemoimmunotherapy for NSCLC: Aligning Current Protocols with Artificial Intelligence

E. Conde[1,2], D. Curto[1], S. Hernandez[1,3], M. Alonso[1,3], V. Adradas[3], M. Peressini[3], L. Paz-Ares[1,2], J. Zugazagoitia[1,4], F. Lopez-Rios[1,2], [1]Hospital Universitario [12] de Octubre, Madrid/ES ,[2]Universidad Complutense de Madrid. Research Institute Hospital [12] de Octubre (i+[12]). CIBERONC, Madrid/ES ,[3]Research Institute Hospital [12] de Octubre (i+[12]), Madrid/ES ,[4]Research Institute Hospital [12] de Octubre (i+[12]). CIBERONC, Madrid/ES

Introduction: Complete pathologic response (CPR) (i.e., 0% viable tumor cells) and major pathologic response (MPR) (i.e., less than or equal to 10% viable tumor cells) have emerged as indicators of survival after neoadjuvant chemotherapy and immune checkpoint inhibition (ICI) in patients with non-small cell lung carcinoma (NSCLC). Artificial intelligence (AI) algorithms have been developed to identify such a role, but their implementation in real-world practice has not been achieved yet.

Methods: Lung resection specimens from 24 patients with NSCLC who had been treated with neoadjuvant chemoimmunotherapy were prospectively included in this study. The residual primary tumor bed was entirely submitted for histopathological evaluation using a standardized grossing protocol. All hematoxylin-eosin (H&E)-stained tumor sections were reviewed by a thoracic pathologist using the IASLC response criteria and a calculator tool. In addition, the slides were scanned, and several tumor parameters (i.e., percent of tumor cells, total number of tumor cells and number of tumor cells per mm2) were extrapolated with the use of an AI algorithm (PathAI, Boston, MA). At the MPR cutoff, discrepancies between the digital and visual percentages were resolved using a second pathologist-in-the-loop approach. Treatment response in lymph nodes was excluded from assessment. A checklist-based standard operating procedure was drafted, integrating grossing with visual and digital assessments.

Results: The patients included 20 men and four women (mean age of 64.7 years and age range of 50-74 years). Fourteen tumors were squamous cell carcinomas, and the remaining 10 were adenocarcinomas. All patients received combined ICI therapy (single agent=22 or dual agent=2) and chemotherapy. The residual tumor bed ranged from 1 cm to 6.1 cm in greatest diameter (mean, 3.5 cm). A total of 313 H&E-stained slides were scored (median, 13 per patient; range, 4-29). Visual and digital MPR (less than or equal to 10% tumor cells, including CPR) were achieved in 79.2% (19/24; 95% CI: 57.8, 92.9) and 70.8% (17/24; 95% CI: 48.9, 87.4) of patients, respectively. On the basis of this cutoff, there was at least moderate agreement between the visual and digital assessments [kappa (95% CI): 0.78 (0.49, 1)]. In two discordant cases that were close to the 10% threshold, the digital percentage of tumor cells was greater than the visual result for both readouts. Interestingly, there was a significant association between the visual MPR and the AI-assisted estimation of both the total number of tumor cells and the number of tumor cells per mm2 (p=0.00012 and p=0.00057, respectively). Despite the short follow-up [median (95% CI): 14 months (12.6, 18.3)], there was a nonsignificant trend toward better outcomes in patients with visual or digital pathologic response.

Conclusions: It is feasible to apply AI algorithms to assist pathologists in predicting the effect of neoadjuvant chemoimmunotherapy in patients with NSCLC. Checklists were particularly helpful for resolving discrepancies. There was at least moderate agreement between the AI algorithm and the visual assessment of the pathologic response. The AI approach has the potential to refine the prognosis of NSCLC patients who do not achieve CPR or MPR after neoadjuvant therapy.

P1.06A.06 Post-COVID-19 Tumor Microenvironment Features and AI-Based Evaluation in KRAS-Mutant NSCLC

Z. Huang[1,2], L. Li[1], S. Wang[3], Z. Peng[4], Y. Jia[4], J. Zhang[5], Q. He[5], S. Zeng[5,6,7], B. Yang[5], Y. He[5], T. Guan[5], Y. Li[1], [1]Fudan University Shanghai Cancer Center, Shanghai/CN ,[2]Shanghai Medical College of Fudan University, Shanghai/CN ,[3]Fudan University, Shanghai/CN ,[4]Alpha X Biotech (Beijing) Co., Beijing/CN ,[5]Shenzhen International Graduate School, Tsinghua University, Shenzhen/CN ,[6]Greater Bay Area National Center of Technology Innovation, Guangzhou/CN ,[7]Shenzhen Shengqiang Technology Co, Ltd., Shenzhen/CN

Introduction: Coronavirus Disease 2019 (COVID-19) is an acute respiratory syndrome, spreading all over the world and threatening human healthy. Its impact of tumor microenvironment (TME) in non-small cell lung cancer (NSCLC) is not well illustrated. KRAS mutation accounts for about 12% of NSCLC in China, which is reported highly related to smoking. Smoking is believed to be a potential risk factor of COVID-19 by upregulating its' receptor angiotensin-converting enzyme-2 receptor (ACE2). However, little is known about the post-COVID-19 TME in smoking-related cancer, especially KRAS-mutate NSCLC.

Methods: We collect 75 KRAS-mutant cases between 2023/3/1 to 2023/6/30 for COVID-19 infection evaluation. Then twelve infected adenocarcinoma cases are enrolled for microenvironment analysis by RNA in situ hybridization (RNA-ISH) and multiplex immunofluorescence (mIHC) staining, as they provide negative evidence for more than 12 weeks before surgery. Finally, 75 cases' TME features are evaluated to predict COVID-19 burden by a new optimized YOLOv8 AI model. The evaluation model is called "C-FAST" short for COVID-19 burden fast prediction.

Results: First, around 86.67% (65/75) KRAS-mutant cases suffer from COVID-19 infection before operation. Most are adenocarcinoma (81.33%, 61/75) rather than other subtypes (18.67%, 14/75). Among the 65 cases who have clear infection history, 12 can provide negative evidence for more than 12 weeks before operation. Further, for the microenvironment analysis, the receptor ACE2 dramatically express a lot in high COVID-19 burden group (Figure A). A reported CAFs subtype (α-SMA+/FGF7low/HGFlow), which can recruit T cell infiltration, is remarkably low in high COVID-19 group tumor area (Figure B). The inflammatory microenvironment is characterized by more TregCD4+FOXP3+ cells (Figure C), less exhausted TCD8+PD-1+LAG3+ cells (Figure D) and less TRMCD8+CD69+CD103+cells in tumor zone of high COVID-19 cases compared to low ones (Figure E). Finally, an optimized AI evaluation model is created based on microenvironment features. The model achieves an mAP50 accuracy of 80% in TME detection and around 99% accuracy rate in TME classification (Figure F-G). The prediction score model (C-FAST) shows a moderate area under the curve (AUC) score (AUC=0.818,p=0.474, Figure H).

Conclusions: Overall, COVID-19 recovered KRAS-mutant patients with high virus burden recruit an immunosuppressive microenvironment, indicating a poor response from immunotherapy. The AI based evaluation could help predict virus burden status depending on detail TME features. To our best knowledge, this is the first report to describe the TME features post-COVID-19 pandemic and propose a novel AI evaluation model on virus burden prediction in KRAS-mutant NSCLC.

P1.06A.07 Prognostic Gene Expression Profiling in Lung Adenocarcinoma Using Deep Learning Applied to Whole-Slide Images

P. Murchan[1], A-M. Baird[1], P. Ó Broin[2], O. Sheils[1], S. Finn[1], [1]Trinity College Dublin, Dublin/IE ,[2]University of Galway, Galway/IE

Introduction: Recent advances in computational pathology have shown potential in predicting biomarkers from haematoxylin and eosin (H&E) whole-slide images (WSI). However, predicting outcome directly from WSIs remains a substantial challenge. In this study, we aimed to investigate how gene expression, predicted from WSIs using deep learning, could be used to evaluate overall survival (OS) in patients with lung adenocarcinoma (LUAD).

Methods: Differentially expressed genes (DEGs) between tumour and normal samples were identified from The Cancer Genome Atlas (TCGA)-LUAD cohort. Cox regression analysis was performed on DEGs to identify genes prognostic of OS. Attention-based multiple instance learning (AMIL) models were trained to predict the expression of identified prognostic genes from WSIs using the TCGA-LUAD dataset using site-stratified cross-validation. Gene expression-based prognostic models were compared with survival-based prognostic models in which OS was evaluated directly from the WSIs. Models were externally validated in the Clinical Proteomic Tumour Analysis Consortium (CPTAC)-LUAD dataset. The prognostic value of predicted gene expression was then compared to the true gene expression measurements. Histological correlates of identified genes were evaluated using WSI heatmaps.

Results: The expression of 239 prognostic genes could be predicted in TCGA-LUAD with cross-validated Pearson's R > 0.4. Predicted gene expression demonstrated prognostic performance, attaining a cross-validated concordance index of up to 0.615 in TCGA-LUAD through Cox regression. For comparison, the survival-based AMIL model achieved a cross-validated concordance index of 0.562. In total, 36 genes had predicted expression in the external validation cohort that was prognostic of OS. Predicted high expression regions of a number of upregulated genes in patients with low OS exhibited tumour necrosis.

Conclusions: Gene expression predicted from WSIs is an effective method of evaluating OS in patients with LUAD. We show that using predicted gene expression from WSIs to evaluate OS in LUAD patients performed better than predicting OS directly from the WSIs. AMIL models trained to predict prognostic gene expression in LUAD tended to learn tumour necrosis as an indicator of poor OS. This explainable predictive capability could be particularly useful in settings where comprehensive molecular profiling of LUAD is not feasible on a clinically relevant timescale.

P1.06B.01 NSCLC in Patients with CTD-ILD: Apobec-Related Mutagenesis, Frequent TP53 Mutations and Paucity of Targetable Alterations

I. Odintsov[1], M.M. Hammer[1], M.M. Awad[2], P.F. Dellaripa[1], L.M. Sholl[1], [1]Brigham and Women's Hospital, Boston/MA/USA ,[2]Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Patients with connective tissue diseases (CTD) have a higher risk of malignancies including lung cancer. Connective tissue disease-associated interstitial lung disease (CTD-ILD) is a proposed risk factor of lung cancer in this population, but the pathogenesis of lung cancer in CTD-ILD is poorly understood. Here, we investigate the cancer genomic changes in patients with CTD-ILD.

Methods: An institutional database of 5,181 non-small cell lung cancer (NSCLC) patients sequenced by our next generation tumor sequencing panel (OncoPanel) was reviewed to identify patients with clinical history of CTD or interstitial pneumonia with autoimmune features (IPAF). Additionally, an institutional pathology database was searched for cases of NSCLC with CTD-ILD. Candidate cases were reviewed for radiologic and/or pathologic pulmonary manifestations of CTD-ILD or IPAF. The final cohort included 20 patients with available genomic data (Figure 1A). Smoking history was categorized into never/light (< 20 pack years [PY], n=9) and moderate/heavy (≥ 20 PY, n=11).

Results: The findings are summarized the Figure 1B-D. Patients with never/light smoking history displayed universal alterations in TP53, that were significantly more frequent when compared to the general LUAD population (9/9, 100% vs 1861/3799, 49%, p = 0.0022). No conventional targetable alterations in EGFR, KRAS, ALK, ROS1, RET, MET, ERBB2, BRAF, NTRK1/2/3 or NRG1 were observed (Figure 1C). Pooled single base substitution (SBS) mutational signature analysis demonstrated predominance of COSMIC SBS 2 and 13 signatures, attributed to the APOBEC family of cytidine deaminases (Figure 1D). Patients with CTD-ILD and moderate/heavy smoking, on the other hand, had mitogenic drivers in 7/11 cases, including KRAS (3/11), BRAF (2/11), MAP2K1 (1/11) and EGFR (1/11) (Figure 1C). Only 5/11 of these patients had TP53 alterations, an incidence that was comparable to the general LUAD population (5/11 vs 1861/3799, p = 0.8). Mutational signature analysis demonstrated both smoking-related COSMIC SBS 4 signature, and APOBEC-related COSMIC SBS 2 and 13 signatures (Figure 1D).

Conclusions: Lung cancer in patients with CTD-ILD and history of never or light smoking demonstrates unique genomic features with frequent TP53 mutations and absence of targetable alterations. The predominance of the APOBEC mutational signature suggests the role of inflammation in the pathogenesis of LUAD in patients with CTD-ILD. Given the contraindication of immunotherapy and a paucity of targetable alterations in patients with CTD-ILD, this population has limited systemic therapeutic options. Further research is necessary to develop optimal preventive and therapeutic strategies for lung cancer in patients with CTD.

P1.06B.02 A Comprehensive Analysis of FGF/FGFR Signaling Alteration in NSCLC

Z. Huang[1,2], L. Li[1,2], Z. Peng[3], Y. Jia[3], Y. Li[1,2], [1]Fudan University Shanghai Cancer Center, Shanghai/CN ,[2]Shanghai Medical College of Fudan University, Shanghai/CN ,[3]Alpha X Biotech (Beijing) Co., Beijing/CN

Introduction: Fibroblast Growth Factor (FGF) ligands and their receptor alteration have been identified as the potent target in non-small cell lung cancer (NSCLC). However, the clinicopathological and microenvironmental characteristics of FGF/FGFR in NSCLC remain poorly understood.

Methods: We investigate 4656 NSCLC cases examined by next-generation sequencing and summarize 478 cases harboring FGF/FGFR alteration, analyzing the clinicopathological features. Fourteen cases carrying NOTCH1 co-mutation are further stained by multiplex immunofluorescence to describe the microenvironment.

Results: First, around 10.27% (478/4656) NSCLC harbor FGF/FGFR alteration. Squamous cell carcinoma (99/236, 41.95%) is much more than adenocarcinoma (331/3978, 8.32%). In 118 cases harboring pathogenic variant (PV), the most frequent variant is FGF/FGFR copy number increase (98/118, 83.05%), and the second is FGFR gene fusion (14/118, 11.86%). Surprisingly, CCND1 always co-amplifies with FGF19 (100.00%). PV group is more invasive and predicts poor survival. Furthermore, FGF PV is proved as an independent risk factor for poor prognosis (overall survival, OS: HR=3.781, p<0.05, disease-free survival, DFS: HR=3.34, p<0.05, Figure 1A-E). One-third of FGFR3-TACC3 fusion cases show clear cytoplasm in histology (Figure 1F). Either CCND1/FGF19 co-amplification or KRAS co-mutation is closely related to cigarette exposure (Figure 1G-H), and KRAS co-mutation acts as an independent factor of poor DFS (HR=6.79, p<0.05, Figure 1A, I-K). Finally, the FGF/FGFR1/NOTCH1 within RB1 variant group has a remarkably high ratio of inner-tumor CD8+ T cell infiltration (Figure 2A, B), non-exhausted T cells (Figure 2A, C), exhausted TCD8+PD-1+LAG3- cells (Figure 2A, D) and TRMCD8+CD69+CD103+cells (Figure 2A, E).

Conclusions: The FGF/FGFR alteration mainly arises in squamous cell carcinoma. Both FGF PV and KRAS co-mutation are the independent factors for poor prognosis. To our best knowledge, this is the first report to describe an inflamed microenvironment recruited by the NOTCH1/RB1 co-mutation, which indicates potential benefit from immunotherapy. Overall, our study provides a comprehensive about FGF/FGFR alteration in NSCLC.

P1.06B.03 Genetic Profiles and Evolutionary Trajectory of Early-Stage Lung Adenocarcinoma (AAH,AIS,MIA and IA) revealed by Multiplex Sequencing

l. lixuan[1], g. hu[2], h. xu[3], s. xiong[4], w. liang[4], [1]guangzhou medical university, guangzhou/CN ,[2]The Tenth Affiliated Hospital of Southern Medical University, guangzhou/CN ,[3]Guangdong Provincial Hospital of Chinese Medicine, guangzhou/CN ,[4]the First Affiliated Hospital of Guangzhou Medical University, guangzhou/CN

Introduction: The advent of early lung cancer screening has facilitated the detection of lung cancer at its nascent stages. The transition from AAH to IA involves a series of pivotal events, and currently needs more substantial data from large sample populations.

Methods: Adhering to the PRISMA guidelines, we conducted a systematic search up to August 1, 2023. PubMed and Web of Science databases were utilized for literature retrieval. Subsequently, we employed OpenMeta-analyst and direct superposition analyses to scrutinize the gene mutation spectrum.

Results: Our study incorporated 5315 samples from 16 articles. We observed a gradual increase in mutation rates of EGFR and TP53 throughout the evolution of lung adenocarcinoma (LUAD): AAH/AIS (24.4%, 5.4%), MIA (45.5%, 8.4%), and IA (51.3%, 26.9%). The mutation ratio of EGFR demonstrated a consistent change, whether assessed through NGS or PCR (NGS: AAH/AIS (20.9%), MIA (35.2%), and IA (63.0%); PCR: AAH/AIS (22.1%), MIA (44.6%), and IA (44.6%)). Conversely, the mutation rate of BRAF exhibited a progressive decrease (AAH/AIS (13.6%), MIA (5.8%), and IA (2.0%)). Additionally, subgroup analysis of samples from China revealed a consistent mutation trend, with EGFR and TP53 mutation rates gradually increasing (AAH/AIS (22.9%, 4.7%), MIA (41.0%, 4.3%), and IA (55.5%, 31.3%)), while BRAF mutation rates decreased (AAH/AIS (13.4%), MIA (5.8%), and IA (1.8%)). Our research shows the escalation of sensitive EGFR mutations, including EGFR-L858R and EGFR-19Del, during the progression of LUAD (AAH/AIS (11.4%, 13.9%), MIA (28.0%, 26.4%), and IA (25.2%, 27.7%)).

Conclusions: This study showed that gene mutations present different adaptations during the progression of LUAD. The low detection rates of EGFR and TP53 mutations among AAH/AIS and increasing trend along progression indicate some of them are not initiation events but serve as a driver for invasiveness. However, BRAF mutations represented an inverse effect, and other mutations showed no difference between different stages.

P1.06B.04 Exploring Circulating Tumor Antigens as a Faster and Lower Cost Alternative to Circulating Tumor DNA in IMpower150

N. Patil, Genentech, South San Francisco/CA/USA

Introduction: Molecular assays for the detection of circulating tumor DNA (ctDNA) or circulating tumor antigens (ctA) can enable the development of accelerated endpoints and provide higher resolution for patient risk stratification compared to standard radiographic imaging. Both ctDNA and ctA testing were deployed in IMpower150, a randomized phase 3 study comparing chemotherapy against combinations of atezolizumab ± bevacizumab + chemotherapy. Previous work showed that a machine learning (ML) model of ctDNA features1 or an optimized cutoff analysis using two ctA2 is able to effectively stratify stable disease (SD) patients in IMpower150 for survival risk. Given the significantly reduced testing time and sample testing cost for ctA, we applied a similar ML model for ctA and asked whether ctA could provide similar or improved predictive ability as ctDNA.

Methods: ctDNA testing was performed as previously described1. ctA testing was performed using electrochemiluminescence immunoassays (ECLIA) for CA 125, CA 15-3, CA19-9, CEA, CYFRA 21-1, HE4, NSE, SCC and ProGRP. Data imputation, normalization and training and testing of the ML model (EM) were done as previously described (1).

Results: Similar to ctDNA analysis using EM, we found that multiple ctA features at C3D1 best predicted risk for OS. Model performance using ctDNA and ctA were found to be similar (C-index of 0.66 and 0.72 for the training cohort, respectively, and 0.67 and 0.68 in the test cohort). OS HR between ctDNA and ctA models were also similar (OS HR: 3.3 [95% CI: 2.2-4.9] and OS HR: 2.82 [95% CI: 1.96-4.06], respectively). The EM, like the optimized cutoff model (2), showed that CYFRA 21-1 and CA 125 levels at C3D1 were among the top features for predicting OS.

Conclusions: ctA testing had similar agreement to ctDNA testing in a ML model for overall survival risk in patients with SD in IMpower150. ctA offers significant advantages over ctDNA as it can be performed for a fraction of the cost and is more accessible in standard clinical settings. Further comparison of the predictive performance of ctA against ctDNA is needed in additional studies and will support the development of this assay for risk assessment, for use as an early endpoint for treatment response, and for informing treatment decisions.

Keywords: NSCLC, circulating tumor antigen biomarker, overall survival surrogate

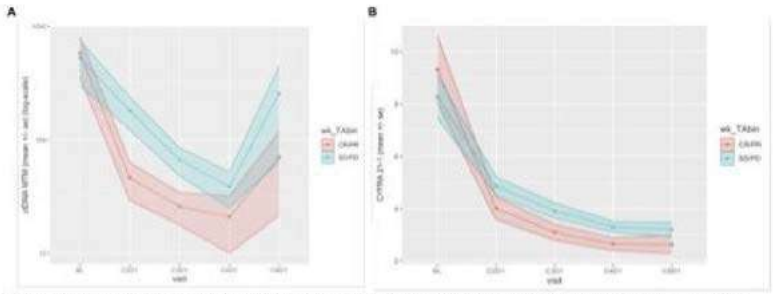

Figure 1. ctDNA and ctA levels over time can stratify patients by objective response. **A**, Mean ctDNA or **B,** mean CYFRA 21-1 levels are shown for responders (CR/PR) or non-responders (SD/PD) over time. BL: baseline.

P1.06B.05 Utility of Molecular Tumor Board Driven by Precision Medicine Service and Cloud-Based Datamart for Therapy and Trial Matching

J.K. Hicks, A. Saltos, A. Aminpour, A. Chiappori, H. Ozakinci, D.E. Rollison, P. Reisman, J. Creed, T.A. Boyle, G.R. Simon, J.E. Gray, Moffitt Cancer Center, Tampa/FL/USA

Introduction: Real-world implementation of precision oncology has several challenges including interpretation and clinical application of complex molecular profiling results. These challenges can result in patients not fully benefiting from precision oncology and may potentiate disparities. To mitigate clinical practice gaps, we established a multidisciplinary thoracic molecular tumor board (MTB) driven by a precision medicine (PM) clinical service and cloud-based data mart that provides real-time interpretation of next generation sequencing (NGS) results to facilitate trial matching and targeted therapy. We evaluated the clinical impact of this novel molecular tumor board approach on patient care.

Methods: A secure PM data mart was created by developing pipelines to ingest discrete genomic data and patient information stored in a cloud-based data warehouse. Within 24 hours of receiving NGS results, genomic and patient information are pulled into the PM data mart that links the information to customizable interpretations that are entered into the electronic health record (EHR) by PM clinical service (Figure 1). The PM data mart also generates a patient list to guide discussion at the weekly thoracic MTB. Recommendations made by the MTB are documented in the EHR and shared with primary oncologist and trial coordinators. We evaluated our novel clinical workflows from July 1, 2023 - December 31, 2023. Patient demographics and treatment history were extracted from either the PM data mart or EHR.

Results: A total of 364 cases (323 unique patients) had a precision medicine consult performed and discussed at the weekly thoracic MTB. Among all cases, 73% had Stage IV disease and 75% adenocarcinoma histology. EGFR mutations (17.9% of cases) and KRASG12C (8.5% of cases) were the most commonly observed targetable alterations. Targeted therapy opportunities were identified for 112 patients (34.7%), with 18.9% being frontline and 15.8% being later line options. For frontline therapy, 91.8% of patients received the matched targeted therapy. Two patients (3.3%) were lost to follow-up, 2 (3.3%) had not yet received systemic therapy, and 1 (1.6%, METexon 14 positive) received chemoimmunotherapy. Clinical trial opportunities were identified for 188 patients (58.2%). During the evaluation period, 60 patients were enrolled onto an interventional clinical trial with 45 (75%) discussed at the weekly thoracic MTB contributing to trial enrollment.

Conclusions: A PM service with subsequent expert review by a thoracic MTB is feasible, allows for real-time review of NGS results, and facilitates targeted therapy and trial matching. The cloud-based PM data mart enabled scalability for large patient volume.

P1.06B.06 Analysis of Antibody-Drug Conjugate Target Expression Across Genomic Subsets of Non-Small Cell Lung Cancer

J.J. Lin, B.Y. Yeap, J.L. Peterson, A. Do, M.K. Banwait, J. Schwartz, M.L. Ganci, A.N. Hata, R.S. Heist, Z. Piotrowska, J.F. Gainor, M. Mino-Kenudson, Massachusetts General Hospital, Boston/MA/USA

Introduction: Antibody-drug conjugates (ADCs) represent an expanding therapeutic modality in non-small cell lung cancer (NSCLC). While the ADC efficacy has variably correlated with corresponding target expression in tumors, limited knowledge exists regarding the landscape of ADC target expression across genomic subsets of NSCLC and whether the expression level differs pre- vs post-targeted therapy.

Methods: Patients with advanced NSCLC harboring EGFR mutations, ALK, ROS1, or RET fusions, or KRAS mutations were retrospectively identified. Pre- or post-targeted therapy formalin-fixed, paraffin-embedded (FFPE) archival tumor samples were retrieved. Expression of MET, HER2, TROP2, CEACAM5, and HER3 was assessed by immunohistochemistry (IHC) using commercial antibodies. The percentages of tumor cells with membrane +/- cytoplasmic staining by IHC at differential intensities (0=absent, 1=weak, 2=moderate, 3=strong) were determined to calculate H-scores (weighted summed scores). Comparisons were made using the Wilcoxon rank-sum, Friedman, and signed-rank tests.

Results: We assessed 106 tumor samples (EGFR, n=29; ALK, n=33; ROS1, n=21; RET, n=9; KRAS, n=14) from 78 patients with NSCLC [median age, 59 (range 22-84); female, 67%; nonsmoking history, 59%]. Among 50 pre-treatment samples, MET, HER2, TROP2, CEACAM5, and HER3 expression per oncogene driver was as summarized in Table; there were no significant differences among genotypes as compared in Table. Across the entire NSCLC cohort, MET, CEACAM5, TROP2 were more heavily expressed compared to HER2 and HER3 (p<0.001). We evaluated the ADC target expression in 9 paired pre- and post-osimertinib samples with EGFR mutations (exon 19 deletion, L858R, G719S/S768I, L861Q), finding no significant difference in the H-scores for MET [250 (100-291) vs 250 (0-300)], HER2 [0 (0-190) vs 3 (0-75)], TROP2 [130 (90-215) vs 115 (30-200)], CEACAM5 [40 (0-240) vs 60 (0-280)], and HER3 [0 (0-10) vs 0 (0-0)]. Similarly, among 15 paired pre- and post-TKI tumors with ALK/ROS1/RET fusions, there was no significant difference in the H-scores for MET [220 (160-300) vs 250 (56-295)], TROP2 [185 (120-265) vs 190 (10-300)], CEACAM5 [50 (0-295) vs 31 (0-290)], and HER3 [0 (0-110) vs 0 (0-131)] whereas HER2 expression decreased post-TKI [90 (0-160) vs 5 (0-130); p=0.010].

Conclusions: Distinct ADC targets demonstrated variable levels of expression across genomic subsets of NSCLC, with MET, TROP2, and CEACAM5 more heavily expressed than HER2 and HER3. In small cohorts of EGFR- and fusion-driven NSCLC, majority of the expression did not differ significantly pre- vs post-TKI. Further systematic assessment of differential expression of ADC targets is warranted and may inform the clinical development of ADCs in NSCLC.

P1.06B.07 Association of NEDD9 Expression and Survival of Patients with KRAS Mutant and STK11 Mutant Non-Small Cell Lung Cancer (KRASMUT/STK11MUT-NSCLC)

J. Judd[1], N. Gandhi[2], J. Xiu[2], A. Deneka[3], H. Khan[4], N.A. Karim[5], S.V. Liu[6], A.R. Naqash[7], H. Borghaei[1], E. Golemis[8], G. Hemenway[1], [1]Fox Chase Cancer Center, Temple University Health System, Philadelphia/PA/USA ,[2]Caris Life Sciences, Phoenix/AZ/USA ,[3]City of Hope, Los Angeles/CA/USA ,[4]The Warren Alpert Medical School, Brown University, Providence/RI/USA ,[5]Inova Schar Cancer Institute, University of Virginia, Fairfax/VA/USA ,[6]Lombardi Comprehensive Cancer Center, Georgetown University, Washington/DC/USA ,[7]Stephenson Cancer Center, The University of Oklahoma, Oklahoma City/OK/USA ,[8]Fox Chase Cancer Center/Temple University, Philadelphia/PA/USA

Introduction: STK11MUT are associated with an aggressive phenotype and worse prognosis in NSCLC. Co-mutations with TP53/KRAS may further influence survival in STK11MUT tumors. There is hence a need to contextualize STK11MUT while identifying biomarkers associated with survival in NSCLC. Pre-clinical studies investigating the role of NEDD9, a SRC activator and intracellular scaffolding protein, in lung tumorigenesis, suggest a relationship with LKB1-AMPK-dependent autophagy in KRASMUT NSCLC. The purpose of this study was to investigate the association between NEDD9 expression and survival in a large real-world cohort of KRASMUT/STK11MUT-NSCLC (KS-NSCLC) with and without TP53 mutations.

Methods: 1852 (KS-NSCLC) specimens with DNA (592-panel/whole exome) and RNA (whole transcriptome) sequencing were profiled at Caris Life Sciences (Phoenix, AZ). Tumors were stratified into NEDD9-high/ low based on the median RNA expression in KRASMUT-NSCLC. Real-world overall survival (OS) was obtained from insurance claims and calculated from tissue biopsy to last contact. Hazard ratio (HR) was calculated using the Cox proportional hazards model. Statistical significance was determined using Chi-square, Fisher's Exact, Mann-Whitney U & log-rank tests and corrected for multiple comparisons where applicable (q<0.05).

Results: High-NEDD9 expression (vs low-NEDD9) was associated with improved OS in patients with both TP53WT and TP53MUT-KS-NSCLC. Interestingly, among high-NEDD9 tumors, mOS of TP53WT (22.9m) was superior to TP53MUT (14.5m), while mOS for low-NEDD9 tumors was similar independent of TP53MUT status (TP53WT:8.3m, TP53MUT:6.2m; Figure). Genomic analysis of these tumors revealed increased prevalence of KEAP1 and SMARCA4 mutations in low-NEDD9 tumors (vs high-NEDD9). Multivariate analysis revealed that NEDD9 was associated with favorable prognosis independent of KEAP1 and SMARCA4 mutations (TP53WT:HR=0.53, p<0.001; TP53MUT:HR=0.69, p<0.001) in KS-NSCLC independent of TP53MUT status. Although not the primary focus of the current study, this analysis was replicated in a KRASMUT/STK11WT-NSCLC cohort and high-NEDD9 expression was associated with improved mOS independent of TP53, KEAP1, and SMARCA4 co-mutations. PD-L1 positivity was inversely associated with NEDD9 expression and significantly different between NEDD9 high and low expressing tumors in the TP53WT KS-NSCLC cohort only (q < 0.001).

Conclusions: Using a large real-world cohort, high-NEDD9 expression is independently associated with improved OS and is an effective prognosticator in KS-NSCLC. Further elucidation of underlying mechanisms and treatment implications is warranted.

P1.06B.08 The Prognostic Value of Histidine-rich Glycoprotein in Patients with Bronchial Carcinoid

D.D. Naves, E. Reuling, T. van Ee, C. Ariño Palao, C. Jimenez, Y. van Kooyk, C. Dickhoff, J. Daniels, F. Böttger, T. Radonic, Amsterdam UMC, Amsterdam/NL

Introduction: Pulmonary carcinoids (PCs) are well-differentiated neuro-endocrine tumors with low metastatic potential. WHO classification designates two grades: typical and atypical carcinoid. The prognostic value of this grading system remains limited. In our previous work, we showed that addition of novel markers CD44/OTP to the WHO classification in combination with Ki-67 predicted the development of distant metastasis in approximately 50% of patients.

Methods: The discovery cohort included 28 surgically-resected PCs (12 metastasized, 16 without metastasis) profiled with liquid chromatography tandem-mass spectrometry (LC-MS/MS-based proteomics). Differentially expressed proteins were validated with immunohistochemistry (IHC) using H-score in a validation cohort of patients with available clinical follow up and OTP/CD44 IHC.

Results: The discovery cohort had a median follow up period of 50 months (IQR 32-72). The LC-MS/MS-based proteomics revealed 22 differentially expressed proteins ($p<0.001$) of which four were selected for IHC validation. Histidine-rich glycoprotein (HRG) was successfully validated and performed in 158 patients. In the validation cohort, 16 patients (10%) had lymph node metastasis and 11 patients (7%) developed distant metastases. HRG had a lower median H-score in patients with distant metastasis (0; IQR 0-50) versus no metastasis (140; IQR 90-200, $p<0.001$). Interestingly, HRG had also a lower median value in tumors with lymph node metastasis 0 (IQR 0-185, $p=0.005$), which was not the case for OTP/CD44. Loss of HRG was independently associated with a higher risk of distant metastasis in multivariate analysis ($p<0.001$). The log-rank test showed signficant differences in distant metastasis-free survival when mitotic count, Ki-67, HRG, CD44/OTP were combined in favorable and unfavorable profiles ($p<0.001$).

Conclusions: Loss of HRG showed promising prognostic value for development of distant metastasis in combination the widely used TC/AC classification, Ki-67 and OTP/CD44. Moreover, it is often lost in lymph node metastasis. This composite biomarker may guide a more tailored approach for the follow-up of patients with PC.

P1.06B.09 Noninvasive Blood Biopsy of CRTAM-Type 3 Immune Axis Enables Dynamic Monitoring of Iraes Over the Course of Immunotherapy in Lung Cancer

S-C. Ma, Z-X. Rong, J-R. Lin, Z-P. Xu, D-H. Wu, Z-Y. Dong, Southern Medical University, Guangzhou/CN

Introduction: Immune checkpoint blockade (ICB)-based immunotherapy has become the first-line option for non-small cell lung cancer (NSCLC) without driver mutations. Nonetheless, the anti-tumor efficacy of immunotherapy comes at a cost of immune-related adverse events (irAEs) which leads to ICB withdrawal, reduced quality of life, and even patient deaths. A clinically scalable biomarker forecasting irAEs is urgently needed.

Methods: ICB-associated colitis, pneumonitis, and myocarditis were mimicked in preclinical models. Murine irAE vs control samples were subjected to RNA-sequencing for differential expression analysis. Genetic knockout mice were generated to explore the function and downstream signaling. An in-house NSCLC cohort was prospectively enrolled to evaluate blood biopsy for irAEs, where blood samples were divided into plasma and cell components. An external NSCLC cohort with plasma proteomics profiling was used for validation.

Results: Anti-PD-1 exacerbated the colitis and pneumonitis syndrome induced by dextran sodium sulfate (DSS) and whole lung radiotherapy (RT), respectively; and Pd1-/-Ctla4+/- exhibited spontaneous myocarditis in the preclinical setting. Integration of differential expressed genes of the irAE models pointed to CRTAM as a conserved biomarker. Crtam-/- mice exhibited compromised irAE phenotypes compared with Crtam+/+ mice after ICB induction (Figure 1). Transcription factor (TF) spectrum of Crtam-/- vs Crtam+/+ mice displayed a dampened expression of type 3 immune TFs. Our in-house cohort showed an upregulation of plasma IL-17 (type 3 immune effector) and CRTAM expression on T cells in irAE samples compared to those without irAEs. In the external cohort, plasma proteomics of irAE vs non-irAE revealed a concomitant increase of CRTAM and type 3 immune cytokines (IL-1 and IL-6) in baseline plasma samples from irAE patients (Figure 2).

Conclusions: Blood biopsy of the CRTAM-type 3 immune axis might be a promising non-invasive testing method for dynamic monitoring of the occurrence and development of irAEs during immunotherapy of NSCLC.

Keywords: immunotherapy, immune-related adverse events, non-small cell lung cancer

P1.06B.10 Post-hoc Biomarker Analysis of Adebrelimab Plus Chemotherapy and Sequential Radiotherapy as First-Line Therapy for ES-SCLC

L. Wang[1], B. Zou[1], B. Li[1], A. Gao[1], W. Huang[1], Q. Shao[1], X. Meng[1], P. Zhang[1], X. Tang[1], X. Hu[1], Y. Zhang[1], J. Guo[1], L. Chin[2], Z. Huang[2], Q. Li[2], C. Zhu[2], C. Zhao[3], J. Yuan[3], J. Yu[1], D. Chen[1], [1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan/CN ,[2]Amoy Diagnostics Co., Ltd., Xiamen City/CN ,[3]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Jiangsu/CN

Introduction: A prospective trial investigating the efficacy and safety of adebrelimab plus first-line chemotherapy followed by sequential thoracic radiotherapy (TRT) combined with adebrelimab was designed (NCT04562337) in extensive-stage small cell lung cancer (ES-SCLC) patients. The improved clinical benefit of progression-free survival (PFS) and overall survival (OS) were reported (L. Wang, et al, ASTRO 2023: 65th Annual Meeting). An exploratory analysis was conducted revealing putative biomarkers indicating therapeutic efficacy.

Methods: Inclusion criteria and study endpoints were disclosed (L. Wang, et al, ASTRO 2023: 65th Annual Meeting). Biospecimens were collected from 55 patients (Figure A). FFPE biopsy tissues (n=31) before initiation of therapy were collected. Plasma and peripheral blood mononuclear cell (PBMC) from 41 patient were collected before 1st (C1D1), 2nd cycle (C2D1) of adebrelimab plus chemotherapy and adebrelimab with consolidate TRT (C7D1). Comprehensive genomic profiling of tissue and cfDNA was performed by 571 cancer-related genes (AmoyDx® Master Panel). Transcriptomic profiling on tissue and PBMC was conducted via RNA-seq (AmoyDx®).

Results: From October 2020 to April 2023, 67 patients with ES-SCLC were enrolled. The cut-off of follow-up was December 22, 2023. Balanced baseline characteristics was found between whole (n=67) and biomarker analysis population (n=55). Co-mutations of TP53/RB1 in tissue (n=28) and peripheral blood (n=35) indicated poorer efficacy (PFS, tissue, HR=2.85, P=0.071; ctDNA, HR=2.76, P=0.06; OS, tissue, HR=3.35, P=0.032; ctDNA, HR=3.87, P=0.031) (Fig B-E). Higher TMB level (≥10Muts/Mb) in tissue implied longer PFS and OS (HR=0.27, P=0.053 and HR=0.37, P=0.086) (Fig B,C). At C7D1 (n=14), ctDNA+ patients had worse PFS (HR=12.28, P=0.0069). Transcriptionally, either radiation sensitivity index (RSI) or GARD score associated with the efficacy of TRT with immunotherapy. While patients with higher expression of CD274 (HR=0.33, P=0.066) or YAP1 displayed longer PFS (HR=0.3, P=0.044) (Fig B, C). Further, two clusters, immune-regulatory (cluster 1) and pro-inflammatory (cluster 2) were categorized in baseline PBMC (Fig D). Two subpopulations of T cells were further revealed at baseline PBMCs indicating opposite response to investigated regimen (Cluster 2 vs 1: PFS, HR=0.15, P=0.01; OS, HR=0.15, P=0.031) (Figure D, E). Patients with higher baseline ZNF683+ CD8+ T cells (cluster 2) got more benefit than those with higher baseline regulatory T cells (PFS, HR=0.14, P=0.04; OS, HR=0.2, P=0.028) (Fig D, E).

Conclusions: Genomic and transcriptomic biomarkers of tissue and peripheral blood were discovered. These biomarkers displayed association with clinical benefit of adebrelimab plus chemotherapy and adebrelimab with consolidate TRT, but further verification was warranted.

P1.06B.11 Plasma MicroRNAs Profiling to Monitor Immunotherapy Response in Advanced NSCLC Patients

C. Proto[1], M.V. Chiaruttini[2], A. Zanghì[1], G. Lo Russo[1], A. Prelaj[1], M. Segale[1], F.G. Greco[1], M. Brambilla[1], M. Occhipinti[1], T. Beninato[1], L. Mazzeo[1], R. Leporati[1], M. Ganzinelli[1], C. Giani[1], D. Miliziano[1], G. Di Liberti[1], G. Mazzoli[1], F. De Braud[1], M.C. Garassino[3], G. Sozzi[1], E. Rulli[2], M. Boeri[1], [1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan/IT ,[2]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan/IT ,[3]Knapp Center for Biomedical Discovery, The University of Chicago, Chicago/IL/USA

Introduction: Immune checkpoint inhibitors (ICIs) have radically changed non-small cell lung cancer (NSCLC) treatment significantly improving patients' outcome. However, about 80% of patients ultimately relapse due to primary or secondary resistance. In this context, the identification of minimally invasive biomarkers to monitor the response to treatment and personalize therapy remains an issue. In this study, we rely on longitudinal circulating microRNA profiling to model disease progression probability over time.

Methods: In the APOLLO trial, we collected clinical, biochemical, radiologic and molecular data, as well as plasma samples at predefined time-points from advanced NSCLC patients treated with ICI monotherapy. RECIST v. 1.1 criteria were used to evaluate radiological disease response. Using a custom RT-qPCR platform, we profiled 24-lung cancer related circulating microRNAs, generating 276 microRNA ratios. To model the probability of disease progression, we used generalized estimating equations (GEE), incorporating microRNA ratios and their interaction with time.

Results: We analyzed 454 plasma samples collected from 211 consecutive advanced NSCLC patients treated with ICI monotherapy at Istituto Nazionale dei Tumori of Milan. By principal component analysis at baseline, variables such as monocyte and leucocyte count, line of therapy, PD-L1 expression, presence of liver metastases and patient age were significantly related with the global microRNA profiling (Figure 1). Using GEE mathematical models, we identified nine circulating microRNA ratios (all featuring miR-145) as significant predictors of disease progression whose modulation was consistent with the radiologic response (Figure 2). Moreover, baseline values of miR-140-5p/miR-145, miR-145/miR-15b, miR-142-3p/miR-145, miR-145/miR-451, miR-145/miR-30b and miR-145/miR-30c were found to be associated with OS, but not with PFS.

Conclusions: Our findings highlight the role of dynamic microRNA profiles, especially miR-145, in response monitoring during ICI monotherapy in advanced NSCLC. Integrating minimally invasive microRNA-based liquid biopsy into clinical practice may help clinicians and improving treatment outcomes.

Keywords: microRNAs, Biomarkers, Immunotherapy

P1.06B.12 Racial and Socioeconomic Disparities in Molecular Diagnostics for NSCLC Patients

S.J. Tuminello, M. Untalan, T. Ivic-Pavlicic, W. Turner, R. Flores, E. Taioli, Icahn School of Medicine at Mount Sinai, New York City/NY/USA

Introduction: Targeted therapies have substantially changed the landscape of non-small cell lung cancer (NSCLC) outcomes. These drugs work by inhibiting specific molecular pathways, such as the epidermal growth factor receptor (EGFR) tyrosine kinase, the anaplastic lymphoma kinase (ALK), KRAS, and BRAF oncogenic pathways. Approximately 30% of NSCLC patients will have tumors with eligible targetable mutations, but a molecular test must be conducted to assess eligibility to these treatments. Disparities in molecular testing could be partially responsible for the disproportionate utilization of targeted therapy across race and socioeconomic status (SES).

Methods: Surveillance, Epidemiology and End Results (SEER)-Medicare linked data was queried for NSCLC patients diagnosed from 2013 (the first year that standard guidelines for molecular testing in lung cancer were available) to 2016. Patients were limited to age over 66 years at diagnosis with continuous Part A and B coverage and no Part C coverage, for 1 year prior and 90 days post-diagnosis. The primary outcome was receipt of a molecular test based on claims data. Race, defined as white, Black or other, was the primary predictor variable. Demographic and clinical characteristics of those receiving vs not receiving a molecular test were compared using $\chi 2$ tests for categorical variables and t-tests for continuous variables. We also performed multivariable logistic regression to assess the association of molecular testing with race adjusting for sex, age, marital status, Charlson comorbidity index, histology, tumor site, stage, and census-level poverty indicator.

Results: There were 28,511 NSCLC patients, of which 9,639 (33.8%) received some type of molecular testing. Black patients were significantly less likely than white patients to have received a molecular test ($p<0.0001$). Only 23.9% of Black patients underwent any molecular testing, compared to 34.6% of white patients. Patients living in census tracts with at least 10% of residents living in poverty were also less likely to receive a molecular test ($p<0.0001$). Patients who were female ($p<0.0001$), married ($p<0.0001$), with fewer comorbidities ($p<0.0001$), adenocarcinoma histology ($p<0.0001$), tumors located in the lower lobe ($p<0.0001$), diagnosed at a later stage ($p=0.0001$) were more likely to have molecular testing. After adjustment, Black patients (ORadj [odds ratio]: 0.65; 95% CI [confidence interval]: 0.59-0.72) and those living in areas with greater poverty (ORadj: 0.87; 95% CI: 0.82-0.91) were statistically significantly less likely to have received molecular testing.

Conclusions: Disparities exist in comprehensive molecular diagnostics, and could explain, at least in part, the high mortality observed among Black NSCLC patients. Addressing barriers to molecular testing could increase uptake of targeted therapy treatment, decreasing disparities and improving patient outcomes.

P1.06B.13 Blood-Based Loss of Heterozygosity in Human Leukocyte Antigen Class I Alleles Reveals Resistance to Immunotherapy in Non-Small Cell Lung Cancer

Y. Dong, J. Wang, Z. Wang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Loss of heterozygosity in Human Leukocyte Antigen class I (HLA-LOH) leads to immune evasion and hints the status of tumor development and immunotherapy response, while studies on blood-based HLA-LOH (bHLA-LOH) remain blank.

Methods: We explored bHLA-LOH characteristic based on 516 paired tissue-blood non-small cell lung cancer (NSCLC) specimens (GPD cohort) and detected baseline and dynamic bHLA-LOH status among 58 patients with advanced NSCLC receiving mono-immunotherapy (NCC cohort).

Results: In GPD cohort, the occurrence rates of tissue-based HLA-LOH (tHLA-LOH) and bHLA-LOH were 46.1% (238/516) and 14.9% (77/516) ,respectively. Similar with tHLA-LOH, bHLA-LOH group (n=439) included more patients with male gender (P = 0.001), smoking-history positive (P = 0.009) , and squamous carcinoma (P = 0.06) , characterized with higher blood-based tumor mutational burden (bTMB, P = 0.01), neoantigens (P = 0.09) and intra-tumor heterogeneity (ITH, P = 0.006) compared with non-bHLA-LOH group (n = 77). Surprisingly, in NCC cohort, patients with baseline bHLA-LOH showed significantly inferior clinical response (mPFS, 2.03 vs. 3.73mths, P < 0.01; mOS, 3.97 vs. 24.03mths, P < 0.01; primary resistance, P < 0.01), consistent with multi-factor analysis. Dynamic blood detection showed that bHLA-LOH was stably detected during immunotherapy(7/7), and three patients were detected with bHLA-LOH firstly as tumour progressed,indicating acquired resistance. Furthermore, baseline bHLA-LOH was associated with higher blood-based tumour mutation burden(bTMB, P < 0.01) and could stratified those with significantly worse response to immunotherapy in bTMB high group (mPFS, 2.03 vs. 3.47mths, P < 0.01; mOS, 3.97 vs. 13.9mths, P = 0.02).

Conclusions: We developed bHLA-LOH, a convenient, readily available, non-invasive predictive biomarker, which could effectively reveal primary and acquired resistance to immunotherapy in patients with NSCLC and guide clinical treatment decision, warranting future clinical trials.

P1.06B.14 Optimal Cut-Off with NGS for Metamplification Andclinical Relevance to MET Inhibitor in Non-Small-Cell Lung Cancer

S-Y.M. Liu[1], Z. Xie[2], L. Yan[3], G-L. Jie[2], J-Y. Deng[2], Q. Zhang[3], Z. Huang[4], J. Wang[5], Z. Zhang[6], Y. Shao[7], H. Meng[8], Y. Zhang[9], X-C. Zhang[2], W-Z. Zhong[10], Q. Zhou[2], Y-L. Wu[2], [1]The First Affiliated Hospital, Jinan University, Guangzhou/CN ,[2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[3]Department of Pathology, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[4]Department of translational medicine, Amoy Diagnostics, Xiamen/CN ,[5]Department of translational medicine, Amoy Diagnostic, Xiamen/CN ,[6]Data science department, Burning Rock Biotech, Guangzhou/CN ,[7]Geneseeq Research Institute, Nanjing Geneseeq Technology Inc, Nanjing/CN ,[8]Berry Oncology Institute, Beijing/CN ,[9]Geneplus-Beijing Institute, Beijing/CN ,[1013609777314@163].com, Guangzhou/CN

Introduction: Current next-generation sequencing (NGS)-based assays lacked a unified standard on the cut-off value for MET amplification in non-small-cell lung cancer (NSCLC) patients. Identify the optimal cut-off with NGS for MET amplification could guide clinical decision.

Methods: We initiated a multiple-site jointing study to optimize cut-off value for MET amplification by using tumor tissue and NGS analysis. The study included two cohorts for training and validation. In training cohort, five NGS panels were used to detect MET gene copy number (GCN) and fluorescence in situ hybridization (FISH) was used as a reference. Receiver operating characteristic (ROC) analysis was used to identify the optimal cut-off with 100% specificity and optimal sensitivity. Result was validated in an independent validation cohort to explore the correlation between MET amplification and the efficacy of MET inhibitors in NSCLC patients. Univariate and multivariate Cox regression analysis was used to explore the association of baseline characteristics and MET amplification status by identified NGS cutoff with PFS of MET-directed therapy.

Results: The clinical and pathological characteristics of the patients in training cohort (n=21) and validation cohort (n=29) was similar. In the training cohort, an optimal MET GCN cut-off was determined by 6.55 (versus FISH GCN 5), yielding an area under curve of 0.9, corresponding to an accuracy of 85.7%. MET polysomy identified by FISH (n=2) was also detected by NGS. All five NGS panels demonstrated good concordance with FISH, with an accuracy ranging from 75.0% to 85.7%. In the validation cohort, NGS analysis also demonstrated good performance, with an accuracy rate of 79.3%. Patients with MET GCN ≥ 6.55 had a significantly longer median progression free survival than those with MET GCN < 6.55 (Figure 1). MET amplification identified by NGS with MET GCN ≥ 6.55 as independent factor was associated with significant PFS benefit in univariable and multivariable analysis. Besides, using MET GCN 10 as positive by FISH, the identified cut-off value of NGS MET GCN 8.63 was explored.

Conclusions: In this study, the optimal cut-off of MET GCN with NGS was 6.55 and patients with MET amplification positive identified with this cut-off had favorable survival benefit from targeted therapy. Future studies are warranted to confirm these results.

Keywords: MET amplification, Next-generation of sequencing, Non-small-cell lung cancer and Targeted therapy

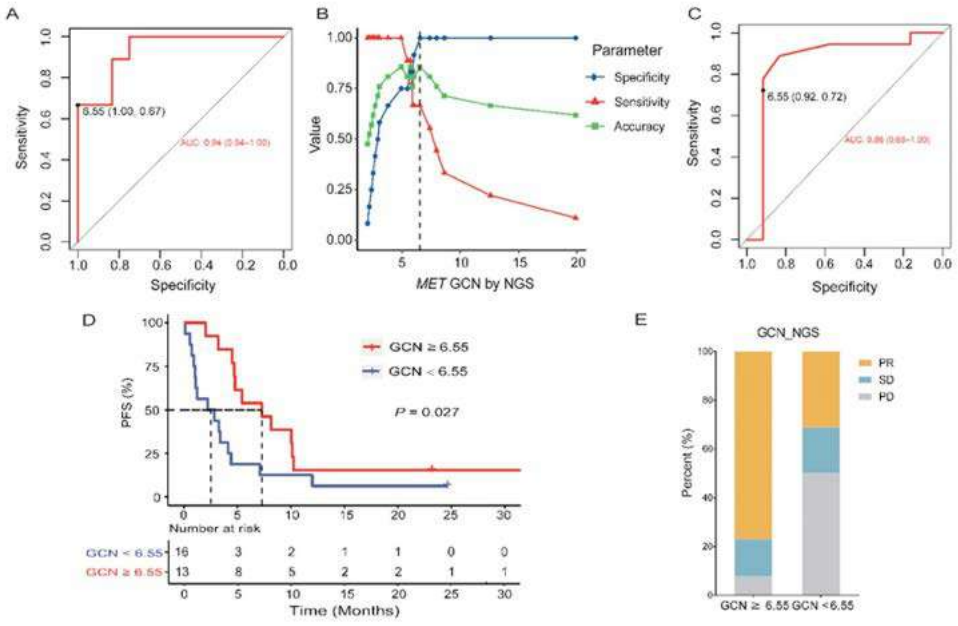

Figure 1: Identification and performance of the optimal cut-off value of MET GCN. (A): Receiver operating characteristic (ROC) curve showed the performance of MET GCN to define MET amplification based on NGS analysis. (B): Landscape of specificity, sensitivity and accuracy of different cut-off value of MET GCN to distinguish MET+ from MET- patients. (C): ROC curve showed optimal cutoff value of 6.55 by NGS in validation cohort. (D): Kaplan-Meier curve showed longer survival benefit from MET-directed therapy in patients with MET GCN≥6.55 by NGS (positive) than in those with MET GCN < 6.55 (negative). (E): Histogram show the better clinical response in MET positive patients than that in MET negative patients which grouped by NGS. Introduction: The MICOS (Mitochondrial Contact Site and Cristae Organizing System) family comprises a group of protein complexes located on the inner membrane of mitochondria, primarily responsible for maintaining the integrity of mitochondrial inner membrane structure and regulating mitochondrial inner membrane morphology. Aberrations in mitochondrial morphology and function have been implicated in the onset, progression, and treatment resistance of tumors, including lung adenocarcinoma. This study aims to comprehensively investigate the function of the MICOS family in the occurrence and development of lung adenocarcinoma and its clinical significance, providing novel scientific insights and clinical guidance for the treatment and prognosis assessment of lung adenocarcinoma.

Methods: Lung adenocarcinoma samples were extracted from The Cancer Genome Atlas (TCGA) dataset. Multiple databases including UALCAN, HPA, and DAVID were utilized to explore the role of MICOS family genes in lung adenocarcinoma, including their modulation of the immune microenvironment. Additionally, we knocked down the expression of MIC19 in lung adenocarcinoma using siRNA and explored its effects on cell proliferation and migration through CCK8, EDU, Transwell, and colony formation experiments.

Results: Bioinformatics analysis revealed that all genes in the MICOS family are closely associated with the occurrence of lung adenocarcinoma, with MIC19 showing the closest correlation with malignant clinical features of lung adenocarcinoma. Furthermore, the expression of MIC19 was significantly correlated with the immune cell infiltration abundance in lung adenocarcinoma patients, suggesting its potential as a prognostic biomarker for lung adenocarcinoma patients. In vitro experiments demonstrated that MIC19 promotes the proliferation and migration of lung adenocarcinoma cells.

Conclusions: This study elucidates for the first time the role of MICOS family members in lung adenocarcinoma, highlighting the importance of MIC19 as a potential novel independent prognostic biomarker and therapeutic target in lung adenocarcinoma.

P1.06B.16 HER3 Expression Across Genomic Subsets of NSCLC

B. Gupta[1], Y. Baca[2], G. Hubbard[2], J.E. Reuss[1], S.C.M. Lau[3], A. Elliott[2], M.C. Garassino[4], A.M. Vanderwalde[2], P.C. Ma[5], B. Halmos[6], S.V. Liu[1], [1]Lombardi Comprehensive Cancer Center, Georgetown University, Washington/DC/USA ,[2]Caris Life Sciences, Phoenix/AZ/USA ,[3]Perlmutter Cancer Center, NYU Langone Health, New York/NY/USA ,[4]The University of Chicago, Chicago/IL/USA ,[5]Penn State Milton S. Hershey Medical Center, Hershey/PA/USA ,[6]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA

Introduction: Human epidermal growth factor 3 (HER3, ERBB3) is frequently expressed in NSCLC and is a target for novel antibody drug conjugates; while known to be highly expressed in tumors harboring mutations in EGFR, little is known about ERBB3 expression in other molecular subtypes of NSCLC. Here, we analyze ERBB3 expression patterns in multiple genomic driver subtypes of NSCLC, explore associations with survival, and characterize the impact of prior tyrosine kinase inhibitor (TKI) exposure on ERBB3 expression.

Methods: Next-generation sequencing of DNA (592-gene or whole exome) and RNA (whole transcriptome) was performed on NSCLC samples (n=52,690) submitted to a CLIA-certified lab (Caris Life Sciences, Phoenix, AZ). ERBB3 expression was reported in transcripts per million (TPM). Real-world overall survival (rwOS) information was obtained from insurance claims data and calculated from time of collection to last contact, while time-on-treatment (TOT) was calculated from date of first treatment to date of last of treatment. P values were calculated using the log-rank test.

Results: In 2,600 tumor specimens with common sensitizing EGFR mutations (exon 19 deletions, exon 21 L858R), the median ERBB3 expression was 71.82 TPM. Median ERBB3 expression was highest in specimens with ERBB2 (HER2) mutations (98.65 TPM, n=433), EGFR exon 20 insertion mutations (83.65 TPM, n=70), and KRAS mutations (73.53 TPM, n=7928). ERBB3 expression was higher in KRAS G12C mutant NSCLC than non-G12C (76.07 TPM, n=5766 versus 70.29 TPM, n=3162). ERBB3 expression was lower in tumors with a ROS1 fusion (60.22 TPM, n=186), an ALK fusion (58.86 TPM, n=665), or a MET exon 14 skipping variant (42.50 TPM, n=925). High ERBB3 expression (top quartile) was associated with improved overall survival in the EGFR L858R (35.5 vs 25.7 months, p=0.028), EGFR exon 19 deletion (36.5 vs 27.4, p=0.012), MET exon 14 skipping (32.0 vs 14.7 months, p<0.0001), and KRAS mutants (21.6 vs 13.8 months, p< .00001). Among EGFR mutant samples, ERBB3 expression was significantly higher in TKI-naive samples compared to TKI-exposed samples (median TPM 68.8 vs 57.2, p=0.001). Time on treatment with EGFR TKI did not vary by ERBB3 expression.

Conclusions: High ERBB3 expression was observed in multiple genomic subsets of NSCLC including those with EGFR, HER2 and KRAS mutations, though expression varies by specific mutation. Within EGFR mutant NSCLC, expression was highest in TKI-naive samples and in the exon 20 insertion mutation subset. High ERBB3 expression was associated with better survival. These data support the role of HER3 as a viable therapeutic target across multiple molecular subsets.

P1.06B.17 Combing Circulating Tumor Cell Associated Liquid Biopsy and Radiomics to Predict the Pathology Grade of LUAD Patients

W. Hongchang, G. Yan, Nanjing Medical University, Nanjing/CN

Introduction: Lung adenocarcinoma (LUAD) is a predominant cause of cancer-related mortality. Achieving accurate diagnostics and effective treatments remains a challenge. Emerging liquid biopsy markers and radiomics have shown promise in enhancing LUAD diagnostics.

Methods: To delineate lung nodules in patients with postoperative adenocarcinoma on low-dose CT (LDCT), 3D Slicer was used for accurate segmentation of the nodules and their peritumoral regions. Following segmentation, the pyradiomics library extracted radiomic features from these regions of interest (ROIs), encompassing shape, intensity, texture, and wavelet attributes. Feature selection and model development employed a combination of ElasticNet-CV, mRMR, Lasso-CV, Random Forest-RFE-CV, and correlation analysis to identify predictive features with minimal redundancy. These features were then integrated using a nomogram approach to construct robust predictive models. Model performance was assessed through ROC curve analysis, focusing on the area under the curve (AUC) to evaluate the models' ability to accurately predict lung adenocarcinoma presence based on radiomic signatures derived from LDCT.

Results: The radiomics model, the clinical model, and the combined model were evaluated for their predictive capabilities: In both training and test groups, the combined model demonstrated optimal performance with an AUC of 0.9420 and 0.9277, respectively. Precision-Recall curves further cemented the combined model's superiority, achieving AP values of 0.9731 for the training set and 0.9691 for the test set, surpassing the performance of the standalone models.

Conclusions: This study clarifies that a combined model integrating CTC counts, radiomics, and other clinical data holds immense promise in refining surgical decisions for LUAD treatment. However, for a holistic understanding and optimization of the diagnostic potential of genetic markers, further comprehensive research is paramount.

P1.06B.18 Pathologic Response Assessment of Resected NSCLC Neoadjuvant Therapy Specimens with Tumor Size Larger Than 3cm by Different Sampling Methods

C. Wu[1], Y. Huang[1], H. Liu[1], S. Li[1], L. Hou[1], G. JunHong[2], [1]Shanghai Pulmonary Hospital, Tongji University School of medicine, Shanghai/CN ,[2]Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Data on pathological evaluation of resected NSCLC specimens with tumor size>3cm after neoadjuvant therapy are limited. This study aims to investigate pathological assessment of resected NSCLC specimens with tumor size>3cm after neoadjuvant treatment using different sampling methods.

Methods: We conducted a retrospective study of resected NSCLC specimens with tumor size>3cm after neoadjuvant therapy between June 2020 and July 2023 at Shanghai Pulmonary hospital. The difference of residual viable tumor (RVT) and pathologic response between IASLC multidisciplinary recommendation for sampling (MRS) and complete sampling (CS) for tumor bed with tumor size>3cm was compared.

Results: This retrospective study enrolled 90 patients with Non-small cell lung cancer (squamous cell carcinoma, n=39; adenocarcinoma, n=51) treated with neoadjuvant therapy including chemotherapy (n=22), targeted therapy (n=14), and chemoimmunotherapy (n=54). In this cohort, there were 62 men and 28 women with an average age of 63 years (range 39 to 74); The average tumor bed size was 4.3cm (range 3.1 to 8.0), and the average number of sampled blocks was 8 blocks (range 5 to 16) and 15 blocks (range 8 to 36) per case by MRS and CS, respectively. The number of patients with major pathological response (MPR) defined as less than or equal to 10% RVT was 34 cases (MRS) and 30 cases (CS), respectively. Four cases showed inconsistent RVT between MRS and CS, including one case of squamous cell carcinoma and three cases of adenocarcinoma. The RVT% of the four inconsistent cases achieved 7% using MRS and 15% by CS, and the kappa value of MPR consistency evaluated by the two sampling methods was 0.893. According to MPR cutoffs of 65% for lung adenocarcinoma (ADC-MPR), 24 cases and 20 cases achieved ADC-MPR by MRS and CS, respectively. Of the four inconsistent cases, the RVT% by MRS was 60% in three cases and 65% in one case, whereas the RVT% by CS was 70%, and the kappa value of the two sampling methods was 0.741.

Conclusions: It's feasible and practical to apply the IASLC multidisciplinary recommendations for sampling of resected NSCLC specimens with tumor size larger than 3cm after neoadjuvant treatment. Further studies are needed to confirm the optimal sampling method for pathologic response assessment.

Keywords: IASLC multidisciplinary recommendation, complete sampling, major pathological response

Patients	Age	Gender	Subtype	Tumor Size(cm)	Blocks by MRS	RVT% by MRS	Blocks by CS	RVT% by CS
Case1	73	Male	Squamous cell carcinoma	3.8	8	7%	11	15%
Case2	72	Male	Adenocarcinoma	5.5	14	7%	23	15%
Case3	61	Male	Adenocarcinoma	4.2	10	5%	18	12%
Case4	65	Female	Adenocarcinoma	3.2	8	9%	12	18%

P1.06B.19 Effect of Gut Microbiota and Metabolites on Malignant Pleural Effusion of Lung Adenocarcinoma

C-G. Liu[1], D. Zang[1], Y. Xin[1], J. Chen[1], M. Lin[2], [1]The Second Hospital of Dalian Medical University, Dalian/CN ,[2]Dalian Medical University, Dalian/CN

Introduction: Malignant pleural effusion (MPE) seriously threatens the quality of life of lung adenocarcinoma (LUAD) patients. Current studies have shown that human gut microbiome are closely related to the tumorigenesis, progression, diagnosis and prognosis of lung cancer. However, the relationship between gut microbiota and metabolites and MPE of LUAD remains unclear.

Methods: The study enrolled 122 newly diagnosed LUAD patients and collected baseline stool samples from all patients before treatment. Patients were divided into MPE group and NPE group according to the presence or absence of MPE at the time of diagnosis. Metagenomic and metabolomic tests were performed on stool samples from the two groups to compare the difference of gut microbiota abundance, metabolite diversity and metabolic pathway changes between the two groups.

Results: In the enrolled LUAD patient population, 53 patients had MPE and 69 patients did not. Our analysis found significant differences in gut microbiota and metabolite composition between the two groups. Compared with patients in the NPE group, the relative abundance of Methanobrevibacter (P=0.0203), Flavobacteriales (P=0.0386), Flavobacteriia (P=0.0358) and Holdemanella_biformis (P=0.0125) in the MPE group was reduced, while the relative abundance of Anaeroglobus (P=0.0003), Alistipes_ihumii (P=0.0317) and Dialister_ invisus (P=0.0163) increased. Metabolites such as DL-o-Tyrosine (P=0.0003) and Brevifolincarboxylic acid (P=0.0011) were up-regulated in MPE group. Kyoto Encyclopedia of Genes and Genomes (KEGG) database was used to enrich the differential metabolites, and the analysis showed that there were most significant differences in lipid metabolism related pathways, including steroid hormone biosynthesis, arachidonic acid metabolism, fatty acid biosvnthesis, etc.

Conclusions: This study suggests that LUAD patients with MPE have novel intestinal flora profiles and metabolic pathways, and these unique gut microbiota and metabolites may serve as potential biomarkers for the diagnosis and prognosis of MPE.

P1.06C.01 Evaluation of Small Pulmonary Pathology Specimen Management in the Province of Quebec, Canada

M. Maranda-Robitaille, K. Pelchat, M. Orain, F. Lamaze, P. Desmeules, P. Joubert, Institut universitaire de cardiologie et de pneumologie de Québec - Université Laval, Quebec/QC/CA

Introduction: The management of lung cancer patients has been revolutionized by the development of targeted therapies. Availability of tumor tissue is no longer vital for diagnostic purpose alone but also for biomarker evaluation. Small specimens such as tissue biopsies and cytology samples require strategic management now more than ever to ensure adequate treatment. The present study aims to investigate small specimen management in the province of Quebec, Canada.

Methods: Using pathological reports, data from 2164 small specimens diagnosed as lung adenocarcinoma, squamous cell carcinoma or non-small cell lung cancer favoring either were collected. Samples were submitted to a reference centre for molecular testing by 36 hospitals, categorized as academic centres, affiliated academic centres, and community hospitals, between 2022 and 2023. Based on the WHO Classification of Tumors of the Lung (2015, 2021), an algorithm was applied to categorize management of small specimens. Management was considered "adequate" when at least one immunohistochemistry stain was positive between TTF-1, Napsin A and/or Mucins (adenocarcinoma) or p40 and/or p63 (squamous cell carcinoma) only if no additional stain was performed. Thus, when one of the key stains was positive and additional stains were performed, management was considered "inadequate". When all the above were negative, management was categorized "adequate", regardless of the immunohistochemistry stains workup.

Results: In academic centres, the rate of adequate management of small specimens was higher (52.33% vs 39.25% vs 31.55%, p<0.0001), immunohistochemistry stains were less frequently performed (4.62 ± 0.15 vs 5.02 ± 0.12 vs 5.70 ± 0.16, p<0.0001), and turnaround times were faster (5.09 ± 0.16 vs 5.81 ± 0.10 vs 7.40 ± 0.18, p<0.0001) compared to affiliated academic centres and community hospitals, respectively (Figure 1). In the whole cohort, adequately managed specimens showed better turnaround times compared to inadequately managed ones (5.62 ± 0.14 vs 6.63 ± 0.12, p<0.0001). The rate of samples with enough tumor tissue for PD-L1 analysis differed between hospital settings (98.33% vs 95.60% vs 97.86% for academic centres, affiliated centres, and community hospitals, respectively, p=0.0041).

Conclusions: Our results show that a high proportion of small specimens were not managed adequately even close to 10 years after the publication of the WHO guidelines. In general, small specimen handling seems better in academic hospital centres compared to affiliated centres or community hospitals. With the growing need to preserve tumor tissue for molecular analyses, education to the pathology community is warranted to minimize the impacts on the patients.

P1.06C.02 Description of A Single Center Thoracic Rapid Tissue Donation Program Experience

H. Ozakinci, G.S. Nazario, S. Acevedo-Acevedo, H. Trejo-Bittar, R. Macaulay, B. Pellini, J.M. Koomen, T.A. Rose, D-T. Chen, J.K. Teer, E.R. Flores, A.A. Beg, M.B. Schabath, E.B. Haura, T.A. Boyle, Moffitt Cancer Center, Tampa/FL/USA

Introduction: The Moffitt Cancer Center Thoracic Rapid Tissue Donation (RTD) program offers significant opportunities for translational research in oncology. RTD has enabled the post-mortem donation of tumor tissue samples and body fluids from lung carcinoma patients to support translational research. These samples are particularly useful for studies of tumor evolution, heterogeneity, immune microenvironment, and treatment resistance mechanisms.

Methods: Between December 2015 and April 2024, 99 patients consented to participate in the RTD program as an alternative to organ donation, and samples from 58 donors were collected. The diagnosis of the donors included 32 with adenocarcinoma, 1 with squamous cell carcinoma, 1 with non-small cell lung cancer (NSCLC) not otherwise specified, and 23 with small cell lung cancer (SCLC), including 2 cases of SCLC transformed from NSCLC, and 1 case of mesothelioma. Tumoral and non-tumoral tissue samples, including formalin-fixed paraffin-embedded (FFPE), snap-frozen tissue, and fresh samples, were collected, processed, and stored. Special processing of fresh samples was performed to expand tumor-infiltrating lymphocytes and create 3D tumor microcultures. Multiple proteogenomic analyses were performed, including DNA sequencing, RNA sequencing, targeted gene expression analyses, immunohistochemistry, multiplex immunofluorescence, and mass spectrometry.

Results: The median interval between death and tissue collection was 10 hours (interquartile range: 5-19). A total of 789 FFPE, 737 snap-frozen, and 235 fresh samples were collected from 58 donors. The clinicopathological features of the 58 donors with lung cancer are summarized in Figure 1. Primary driver mutations were determined during clinical care and in the postmortem samples of 24 NSCLC donors, and only in postmortem samples of 3 NSCLC donors. Driver mutations included EGFR (N=3), KRAS (N=17), and NRAS (N=1) mutations, MET exon 14 skipping (N=1), and ALK (N=4) and ROS1 (N=1) fusions.

Conclusions: RTD enables the timely collection of high-quality tissue samples, allowing studies of tumor evolution, disease progression, therapeutic resistance, and heterogeneity within individual patients. Multiple lung cancer translational studies are in progress using these valuable post-therapy samples and data.

P1.06C.03 Prediction of STAS by Intraoperative Frozen Section for cT1N0M0 Lung Adenocarcinoma: A Prospective, Multi-Center Clinical Trial (ECTOP-1016)

Y. Zhang, Fudan University Shanghai Cancer Center, Shanghai/CN

Introduction: Surgical decision-making based on frozen section (FS) diagnosis of tumor spread through air spaces (STAS) may be useful to prevent local control failure after sublobar resection. However, there is little evidence to demonstrate the diagnostic accuracy of identifying STAS as high-risk histologic features on FS.To investigate the value of intraoperative assessment of STAS on FS in peripheral small-sized lung adenocarcinoma.

Methods: We conducted a prospective, multicenter (7 centers) study of consecutive patients with cT1N0M0 invasive lung adenocarcinoma to evaluate the accuracy of FS for intraoperative detection of STAS. The final pathology (FP) diagnosis of STAS was based on corresponding permanent paraffin sections. The inter-observer agreement for identifying STAS on FS was evaluated among three pathologists.

Results: The study included a cohort of 878 patients with cT1N0M0 invasive lung adenocarcinoma. 833 cases (95%) were assessable for STAS on FS. 26.4% of the cases evaluated positive for STAS on FP, whereas 18.2% on FS. The accuracy, sensitivity, and specificity of FS diagnosis of STAS were 85.1%, 56.4%, and 95.4%, respectively, with a moderate agreement (κ=0.575). Inter-observer agreement was substantial (κ=0.756) among three pathologists. Patients were further categorized based on tumor size or consolidation-to-tumor ratio for subgroup analysis of concordance, all with moderate agreement (κ: 0.54-0.58). After rigorous reassessment of false positive cases, the presence of artifacts may be the main cause of interpretation errors. Additionally, true positive cases showed more high-grade histological patterns and more advanced p-TNM stage than false negatives.

Conclusions: This is the largest prospective trial evaluating STAS on FS in cT1N0M0 invasive lung adenocarcinoma. FS is highly specific with moderate agreement but not sensitive for STAS detection. Appropriately reporting STAS on FS may provide surgeons with valuable information in intraoperative decision-making.

P1.06C.04 Low-Level Deletion of Chromosome 19p Genes May Be Sufficient to Drive Histology-Dependent Phenotypes in Lung Cancer

B. Henick, S. Mallick, N. Zhakula-Kostadinova, Y. Georgis, B. Herzberg, C. Concepcion-Crisol, A.M. Taylor, Columbia University, New York/NY/USA

Introduction: Deleterious mutations in chromosome 19p (chr19p) genes STK11/LKB1, KEAP1, and SMARCA4 have all been shown to contribute to lung adenocarcinoma biology and treatment response. However, the biological implications of low-level copy number deletion of chr19p have not been described.

Methods: We analyzed mutation, copy number, and gene expression data from non-small cell lung cancer cohorts in the Cancer Genome Atlas (TCGA), comparing lung adenocarcinoma with lung squamous cell carcinoma. For this dataset, we also evaluated immune infiltrate estimates calculated by methylation or gene expression patterns. In addition, we examined genomic data from immunotherapy-treated cohorts, including AACR Genie.

Results: Chr19p is frequently deleted across cancers in the TCGA dataset, with higher rates in lung adenocarcinoma. Immune infiltrate was significantly reduced in tumors with chr19p deletion when controlling for tumor type and overall copy number load; however, this was only observed in lung adenocarcinoma. The same was observed for low-level deletion of individual chr19p genes, including STK11 and KEAP1. Correlations of chr19p copy number and immune gene expression were also histology specific; chr19p loss significantly correlated with decreased immune signatures in lung adenocarcinoma and increased immune signatures in lung squamous cell carcinoma. Chr19p loss (or STK11 loss) also significantly correlated with STK11 deficiency based on gene expression patterns, again specific to lung adenocarcinoma. Based on these findings, we wanted to characterize the association between copy number of chr19p genes and immunotherapy response, turning to the AACR GENIE non-small cell lung cancer (NSCLC) biopharma collective (BPC) dataset. A subset of this cohort included patients treated with immunotherapy (atezolizumab, nivolumab, and/or pembrolizumab) and with copy number data available or GISTIC analysis of individual genes (n = 204). This subset largely comprised of lung adenocarcinoma patients. Here, deletion of any of these three chr19p genes correlated with worse overall survival, and this was statistically significant for STK11 deletion.

Conclusions: Overall, our analyses have found that (1) low-level copy deletion of chr19p genes can contribute to immune phenotypes and (2) there is a histology-specific effect of chr19p loss.

Introduction: The 9th edition of the IASLC TNM classification for NSCLC will not include lymphovascular invasion. We analyzed the significance of lymphovascular invasion and examined its influence on long-term survival in a large cohort of primary resectable NSCLC patients.

Methods: After applying the exclusion criteria (stage >IIIA, neoadjuvant therapy, positive resection margin, survival <90 days) we analyzed all consecutive adult patients who were resected at our institution between 2010 and 2022. Patients received adjuvant radio-/chemotherapy in accordance with current guidelines. We compared patients with lymphatic invasion (LI+), arterial/venous vascular invasion (VI+) and combined lymphovascular invasion (LIVI+) to a negative control group (LIVI-) after matching both cohorts according to the 8th edition of the IASLC TNM classification. Median-survival, 3- and 5- year survival rates and the hazard ratio (HR) for lymphovascular invasion were calculated.

Results: A total of 3,588 patients were included in this retrospective study. Mean age was 65.6±9.7 years and 56.6% (n=2031) of the patients were male. The right upper lobe was the most common tumor location (30.0%; n=1075) and adenocarcinoma (51.6%; n=1853) the most common histologic type. There were no significant differences between the groups (LIVI-: n=2409; LI+: n=279; VI+: n=735; LIVI+: n=165) in terms of stage, gender, age, histology, comorbidity and ECOG performance status. Stage-adjusted median survival in months was significantly longer for LIVI- patients (84.2±3.2) compared to patients with lymphovascular invasion (LI+: 48.5±5.3 vs VI+: 50.9±3.8 vs LIVI+: 36.3±5.3; p-value<0.0001). 3-year (LIVI-: 76.0% vs LI+: 59.6% vs VI+: 60.6% vs LIVI+: 48.5%; p-value<0.0001) and 5- year survival rates (LIVI-: 56.7% vs LI+: 25.4% vs VI+: 41.8% vs LIVI+: 25.0%; p-value=0.003) were significantly higher for patients without lymphovascular invasion. The hazard ratio (HR) for OS was 1.45 [95%-CI: 1.29-1.63] in case of lymphatic invasion, 1.27 [95%-CI: 1.19-1.35] in vascular invasion and 1.51 [95%-CI: 1.29-1.77] in a combined lymphovascular invasion. Survival was increased in node negative (LIVI-: 102.0±3.1 months vs LI+: 67.1±4.3 vs VI+: 66.5±7.0 vs LIVI+: 42.6±15.0; p<0.0001) versus node positive patients (LIVI-: 50.1±3.2 months vs LI+: 38.9±5.5 vs VI+: 41.3±4.2 vs LIVI+: 34.9±3.2; p=0.0029).

Conclusions: Our large single-institution analysis demonstrates the negative impact of lymphovascular invasion on long-term survival following NSCLC resection. While our findings are limited in their generalizability, this work could potentially serve as a foundation piece in advocating for the inclusion of lymphovascular invasion in subsequent IASLC classifications for NSCLC.

P1.06C.06 The Prognostic Impacts of Three Invasive Patterns in Pulmonary Peripheral Squamous Cell Carcinoma

H. Iguchi[1,2], Y. Hirai[1], T. Nakaya[1], A. Fusamoto[1], Y. Yata[1], Y. Mikasa[1], I. Matsuzaki[1], I. Hirai[2], S-I. Murata[1], Y. Nishimura[1], [1]Wakayama Medical University, Wakayama/JP ,[2]Naga Municipal Hospital, Kinokawa/JP

Introduction: Squamous cell carcinomas (SqCCs) account for ~20% of all non-small cell lung carcinomas. Despite advances in treatment strategies, SqCC prognosis is generally poor. Clinical trials have revealed the clinical utility of limited resection surgery for small pulmonary SqCCs. Therefore, determining the prognosis of surgically resected SqCCs is crucial. We explored the histopathological growth/invasive patterns of small SqCCs as a prognostic factor.

Methods: In this retrospective study, we analyzed data of 70 surgically resected cases of peripheral SqCCs at clinical stage I. We reviewed hematoxylin and eosin stained sections and TTF-1 and p40 immunohistochemically stained sections to evaluate peri- and intra-tumorous growth and invasive patterns in addition to quantitatively assessing the amount of alveolar structure remains.

Results: We found three distinct growth/invasive patterns of SqCCs with or without alveolar remains: intra-alveolar invasive pattern with alveolar remain (I-AR, Figure a-c), peri-alveolar invasive pattern with alveolar remain (P-AR, Figure d-f), and destructive invasive pattern with no alveolar remain (N-AR, Figure g-i) in 81.4%, 71.4% and 17.1% of the cases, respectively. Quantitative assessment of amount of intra-tumorous alveolar structure remains revealed that I-AR and P-AR values <10 and >11 showed significant differences in overall survival (p = 0.009 and 0.039, respectively, Figure j-k). Moreover, I-AR was an independent prognostic factor with excellent Hazard ratio (0.53). Pulmonary SqCCs show three distinct growth/invasive patterns with or without intra-tumorous alveolar remains. Amount of intra-tumorous alveolar remains is related with SqCC clinical prognosis.

Conclusions: This is the first report that growth/invasive patterns of SqCCs with intra-tumorous alveolar remains are strong prognostic factors.

P1.08A LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER - ADJUVANT THERAPY
SUNDAY, SEPTEMBER 8, 2024 - 12:00 - 14:00

P1.08A.01 Identifying Candidates for Postoperative Radiotherapy in Patients with Non-Small Cell Lung Cancer: A Multicenter Study

Z. Ma[1], Z. Hui[1], [1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: The value of postoperative radiotherapy (PORT) for patients with non-small cell lung cancer (NSCLC) is under great debate. This study aimed to evaluate the efficacy of a deep learning model in predicting disease-free survival (DFS) and to identify which patients could benefit from PORT.

Methods: Patients with histologically proven pN2 NSCLC who underwent complete resection were enrolled in one institution as the training set. Participants in the PORT-C randomized controlled trial were included as the test set. Patients across the other four independent medical centers were enrolled as external validation sets. A deep learning algorithm, DeepSurv, was trained on key clinicopathological variables. The model's performance was assessed using the concordance index (C-index). Patients were categorized into two subgroups based on DeepSurv recommendations: those recommended to receive PORT and those not. The clinical impact of model-recommended treatments was determined by comparing DFS in different subgroups of patients.

Results: The training, test, and external validation datasets comprised 1400, 364, and 841 individuals. DeepSurv demonstrated a C-index of 0.77 (CI, 0.75-0.78), 0.77 (CI, 0.74-0.79), and 0.70 (CI, 0.68-0.71) across these datasets, respectively. Patients were categorized into two subgroups based on DeepSurv recommendations: those recommended to receive PORT and those not. Within the training set, in the subgroup recommended for PORT, patients who received PORT demonstrated a significant improvement in median DFS (40.5 months, CI: 24.2-NA) compared to those who did not (24.9 months, CI: 18.5-31.6, P<0.01). Conversely, in the subgroup not recommended for PORT, no significant difference in median DFS was observed between those who underwent PORT (20.9 months, CI: 18.0 -36.8) and those who did not (24.9 months, CI: 21.4-32.3, P=0.74). The test and external validation set showed consistent results.

Conclusions: The deep learning model could predict DFS and tailor PORT for patients with NSCLC based on key clinicopathological variables.

P1.08B.01 Predicting Tumor Recurrence Risk in Locally Advanced NSCLC with Detectable ctDNA-Based Molecular Residual Disease: An Xgboost Model Analysis

Y. Pan[1], J-T. Zhang[1], X. Gao[2], Z-C. Jiao[2], Z-Y. Chen[1], H. Lin[1], S-Y.M. Liu[3], L-B. Tang[1], H-H. Yan[1], S. Dong[1], H-J. Chen[1], B-C. Wang[1], H-Y. Tu[1], X-N. Yang[1], J-J. Yang[1], W-Z. Zhong[1], Q. Zhou[1], Y-L. Wu[1,4], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Geneplus-Beijing Institute, Beijing/CN ,[3]First Affiliated Hospital, Institute of Hematology, School of Medicine; Key Laboratory for Regenerative Medicine of Ministry of Education, Jinan University, Guangzhou/CN ,[4]Chinese Thoracic Oncology Group (CTONG), Guangzhou/CN

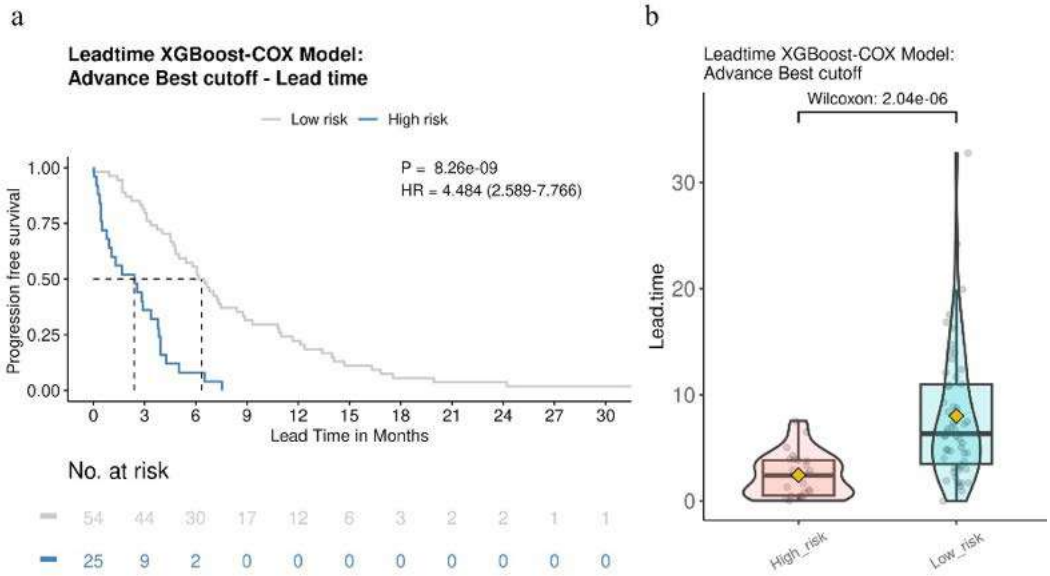
Introduction: Circulating tumor DNA (ctDNA)-based molecular residual disease (MRD) detection serves as a critical tool for monitoring disease recurrence after curative treatment in non-small cell lung cancer (NSCLC). Although detectable MRD indicates disease recurrence or progression, the variability in lead time, the interval from MRD detection to radiographical or clinical relapse, complicates its clinical utility, presenting a challenge for effective management.

Methods: We conducted an exploratory analysis within a cohort from our previous prospective study focused on dynamic ctDNA-MRD monitoring in locally advanced NSCLC patients undergoing chemoradiotherapy. This analysis included patients who presented with detectable MRD during surveillance. ctDNA alterations and their association with progression-free survival (PFS) and lead time were investigated. Significant variables were identified through univariate analysis and elastic net regression, followed by the development of a predictive model for lead time using the XGBoost algorithm.

Results: A total of 107 patients with detectable MRD were included, of which 79 experienced disease recurrence. The median age was 62(range 28-78), and 90.6% were male. The analysis revealed that higher ctDNA alteration copy numbers, increased tumor mutation burden (TMB), and the presence of pathogenic alterations were significantly associated with shorter lead time and poorer prognosis. Specifically, all 35 patients with a TMB ≥3 mutations per megabase experienced disease progression, demonstrating a notably shorter median lead time (4.97 vs. 7.12 months, p<0.0001) compared to those with a TMB <3. Furthermore, patients with pathogenic alterations identified in the ClinVar database at the time of MRD detection had a median lead time of 4.1 months, significantly shorter than those without such alterations. Multivariate analysis confirmed that ctDNA level, pathogenic alteration detection, and consistent detection of pathogenic alterations at both baseline and MRD detection were independent predictors of shorter lead time and adverse prognosis. A predictive model, empowered by a XGBoost algorithm-enhanced Cox regression, differentiated patients into high- and low-risk categories, where high-risk individuals had a shorter median lead time (2.4 vs. 6.3 months, HR=2.322 p<0.0001) and decreased 3-month PFS (36% vs. 80%, p<0.0001).

Conclusions: The clinical implications of detectable MRD in NSCLC may be different. High ctDNA levels and the presence of pathogenic alterations, especially those identified at both baseline and MRD detection, are associated with a higher likelihood ofrapid progression within 3 months. This study highlights the potential significance of ctDNA characteristics in stratifying recurrence risk and guiding clinical management strategies in NSCLC.

Keywords: circulating tumor DNA, molecular residual disease, lead time



P1.08B.02 Circulating T-Cell Immunosenescence in Patients with Unresectable Locally Advanced NSCLC: Preliminary Results of the SENLOAD Study

J.C. Benítez[1], M.v. SANCHEZ-BECERRA[2], N. Chaput[2], M. Naigeon[2], L. Cassard[2], L. Girard[2], D. Korera[2], N. Cozic[2], P. Lavaud[2], P. Abdayem[2], V. Albarragan-Artahona[2], A. Botticella[2], D. Planchard[2], J. Remon[2], F. Barlesi[2], C. Le Pechoux[2], B. Besse[2], A. Levy[2], [1]Gustave Roussy, Villejuif, Cedex/FR ,[2]Gustave Roussy Cancer Center, Villejuif, Cedex/FR

Introduction: Standard of care for patients with unresectable locally advanced (LA) non-small cell lung cancer (NSCLC) is concomitant platinum-based chemotherapy radiotherapy (CTRT) followed by anti-PD-L1 immune checkpoint blocker (ICB) durvalumab consolidation. The impact of T-cell immunosenescence, a mechanism of anti-PD-1/-L1 resistance in advanced NSCLC (aNSCLC), needs to be assessed in unresectable LA NSCLC. We present here the preliminary results of the SENLOAD study.

Methods: Blood samples at various timepoints were obtained for 60/117 planned patients enrolled within STING study (NCT04932525): baseline pre-CT (V0), before RT (V1), before ICB (V2), after 8 weeks of ICB (V3) and at progression (V4). The percentage of CD28-, CD57+, KLRG1+ among CD8+ T cells [senescent immune phenotype (SIP)] was assessed by blood flow cytometry. The primary goal is to evaluate SIP at baseline as prognostic factor of PFS in LA NSCLC receiving CTRT and ICB. A SIP cut-off of 39.5% was previously defined in aNSCLC.

Results: Median age was 62 (range, 38-77) years, most patients were male (63%) and the most frequent histology was adenocarcinoma (68%). Most tumors expressed PD-L1 (63%) and 20/60 of them (33%) were ≥50%. 48/60 patients (80%) received anti-PDL1 ICB and 12 (20%) did not receive ICB consolidation given progression or contraindication. 23/60 patients (38%) and 13/60 (22%) shown CRT- or ICB-related any grade toxicity. Median follow-up was 21 months. Mean PFS and OS were 23 months (95%CI 20-26.3) and 27 months (95%CI 24.6-29.8), respectively. The overall response rate of the whole cohort after CRT was 41.6% with a disease control rate of 75% for patients receiving durvalumab. The SIP+ results at each timepoint is shown in the Table 1. 30.4% and 14.2% SIP+ profile was found at baseline and at V2, respectively. Among 20 patients who experienced disease progression, 7 (35%) were SIP+ before ICB, including 2/20 (10%) who became SIP+ after CTRT. There were no differences between pts presenting ICB-related toxicity or not according to SIP+ profiles (15.4% vs 14.8%).

Conclusions: Circulating T-cell immunosenescence variations were observed along the course of treatment. We found 43% of senescence CD8-T during ICB progression. Assessment of Immunosenescence profile in stage III-NSCLC treatment strategy may contribute to improve personalization but did not seem related to toxicity. Further analyses are expected.

P1.08C.01 Targeted Therapy or Chemotherapy as Neoadjuvant Treatment for Resectable Stage II-IIIB EGFRm Lung Adenocarcinoma: A Study Between Four Cohorts

F-L. Lu, C. Lv, X. Yang, M.L. Zhuo, N. Wu, Beijing Cancer Hospital, Beijing/CN

Introduction: Neoadjuvant therapy is a promising strategy to reduce tumor size and increase the possibility of radical resection. Neoadjuvant chemotherapy and EGFR-TKIs therapy have both shown activity in previous studys. This study aimed to evaluate the efficacy of different neoadjuvant therapy for stage II-IIIB EGFR-mutant (EGFRm) NSCLC.

Methods: We selected two prospective study cohorts ("NEOS, ChiCTR1800016948" & "NEOIPOWER, NCT05104788") and retrospectively reviewed clinical records of stage II-IIIA lung adenocarcinoma patients treated with neoadjuvant targeted therapy or chemotherapy prior to surgery. The collected data were compared between the four groups of different neoadjuvant regimens: 1) chemotherapy group;2) first-generation EGFR-TKIs group;3) first-generation EGFR-TKIs plus chemotherapy group;4) third-generation EGFR-TKIs group.Tumor samples were collected for further sequencing analysis to explore resistance mechanisms.

Results: A total of 133 patients were enrolled, 32 patients in chemotherapy group;31 patients in first-generation EGFR-TKIs group;30 patients in first-generation EGFR-TKI (icotinib) plus chemotherapy group ("NEOIPOWER" study);40 patients in third-generation EGFR-TKI (Osimertinib) group ("NEOS" study). The baseline characteristics and clinical outcomes are shown in Table 1. Among all the four cohorts of patients who had completed the neoadjuvant treatment, the ORR as per RECIST were 40.6% (13/32), 45.2% (14/31), 83.3% (25/30) and 71.1 % (27/38). Logistic regression analysis identified neoadjuvant regimen significant correlation with ORR (p=0.001),while sex (p=0.467), smoking history(p=0.092), clinical staging (p=0.098) and EGFR mutation type (Exon 19 & 21, p=0.631) were not. Compared with neoadjuvant chemotherapy,the other three groups had higher ORR, with ORs of 1.204 (95% CI, 0.443-3.269), 7.308 (95% CI, 2.220-24.057) and 3.587 (95% CI, 1.327-9.699), in first-generation EGFR-TKIs, first-generation EGFR-TKI plus chemotherapy, and third-generation EGFR-TKI group, respectively. For pathological response assessment, 7.1% (2/28) and 10.7% (3/28) achieved a major pathological response (MPR) in first-generation EGFR-TKI plus chemotherapy group and in third generation EGFR-TKI monotherapy group, respectively. TRAEs were reported in 33 (82.5 %) of 40 patients in third-generation EGFR-TKI group, and in 25 (83.3 %) of 30 patients in first-generation EGFR-TKI plus chemotherapy group; of grades ≥3, 7.5 % occurred in third-generation EGFR-TKI group, and 13.3% occurred in first-generation EGFR-TKI plus chemotherapy group. No preoperative treatment-related AEs of grade 4 or 5 were observed.

Conclusions: Interim analysis from this study indicated that, compared with classical chemotherapy, neoadjuvant targeted therapy, especially third-generation EGFR-TKI and EGFR-TKI plus chemotherapy seemed to be more effective for patients with resectable stage II-IIIB EGFRm NSCLC, with higher radiographic response and tolerable toxic effects.

P1.08C.02 Revisiting the ACS 3N2 + 1N1 Mandate: Should Old Data Define Today's Standard?

S. Gulati, R. Flores, T. Ivic-pavlicic, M. Untalan, E. Taioli, B. Housman, A. Kulshrestha, Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: In 2021, the American College of Surgeons Commission on Cancer introduced Operative Standard 5.8. The directive changed lymph node sampling recommendations from a total of 10 lymph nodes to 1 lymph node from a hilar (N1) station and another 3 from 3 separate mediastinal (N2) stations. Unfortunately, the research underlying this decision comes largely from a 2012 retrospective study of the SEER database from 1998 - 2002. The published findings reflect antiquated operative habits, and several metrics inconsistent with expected clinical outcomes. Worse, nothing in the study supports an oncologic principle that defines a specific number or pattern of required lymph nodes. We sought to reproduce this study with more current data and assist in clarifying surgical recommendations.

Methods: Data was queried from the SEER database. We collected information from 2018 - 2020 to ensure outcomes that shared staging criteria. We sought to emulate the 2012 study by evaluating survival in patients who underwent anatomic resection with and without mediastinal lymph node dissection.

Results: A total of 19,778 patients received a lobectomy or bi-lobectomy. Of those, 91.7% (n = 18,129) underwent MLD and 8.3% (n = 1,649) did not ($p < 0.0001$). There were another 531 patients who underwent pneumonectomy. Of those, 79.7% (n = 423) underwent MLD and 20.3% (n = 108) did not ($p < 0.0001$). Among patients who did not undergo MLD, 9.6% of patients were N1 (n = 229), and curiously 6% of patients were N2 (n = 114), and 12.2% of patients were N3 (n = 9). Additionally, 2.1% of patients undergoing MLD (n = 384) were classified as having stage IV disease. Patients who underwent MLD had significantly more lymph nodes removed at the time of surgery. The average number examined was 13.48 in patients who underwent MLD and 7.91 in patients who did not ($p < 0.0001$). Compared to patients who did not undergo MLD, patients who received a MLD were statistically significantly more likely to die from non-lung solid malignancy, cardiac disease, and other causes. They were less likely to die from lung cancer related causes, hematopoietic malignancy, and COPD. Performing a MLD carried a hazard ratio of 0.72 (95% CI 0.62 - 0.83). Though positive lymph nodes were associated with increased mortality (HR 1.06, 95% CI 1.04 - 1.08), there was no additional survival advantage to removing a greater quantity of lymph nodes (HR 0.99, 95% CI 0.99 - 1.00). Sub-group analysis will investigate the frequency of MLD in N0 and N1 patients, improved survival with MLD by N stage, and lung cancer specific mortality.

Conclusions: It comes as no surprise that MLD is associated with a decreased risk of mortality; lymph node sampling is essential for staging, procedural decision-making, and adjuvant therapy. However, the ACS has utilized a study to draw conclusions that are not supported and seeks to correct a problem that does not exist. Blanket policies have the potential to bottleneck safe surgical judgment and force hazardous dissection on vulnerable patients.

P1.08C.03 Updated Event-Free Survival of Tislelizumab Plus Chemotherapy Asneoadjuvant/adjuvant Therapy for Stage IIB-IIIC NSCLC (lungmark Study)

Y-B. Lin[1], Y-H. Chen[2], Z-C. Lin[3], M. Zhou[4], W-Y. Zhai[1], Y-H. Zhou[1], S-C. Feng[1], B-Y. Rao[1], M. Huang[2], H. Long[1], [1]Sun Yat-Sen University Cancer Center, Guangzhou/CN ,[2]Sun Yat-sen University, Guangzhou/CN ,[3]Jiangmen Central Hospital, Jiangmen/CN ,[4]Cancer Center of Guangzhou Medical University, Guangzhou/CN

Introduction: LungMark study is a phase II study investigating the feasibility of neoadjuvant PD-1 inhibitor tislelizumab with chemotherapy in patients with stage IIB-IIIC non-small-cell lung cancer (NSCLC). The preliminary results of this trial have been presented in 2023 ASCO abstract 8564, demonstrating a major pathological response (MPR) rate of 72.7% and a pathological complete response(pCR) rate of 47.7% in the surgical resection population. Here, we report the two-year event-free survival (EFS) rate of the study.

Methods: The study enrolled treatment-naïve patients with stage IIB-IIIC NSCLCs. Surgical resection was performed 4-6 weeks after 3~4 cycles of neoadjuvant PD-1 inhibitor tislelizumab (200mg), carboplatin (area under the curve 5), and pemetrexed (500 mg/m 2 for adenocarcinoma) or nab-paclitaxel (260 mg/m 2 for other subtypes) on day 1 of each 21-day cycle. Adjuvant tislelizumab monotherapy was followed for 1 year. The primary endpoint was the safety. EFS, MPR, pCR were set as secondary endpoints.This study is registered with ClinicalTrials.gov, NCT05244837.

Results: On March 15, 2024, the median follow-up duration was 24 (range: 12.8-20.0) months in the intention-to-treat population. Forty-four of the 53 (83.0%) enrolled patients underwent resection, in which 36 (67.9%) received tislelizumab monotherapy as adjuvant treatment following the operation with median 10 (range 1-13) cycles. Recurrence occurred in 36.1% of pts who had surgery. Possible reason for this result was that 23 patients (23/53, 43.4%) with stage IIIB/IIIC were enrolled in this trial. The median EFS was 30 (95%CI:23-NR) months in the intention-to-treat population, with a 12-month and 24-month EFS rates of 85.1% (95%CI:46.4-77.8) and 64.4%(95%CI:71.2-92.6), respectively. Patients who achieved MPR showed longer EFS as compared with those without MPR (median EFS: 39 vs.26 months).

Conclusions: Tislelizumab plus chemotherapy as a neoadjuvant treatment showed a promising pathological response and manageable TRAEs. Neoadjuvant and adjuvant tislelizumab combined with chemotherapy showed long-term EFS benefit in stage IIB-IIIC NSCLC.

P1.08C.04 Delineating the Prognosis Spectrum: Disentangling Primary Tumor and Lymph Node Responses in NSCLC Following Neoadjuvant Immunotherapy

L. Jiang, S. Jiang, Shanghai Chest Hospital , Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Neoadjuvant immunotherapy has emerged as a promising treatment paradigm for Non-Small Cell Lung Cancer (NSCLC). However, the discordance between primary tumor (PT) and lymph node (LN) response raises questions about their independent prognostic implications, especially considering that patients achieving pathological Complete Response (pCR) and Major Pathological Response (MPR) have shown better prognosis. This study aims to elucidate the independent prognostic implications of PT and LN response through semi-quantitative analysis.

Methods: In this retrospective study, we collated data from patients who received neoadjuvant immunotherapy between December 2018 and December 2023. A comprehensive record of demographics, disease characteristics, responses to neoadjuvant treatment, surgical techniques applied, post-operative outcomes, and survival rates was maintained. PT responses were meticulously categorized into eight groups based on the residual tumor burden: pCR (no residual tumor), 0-5%, 5%-10%, 10%-20%, 20%-30%, 30%-40%, 40%-50%, and over 50% residual tumor. LN responses were dichotomized into two broad categories: complete regression and incomplete regression. The impact of PT and LN responses on prognosis was assessed leveraging Cox regression model, which allowed us to estimate the independent effect of these variables on patient outcomes.

Results: The study population comprised 315 patients all treated with a uniform protocol of combinatory immunotherapy and chemotherapy. The R0 resection rate among these patients was remarkable, standing at 97.1% (306 patients). The median Disease-Free Survival (DFS) was 32.6 months (95% CI, 28.6-36.6). The median for Overall Survival (OS) was unreached. In six groups of patients with PT residual rates ranging from 0-5%, 5%-10%, 10%-20%, 20%-30%, 30%-40% to 40%-50%, there was an absence of tumor progression in patients demonstrating complete LN regression. Subsequently, patients were stratified into four groups: those with PT residual >50% and incomplete LN regression (PT>50%+nNpCR), those with PT residual >50% and complete LN regression (PT>50%+NpCR), those with PT residual <=50% and incomplete LN regression (PT<=50%+nNpCR), and those with PT residual <=50% and complete LN regression (PT<=50%+NpCR). Upon survival analysis, the median DFS for the four groups were reported as follows - PT<=50%+NpCR: 40.0 months (95% CI, 36.4-43.6), PT>50%+NpCR: 28.1 months (95% CI, 20.3-35.9), PT<=50%+nNpCR: 25.5 months (95%CI, 19.3-31.6), and PT>50%+nNpCR: 9.8 months (95% CI, 2.8-16.9).

Conclusions: The findings highlight the paramount significance of LN response over PT response in determining prognosis post-neoadjuvant immunotherapy in NSCLC. The beneficial influence of complete LN regression on survival outcomes underscores the need for further large-scale prospective studies to validate these findings. Additionally, mechanistic exploration targeting this phenomenon could lead to more personalized therapeutic interventions.

Introduction: The skip N2 lymph node metastases, defined as mediastinal lymph node involvement (pN2) without hilar and intrapulmonary lymph nodes (pN1), frequently occur in non-small cell lung cancer (NSCLC). It has been reported that skip-N2 present a better prognosis compared to the non-skip-N2 metastases. However, the factors associated with skip-N2 remain controversial. This study aimed to investigate the clinicopathological features associated with skip-N2 and its impact on the survival in patients with clinical-N0 (cN0) NSCLC.

Methods: A retrospective multicenter study involving 22 institutions was conducted. The medical records of patients with cN0pN1-2 NSCLC between January 2012 and December 2021 were reviewed. Patients were categorized into three groups: pN1 group, skip-N2 group, and non-skip-N2 group (pN1N2), and clinical, radiological, and pathological findings were analyzed. Disease staging was reassigned according to the 8th edition of the TNM staging system.

Results: A total of 757 patients who underwent pulmonary resection with mediastinal lymph node dissection (ND2a-1 or ND2a-2) were enrolled. The median age at the time of surgery was 70 years (range, 28-90), and 473 patients were male. The clinical T categories were Tis (n = 1), T1 (n = 357), T2 (n = 307), T3 (n = 72), and T4 (n = 20). CT findings showed pure-solid tumors (n = 645), part-solid tumors (n = 111), and a ground-glass tumor (n = 1). Pleural attachment and indentation were observed in 552 cases. Tumors were located in the right upper lobe (n = 213), right middle lobe (n = 34), right lower lobe (n = 190), left upper lobe (n = 172), and left lower lobe (n = 148). Tumor histological types were adenocarcinoma (n = 554), squamous cell carcinoma (n = 153), and others (n = 50). The pathological nodal statuses were pN1 (n = 357) and pN2 (n = 400). Among pN2 cases, 175 cases (44%) were skip-N2. Tumor location on the right side (p = 0.003), contact with the pleura (p < 0.001), peripheral lesion (p = 0.007), pl-positive (pl1-3)(p = 0.004), Ly0 (p = 0.001), and v0 (p = 0.023) were significantly related to skip-N2. In total group, the median follow-up was 3.6 years, and the 3-, 5-year overall survival rates (OS) were 75.6% and 60.8%, respectively. The 5-year OS was 62.7% in pN1, 65.3% in skip-N2, and 54.3% in non-skip-N2. Skip-N2 had significantly better prognosis compared to non-skip-N2 (p = 0.010), and rather demonstrated a prognosis similar to pN1.

Conclusions: Skip-N2 disease occurs frequently and has a favorable outcome with curative surgical resection. Standard hilar and mediastinal lymph node dissection should be required, especially in the patients with NSCLC with pleural attachment on the right side.

Introduction: The consolidation therapy of durvalumab after chemoradiation therapy (CRT) has been shown to improve prognosis in unresectable stage III non-small cell lung cancer (NSCLC). However, the efficacy of durvalumab after CRT in EGFR-mutated NSCLC and the safety of EGFR-TKI after durvalumab is unknown. The aim of this study is to evaluate the efficacy and the safety of durvalumab after concurrent CRT (CCRT) in EGFR-mutated NSCLC patients (pts).

Methods: We conducted a multicenter (48 centers in Japan) retrospective cohort study of consecutive EGFR mutated stage III NSCLC patients who received radical CCRT between July 2015 to June 2022, and compared outcomes in patients who received durvalumab with those who did not. On survival analysis, we excluded pts whose genetic testing were performed after recurrence after CCRT and used propensity score matching based on prespecified explanatory variables. Furthermore, to align the observation periods as much as possible, we prespecified the maximum observation period was 3 years for the progression-free survival (PFS), 4 years for other analysis. In addition, we examined the safety of EGFR-TKI as posttreatments in both groups.

Results: A total of 207 pts were enrolled: pts with durvalumab were 134, pts with CRT alone were 73, 190 pts were eligible for survival analysis: pts with durvalumab were 123, pts with CRT alone were 67. After propensity score matching, there were no significant differences in patient background between pts with durvalumab (N=65) and pts with CRT alone (N=65): median (range) age 69 (44-85) vs 68 (40-84); 38 (58.5%) vs 41 (63.1%) female; 35 (53.8%) vs 36 (55.4%) Stage IIIA, 24 (36.9%) vs 25 (38.5%) IIIB, 6 (9.2%) vs 4 (6.2%) IIIC; 61 (93.8%) vs 62 (95.4%) Adenocarcinoma, 3 (4.6%) vs 2 (3.1%) Squamous cell carcinoma, 1 (1.5%) vs 1 (1.5%) Not otherwise specified; 31 (47.7%) vs 23 (35.4%) Exon 21 L858R, 26 (40.0%) vs 31 (47.7%) Exon 19 deletion, 1(1.5%) vs 1 (1.5%) Exon 20 insertion, 7 (8.8%) vs 10 (15.4%) other uncommon or compound. The median PFS of pts with durvalumab was significantly longer than that of pts with CRT alone (23.0 months (95%CI, 15.8-NA) vs 12.1 months (9.4-21.0); hazard ratio (HR) 0.56 (95%CI, 0.36-0.87); p=0.009). PFS rates of 1y, 2y, 3y, were 71.7% (95%CI, 58.9-81.1) vs 50.7% (37.8-62.3), 48.5% (35.6-60.3) vs 27.9% (17.1-39.7), 41.7% (28.7-54.2) vs 20.0% (10.7-31.4), respectively. There was no statistically significant difference in median overall survival (OS) between pts with durvalumab and pts with CRT alone (HR 0.63 (95%CI, 0.29-1.38); p=0.25). OS rates of 1y, 2y, 3y, 4y were 98.4% (95%CI, 89.3-99.8) vs 92.1% (82.0-96.6), 91.7% (81.2-96.5) vs 83.5% (71.4-90.8), 80.7% (66.6-89.3) vs 75.4% (61.8-84.7), 80.7% (54.1-79.4) vs 68.7% (54.1-79.4), respectively. There were no differences in the frequency of adverse events ≥CTCAE grade 3 of subsequent EGFR-TKIs between both groups (27.8% vs 26.0%, p=1.0).

Conclusions: In our real-world data for EGFR-mutated stage III NSCLC, durvalumab after CCRT improved PFS and did not increase the frequency of adverse events ≥CTCAE grade 3 of subsequent EGFR-TKI compared with CRT alone.

SUNDAY, SEPTEMBER 8, 2024 - 12:00 - 14:00

P1.08D.02 Survival after Salvage Treatment Following Durvalumab Consolidation in Locally Advanced Non-Small Cell Lung Cancer (LA-NSCLC)

M. Stalker, M. Marmarelis, C. Langer, R.B. Cohen, A. Singh, C. Aggarwal, L. Sun, Hospital of the University of Pennsylvania, Philadelphia/PA/USA

Introduction: PACIFIC established adjuvant durvalumab as standard of care in LA-NSCLC, but only about half of enrollees completed 1 full year of therapy due either to toxicity or progression. Data on practice patterns and outcomes after durvalumab treatment are limited. We sought to investigate nationwide treatment practices and survival in patients who received systemic therapy after consolidative durvalumab.

Methods: Our analysis included adult patients (pts) from the Flatiron Health electronic health record-derived database with LA-NSCLC who received at least one dose of consolidative durvalumab between 2017-2023 and had subsequent systemic therapy, classified as PD-(L)1 monotherapy, PD-(L)1+chemotherapy, chemotherapy alone, PD-(L)1+CTLA4, or targeted therapy (TT). Time to next treatment (TTNT) was analyzed from durvalumab start and finish to next line of therapy. Overall survival (OS), defined from start of post-durvalumab therapy to death or censoring at last contact, was analyzed using Kaplan Meier methodology.

Results: Our cohort included 751 pts, median age 68 (IQR 61-74), 53% female, 80% White, 91% ECOG 0-1, 90% smoking history, and 53% non-squamous histology. Of 482 pts with known PD-(L)1 expression, distribution of 0%/1-49%/≥50% was 41%/36%/23%, respectively. The most common post-durvalumab treatment was chemotherapy alone in 349 (46%), followed by PD-(L)1+chemotherapy in 147 (20%), PD-(L)1 monotherapy in 114 (15%), and TT in 104 (14%), which was most commonly osimertinib (24%) or alectinib (14%). Median duration of durvalumab treatment was 5.5 months (IQR 2.3-10.6); only 9% of patients received a full year of durvalumab, and 64% started next treatment within a year of durvalumab initiation. TTNT from durvalumab start/end was shorter in the chemotherapy and TT cohorts compared to the PD(L)1 +/- CTLA4 cohorts (Table 1). Median OS from post-durvalumab therapy initiation was 10.8 (5.6-18.8) mos in the chemotherapy cohort and 12.9 (6.0-24.2) mos in the chemoimmunotherapy cohort, versus 23.8 (8.7-34.5) mos in the PD-(L)1 monotherapy and 30.1 (9.5-NR) mos in the TT cohorts (p<0.001).

Conclusions: In a real-world cohort of pts receiving salvage therapy after durvalumab consolidation for LA-NSCLC, majority received less than 6 months of durvalumab, had subsequent therapy within a year of durvalumab initiation, and were treated with chemotherapy-based approaches. This cohort had a poorer mOS (10-13 months) compared to the expected contemporary mOS for pts with de novo recurrent/metastatic disease, likely reflecting poor prognosis in pts who were refractory or resistant to immunotherapy. Overall, this study shows a high prevalence of rapid disease progression after durvalumab, and highlights the need for better treatment strategies.

Keywords: locally-advanced NSCLC, post-durvalumab, overall survival

Treatment Category	Patients (n)	Median Mos from Durvalumab Start to Subsequent Therapy (IQR)	Median Mos from Durvalumab End to Subsequent Therapy (IQR)	Median Overall Survival from Start of Post-durvalumab Therapy, mos (IQR)
Chemotherapy	349	8.0 (4.4-13.0)	1.8 (0.9-5.2)	10.8 (5.6-18.8)
Chemotherapy + PD-(L)1	147	8.3 (3.9-17.7)	1.5 (0.9-7.2)	12.9 (6.0-24.2)
PD-(L)1 monotherapy	114	14.2 (6.2-20.8)	3.3 (1.4-11.6)	23.8 (8.7-34.5)
PD-(L)1+CTLA4	37	14.0 (8.5-21.9)	5.5 (1.7-13.2)	12.7 (4.5-20.7)
Targeted Therapy	104	7.6 (5.0-13.7)	1.9 (1.0-4.9)	30.1 (9.5-NR)

P1.08D.03 Induction Durvalumab Followed by Chemoradiation and Consolidation Durvalumab for Stage III Non-Small Cell Lung Cancer (NSCLC)

R.E. Sanborn[1], D. Hanes[2], D. Shaker[3], M.J. Fidler[4], S. Gurubhagavatula[5], S-C. Chang[2], W.L. Redmond[1], [1]Earle A. Chiles Research Institute, Providence Cancer Institute, Portland/OR/USA ,[2]Providence Cancer Institute, Portland/OR/USA ,[3]Cancer Center of Kansas, Wichita/KS/USA ,[4]Rush University Medical Center, Chicago/IL/USA ,[5]Summit Health, Florham Park/NJ/USA

Introduction: Concurrent chemoradiation followed by consolidation durvalumab (D) is the current gold standard for patients (pts) with unresectable stage III NSCLC, based on the PACIFIC trial (including 12-month progression-free survival (PFS), measured starting after chemoradiation, reported as 55.9%). Our study evaluated the addition of induction D prior to concurrent chemoradiation and consolidation D to assess for potential improvement in 12-month PFS compared with PACIFIC as historical control.

Methods: This was a single arm study of 1 dose induction D, 1500 mg IV prior to concurrent chemoradiation, followed by consolidation D (1500 mg IV every 4 weeks) for up to 12 cycles after completion of radiation. Study plan was for safety run-in of 10 patients enrolled, followed by completion of accrual with 54 total planned patients. Primary objectives were 12-month PFS measured from completion of chemoradiation, safety, and feasibility. Exploratory objectives: Objective response rate (ORR); outcomes based on PD-L1, TMB status; banking for future correlative studies.

Results: Enrollment was halted after 10 pts were enrolled due to pandemic-related slow accrual. Pt characteristics included 6 male/4 female; mean age 67; 7 White/2 Black/1 Asian; 4 adenocarcinoma/1 adenosquamous/5 squamous. Chemotherapy: Carboplatin/paclitaxel (8); carboplatin/pemetrexed (1); cisplatin/etoposide (1). No pts progressed prior to consolidation, and all pts were able to receive consolidation D. Median number of consolidation D cycles was 7.5 (range 2-12). Outcomes: ORR: 70%; 12-mo PFS: 30%. There was no deepening of response during consolidation. 2 pts had complete response (CR) after chemoradiation and remain in CR. 7 pts progressed during consolidation. No signal relating to PD-L1 expression level and PFS was noted. All 3 pts who had high TMB (by institutional standard of care testing) were without progression at 12 months. All 7 pts with progression had tumors that were TMB low or unknown. No new safety signals were identified. Notable toxicities attributed to D included pneumonitis, hypothyroid, elevated creatinine, thrombocytopenia (1 pt each, grade 2), infusion reaction, dyspnea, neutropenia (1 pt each, grade 3), all during consolidation.

Conclusions: Conclusions are limited due to the small number of patients in this trial which closed early due to pandemic-related slow accrual. No new safety signals were seen with the addition of a single dose of induction D prior to chemoradiation and consolidation D. The initial 12-month PFS of 30% is disappointing, although not statistically significant as intended to compare with historical control. Interestingly, all 3 pts progression-free at 12 months had high TMB, without apparent relation to PD-L1 status.

P1.08D.04 The Clinical Outcomes of Contralateral Esophagus Sparing IMRT in Concurrent Chemoradiotherapy for Stage III Lung Cancer

H. LIM[1], K. Yang[1], J.M. Noh[1], H. Pyo[1], D.Y. Kwon[1], J.M. Kim[1], S.G. Ju[1], Y.C. Ahn[1], [1]Samsung Medical Center, Seoul/KR

Introduction: Radiation esophagitis is frequent and annoying toxicity in high dose thoracic radiation therapy. Contralateral esophagus sparing intensity modulated radiation therapy (CES-IMRT) has been proposed to mitigate this problem, and this is to report impact of CES-IMRT in definitive concurrent chemoradiotherapy (dCCRT) for lung cancer patients.

Methods: From January 2021 till May 2023, 183 stage III non-small cell lung cancer patients underwent dCCRT. Esophagus was located within 1 cm from internal target volume in 159 patients. We comparatively evaluated frequency and severity of esophagitis by pain-killer usage, analgesic quantification algorithm (AQA) score, and failure patterns in 159 CES-necessary patients.

Results: All patients underwent dCCRT (66 Gy in 30 fractions with concurrent chemotherapy). Actual CES-IMRT application was determined based on discretion of responsible radiation oncologists: CES-applied in 41 patients; and CES-unapplied in 118. CES-applied patients experienced pain events less frequently (pain-killer usage: 53.7% vs. 77.1%, p=0.008) and less severely (AQA score of 2-3: 39.0% vs. 68.6%, p=0.002). On multivariate analyses, overlapping volume of esophagus and planning target (HR = 1.32, 95% CI 1.12~1.55, p=0.001) and CES-IMRT application (HR = 0.31, 95% CI 0.13~0.76, p=0.010) were associated with AQA score of 2-3 less frequently. There were no differences in failure pattern, progression-free survival, and overall survival.

Conclusions: CES-IMRT application resulted in less frequent and less severe pain events without compromising oncologic outcomes. Further studies, preferably in a randomized fashion, would be desired.

P1.09A.01 The Effectiveness of Split-course Stereotactic Body Radiation Therapy in Treating Large Thoracic Cancer

S. Tian[1], Y. Jie[2], L. Shang[1], C. Wang[1], M. E[1], A. Gu[1], [1]HarbinMedicalUniversityCancerHospital, Harbin/CN ,[2]Harbin Medical University Affiliated Fourth Hospital, Harbin/CN

Introduction: Single-course SBRT for large thoracic tumors often results in heavy injury to normal tissue. In this study, we investigated the effectiveness and safety of split-course stereotactic body radiation therapy (SBRT) in patients diagnosed with large thoracic cancer that is inoperable. The inclusion criteria were tumors larger than 5 cm, central and ultra-central large tumors, and the larger one in pulmonary oligometastases. Our aim is to achieve superior local tumor control while mitigating adverse events.

Methods: Based on tumor location, pathological and imaging evaluations, we designed personalized treatment plans, with most patients receiving doses ranging from 50 to 70 Gy in 10 fractions, split into two phases of radiotherapy with a gap of 3 weeks between them. Evaluations of local tumor control were conducted during treatment, at 4 weeks post-treatment, and then every 3 months thereafter. The Kaplan-Meier method was used to calculate local control (LC), local area control (LRC), progression-free survival (PFS), overall survival (OS), and treatment-related toxicity.

Results: From April 2023 to February 2024, 52 patients were enrolled in our study. By the end of March 2024, 44 of these patients had completed split-course SBRT. The median follow-up is 3.2 months. The proportions of complete response (CR), partial response (PR), and stable disease (SD) were 45.5%, 47.7%, and 2.3%, respectively. In terms of long-term efficacy, due to the limited follow-up time, the local control rate at 6 months was 95.8%. The 6-month recurrence-free survival rate (PFS) was 70.8%. In terms of toxicity and side effects, some patients (36.4%) only had grade 1-2 toxicity, and only 1 patient (2.3%) had grade 3 dyspnea toxicity.

Conclusions: Split-course SBRT effectively enhances local control for large thoracic cancers, with minimal toxicities. However, the integration of biomarkers is essential to evaluate tumor local-contorl in future.

P1.09A.02 Pathologic Tumor Positivity vs Only Necrosis in Clinically Suspected Recurrent Brain Metastasis Post-Radiation

R. Kotecha[1], M. McDermott[1], M. Garcia[2], D. Brachman[2], S. Patel[2], [1]Miami Cancer Institute-Baptist Health South Florida, Miami/FL/USA ,[2]GT Medical Technologies, Tempe/AZ/USA

Introduction: For recurrent brain metastasis (RBM), determining progression after previous radiation therapy (RT) by imaging alone can be challenging, and on pathology, necrosis and tumor frequently co-exist. To better understand the rate of pathologic tumor positivity (TUM+) vs necrosis without tumor (TUM-), we examined frozen section results in a cohort of patients with prior same site RT undergoing resection of presumed RBM.

Methods: We examined the rates of intraoperative pathology disclosing tumor (TUM+) or necrosis without tumor (TUM-) in patients with presumed RBM and prior same-site RT undergoing a planned resection. All cases had been prospectively enrolled on a multi-institution registry of patients undergoing resection and intraoperative placement of cesium-131 collagen tile brachytherapy (NCT04427384) (GammaTile, GT Medical Technologies, Tempe AZ, USA). Preoperative evaluation varied by center; we also examined patient demographics, primary site, lesion size, and prior therapies.

Results: From Oct2020 to Feb2024, 60 patients with 64 lesions and prior same-site RT underwent open resection and intraoperative pathology evaluation. Per patient, primary sites were lung in 53%, melanoma 15%, breast 13%, renal 7%, and other 10%. Median age was 62 (range 28-81), F:M 31:29, maximum preoperative diameter was 2.9 cm (range 1.4-5.7), and median KPS was 80 (range 50-100). Time from last RT was 15.4 months (range 1-69). On a per patient basis across all histologies, TUM+ was found in 88% (53/60) and TUM- in 12% (7/60). Per patient rates of TUM- varied by cancer primary, with lung showing the highest rate at 16%, breast 13%, and melanoma 11% (Table 1). Taken together, the TUM- rate for non-lung primary metastasis was 7% vs 16% for lung origin. All TUM- patients received RT+prior chemotherapy, immunotherapy, or both.

Conclusions: This multi-institutional sample of previously irradiated metastasis, the frozen section pathology demonstrated a 12% rate of TUM- for all cancers and 16% for lung cancer. As they necessitated surgery, the adverse event RT injury grading would be > Gr 4. These findings highlight the importance of pathologic confirmation before undertaking re-irradiation, as the optimal treatment of RT injury is not additional radiation.

P1.09A.03 Concurrent Combination of EGFR-TKIs and Thoracic Radiation Therapy for Metastatic Non Small Cell Lung Cancer Patients

M. Yoshida, T. Fujii, K. Shida, C. Osumi, T. Fujii, A. Kawata, T. Kishigami, Y. Nishimoto, M. Hasegawa, M. Kikuchi, T. Gomi, Toho University Ohashi Medical Center, Tokyo/JP

Introduction: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) has asignificant therapeutic effect in the treatment of metastatic non-small-cell lungcancer (NSCLC) patients with EGFR mutations.In addition, EGFR-TKIs exhibits a radiosensitizing effect in preclinical models.However, the tolerability and the efficacy of EGFR-TKIs plus concurrent thoracicradiation therapy has not been well investigated.

Methods: We conducted this retrospective study to review medical records and database of patients who received radiation therapy from October 2018 to December2023.We extracted the patients from the database who underwent the concurrent combination of EGFR-TKIs and thoracic radiation therapy and analyzed the treatment outcomes and toxicities.

Results: Among 157 NSCLC patients who were treated with radiation therapy fromOctober 2018 to December 2023, 3 cases underwent the concurrentcombination of EGFR-TKIs and thoracic radiation therapy. One patient who had exon 19 deletion mutation underwent radiation therapy for mediastinal lymph nodes with intake of erlotinib. Another patient who had exon 21 L861Q mutation underwent radiation therapy for lung, and later formediastinal lymph nodes with intake of osimertinib.The median follow-up period was 19.0 (range 7-33) months. ECOG performance status (PS) 0/1/2 were 1/1/1 respectively.The prescribed radiation dose was 60-66 Gy in 30-33 fractionations usingvolumetric modulated arc therapy.The median lung V5, lung V20, MLD (Mean Lung Dose), MHD (Mean HeartDose) and MED (Mean Esophagus Dose) were 51.3 (range 27.1-77.6) %, 15.4(range 6.7-34.2) %, 10.7(range 5.0-17.9) Gy, 3.3(range 1.2-15.2) Gy, and11.5(range 7.0-30.4) Gy respectively. The first patient underwent elective nodal irradiation for mediastinal lymphnodes metastases, therefore high dose was irradiated to lung, heart, andesophagus.No acute and late toxicities were observed including radiation dermatitis,esophagitis, and radiation pneumonitis.The median overall survival time was 19.0 (range 7-33) months.No local recurrence was observed in the irradiated volume.

Conclusions: This retrospective study revealed the well-tolerability and the efficacy of EGFR-TKIs plus concurrent thoracic radiation therapy in patients with metastaticNSCLC having EGFR mutations.

Keywords: Radiation therapy, EGFR-TKIs, Concurrent targeted therapy and radiation therapy

Introduction: NSCLC with EGFR mutations represents one of the malignancies benefiting the most from targeted therapies. Still hardly any patient might be cured with contemporary targeted approach. The reason for failure is resistant population that either arise or reside in the residual tumor tissue after response nadir is achieved. We suggested that surgical excision of the «persister» tissue might augment the maturation of resistant clone and postpone disease progression

Methods: Out of 230 EGFR associated NSCLC patients treated with 1st line TKI we identified 41 (17%) case who underwent surgical cytoreduction during the response to TKI before radiographic progression

Results: mPFS was significantly longer in operated patients (Group A) - 24.8 mon [18.3-31.2] than in resectable at nadir but not operated (Group B) - 14.4 mon [11.7-17.2], p = 0.035 or unresectable (Group C) - 17.6 mon [15.0-20.2], p = 0.006. mOS was also longer in Group A - 62.1 mon [45.9-78.2] versus Group B - 37.1 mon [11.8-62.4], p = 0.010 versus 44.7 mon [27.8-61.6], p = 0.041, respectively. Median time to surgery from TKI start was 7.3 mon [0.5-24.2]. Post-surgical complication rate was 36.5%. Propensity score matching analysis confirmed statistically significant advantage in OS (56.0 mon [35.5-76.5] versus 37.1 mon [11.8 - 62.5], log rank p = 0.045) and numerical in PFS (24.7 mon [21.2-28.3] and 14.4 mon [11.7-17.2] in operated group over non operated. 26 of 41 operated patients had disease progression in distant sites (21/26), regional (1/26) and both (4/26). 14/41 patients are without progression after surgery at the median follow-up of 54.1+ mon. (8.23 - 79.07).

Conclusions: Complete cytoreduction at nadir of response to 1st line TKI is feasible for pts with locally advance or metastatic NSCLC and leads to survival advantage in a proportion of patients.

P1.09B.02 Double Lung Transplantation in Patients with Metastatic Lung-limited Non-Small Cell Lung Carcinoma (NSCLC).

Y.K. Chae, T. Demir, L.I-Y. Chung, W. Woo, C. Moloney, B. Sanson, R. Dwyer, C.M. Jung, R. Tomic, A. Bharat, Feinberg School of Medicine, Northwestern University, Chicago/IL/USA

Introduction: Double lung transplantation (DLT) may offer curative treatment for metastatic lung-limited NSCLC patients without extrapulmonary disease. We present a case series of consecutive NSCLC patients who underwent DLT.

Methods: Patients treated with DLT were identified between 09/2021 and 04/2024 at Canning Thoracic Institute of Northwestern University. All patients had enrolled in the DLT registry aimed for lung-limited malignancies (DREAM) study cohort A (NCT05671887). Exclusion criteria includes presence of extrapulmonary disease.

Results: Seven patients with stage IVA NSCLC who underwent lung transplantation were included. Six (85.7%) patients underwent double lung, and one (14.3%) patient single lung transplantation. Five (71.4%) patients had invasive mucinous, and two (28.6%) had invasive non-mucinous adenocarcinoma histology. One of the two invasive non-mucinous patients had acinar, and the other had mixed lepidic, papillary, and acinar histology. Patients were aged 56-71; one (14.3%) was Asian, six (85.7%) were White, four (57.1%) were male, and three (42.9%) had a history of smoking. One (14.3%) patient had a past medical history of interstitial lung disease (ILD) and chronic obstructive pulmonary disease (COPD). The median pretransplant treatment lines were 3 (1-5). All patients had high oxygen requirements before DLT due to cancer progression. Pre-transplant endobronchial ultrasound and evaluation of bilateral pneumonectomy lungs found no lymph node involvement (pN0). One patient had an epidermal growth factor receptor (EGFR) mutated cancer but had failed relevant targeted therapy prior to transplant. All patients had disease progression on standard of care treatments with/without clinical trials. The indication for DLT was respiratory failure or refractory cancer for all patients. After DLT, one patient had a recurrence of the disease at 18 months with a 1cm solid nodule and was treated with stereotactic body radiotherapy (SBRT). Both original and recurrent tumors had invasive mucinous adenocarcinoma histology, negative PD-L1 expression, and the same JAK3 c.2174C > T, P725L mutated clone. It suggests that the recurrence likely arose from the original cancer. Transplant rejection did not occur in any of the cases. Following the transplant, there was no requirement for oxygen therapy for any patient. All patients are alive with 30, 20, 10, 10, 8, 6 and 1-month posttransplant follow-up.

Conclusions: Seven patients underwent DLT successfully without significant complications. All patients were alive and in good health. Ongoing DREAM study will continue to investigate the role of DLT in metastatic lung-limited NSCLC patients (especially in pN0).

P1.09B.03 Ex-Situ Lung Transplantation without Heparinization: A Novel Surgical Approach for Locally Advanced and Central Lung Carcinoma

H. Pan[1], S. Yang[1], C. Zheng[1], K. Shi[1], W. Han[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicin, Hangzhou/CN

Introduction: Ex-situ lung transplantation represents an unconventional surgical intervention for patients with central lung cancer invading critical helium structures and compromised lung function. Previous reports on ex-situ lung transplantation have predominantly employed heparinization. This study presents our experience with ex-situ lung transplantation in patients with central lung cancer, conducted without heparinization.

Methods: Ethical approval for all surgical procedures was obtained from the ethics committee of the First Affiliated Hospital, Zhejiang University School of Medicine. The fifth intercostal lateral thoracotomy approach was uniformly employed. Careful dissection of the pulmonary hilum was performed. Without heparinization, occlusion of the pulmonary artery and vein was achieved using a pulmonary artery clamp(Fig.1a). Subsequently, the affected lung was excised, and the lesion removed ex vivo. All patients underwent R0 resection confirmed by intraoperative cryopathology. Ex-vivo lung perfusion was conducted using Perfedex(Fig.1b). Veins and bronchus were sutured with 4-0 prolene(Fig.1c), end-to-end anastomosis, while 5-0 prolene was used for end-to-end anastomosis of the pulmonary artery(Fig.1d).

Results: Four patients who underwent ex-situ transplantation were included. The median age of the patients was 69 years. All patients were diagnosed with stage III squamous cell lung cancer following biopsy. Neoadjuvant treatment was administered to all patients. Preoperative planning, guided by CT imaging(Fig.2a,c,e,g), facilitated successful ex-situ transplantation in all cases. The median surgery duration was 337 minutes, with a median blood loss of 100 ml. Median postoperative intubation time was 1 day, and median hospital stay was 9 days. One patient experienced a non-fatal partial branch embolism of the contralateral pulmonary artery. At the 3-month postoperative follow-up, all patients were asymptomatic(Fig.2b,d,f,h).

Conclusions: Ex-situ lung transplantation emerges as a superior alternative to pneumonectomy for patients with locally advanced lung cancer. Our findings suggest that heparinization may not be necessary for this procedure.

P1.09B.04 Impact of BMI on TTFields in Patients with Mnsclc: Post-hoc Analysis from the Phase 3 LUNAR Study and Simulation Model Data

C. Rolfo[1], D.E. Gerber[2], R. Kotecha[3], J. Ward[4], W. Akerley[5], A. Naveh[6], N. Shapira[6], T. Leal[7], C. Langer[8], [1]Center for Thoracic Oncology, The Tisch Cancer Institute Icahn School of Medicine at Mount Sinai Mount Sinai Health System, New York/NY/USA ,[2]Harold C. Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas/TX/USA ,[3]Miami Cancer Institute, Baptist Health South Florida, Miami/FL/USA ,[4]Washington University School of Medicine, St. Louis/MO/USA ,[5]Huntsman Cancer Institute University of Utah, Salt Lake City/UT/USA ,[6]Novocure Ltd, Haifa/IL ,[7]Winship Cancer Institute of Emory University, Atlanta/GA/USA ,[8]Abramson Cancer Center, Perelman School of Medicine, University of Pennsylvania, Philadelphia/PA/USA

Introduction: Tumor Treating Fields (TTFields) are electric fields that disrupt processes critical to cancer cell viability and tumor progression and are delivered non-invasively to the tumor site via skin-placed arrays. Recently, the randomized, pivotal (phase 3) LUNAR study (NCT02973789) demonstrated improved overall survival (OS) for TTFields therapy (150 kHz) delivered continuously until progression or intolerable toxicity together with an immune checkpoint inhibitor (ICI) or docetaxel (DTX) vs ICI/DTX alone in patients with metastatic non-small cell lung cancer (mNSCLC) following progression on or after platinum-based therapy (HR 0.74 [95% CI, 0.56-0.98]; P=0.035). The effects of TTFields are dependent on several factors, including intensity, frequency, and distribution, all of which may be affected by tissue conductivity and array layout used. We therefore evaluated the effect of body mass index (BMI) on the delivery of TTFields to the lungs using clinical data from the LUNAR study and data from a simulation study.

Methods: We performed a post-hoc analysis of the LUNAR study to evaluate OS in patients with varying BMIs. A simulation study was also conducted to evaluate TTFields intensity and distribution using 2 array sizes (small and large) in computerized phantom models with healthy (BMI 22 kg/m2), overweight (BMI 26 kg/m2), and obese (BMI 30 kg/m2) BMIs.

Results: Of the 276 patients included in the intent-to-treat population of the LUNAR study, BMI data was available for 259 patients (94%). Mean ± standard deviation BMI was 24.7 ± 5.3 kg/m2 in the TTFields + ICI/DTX arm (n=131) and 26.0 ± 4.9 kg/m2 in the ICI/DTX arm (n=128). In the BMI <25 kg/m2 subgroup (n=140), median OS (95% CI) was 11.6 months (8.5-16.1) in the TTFields + ICI/DTX arm compared with 8.2 months (6.1-14.3) in the ICI/DTX arm (hazard ratio [HR] 0.70 [95% CI, 0.47-1.04]; P=0.08). In the BMI ≥25 kg/m2 subgroup (n=119), median OS (95% CI) was 13.9 months (9.7-23.3) in the TTFields + ICI/DTX arm compared with 10.2 months (8.9-14.7) in the ICI/DTX arm (HR 0.74 [95% CI, 0.49-1.13]; P=0.27). Therapeutic electric field intensities (amplitude in the order of >1 V/cm) were achieved in all lobes of the lung for all simulation models when using the appropriately sized arrays.

Conclusions: This post-hoc analysis of the LUNAR study did not identify a difference in OS benefit between patients with a BMI <25 kg/m2 vs BMI ≥25 kg/m2 receiving TTFields therapy. The simulation-based study demonstrated the feasibility of delivering TTFields therapy at a therapeutic intensity to the lungs of patients with varying BMIs. These data suggest TTFields are delivered adequately to the lungs of patients and provide clinical benefit across a range of BMIs.

P1.09B.05 Improved Survival of Primary Tumor Resectionfor Metastatic Non Small Cell Lung Cancer:a Propensity Score-matched Analysis

J. Wu[1,2], F. Qin[1,2], X. Qin[1,2], Y. Zheng[1,2], H. Zheng[1,2], J. Chen[1,2], Z. Liu[1,2], B. Jian[1,2], G. Wang[3], H. Liao[1,2], [1]Department of Thoracic Surgery, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou/CN ,[2]Biomedical Innovation Center, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou/CN ,[3]Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou/CN

Introduction: Lung cancer is the second most common malignancy, and about 85% of those patients are non-small cell lung cancer (NSCLC). For NSCLC patients with distant metastases such as lung or liver lesions, primary tumor resection (PTR) whether should be considered is still controversial. The study aims to assess the survival effect of PTR on NSCLC patients with synchronous lung or/and liver metastases.

Methods: NSCLC patients with synchronous lung or/and liver metastases were identified from the SEER database from 2010 to 2015. And 1:1 propensity-score matching(PSM) analysis were used to minimize heterogeneity between PTR and no-PTR groups. The cox models were used to identify predictors of overall survival (OS) and cancer-specific survival (CSS) for those metastatic NSCLC patients.

Results: Of 7660 NSCLC patients with synchronous lung or/and liver metastases, 788 were enrolled in the PSM cohort. Patients underwent PTR had a better median OS (18.0 months vs. 9.0 months, p < 0.001) and median CSS (13.0 months vs. 7.0 months, p < 0.001) than those patients did not in PSM cohort.

Additionally, multivariable cox analysis similarly demonstrated that PTR was a significantly protective factor for those metastatic NSCLC patients in OS (HR: 0.52; 95% CI, 0.44 to 0.61, P < 0.001). Also, multivariate cox analysis identified the independent risk factors for those metastatic NSCLC patients as as follows: no primary resection surgery, age >65 years, male, N1-N3, tumor size>5 cm, worse differentiation, no systemic therapy. However, metastasectomy is not a significantly protective factor.

In stratified analyses by N stage, tumor differentiation, tumor histology and systemic therapy, those patients with PTR had a better prognosis. And PTR combined with chemotherapy and NSCLC patients with only lung metastases was associated with the greatest treatment effect.

Conclusions: Primary tumor resection can improve the survival of NSCLC patients with synchronous lung or/and liver metastases.

SUNDAY, SEPTEMBER 8, 2024 - 12:00 - 14:00

P1.09C.01 A Multicenter, Randomized, Phase II Trial of EGFR TKI with Primary Tumor Resection for EGFR-Mutant Metastatic NSCLC Patients

P-H. Chen[1,2], H-H. Hsu[3], T-H. Young[1], J-S. Chen[2], [1]Institute of Biomedical Engineering, College of Medicine and College of Engineering, National Taiwan University, Taipei/TW ,[2]National Taiwan University Hospital, Taipei/TW ,[3]National Taiwan University Cancer Centor, Taipei/TW

Introduction: Several phase II trials have investigated the use of combination local consolidation therapies in EGFR-mutant advanced lung cancer to potentially improve survival. However, there has been no specific trial design for on evaluating the efficacy of primary thoracic tumor resection with EGFR TKI before disease progression.Our hypothesis posits that surgery, targeted at eradicating pre-existing resistant subclones or reducing tumor burden resulting from drug-induced resistance, could significantly improve outcomes related to non-progression intervals by reducing the chance of subsequent resistance development. This approach aims not to cure the disease but to achieve a superior control effect, exceeding the results achievable with standard EGFR TKI therapy alone.

Methods: We are conducting a two-arm, phase II clinical trial to assess the impact of primary tumor resection in patients with EGFR-mutant advanced non-small cell lung cancer (NSCLC) that is suitable for thoracic surgery, utilizing data from two major centers in Taiwan. The goal is to enroll 100 stage IV patients to evaluate their response to treatment.

Eligible patients must have an Eastern Cooperative Oncology Group (ECOG) performance status of ≤1 and be considered candidates for surgery with curative intent at at least one disease site. Additionally, patients must exhibit NSCLC with either an EGFR exon 19 deletion or an L858R mutation. Patients exhibiting progressive disease (PD) will be excluded. Following an initial 12 weeks of afatinib (40mg,day) therapy, participants will be randomized (1:1) to receive either afatinib monotherapy or primary tumor resection and/or radiation therapy targeting residual distant disease.

The primary goal of thoracic surgery is to achieve optimal locoregional disease control and potentially secure a negative resection margin. Those in the surgical arm will continue with afatinib post-surgery. The radiation therapy will be administered at the discretion of the multidisciplinary team of investigators, which is will be completed after first dose of afatinib. The primary endpoint of this trial is the two-year progression-free survival (PFS). Secondary endpoints include progression-free survival and overall survival (OS), involving a total of 100 subjects.

Results: Initial results (Fig.1) suggest that combining primary tumor resection with EGFR TKI may reduce the risk of disease progression by more than 50% compared to EGFR TKI alone.

Conclusions: This trend points towards a potential increase in benefit, which could become statistically significant with longer follow-up.

P1.09C.02 SiCARIO: A Phase I/II Study of Split Course Adaptive Radioimmunotherapy for the Treatment of Oligometastatic Non-Small Cell Lung Cancer

R. Whitaker, K. McComas, E. Osmundson, Vanderbilt University Medical Center, Nashville/TN/USA

Introduction: The current standard of care (SOC) for non-driver mutation oligometastatic NSCLC involves treatment with cytotoxic chemotherapy alone, chemotherapy combined with immune checkpoint blockade (ICB), or ICB alone based on tumor PD-L1 expression level. While improvements associated with addition of ICB have been observed in this cohort, local and/or distant failure remains a near certainty. New strategies are needed to enhance the efficacy of these agents to provide more durable responses and in select patients, potentially curative approaches. Increasing pre-clinical data supports synergy between radiotherapy (RT) and immune-based therapies; however, radiation treatment paradigms have not been updated to better harness the potential biologic interactions between RT and the immune system. This study seeks to determine if high-dose per fraction, split course, anatomically and biologically adapted RT timed concurrently with immunotherapy containing systemic regimens can improve outcomes. Emerging clinical evidence supports concurrent treatment with high-dose per fraction RT as an optimal approach to induce antitumor immunity in combination with ICB. Use of a split course approach may improve the therapeutic window of RT in this setting, and act to sequentially re-prime the immune system to the evolving antigenic signature of the tumor and micro-environment.

Methods: This is a phase I/II, single institution, open label clinical trial in patients with de novo non-driver mutation metastatic NSCLC with up to 10 sites of extracranial metastases. Patients with brain metastases which can be addressed with surgery and/or stereotactic radiosurgery are eligible. Patients receive RT to all sites of extracranial disease and thoracic primary in 8 Gy fractions every 3 weeks to a total dose of 40 Gy in 5 fractions concurrent with SOC (chemo)immunotherapy. RT plans are adapted between fractions as needed using a novel, CT-linac-based adaptive RT platform (Varian Medical Systems). Planned enrollment is 25 patients to observe an improvement in best overall response rate (ORR) to 75% compared to historical controls. The primary objectives are to assess safety, tolerability and ORR of the SiCARIO regimen combined with SOC systemic therapy. Secondary objectives include PFS, OS and new metastasis free survival. Exploratory objectives include serum biomarkers of response (ctDNA and immune profiling) and imaging biomarkers including 18F-FDG PET and 18F-FSPG PET response. This study will also serve as a practical evaluation of a CT-linac-based adaptive platform for development of efficient clinical workflows integrating both anatomic and functional imaging data to deliver complex, multi-site RT plans. Enrollment is currently ongoing with potential for future expansion pending initial outcomes.

P1.09C.03 IMMUNOResist: Defining the Immunophenotype of Immunotherapy Resistance with PD-L1 and CD8 Novel Tracer PET

F. Hegi-Johnson, T. Akhurst, T. John, A. Scott, S. Parakh, B. Blyth, S. Wong, M. MacManus, Peter MacCallum Cancer Centre, Melbourne/AU

Introduction: IMMUNOResist is a multicentre, single arm pilot study investigating the use of the ImmunePET tracers 89Zr-DFO-Sq-durvalumab (89Zr-durva) and 89Zr-89 crefmirlimab berdoxam (CD8) PET/CT to interrogate PD-L1expression and infiltration of CD8 T-cells in non-small cell lung cancer(NSCLC) patients undergoing radiotherapy after progression on immunotherapy. We have established that 89Zr-durva PET/CT can provide information about PD-L1 expression in patients who are progressing on immunotherapy and receiving radiotherapy (See Fig1)[1].

Methods: This is a prospective, observational, single arm open-label pilot study of 5 patients with NSCLC who are receiving radiotherapy to progressive disease after 1st line immunotherapy. ECOG 0-1 NSCLC patients of any PD-L1, EGFR, ALK or ROS mutation status and histology are eligible. Patients have CD8-PET/CT before and after radiotherapy, and 89Zr-durva PET/CT after radiotherapy. Patients also undergo liquid biopsy before the first day and after the completion of radiotherapy. Baseline tissue genomic analysis, analysis of blood samples with mass cytometry of PBMC, TCR characterization and cytokine profiling will be performed. Please see Figure 2 for details of study design.

Aims: To use dual 89Zr-durva and CD8 ImmunoPET imaging to investigate PD-L1 expression and activated T-cell infiltration NSCLC progressing after immunotherapy who are receiving radiotherapy to progressive disease. To interrogate the host immune response with Tissue DNA analysis, PBMC mass cytometry, TCR and cytokine profiling.

Endpoints: 1.Qualitative evaluation of 89Zr-durva and CD8 PET/CT imaging will be compared with FDG PET/CT. 2.Quantitative measures, including SUVmax, SUVmean, SUVpeak & %ID will be compared. 3.Comparison of 89Zr-durva uptake and CD8-PET/CT with PD-L1 IHC on tissue 4.PD-L1 expression and CD8 T-cell recruitment seen on PET/CT will be compared with host immunity interrogated with PBMC, TCR and cytokine analysis **Conclusions:** We have previously demonstrated the feasibility of ImmunePET imaging in a multicentre trial, and will use this pilot study to evaluate whether dual CD8 and 89Zr-Durva PET imaging may enable characterisation of the immunophenotype during radiotherapy treatment.

P1.12A.01 Real-World Outcomes and Treatment Patterns after First-Line Osimertinib in Patients with Advanced NSCLC and Uncommon EGFRm

J. Nieva[1], J. Chapaneri[2], Y.K. Lau[3], M. Cooper[4], P.S. Karia[5], [1]Medical Oncology, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles/CA/USA ,[2]Oncology Business Unit, AstraZeneca, Cambridge/GB ,[3]Center for Oncology Data Excellence, AstraZeneca, Gaithersburg/MD/USA ,[4]Oncology Biometrics, AstraZeneca, Macclesfield/GB ,[5]Oncology Outcomes Research, AstraZeneca, Gaithersburg/MD/USA

Introduction: Uncommon EGFR mutations (ucEGFRm), a highly heterogenous group of alterations within exons 18-21, represent about 10% of all EGFR mutations that are detected in patients with advanced NSCLC. Multiple clinical practice guidelines recommend osimertinib as a treatment option for patients with advanced NSCLC and ucEGFRm; however, data on the real-world effectiveness of first-line osimertinib in this setting are lacking. We characterized outcomes and subsequent treatment patterns after first-line osimertinib in a U.S. cohort of patients with advanced NSCLC and ucEGFRm.

Methods: Patients with advanced NSCLC and ucEGFRm who were treated with first-line osimertinib between April 01, 2018 and March 31, 2020 were identified from the Flatiron Health Spotlight Database. Patients were divided into two subgroups: those with multiple mutations comprising a combination of common mutations and ucEGFRm (Group A) and those with ucEGFRm only (Group B). Time-to-next treatment or death (TTNTD), time-to-treatment discontinuation (TTD), real-world progression-free survival (rwPFS), real-world overall survival (rwOS), and second-line treatment patterns were described for the overall cohort and in the ucEGFRm subgroups (Groups A and B).

Results: Among 61 patients in the overall cohort, median age was 71 years (interquartile range [IQR]: 63-77), 77% were female, 67% were White, 52% had a history of smoking, 57% had an ECOG score of 0-1, 31% had brain metastasis, and median follow-up after first-line treatment was 10 months (IQR: 3-29). Group A represented 31% of patients (n=19) and Group B 69% (n=42). The table shows median TTNTD, TTD, rwPFS, and rwOS for the overall cohort and the ucEGFRm subgroups. At the end of study follow-up, 13% (n=8) of patients remained on osimertinib (Group A: 26%, Group B: 7%), 54% (n=33) discontinued osimertinib because they had died (Group A: 37%, Group B: 62%), and 33% (n=20) received subsequent treatment (Group A: 37%, Group B: 31%). Of the 20 patients who received second-line treatment, 35% received chemotherapy, 25% received osimertinib combination therapy, 15% received immunotherapy alone, 15% received EGFR-TKIs (including osimertinib), 5% received immunotherapy with chemotherapy, and 5% received clinical study drug.

Conclusions: Our study represents the largest set of patients with advanced NSCLC and ucEGFRm treated with first-line osimertinib. Our results support current clinical guidelines that recommend first-line osimertinib as a treatment option for patients with advanced NSCLC and ucEGFRm.

P1.12A.02 Efficacy of EGFR-Tyrosine Kinase Inhibitors in Patients with NSCLC Harboring EGFR Exon 19 Insertions: A Report from the LC-SCRUM-Asia

Y. Uehara[1,2], H. Izumi[1], I.S. Kobayashi[3], S. Matsumoto[1], Y. Hosomi[2], T. Okuno[4], J. Sugisaka[5], N. Takase[6], K. Taima[7], S. Sasaki[8], S. Teranishi[9], S. Miyamoto[10], M. Mori[11], C. Nakashima[12], S. Asano[13], Y. Zenke[1], K. Yoh[1], D.B. Costa[3], S.S. Kobayashi[3,14], K. Goto[1], [1]National Cancer Center Hospital East, Kashiwa/JP ,[2]Tokyo Metropolitan Cancer and Infectious Diseases Center, Komagome Hospital, Tokyo/JP ,[3]Beth Israel Deaconess Medical Center, Boston/MA/USA ,[4]Shimane University Faculty of Medicine, Izumo/JP ,[5]Sendai Kousei Hospital, Sendai/JP ,[6]Takarazuka City Hospital, Takarazuka/JP ,[7]Hirosaki University Graduate School of Medicine, Hirosaki/JP ,[8]Juntendo University Urayasu Hospital, Urayasu/JP ,[9]Yokohama City University Medical Center, Yokohama/JP ,[10]Japanese Red Cross Medical Center, Tokyo/JP ,[11]NHO Osaka Toneyama Medical Center, Toyonaka/JP ,[12]Saga University, Saga/JP ,[13]Japan Community Health Care Organization Chukyo Hospital, Nagoya/JP ,[14]National Cancer Center, Kashiwa/JP

Introduction: EGFR exon 19 insertions occur in 0.1-0.4% of NSCLC and the most common variant is K745_E746insIPVAIK. Due to their rarity, the clinical-genomic characteristics and outcomes with EGFR-tyrosine kinase inhibitors (TKIs) remain uncertain.

Methods: We evaluated the clinical-genomic characteristics and outcomes of EGFR-TKI therapies for NSCLC with EGFR exon 19 insertions in this multi-institutional prospective lung cancer genomic screening project (LC-SCRUM-Asia), using targeted next-generation sequencing (Oncomine Comprehensive Assay or Oncomine Precision Assay). We also studied preclinical Ba/F3 models expressing EGFR-K745_E746insIPVAIK (Ba/F3-IPVAIK) and EGFR-delE746_A750 (Ba/F3-Del19) to investigate the sensitivity to 1st-generation (gen) (gefitinib and erlotinib), 2nd-gen (afatinib, dacomitinib, and poziotinib), 3rd-gen (osimertinib), and EGFR exon 20 insertion active TKIs (mobocertinib, sunvozertinib, and zipalertinib).

Results: In LC-SCRUM-Asia, 16,204 NSCLC patients were enrolled from March 2015 to December 2023. EGFR exon 19 insertions were detected in 13 samples (0.1% of NSCLC and 0.4% of EGFR-mutated NSCLC). The median age was 72 years (range, 38 to 80), patients were predominantly female (77%) and never-smokers (62%). Twelve patients (93%) had adenocarcinoma histology and one had adenosquamous carcinoma. Three patients (23%) had brain metastasis at diagnosis. When compared to patients with major EGFR mutations (1,359 patients) from LC-SCRUM-Asia, no distinct differences in clinical characteristics were observed. Twelve patients (93%) had EGFR-K745_E746insIPVAIK, and one (7%) had EGFR-K745_E746insVPVAIK. The most frequent concomitant mutation was TP53 (62%), followed by EGFR amplification (15%), CDKN2B amplification (15%), PIK3CA mutation (8%), and FGFR mutation (8%). No patients had any other driver alterations. Eleven patients received EGFR-TKIs; four (36%) experienced a partial response. The median progression-free survival (PFS) of EGFR-TKIs and overall survival (OS) were 7.4 months (95% confidence interval [CI], 6.0-not reached [NR]) and 29.6 months (95%CI, 21.4-NR), respectively. When broken down by EGFR-TKI generation, response rates for 1st, 2nd, and 3rd-gen TKIs were 50% (1/2), 60% (3/5), and 0% (0/4), respectively. The median PFS for 1st, 2nd, and 3rd-gen TKIs was 8.7 months (95% CI, 7.4-NR), 13.8 months (95% CI, 7.2-NR), and 3.9 months (95% CI, 1.0-NR), respectively. The median OS for 1st, 2nd, and 3rd-gen TKIs was 25.5 months (95% CI, 21.4-NR), NR, and NR, respectively. In the preclinical study, Ba/F3-IPVAIK showed the highest sensitivity to 2nd-gen EGFR-TKIs (IC50 range: 0.57-0.95 pM) compared to other EGFR-TKIs (IC50 range: 1st-gen, 61-158 nM; 3rd-gen, 13.8 nM; exon 20 insertion active, 1.78-21.3 nM). The preclinical therapeutic window of Ba/F3-IPVAIK and Ba/F3-Del19 for all the 2nd generation TKIs were similarly favorable, whereas Ba/F3-IPVAIK had much unfavorable therapeutic windows to other EGFR-TKIs compared to Ba/F3-Del19.

Conclusions: Our clinical and preclinical findings indicate 2nd-gen EGFR-TKIs are more effective than 1st and 3rd-gen EGFR-TKIs in patients with EGFR exon 19 insertions.

P1.12A.03 Outcome and Transcriptomic Features of Dual EGFR and MET Blockade in NSCLC

D.D-W. Lee[1,2], W.P. Ng[2,3], S.F. Ang[2], D.P. Lau[2], L.Y. Wang[2], G.G.Y. Lai[2,4], M.Y.W. Boey[2], T.K.H. Lim[2], D.S.W. Tan[2,4], [1]University of Malaya, Kuala Lumpur/MY ,[2]National Cancer Center Singapore, Singapore/SG ,[3]Genome Institute of Singapore, Singapore/SG ,[4]Duke-NUS Medical School, Singapore/SG

Introduction: MET alterations are known resistance mechanisms to EGFR tyrosine kinase inhibitors (TKI). Dual EGFR and MET inhibition have shown promise in overcoming EGFR resistance post EGFR TKI. We present the outcome of patients treated with MET inhibitors with or without EGFR TKI after EGFR TKI failure.

Methods: NSCLC patients with both MET alterations (amplification, polysomy, and mutation) and EGFR mutation who received crizotinib, capmatinib, or tepotinib with or without an EGFR TKI after progression on EGFR TKI in our database were included in this study. MET alterations were detected by FISH or next-generation sequencing. We performed whole exome sequencing (WES) and RNA-seq for 6 tissue samples available.

Results: From 2012 to 2020, 46 patients who fulfilled our search criteria were identified. The median age of diagnosis was 60 years old (31 - 80), 58.7% were male and 76% were never smokers. The MET alterations detected were MET amplification (50%, 23/46), MET polysomy (47.8%, 22/46), and MET mutation (2.2%, 1/46). Notably, 17 patients fulfilled the criteria of primary EGFR resistance (Progression-free survival of less than 6 months on EGFR TKI). Thirteen patients received single-agent MET inhibitors and 33 patients received dual EGFR/MET inhibitors. The overall median duration of response (DOR) was 2.8 months (2.0 months for MET blockade and 4.2 months for dual MET and EGFR blockade). Among patients with MET polysomy, the median DOR was 5.8 months versus 1.9 months in those with MET amplifications. In evaluable patients, 54% (20/37) had disease progression, 27% (10/37) had a partial response and 19% (7/37) had stable disease. All patients who had partial response received dual EGFR/MET inhibitors. Six tissue samples among patients that received both EGFR and MET inhibitors - 3 from responders (DOR > 2 months) and 3 from non-responders (DOR < 2 months) were evaluated with WES and RNA-seq. All responders were female and all non-responders were male. Responders showed higher tumor content (purity estimate by PUREE). All responders show TRU (terminal respiratory unit) subtype, whereas non-responders show either PI (proximal-inflammatory) or PP (proximal proliferative) subtypes. There were no remarkable differences in mutational signatures, CIBERSORT, and GEP scores.

Conclusions: Our data suggest the possible benefit of adding MET inhibitor while continuing EGFR TKI for patients harboring both EGFR and MET alterations. Other possible predictive factors are MET polysomy, high tumor content, and TRU subtype. We suggest further investigation to define MET amplification cut-off and patient selection based on responsiveness to EGFR TKI.

P1.12A.04 Socioeconomic Disparities and Overall Survival Differences Among Ethnic-Minority Patients with EGFR-Mutated NSCLC Treated with Osimertinib

M. Lee[1], E. Miao[2], C. Zhang[2], X. Xue[2], S. Tuckman[3], N. Ohri[1], B. Halmos[1], H. Cheng[1], [1]Montefiore Einstein Comprehensive Cancer Center (MECCC), The Bronx/NY/USA ,[2]Albert Einstein College of Medicine, The Bronx/NY/USA ,[3]Montefiore Medical Center, Bronx/NY/USA

Introduction: Osimertinib (Osi) is a key treatment for EGFR-mutated NSCLC, yet knowledge gaps persist regarding treatment adherence and clinical outcomes in ethnic minorities. Building upon previous research at our institution demonstrating inferior survival among black patients before the wide use of Osi, this study aims to provide updated insights into the impact of race/ethnicity, adherence and other demographic, socioeconomic and clinical factors on outcomes for NSCLC patients treated with Osi.

Methods: We conducted a retrospective cohort study involving 168 patients (pts) with EGFR mutated NSCLC who were prescribed Osi from 1/1/16-3/31/24, including 60 pts within Montefiore's specialty pharmacy with comprehensive claims data. Adherence was measured using proportion of days covered (PDC). Primary endpoint was overall survival (OS) along with secondary endpoints of progression-free survival (PFS) and treatment duration from the start of Osi, compared minority vs non-minority using log-rank testing and survival analysis with cox proportional models.

Results: This cohort constituted of 26.2% of Non-Hispanic Black (NHB), 32.7% Hispanics, 28.6% non-Hispanic Whites (NHW) 28.6%, and 12.5% non-Hispanic Asians with a median age of 70 years. Treatment adherence based on PDC did not differ between Blacks (76%) vs non-Blacks (84%) or Hispanics (86%) vs non-Hispanics (78%). The average out of pocket cost for our pts was $78 (USD) per month, significantly lower for minority patients with lower median household incomes. With a median follow-up time was 16.3 months (mons), in a univariate analysis, significantly higher OS is associated with an income of >50,000 (USD) compared to <50,000 (USD), and Medicare insurance compared to Commercial insurance. NHB showed Inferior OS compared to NHW (12.1 mons vs 22.6 mons, p=0.035), also with a trend towards lower OS in Hispanics (22.6 mons vs 16.6 mons, p=0.054) despite no differences in duration and adherence of Osi. PFS was longer in Medicare patients compared to commercial insurance (p=0.010), and worse in Uncommon non-sensitizing EGFR alterations (p=0.045), although no OS differences. Multivariate results confirmed higher mortality and progression risk in NHB compared to NHW (p<0.05). Further results are summarized in Table 1.

Conclusions: Our study demonstrates that although Osi adherence and treatment duration were similar across racial/ethnic groups, a persistent inferior OS was observed in NHB, and Hispanics compared to NHW. This underscores the need for further investigation into underlying mechanisms impacting outcomes of EGFR-mut NSCLC, particularly in NHB pts, and exploration of how income and insurance disparities may contribute to these disparities in clinical outcomes.

P1.12A.05 Aumolertinib in Treatment-Naïve EGFR-Mutant NSCLC Patients with Brain Metastases:Efficacy and Safety Data from the ARTISTRY

X. Zhang, M. Zhang, C. Wei, X. Du, G. Zhang, Y. Niu, X. Yan, J. Yang, H. Wang, The affiliated hospital of Zhengzhou university, Henan Cancer Hospital, Zhengzhou/CN

Introduction: Brain metastases (BMs) are the most common site of distant metastasis in non-small cell lung cancer (NSCLC), and the patients have a poor prognosis. Epidermal growth factor receptor (EGFR) gene are one of the main driver genes in NSCLC, and the incidence of brain metastases is higher in EGFR mutation-positive patients (44%-63%). Therefore, it is of great clinical significance to investigate the optimal treatment of BMs in patients with EGFR-mutated NSCLC. The third-generation EGFR-TKI is the optimization regimens of EGFR-mutated patients with BMs. The third-generation EGFR-TKIs showed significant efficacy and safety in patients with BMs harboring EGFR-sensitive mutations compared with first-generation EGFR-TKIs in FLAURA and AENEAS trial. The Bloom study proved it high dose of EGFR-TKIs have superior efficacy of EGFR-mutant NSCLC patients with leptomeningeal metastases. ARTISTRY (NCT04778800) is an ongoing dose-escalation study evaluating third-generation EGFR-TKI aumolertinib in three cohorts of EGFR-mutant NSCLC patients with brain/leptomeningeal metastases. The primary efficacy and safety data was previously presented at WCLC 2022. Here, we report update efficacy and safety data of the brain parenchyma metastases cohort 1 from the ARTISTRY.

Methods: Treatment-naïve EGFR-mutant NSCLC patients with brain parenchyma metastases received aumolertinib 110mg orally once daily. The dose was then escalated to 165mg in case of only intracranial progression. Assessments were performed every 4 weeks and then every 8 weeks after 2 consecutive disease control until extracranial progression as per RECIST v1.1. Endpoints included intracranial objective response rate (iORR), intracranial disease control rate (iDCR), ORR, DCR, progression free survival (PFS) and safety.

Results: At data cut-off (March 15, 2024), a total of 26 patients were enrolled and the median follow-up time was 23.4 months (range, 1.3-39.7). In the 110 mg group, the iORR was 88.5% (23/26; 95% CI: 76.2-100), the iDCR was 96.2% (25/26; 95% CI: 88.8-100), the ORR was 88.5% (23/26; 95% CI: 76.2-100), the DCR was 96.2% (25/26; 95% CI: 88.8-100), and the median PFS was 18.5 months (95% CI: 15.0-30.9). Total 5 patients dropped out due to lung lesions progression, but the brain lesions remained partial response (PR); 2 patients dropped out because of lung and brain lesions progression. In the 165mg group, the iORR and iDCR were 20% (1/5) and 80% (4/5), respectively, and the mPFS was 7.4 months (95% CI:2.0-15.2). The most common grade 1-2 adverse events (AEs) in all patients were elevated creatine kinase, alanine aminotransferase increased, glutamic aminotransferase increased.

Conclusions: Aumolertinib showed superior antitumor activity with a manageable safety profile as first-line therapy in EGFR-mutant NSCLC patients with brain metastases, and patients with brain metastases progression still benefit from high dose Aumolertinib. Enrollment for this trial will continue, and further analyses are warranted to determine longer-term outcomes.

P1.12A.06 A Phase II 80 Mg Osimertinib in Patients with Leptomeningeal Metastases Associated with EGFR Mutation-Positive NSCLC (BLOSSOM)

S. Park[1], R. Baldry[2], H.A. Jung[1], J-M. Sun[1], S-H. Lee[1], J.S. Ahn[1], Y.J. Kim[3], Y. Lee[4], D-W. Kim[5], S-W. Kim[6], K.H. Lee[7], W.J. Lee[1], J.W. Choi[1], K. Chong[1], J-I. Lee[1], S-H. Gwon[8], N-H. Son[8], M-J. Ahn[1], J. Kim[1], [1]Samsung Medical Center, Seoul/KR ,[2]AstraZeneca, Cambridge/GB ,[3]Seoul National University Bundang Hospital, Seongnam/KR ,[4]National Cancer Center, Goyang-si/KR ,[5]Seoul National University Hospital, Seoul/KR ,[6]Asan Medical Center, Seoul/KR ,[7]Chungbuk National University College of Medicine, Cheongju/KR ,[8]Keimyung University, Daegu/KR

Introduction: Leptomeningeal metastases (LM) exhibit a high incidence in patients with EGFR-mutated non-small cell lung cancer (NSCLC) post-treatment with first- or second-generation EGFR tyrosine kinase inhibitors (TKIs). This investigation evaluates the efficacy, safety, and pharmacokinetics of 80 mg osimertinib in LM patients resistant to prior first- or second-generation EGFR TKIs.

Methods:

In this Phase II multicenter, open-label, single-arm study, 80 mg osimertinib was administered to patients with EGFR-mutated NSCLC who had developed LM subsequent to treatment with prior EGFR TKIs. The primary endpoint was overall survival (OS), assessed alongside objective response rate by the blinded independent central review (BICR) and a pharmacokinetic analysis of plasma and cerebrospinal fluid (CSF) on the first day of cycles 3 and 6.

Results: A total of 73 patients diagnosed with LM were treated with osimertinib, including 64 patients evaluable for the LM efficacy set—T790M negative (n=62) and T790M positive (n=2). The median OS in the full-analysis set was 15.6 months (95% CI: 11.5-20.2). The objective response rate for LM was 51.6%, including a 15.6% complete response rate, and the disease control rate was 81.3% by BICR in the LM efficacy evaluable set. The median LM progression-free survival was 11.2 months (7.7-15.3), the duration of response was 12.6 months (7.6-17.7), and OS was 15.0 months (11.3-18.7). Pharmacokinetic analysis showed that the CSF to free plasma osimertinib ratio was 22%. Most safety profiles were grade 1 and 2.

Conclusions: The study demonstrates significant intracranial efficacy and survival benefits of 80 mg osimertinib in NSCLC patients with LM. The data support considering 80 mg of osimertinib as a treatment option for EGFR-mutated NSCLC patients with LM, irrespective of T790M mutation status.

P1.12A.07 A Phase 1 Study of TY-9591 in Advanced Non-Small Cell Lung Cancer (NSCLC) Patients with EGFR Positive Mutation.

B. Han[1], W. Zhang[1], L. Wu[2], B. Chen[2], Y. Zhao[3], J. Liu[3], J. He[4], Y. Liu[5], Z. Zhang[5], H. Chen[5], X. Chen[5], Y. Wu[5], [1]Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/CN ,[2]Hunan Cancer Hospital, the Affiliated Cancer Hospital of Xiangya School of Medicine, Changsha/CN ,[3]Henan Cancer Hospital,The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/CN ,[4]Cancer Institute of Guangxi,Guangxi Medical University Cancer Hospital, Nanning/CN ,[5]TYK medicines, Shanghai/CN

Introduction: TY-9591 is an efficient, ATP competitive, irreversible, oral third-generation EGFR-TKI with antitumor effects on both EGFR-sensitizing mutations and EGFR T790M resistance mutations. This study aimed to evaluate the safety and efficacy of TY-9591 in patients with locally advanced or metastatic EGFRm+ NSCLC.

Methods: In this study, 105 patients with EGFRm+ advanced NSCLC were assigned to receive TY-9591 (19 patients in the "3+3" dose-escalation phase, at a dose of 20-200 mg once daily, and 86 patients in the dose-expansion phase, at a dose of 80, 120, 160 mg once daily) (NCT04204473). 79 of 86 patients in the dose-expansion phase were EGFR-TKIs treatment naïve and EGFR sensitizing mutated (exon 19 deletion or exon 21 L858R substitution). The primary efficacy end point was objective response rate (ORR) assessed every 6 weeks by investigator based on RECIST v1.1.

Results: As off May 18, 2023, median follow-up time during the dose-escalation phase and expansion phase was 29.1 and 23.7 months respectively. No DLT was observed and MTD was not reached. For the intention-to-treat population (n=105), most common treatment-related adverse events (TRAEs) (≥10%) were hematologic toxicity, such as white blood cell count decreased (54.3%) , anaemia (39.0%), platelet count decreased (37.1%), lymphocyte count decreased(19.0%), diarrhea (30.5%), rash (17.1%) , etc, and most of them were Grade 1 or 2. Grade 3-4 TEAEs were occurred in 43.8% patients. Treatment-related SAEs were reported in 7.6% of patients. No interstitial lung disease (ILD), cardiomyopathy and keratitis was reported. The exposure level of metabolite (TY-9591-D1) was approximately 4.76% to 6.36% of that of the original drug. For the efficacy-evaluable treatment naive population with EGFR sensitizing mutation (n=78), the overall confirmed ORR of all doses (80/120/160mg) was 85.9% (95% confidence interval [CI]: 76.2-92.7). The median duration of response (DOR) was 20.2 months (95% CI: 15.9, -). The disease control rate (DCR) was 94.9% (95% CI:87.4-98.6). The median depth of response (DepOR) was 50.46% (95% CI: 9.8-84.3), which was above 30% in 72 patients. In the 160 mg dose group (n=12), the confirmed ORR was 91.7% (95% CI: 61.5-99.8), the median DOR was not reached, the median DCR was 100.0% (95% CI: -, -). The median progression-free survival (PFS) was 21.5 months (95% CI: 17.3-27.3) , which of exon 19 deletion and exon21 L858R subgroups was 25.7 months (95%CI:17.5-) and 19.3 months (95%CI:13.1-23.5) , respectively. The median OS has not been reached. Among patients diagnosed with disease progression through radiology, 7 patients (8.9%) experienced progression due to brain metastases, most of them (6/7 patients) have baseline brain metastases. Among 11 patients with measurable intracranial lesions, the intracranial ORR (iORR) based on RECIST v1.1 was 90.9% (4 patients achieved CR, 6 patients achieved PR and 1 patient remained SD), most response occurred in the 160mg dose group (iORR was 100.0%, n=8).

Conclusions: TY-9591 is a highly effective and well-tolerated third-generation EGFR TKI for patients with EGFR sensitizing mutation advanced NSCLC, especially for patients with L858R mutations or with brain metastases. Pivotal phase 2 (NCT05948813) and phase 3 trials (NCT05382728) are onging.

P1.12A.08 The Mechanism Study on a Novel CD3-EGFR Bispecific Antibody Combo Improves Osimertinib-Resistant NSCLC Tumor Environment

H. Guo[1], F. Zhou[2], C. Zhou[2], [1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]Shanghai East Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Mechanisms of Osimertinib resistance are unclear in 50% of cases, highlighting the urgent need for novel therapeutic strategies. We reported the antitumor effect of BC3448 (CD3×EGFR) in Osimertinib-resistant NSCLC cell lines and xenograft tumors (WCLC 2024, MA04.04). Here, we propose a combinational therapy with Tucidinostat (HDAC inhibitor) and WBP3425 (4-1BB Agonist) to target resistant tumors and remodel the tumor microenvironment.

Methods: Osimertinib-resistant cell lines (H1975-OR and HCC827-OR) were established via stepwise escalating exposure and maintaining in 1M Osimertinib. HuHSC-NOG-EXL mice were purchased from Charles River Laboratories. Experimental mice were divided into seven groups, with the exposure of following drugs including Osimertinib (5 mg/kg, i.g., qd), BC3448 (0.3 mg/kg, i.p., biw), Tucidinostat (12.5 mg/kg, i.g., qd), and WBP3425 (10 mg/kg, i.p., biw). At the endpoint, we performed scRNA-seq for humanized mouse tumors with BD Rhapsody Single-Cell Analysis System.

Results: In vivo, BC3448 effectively suppressed the growth of these tumors, with added WBP3425 and Tucidinostat boosting efficacy (Fig. 1A and 1B). However, combining BC3448 with Osimertinib did not overcome resistance. Flow cytometry analysis revealed that the triple drug therapy involving BC3448, WBP3425, and Tucidinostat activated more CD8+ T cells, facilitated the differentiation of stem memory T cells, and reduced the infiltration of Treg, M2, and PNM-MDSC populations (Fig. 1C). scRNA-seq) demonstrated that compared to BC3448 mono-therapy (Mono), the triple therapy (Tri) recruited more mast cells, monocytes, monocyte-derived macrophages (mono.mac), NK T cells, cycling NK, with reduced fibroblast and tissue-resident macrophage (TRM) infiltration (Fig. 1D). Regarding T cell subtypes, the Tri group showed a dominance of interferon-stimulated gene (ISG)-CD4 T, CD4 central memory T (Tcm), CD4 naïve T (Tn), FCER1G-CD4 effector T (Teff), and CD8 Teff cells, while CD4 exhausted T (Tex) and Treg cells were more prevalent in the Mono group (Fig. 1E). In terms of cycling T cell subtypes, cycling CD4 Tcm, cycling CD4 Teff, and cycling CD4 Tn significantly increased in the Tri group, while cycling Treg and cycling CD8 Tex did not show notable changes (Fig 1E). Comparatively, Mono.mac in the Tri group upregulated pathways related to antigen processing and presentation, antitumor (AT) responses, and macrophage recruitment to the tumor, while downregulating angiogenesis pathways (Ang) as demonstrated in Figure 1G.

Conclusions: The additional combination of WBP3425 and Tucidnostat with BC3448 demonstrated a synergistic efficacy to Osimertinib-resistant tumors via a multidimensional reshaping of the microenvironment, potentially offering a comprehensive approach to combat NSCLC resistance.

P1.12A.09 A Phase 1b Study of the MER Tyrosine Kinase Inhibitor, MRX-2843, in Combination with Osimertinib in Advanced EGFR Mutant Non-Small Cell Lung Cancer

C. Steuer[1], J. Carlisle[1], T. Leal[1], F. Ardeshir[1], M. Holmes[1], F. Schneider[1], Z. Chen[2], J. Switchenko[1], J. Ross[3], G. Selvagi[3], T. Owonikoko[4], S. Ramalingam[1], [1]Winship Cancer institute of Emory University, atlanta/GA/USA ,[2]Division of Epidemiology and Biostatistics, School of Public Health,, Chicago/IL/USA ,[3]Xcovery, Miami/FL/USA ,[4]University of Maryland, maryland/MD/USA

Introduction: The 3rd generation EGFR TKI, osimertinib, is an effective treatment of EGFRm NSCLC, but resistance eventually develops. MER tyrosine kinase (MERTK), a member of the TAM (TYRO3, AXL, MERTK) family of receptor tyrosine kinases mediates resistance to osimertinib. MRX-2843 is a novel small molecule MERTK TKI; we conducted a phase Ib study to evaluate the safety and efficacy of MRX-2843 in combination with osimertinib in participants (pts) with EGFRm NSCLC.

Methods: Pts were enrolled in cohorts of 3 during the dose escalation phase to test the combination of osimertinib (80mg orally once daily) along with increasing doses of MRX-2843 (orally once daily) using an escalation with overdose control (EWOC) design with a target toxicity level of 0.33. The activity of this combination is being investigated in the dose expansion cohorts of 20 pts with EGFRm NSCLC who are osimertinib naive and another with osimertinib resistance.

Results: The first pt enrolled in February 2021. Dose escalation cohorts of MRX-2843 at 60, 80, 100 and 120 and 160mg (dose levels 1-5, respectively) with osimertinib 80mg have completed enrollment. Overall, 20 pts have enrolled in the dose escalation phase. Baseline characteristics include: median age 70 years (range 51-80), 17 were female and 12 White/5 Black/3 Asian participants.There were no DLTs in dose levels 1-4. A total of 9 patients were enrolled in dose level 5, MRX-2843 160 mg. Three patients experienced DLTs at dose level 5; therefore, this was determined to be the MTD of the combination, according to the EWOC design. These DLT included G2 nausea/vomiting causing patient to receive <75% MRX-2843; G4 hyponatremia and G3 pneumonitis. Table 1 demonstrates the adverse events. In the dose escalation phase, though there was no CR/PR; 60% had disease stabilization by RECIST 1.1 and 25% were free from progression at 6 months.

Conclusions: The combination of MRX-2843 and osimertinib is safe at doses up to 160 mg/d and 80 mg/d respectively. Based on suggestion of preliminary evidence of efficacy, expansion cohorts to include both treatment-naïve and osimertinib-resistant patients is currently underway. (NCT # 04762199)

P1.12A.10 Effect of De Novo Co-Mutations on Clinical Outcomes in Patients Receiving First-Line Osimertinib for EGFR-Mutated NSCLC

F. Sun[1], M.K. Banwait[2], A. Herrmann[3], Z. Piotrowska[2], K. Yun[3], L.A. Bazhenova[3], H.A. Wakelee[1], J.W. Neal[1], M.S. Das[4], K.J. Ramchandran[1], M. Roy[1], M. Diehn[1], N.J. Myall[1], [1]Stanford University, Stanford/CA/USA ,[2]Massachusetts General Hospital Cancer Center, Boston/MA/USA ,[3]University of California San Diego Moores Cancer Center, San Diego/CA/USA ,[4]VA Palo Alto Health Care System, Palo Alto/CA/USA

Introduction: Osimertinib remains the standard-of-care first-line therapy for most patients with EGFR-mutated advanced non-small cell lung cancer (NSCLC). Since FLAURA2, and with other novel therapeutic combinations on the horizon, identifying patients at higher risk for inferior outcomes to first-line osimertinib may enable more appropriate selection for treatment intensification and improve prognostic assessment. While the negative prognostic impact of TP53 co-mutations has been previously characterized in general and in the setting of earlier EGFR-targeted therapies, here we seek to expand on the impact of de novo co-mutations among patients receiving first-line osimertinib for metastatic NSCLC.

Methods: This multicenter retrospective study across 3 U.S. sites included adult patients with metastatic NSCLC and classic sensitizing EGFR mutations (exon 19 deletion, exon 21 L858R) receiving first-line osimertinib monotherapy and with tissue-based next-generation sequencing at diagnosis. Clinicopathologic characteristics, including frequency of co-occurring pathogenic or likely pathogenic genetic alterations, were collected. Kaplan-Meier survival analyses and Cox regression were used to estimate time-to-treatment failure (TTF) and overall survival (OS) by number of co-mutations, individual mutations, and molecular pathways of interest (P53, cell cycle, AKT/PI3K, WNT/beta-catenin, epigenetic modification, and EGFR amplification).

Results: 180 eligible patients were included (median age 68, 62% female, 72% never smokers, 98% adenocarcinoma histology, 51% CNS metastases at diagnosis). Patients with 2 or more co-occurring genetic alterations had increased risk of death (HR 1.9, p=0.023), shorter median OS (25.7 vs 48.6 months), and numerically inferior median TTF (15.9 vs 20.9 months, p=0.25) compared to those without co-mutations. The OS difference remained significant on multivariate analysis accounting for primary EGFR mutation. There were no significant OS or TTF differences for those with only 1 co-mutation, compared to no co-mutations. TP53 was most frequently co-mutated (59%), followed by EGFR amplification (11%), RB1 (8%), PIK3CA (7%), CTNNB1 (7%), and CDKN2A (6%). Conversely, KEAP1 (0%) and STK11 (1%) mutations were infrequent in this cohort. Co-mutation of both TP53 and PIK3CA (TP53mut/PIK3CAmut) demonstrated inferior OS compared to TP53 mutation alone (TP53mut/PIK3CAwt) or TP53 and PIK3CA wild-type (TP53wt/PIK3CAwt) (21.9 vs 40.4 and 41.8 months, p=0.04), with similar numerical trend for median TTF (14.1 vs 20.9 and 24.5 months, p=0.17). No such differences were identified for other TP53 co-mutation pairs. Among molecular pathways, the presence of co-mutations in genes involved in epigenetic modification (ARID1A, IDH1/2, MYC) was associated with shorter median OS (19.9 vs 39.8 months, p=0.03) and numerically shorter median TTF (11.6 vs 20.9 months, p=0.24) compared to those without these alterations.

Conclusions: The presence of 2 or more de novo co-mutations, particularly co-mutation of TP53 and PIK3CA, as well as alterations in epigenetic pathway genes, was associated with inferior OS in EGFR-mutated NSCLC patients receiving first-line osimertinib. While TTF on osimertinib trended similarly, we hypothesize that tumors with these findings at baseline have increased propensity for mutagenesis and therapeutic resistance to both first-line osimertinib and subsequent therapies. Given the evolving landscape of EGFR-mutated NSCLC, these high-risk subgroups may reap particular benefit from combination treatment strategies such as the addition of chemotherapy or amivantamab to first-line tyrosine kinase inhibitors.

P1.12A.11 Analysis of Uncommon EGFR Exon 19 Alterations Identified by Liquid Biopsy in Advanced Non-Small Cell Lung Cancer (NSCLC)

J. Porter[1], L. Bucheit[2], J. Patterson[2], A. Bubie[2], L. Welch[2], [1]West Cancer Center and Research Institute, Germantown/TN/USA ,[2]Guardant Health, Redwood City/CA/USA

Introduction: EGFR exon 19 deletions (ex19del) are heterogeneous and comprised of >40 distinct insertion/deletions (indels). Uncommon ex19dels studied pre-clinically show mixed response to EGFR tyrosine kinase inhibitors (TKI), with limited literature on co-alterations and resistance mechanisms. Following observation of two uncommon EGFR ex19del cases (L747_P753delinsS and L747_A750delinsP) at the West Cancer Center/Guardant Health molecular tumor board, discussion proved optimal selection of EGFR TKI in this scenario is challenging. As such, we assessed uncommon EGFR ex19del alterations identified by liquid biopsy and herein report a large dataset describing prevalence and co-alterations to inform clinical decision-making.

Methods: Patients with NSCLC and >1 EGFR ex19del identified as part of clinical Guardant360 testing from 02/2015-09/2023 were queried to assess prevalence of uncommon ex19del and co-alterations. Mutations were profiled as “common” or “uncommon” based on public sources in cBioPortal, including TCGA and MSK datasets. Co-alterations were analyzed in cohorts of common EGFR L746_A750del (n=4540), uncommon EGFR ex19del (n=2733), treatment naive timepoint (T0, n=1816), and other time points (Tother, n=3088); groups were compared using Fisher’s Exact Test (significance defined as p<0.05).

Results: EGFR ex19del were identified in 8% of patients with cfDNA alterations detected similar to published rates (9.1%, AACR GENIE). EGFR ex19indels were identified in 7273 unique patients, with common EGFR L746_A750del observed in (62%) and uncommon ex19del variants observed in 38% (Figure 1). Frequencies of common / uncommon ex19del and co-alterations, such as TP53, EGFR, PIK3CA variants and EGFR copy number amplifications (CNA), did not vary by T0/tother timepoints. EGFR SNVs T790M, C797S, and G724S were the most prevalent co-occurring alterations within the Tother cohort and nearly absent in the T0 cohort, likely due to their association with acquired resistance. Significant co-alteration differences between common / uncommon ex19del groups were noted in BRAF SNVs (p=0.003), ALK indels (p= 0. 001), FGFR2 fusions (p=0.005) and other genes. Co-alterations in 15 genes were significantly different in prevalence between T0 and Tother cohorts, including MET amplifications and SNVs in BRAF, PIK3CA and MET (all p <0.0001), all with increased frequency in Tother, likely due to their association with EGFR TKI resistance.

Conclusions: To our knowledge, this is the largest liquid biopsy analysis comparing common/uncommon ex19dels in NSCLC and shows similar genomic findings across groups. Further work should be done to explore additional genomic and non-genomic factors to aid in patient selection for EGFR TKIs for uncommon findings.

P1.12A.12 Liquid Biopsy Based Risk Stratification and Intensification of Treatment in EGFR Mutant Advanced NSCLC (L-BRITE) Preliminary Analysis

H. baskarane[1], P.S. MALIK[1], D. JAIN[1], S. KHURANA[1], D. PUSHPAM[1], S. KUMAR SINGLA[1], [1]AIIMS, NEW DELHI/IN

Introduction: Documentation of ctDNA clearance at various time points after targeted therapy correlates with better progression free survival (PFS). Serial plasma ctDNA monitoring may provide risk stratification strategy by selecting the poor risk and a window of opportunity of treatment escalation which has not been formally tested. Patients of advanced NSCLC with EGFR mutations are treated with TKIs alone and Osimertinib is preferred over first generation TKIs. Recently, combination chemotherapy with TKIs have shown promising results. In this trial, we evaluated the role of combining chemotherapy in patients with residual ctDNA after gefitinib monotherapy for initial 9-12 weeks, in terms of 6 months PFS rates.

Methods: We conducted a phase II study at a single center on treatment-naïve metastatic NSCLC patients with EGFR mutations detected by liquid biopsy. Treatment consisted of gefitinib monotherapy for 9-12 weeks followed by the addition of 4 cycles of carboplatin and pemetrexed followed by pemetrexed maintenance in patients with residual ctDNA. Serial ctDNA monitoring using ddpCR was planned at 3 monthly intervals. The primary endpoint of the study was to evaluate 6-month Progression-free survival (PFS) rate by adding chemotherapy to gefitinib in patients with residual CtDNA after gefitinib monotherapy with the presumption that it would improve 6 month PFS rates in these patients from 40% to 65%. Secondary objectives include evaluating 6 month PFS in ctDNA cleared patients post gefitinib, overall survival, resistance mutation development, safety, and quality of life, employing Simon's two-stage design to reach a target sample size of 31.

Results: Between May 2022 and December 2023, 60 out of 84 screened patients were enrolled in the study, with 21 of them being included for primary efficacy analysis. The median participant age was 52, with the majority having Exon 19 EGFR mutations (71.6%). Most (over 83%) presented with multiple metastases(>1), commonly in bones (75%). At the start, 35% had brain metastases; 66.6% of these were symptomatic, with 76% completing WBRT. At 9-11 weeks of gefitinib treatment, 42% showed CtDNA clearance. Among the 56.1% non-responders, 3 had progressive disease, prompting treatment intensification for 26 patients. In the study, the median progression-free survival (PFS) in ITT population was 12 months, with a 6-month PFS rate of 76.9%. Molecular response influenced 6-month PFS rates following the start of gefitinib, with 75.7% in ctDNA positive vs 85.7% in ctDNA negative groups. This difference was not statistically significant (P=0.44), likely due to the effect of added chemotherapy. Addition of chemotherapy led to an 84.8% 6-month PFS rate, achieving its primary endpoint in residual ctDNA patients over 8.6 months of follow up.In the intervention group (26 patients), 21 completed 4 chemotherapy cycles, experiencing 9 grade 3 adverse events. Post-chemotherapy, 8 showed partial response, 12 stable disease, and 1 progressive disease. Reevaluation of ctDNA in 18 patients showed a 50% clearance rate.

Conclusions: In conclusion, initial results indicate the potential benefits of a liquid biopsy-based escalation strategy, though constrained by a small cohort and short follow-up. The trial is still ongoing to complete accrual, with current findings still considered preliminary.

P1.12A.13 When Targeted Therapy Targets the Heart: Osimertinib-related Cardiotoxicity in EGFR Mutated Non-Small Cell Lung Cancer

F.J. Martinez[1], R. Liu[1], S. Zhu[2], L. Sakoda[3], C. Goh[4], V. Ropko[5], V. Sarovar[6], M. Suga[7], [1]Hematology/Oncology, The Permanente Medical Group, San Francisco/CA/USA ,[2]Division of Research, Kaiser Permanente Northern California, Oakland/CA/USA ,[3]Division of Research, Kaiser Permanente Northern California, Pleasanton/CA/USA ,[4]Cardiology The Permanente Medical Group, San Francisco/CA/USA ,[5]Kaiser Permanente Medical Group, San Francisco/CA/USA ,[6]Division of Research, Kaiser Permanente Northern California,, Oakland/CA/USA ,[7]Hematology/Oncology, The Permanente Medical Group, Vallejo/CA/USA

Introduction: Epidermal Growth Factor Receptor (EGFR) mutations are present in approximately 15% of lung adenocarcinomas in the United States. Osimertinib has proven efficacy for patients with lung cancer harboring certain EGFR mutations. Despite its efficacy, Osimertinib is associated with increased risk of cardiac adverse events, including heart failure (HF). This retrospective analysis examines the use of cardiac imaging in detecting HF among Osimertinib-treated patients.

Methods: The analysis investigated EGFR-positive non-small cell lung cancer patients prescribed Osimertinib from 01/01/2017 to 12/31/2022 within Kaiser Permanente Northern California, an integrated healthcare system with 21 community cancer centers serving 4.4 million patients. We assessed the use of cardiac imaging with transthoracic echocardiogram (TTE) or multigated acquisition scan (MUGA) and change in ejection fraction (EF) measured by TTE or MUGA between one year before treatment up to one year after treatment discontinuation. Patients were followed for HF-related admissions or ED visits from medication initiation until one-year post-discontinuation, death, health plan disenrollment, or study end (12/31/2023), whichever occurred earliest.

Results: This study evaluated 832 patients (median age: 76.4 years; 67.5% female; 50.5% Asian; 60.1% never smoked). The proportion of patients who underwent both baseline and follow-up cardiac imaging was 70.1%. Those in the EF reduction group commonly had a history of atrial fibrillation or already diminished EF (Table 1). During the research period, a total of 3,741 TTEs and 691 MUGA scans were conducted. The occurrence of HF-related ED visits or hospital admissions, which could be associated with Osimertinib therapy, was minimal, with only six cases identified. This translates to an incidence rate of 0.4 cases per 100 person-years, The median time from the latest cardiac imaging to HF related event was 24.5 days. All six patients for HF had existing cardiac comorbidities with the most common being atrial fib. All patients presented with clinical symptoms, including shortness of breath with bilateral pleural effusions.

Conclusions: Our retrospective analysis sheds light on the real-world application of cardiac imaging for patients with EGFR-positive NSCLC on Osimertinib. Findings point to a rare incidence of heart failure from Osimertinib. The expected benefit of outpatient cardiac imaging in averting heart failure related hospital visits was unsupported. These insights call for a re-evaluation of regular EF monitoring, which may be unnecessary for all patients and instead should be tailored for those at highest risk for developing heart failure complications or those with preexisting cardiac conditions.

EF Reduction is defined as a change in EF greater than or equal to 10% and EF<53%
(*) denotes significant P-value <0.05
This table details the demographics and comorbidities of 832 patients, stratified by the extent and findings of cardiac monitoring, including no EF measurement, EF reduction, no EF reduction, baseline EF only, and follow-up EF only groups. EF reduction is defined by at least two comparable measurements, signifying active cardiac surveillance. The 'follow-up EF only' group represents patients monitored from Osimertinib initiation without a prior EF assessment, whereas 'baseline EF only' refers to patients with a single assessment within one year, with no subsequent monitoring during therapy. Differences in demographic and clinical characteristics were compared using chi-square tests for categorical variables and ANOVA for continuous variables. Heart-failure ED or hospitalizations were obtained through databases using ICD codes and validated by chart review to confirm if the event was Osimertinib-induced.

P1.12B.01 Intracranial Efficacy of Lorlatinib via RANO-BM in ALK-Fusion NSCLC with CNS Metastases: A Retrospective, Multicenter Study

J. Li[1], Z. Wei[1], H. Lan[2], Y. Wei[1], J. Fan[3], Y. Zhu[1], H. Li[2], J. Ge[1], [1]Sichuan Cancer Hospital, Chengdu/CN ,[2]The People's Hospital of Sichuan, Chengdu/CN ,[3]The Affiliated Hospital of Southwest Medical University, Luzhou/CN

Introduction: Despite the remarkable systemic efficacy achieved with lorlatinib in first-line phase III CROWN study and the later-line phase II B7461024 study, intracranial efficacy of lorlatinib via RANO-BM criteria in ALK fusion NSCLC patients with brain metastases (BMs) or leptomeningeal metastases (LMs) still unknown.

Methods: Adults diagnosed with metastatic ALK-positive NSCLC who had baseline BMs and/or LMs before administration of lorlatinib were enrolled in the retrospective multicenter study. The evaluation of intracranial lesions was based on RANO-BM criteria. The primary endpoint was intracranial objective response rate (iORR). The secondary endpoints were median intracranial progression-free survival (miPFS), intracranial disease control rate (iDCR), median duration of treatment (mDOT), median overall survival (mOS), and safety.

Results: Between July 1, 2022 and July 1, 2023, 27 participants from 3 institutions were enrolled. At the data cutoff (December 24, 2023), median follow-up was 9.0 months. Among all patients, 18.5% were with LMs, median prior therapy lines were 3. The iORR was 44.4% in all patients including 11.1% with complete responses. The iORR was 36.4% in patients who progressed after second-generation ALK inhibitor(s). Among 19 patients with detectable baseline BMs, iORR was 57.9%, and 73.7% had brain lesions reduced. The iORR of patients with LMs was 20.0%. In all patients, the iDCR, miPFS, mOS, and mDOT were 66.7%, 8.6, 16.1, and 8.5 months while the iDCR, miPFS, and mOS for patients with LMs were 60.0%, 4.0, and 8.6 months, respectively. Common adverse events (≥10%) included hypercholesterolemia (85.2%), hypertriglyceridemia (60.3%), and edema (18.5%) were no greater than grade 2.

Conclusions: This is the first report shows the intracranial efficacy of lorlatinib in NSCLC patients with BMs and/or LMs assessed by RANO-BM criteria. Our study demonstrated that lorlatinib showed robust intracranial efficacy and manageable safety for patients with CNS metastases in the real-world setting.

P1.12B.02 Mechanisms of Resistance to First-Line vs Later-Line Alectinib in ALK Fusion-Positive Non-Small Cell Lung Cancer

S. Waliany, A. Do, A. Liu, J. Peterson, A. Hata, I. Dagogo-Jack, J. Gainor, J.J. Lin, Massachusetts General Hospital Cancer Center, Boston/MA/USA

Introduction: Next-generation ALK tyrosine kinase inhibitors (TKI) such as alectinib have supplanted crizotinib as a standard first-line (1L) therapy for patients (pts) with ALK fusion-positive (ALK+) advanced/metastatic non-small cell lung cancer (mNSCLC). Post-progression biopsies can identify mechanisms of resistance and may guide therapy selection. Most studies on ALK resistance to date have evaluated pts who received alectinib as second- or later (2+) line therapy after prior crizotinib, with limited data on mechanisms of resistance when alectinib is used as 1L therapy.

Methods: This retrospective study included pts with ALK+ mNSCLC who received alectinib either as 1L therapy or 2L+ therapy after prior crizotinib. Tissue or plasma specimens obtained at progression (i.e., alectinib-resistant) were analyzed by next-generation sequencing (NGS). The frequency of detection of ALK resistance mutation(s), MET amplification, or histologic transformation was compared between the 1L and 2L+ cohorts.

Results: We identified 125 pts (median age, 54 years; 70.4% women) with ALK+ mNSCLC who received alectinib as 1L (n=66) or 2L+ (n=59) therapy and underwent post-alectinib biopsies. Median follow-up was 56.1 months. In total, 162 post-alectinib specimens underwent NGS (tissue: n=86 [81 pts]; plasma: n=76 [69 pts]); 21 (16.8%) pts had both tissue/plasma. Among 81 pts with post-alectinib tissue biopsies, 43 (53.1%) had ≥1 ALK resistance mutation detected, including ≥2 co-occurring ALK mutations in 2 (2.5%) pts. The most common ALK mutations among tissue biopsies were G1202R (n=17, 21.0%), I1171X (n=13, 16.0%), L1196X (n=7, 8.6%), and V1180L (n=6, 7.4%). When comparing the alectinib resistance landscape in 1L vs 2L+ cohorts, ALK resistance mutations were detected at a significantly lower frequency in the 1L vs the 2L+ tissue cohort (1L: 42.2% vs 2L+: 66.7%, p=0.029). ALK mutations were also detected at a numerically lower frequency in the 1L vs the 2L+ plasma cohort (1L: 35.9% vs 2L+: 58.6%, p=0.063), although this did not reach statistical significance. MET amplification had a trend towards more frequent detection in the 1L vs 2L+ tissue cohort (1L: 11.1% vs 2L+: 0%, p=0.062). Histologic transformation was identified in 4.4% (2/45) of 1L and 2.8% (1/36) of 2L+ post-alectinib tissue biopsies. We also compared the findings between plasma vs tissue post-alectinib biopsies. Plasma biopsy was more likely to detect ≥2 co-occurring ALK mutations than tissue in the 2L+ cohort (plasma: 20.7% vs tissue: 2.8%, p=0.039), though not in the 1L cohort (plasma: 7.7% vs tissue: 2.2%, p=0.33). There was a trend towards higher likelihood of detection of MET amplification by tissue than plasma in the 1L cohort (tissue: 11.1% vs plasma: 0%, p=0.058).

Conclusions: In this largest series of alectinib-resistant biopsies to date, on-target resistance (i.e., ALK resistance mutation) was significantly less common when alectinib was used as 1L vs 2L+ therapy, highlighting the importance of elucidating strategies to overcome off-target resistance to next-generation ALK TKI. Our findings additionally underscore the complementary role of tissue and plasma re-biopsies in delineating the resistance landscape, with tissue more likely to detect MET amplification and capable of identifying histologic transformation and plasma more likely to detect ≥2 co-occurring ALK mutations.

Introduction: In the phase III ALTA-1L trial, brigatinib showed superior efficacy vs. crizotinib in first line (1L) for anaplastic lymphoma kinase positive (ALK+) non-small cell lung cancer (NSCLC). A retrospective, non-interventional, multinational study reported real-world (rw) outcomes post-1L brigatinib1. This analysis assessed additional subgroups, including those stratified by response to 1L brigatinib.

Methods: Patients were previously enrolled in the brigatinib arm of ALTA-1L and discontinued 1L brigatinib during/after the trial. They were followed from last brigatinib dose until end of follow-up/death. Data were extracted from electronic case report forms. Second-line (2L) time-to-treatment discontinuation (TTD), 2L progression-free survival (PFS), and overall survival (OS) were estimated using Kaplan-Meier methods. Analyses evaluated patients who received any 2L ALK tyrosine kinase inhibitor (TKI), or 2L lorlatinib, or 2L alectinib. Patients receiving 2L ALK TKIs were also stratified as 1L brigatinib responders (best of complete or partial response by blinded independent review committee) or non-responders.

Results: As of October 18, 2023, 48 patients were enrolled (20 sites; 10 countries), and 40 (83.3%) received subsequent systemic anticancer therapies. Of these, 30 received a 2L ALK TKI (median follow-up, 17.0 months; median age, 57.5 years; White, 46.7%; Asian, 50.0%; female, 60.0%), including 16 (53.3%) on 2L lorlatinib and 8 (26.7%) on 2L alectinib. There were 23 (76.7%) 1L responders and 7 (23.3%) 1L non-responders, consistent with ALTA-1L results. For 2L ALK TKIs, rw objective response rate (rwORR) was 33.3% and disease control rate (rwDCR) was 70.8%. Median (95% CI) rwTTD was 34.7 (4.6, NR) months for 2L ALK TKIs, 37.2 (6.0, NR) months for 2L lorlatinib, and NR (1.1, NR) for 2L alectinib. Median (95% CI) rwPFS was 16.1 (4.4, NR) months for 2L ALK TKIs, 25.6 (3.8, NR) months for 2L lorlatinib, and 16.1 (1.1, NR) months for 2L alectinib. For 1L responders receiving 2L ALK TKIs, median (95% CI) rwTTD was 37.2 (3.6, NR) months and median (95% CI) rwPFS was 25.6 (3.8, NR) months. For 1L non-responders, median (95% CI) rwTTD was 11.6 (2.8, NR) months and median (95% CI) rwPFS was 13.0 (2.4, NR) months (Table).

Conclusions: This is the first long-term study evaluating rw outcomes post-1L brigatinib. Following 1L brigatinib discontinuation, most patients started another ALK TKI and had prolonged clinical benefit. 1L brigatinib responders appeared to have longer time on subsequent ALK TKI than 1L non-responders. This study was limited by small sample size. 1Delmonte A. Poster #38P ELCC 2024

P1.12B.04 Central Nervous System (CNS) Progression on CNS Penetrable ALK TKI: Real-World Practice Patterns and Patient Outcomes

S. Singhal[1], C. Hui[2], J. Neal[2], M. Roy[2], M. Das[2], K. Ramchandran[2], E. Pollom[2], G. Selvaggi[3], H. Wakelee[2], N. Myall[2], [1]University of California Davis, Sacramento/CA/USA ,[2]Stanford University, Stanford/CA/USA ,[3]Xcovery Holdings, Inc, Palm Beach/FL/USA

Introduction: Central nervous system (CNS) metastases are common in ALK-rearranged non-small cell lung cancer (NSCLC). The optimal treatment strategy for patients who develop CNS progression during treatment with CNS penetrable ALK tyrosine kinase inhibitors (TKIs) is unknown. Here, we characterize practice patterns and outcomes for patients who developed CNS progression during treatment with CNS penetrable ALK TKI.

Methods: Patients treated at Stanford Cancer Center who developed CNS progression (time 0, [T0]) on CNS penetrable ALK TKI (alectinib, brigatinib, ensartinib, lorlatinib) were identified. Patients were categorized according to TKI management (e.g., TKI unaltered, TKI altered [switched TKI or increased TKI dose], TKI discontinued) at T0. CNS progression-free survival (PFS) was evaluated using Kaplan-Meier and compared by log-rank test.

Results: We identified 36 patients (mean age 59) who developed CNS progression on CNS penetrable ALK TKI. Overall, 33 (92%) developed CNS parenchymal progression, 7 (19%) developed leptomeningeal progression and 18 (50%) developed concurrent systemic progression. At T0, 16 (44%) had TKI unaltered, 14 (39%) had TKI altered (8 switched TKI, 6 increased TKI dose), and 6 (17%) discontinued TKI (Table). Those patients who had their TKI altered tended to have a higher burden of disease at T0 progression (e.g., leptomeningeal disease, concurrent systemic progression). Radiation to the CNS was given concurrently at T0 in 14 (88%) of TKI unaltered and 3 (21%) of TKI altered patients. The median CNS PFS from T0 was not significantly different between these two groups (TKI altered versus unaltered; p=0.21) (Figure).

Conclusions: For patients with ALK-rearranged NSCLC with leptomeningeal progression and/or concurrent systemic progression, TKI change or dose increase was a feasible salvage strategy for CNS progression during treatment with CNS penetrable TKI. Our findings support continuing some form of TKI therapy among select patients with ALK-rearranged NSCLC who develop CNS progression on a CNS penetrable TKI.

P1.12B.05 Patient and Oncologist Preferences for ALK+ Advanced Non-Small Cell Lung Cancer Tyrosine Kinase Inhibitor Treatments

H. Le[1], J. Coulter[2], J.C. Cappelleri[2], H. Lu[3], M. Quaife[3], K. Meginnis[3], G. Fernandez[3], K. Culver[4], S. Vaghela[2], N. Rifi[2], T. Stinchcombe[5], [1]Pfizer, Fairfax/VA/USA ,[2]Pfizer, New York/NY/USA ,[3]Evidera, Cambridge/GB ,[4]ALK Positive, Atlanta/GA/USA ,[5]Duke Health, Durham/NC/USA

Introduction: We aimed to understand the preferences of US patients and oncologists regarding key attributes associated with anaplastic lymphoma kinase positive (ALK+) tyrosine kinase inhibitors (TKIs) in the 1L setting and their willingness to tradeoff between benefits and risks.

Methods: ALK+ advanced non-small cell lung cancer (aNSCLC) patients on TKIs and treating oncologists were recruited to participate in an online discrete choice experiment (DCE). The DCE was informed by a literature review of all 1L ALK TKIs, 30 qualitative interviews, and consultation with a steering committee including an oncologist and a patient advocate. The experiment comprised eight attributes: chance of lung cancer control at 3 years [3y-PFS], 3y stopping brain metastases (BM) development, 3y BM control, metabolic events, weight gain, central nervous system (CNS) effects, fatigue/asthenia, muscle and bone pain. DCE responses were analysed using a mixed logit model. Relative attribute importance (RAI) scores, which sum to 100%, were calculated to represent the relative impact of improving each attribute from the worst to the best level on overall treatment preference. The minimal benefit improvement in 3y-PFS that participants required to accept treatment-related risks was also calculated.

Results: 151 patients and 150 oncologists participated. Patients had mean age of 58.5 years (range 52-65), with most being male (65%). Over half (55%) had BM and were in 1L treatment (50%). Most oncologists practiced in academic (43%) or community hospitals (31%) and had been board-verified in oncology for over 5 years (89%). RAI scores (Figure 1) showed that the treatment benefits outweighed risks for both patients and oncologists, contributing to 84% of patient choices and 68% of physician choices. Preventing BM development was most important to patients (27%), while for oncologists PFS (37%) was most important. To compensate for the increased risk of moderate fatigue and moderate muscle and bone pain, patients required a treatment to increase 3y-PFS by 5.0% and 4.5% respectively, nearly four times more than required for risk of metabolic events or weight gain. Oncologists required at least a 3% improvement in 3y-PFS to accept a muscle or bone pain risk or metabolic events. Oncologists required a three-times greater increase in 3y-PFS than patients to accept increased risk of metabolic events.

Conclusions: Understanding trade-offs that oncologists and patients are willing to make between treatment attributes may facilitate shared decision-making in the 1L setting of ALK+ aNSCLC. Both patients and oncologists were willing to accept risks in exchange for treatment benefits.

P1.12B.06 Deulorlatinib (TGRX-326)in Patients with ALK Fusion-Positive NSCLC: Update from the Phase 1 Trial

L. Zhang[1], H. Zhao[1], S. Zhao[1], H. Zhou[1], Y. Ma[1], N. Yang[2], Z. Wang[3], W. Jin[4], X. Li[5], Y. Liu[6], R. Meng[7], J. Zhou[8], Y. Cheng[9], Y. Wang[10], Z. Yu[11], [1]Sun Yat-sen University Cancer Center, Guangzhou/CN ,[2]of Medicine, Central South University, Changsha/CN ,[3]Shandong Cancer Hospital, Jinan/CN ,[4]Jiangxi Cancer Hospital, Nanchang/CN ,[5]The First Affiliated Hospital of Zhengzhou University, Zhengzhou/CN ,[6]The First Hospital of China Medical University, Shenyang/CN ,[7]Union Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan/CN ,[8]The First Affiliated Hospital Zhejiang University School of Medicine, Hangzhou/CN ,[9]Jilin Cancer Hospital, Changchun/CN ,[10]West China Hospital clinics, Chengdu/CN ,[11]The Affiliated Hospital of Qingdao University, Qingdao/CN

Introduction: Deulorlatinib (TGRX-326), a deuterated derivative of lorlatinib, demonstrated desirable safety and durable activity in ALK-positive advanced NSCLC in a phase 1 trial (NCT05441956; data cutoff: 13 Jan 2023). Here we report the updated safety, efficacy and biomarker analysis of deulorlatinib from the phase 1 trial.

Methods: Patients with ALK-positive, advanced NSCLC received deulorlatinib 5-125mg once daily (qd) during dose-escalation stage, deulorlatinib 40, 60, or 80mg qd during dose-expansion, and deulorlatinib at recommended phase 2 dose (RP2D) during cohort-expansion stage. Cohort-expansion stage enrolled ALK-positive patients with disease progression after crizotinib with or without chemotherapy (EXP-A1), ALK-positive patients with disease progression after at least one second-generation ALK inhibitors (EXP-A2) and TKI-naïve ALK-positive patients (EXP-C). Primary objectives were safety and tolerability. Pharmacokinetics, clinical activity and potential biomarkers were also evaluated.

Results: A total of 198 patients were enrolled. At data cutoff (February 21, 2024), median (range) treatment duration in the primary efficacy cohorts was 19.2 (2.5-22.1) months in cohort A1 (n=14), 6.9 (0.9-23.0) months in cohort A2 (n=97) and 18.1 (1.2-22.1) months in cohort C (n=33). No new safety signals were detected with long-term treatment duration. Common TRAEs were hypercholesterolemia (77.8%), hypertriglyceridemia (74.2%) and weight gain (46.0%). TRAE-associated dose interruptions, reduction and discontinuation occurred in 8.6%, 2.5% and 1.5% of patients, respectively. Treatment-related CNS effects occurred in 7.6% of patients, with 0.5% (n=1) requiring dose modification. In cohort A1, confirmed ORR (cORR) was 71.4% (95% CI, 41.9-91.6); median (95% CI) DOR and PFS were NA (11.8-NA) months and NA (9.7-NA) months. In cohort A2, cORR was 39.2% (95% CI, 29.4-49.6); median (95% CI) DOR and PFS were 18.0 (15.1-NA) months and 9.0 (5.7-16.8) months. In cohort C, cORR was 87.9% (95% CI, 71.8-96.6); median (95% CI) DOR and PFS were both NA (NA-NA). The efficacy of the treatment is summarized in the table below. Responses were observed across ALK variants and mutations. 158 patients provided plasma samples for biomarker analysis. Detectable ALK alterations and concurrent mutations in DNA damage repair pathway at baseline predicted worse outcomes. ALK clearance at week 6 correlated with significantly prolonged progression-free survival and overall survival.

Conclusions: After long-term follow-up, deulorlatinib continues to demonstrate durable efficacy in patients with ALK-positive NSCLC regardless of prior therapies. Safety profile was manageable and consistent with previous report. Based on these findings, 2 pivotal studies (NCT05955391/NCT06082635) are currently ongoing.

Introduction: Iruplinalkib, a highly-selective anaplastic lymphoma kinase (ALK)/c-ros oncogene 1 tyrosine kinase inhibitor (TKI), demonstrated favorable efficacy and manageable safety in patients with non-small cell lung cancer (NSCLC). Here we report the updated results with two years' additional follow-up of a phase 2 trial (INTELLECT) evaluating the efficacy and safety of iruplinalkib in ALK-positive crizotinib-resistant advanced NSCLC (NCT04641754).

Methods: INTELLECT recruited 146 patients with histopathologically- or cytologically-confirmed ALK-positive advanced NSCLC who had disease progression after continuous treatment with crizotinib of ≥12 weeks. After a 7-day lead-in phase of iruplinalkib at 60 mg once daily, patients were orally administered iruplinalkib at 180 mg once daily in a 21-day cycle. Efficacy evaluation was performed every 12 weeks until disease progression, loss of follow-up, start of other anti-tumor treatment, or death. Central nervous system (CNS) efficacy was evaluated according to the Response Assessment in Neuro-Oncology criteria. Adverse events were evaluated according to the Common Terminology Criteria for Adverse Events version 4.03.

Results: At the data cut-off date on December 29, 2023, median follow-up time was 42.41 months (range, 41.07 to 43.14). Per investigator, median duration of response, progression-free survival, and time to progression was 14.06 months (95% confidence interval [CI], 10.35 to 18.60), 14.55 months (95% CI, 11.73 to 19.91), and 14.55 months (95% CI, 11.73 to 19.98), respectively. In 146 patients, 72 (49.3%) died, and 16 (11.0%) were lost to follow-up. The median overall survival was 41.79 months (95% CI, 28.78 to not evaluable). Ninety-six (65.8%) patients received at least once anti-tumor therapy after discontinuation of iruplinalkib treatment. The most common subsequent anti-tumor therapy was ALK TKI (73 [50.0%]), of which alectinib accounted for the most (50 [34.2%]). Table 1 presents subgroup analysis per investigator in patients with measurable intracranial lesions and with CNS metastases. Treatment-related adverse events (TRAEs) occurred in 137/146 (93.8%) patients. The most common TRAEs were aspartate aminotransferase increased (66 [45.2%]), hypercholesterolemia (55 [37.7%]), alanine aminotransferase increased (54 [37.0%]), and creatine phosphokinase increased (52 [35.6%]). TRAE leading to treatment interruption and discontinuation occurred in 23 (15.8%) and five (3.4%) patients, respectively. Two patients (1.4%) died due to TRAE of multiple organ dysfunction syndrome and intracranial hemorrhage, respectively.

Conclusions: The long-term follow-up results of INTELLECT confirmed the robust efficacy and safety of iruplinalkib with promising survival prognosis and no new safety signal. The updated results provided new evidence for the use of iruplinalkib in patients with ALK-positive crizotinib-resistant advanced NSCLC.

P1.12B.08 Thrombotic Events at Diagnosis are Associated with Poorer First Line TKI Outcomes Among Metastatic ALK and ROS1 NSCLC Patients

M. Sakamoto, J. Hu, V. Alami, A. Watson, R. Camidge, E. Schenk, P.A. Bunn, S. Pine, T. Patil, University of Colorado School of Medicine, Aurora/CO/USA

Introduction: ALK and ROS1 NSCLC have been associated with increased rates of thrombotic events at diagnosis. The relationship between thrombotic events (TEs) and clinical outcomes to first line TKIs among patients with ALK, ROS1, and EGFR mutant NSCLC is less well defined.

Methods: Retrospective review of patients with metastatic ALK, ROS1, or EGFR mutant NSCLC seen between 2014 - 2024 at the University of Colorado who received first line TKIs was performed. TEs were defined as deep venous thrombosis, pulmonary embolism, arterial embolism, or stroke occurring within 90 days of diagnosis. Clinicopathologic features, treatment outcomes, and genomic data were collected. Progression free survival (PFS) and overall survival (OS) were assessed using Kaplan Meier methods using both univariate and multivariate modeling.

Results: Baseline characteristics of 135 patients are shown in Table 1. Univariate analysis of the entire dataset showed that patients with TEs had worse PFS (10 vs 14 months; HR 1.47, 95% CI 1.08 - 2.16, p=0.03) and OS (40 vs 43 months; HR 1.80, 95% CI 1.18 - 2.78, p = 0.01). When analyzed by oncogene, TEs at diagnosis were associated with worse PFS and OS for patients with ALK and ROS1 fusions, but not for patients with sensitizing EGFR mutations [Figure 1]. Multivariate modeling found no association with brain metastases (HR 0.77, 0.18 - 3.02, p=0.36), lines of therapy (HR 1.04, 0.52 - 2.09, p=0.92), CNS penetrance of TKI (HR 1.36, 0.80 - 2.33, p=0.25), or TP53 alterations (HR 1.20, 0.72 - 1.99, p=0.48) on PFS or OS.

Conclusions: Thrombotic events at diagnosis are independently associated with worse PFS and OS among patients with ALK and ROS1 fusions, but not among patients with EGFR mutations. Further studies exploring the nature of this relationship are warranted.

P1.12B.09 Efficacy of Selpercatinib by RET Fusion Partner in RET+ NSCLC: Results from the LIBRETTO-001 and LIBRETTO-431 Trials

B. Solomon[1], A. Drilon[2], K. Park[3], S. Novello[4], E. Nadal[5], B. Besse[6], N. Peled[7], P. Peterson[8], S. Barker[8], A. Szpurka[8], O. Grbovic-Huezo[8], H. Loong[9], [1]Peter MacCallum Cancer Institute, Melbourne/AU ,[2]Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York/NY/USA ,[3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR ,[4]University of Turin, AOU San Luigi, Orbassano/IT ,[5]Institut Català d'Oncologia, L'Hospitalet de Llobregat, Barcelona/ES ,[6]Institut Gustave Roussy, Villejuif/FR ,[7]Soroka University Medical Center, Beer-Sheva/IL ,[8]Eli Lilly and Co., Indianapolis/IN/USA ,[9]The Chinese University of Hong Kong, Hong Kong/CN

Introduction: Selpercatinib is a highly selective and potent CNS active RET-inhibitor approved for treatment of advanced RET-driven cancers, including non-small-cell lung cancer (NSCLC). In the phase 1/2 LIBRETTO-001 (NCT03157128) and phase 3 LIBRETTO-431 (NCT04194944) studies, the clinical benefit of selpercatinib was demonstrated in patients with RET fusion-positive (RET+) NSCLC, regardless of fusion partner. Here, the relationship between selpercatinib efficacy and RET fusion partner was examined in a combined cohort of patients from both studies.

Methods: The primary analysis population included untreated and previously treated RET+ NSCLC patients who received selpercatinib in LIBRETTO-001 and LIBRETTO-431. LIBRETTO-431 patients were included in a separate controlled analysis of selpercatinib treatment versus platinum/pemetrexed chemotherapy +/- pembrolizumab (control), which was limited to KIF5B-RET due to low numbers of patients with other fusion partners. RET fusion partners were primarily identified in tumor tissue by NGS. Time-to-event efficacy outcomes were analyzed using the Kaplan-Meier method.

Results: Of the 415 patients who received selpercatinib, 263 (63.4%) were previously treated for advanced disease while 152 (36.6%) patients received no prior treatment. The most commonly identified RET fusion partners were KIF5B-RET (71.6%) or CCDC6-RET (21.2%). In patients with KIF5B-RET fusion, the median PFS was 19.4 months (95% CI: 17.1-22.7), while mPFS was not reached in patients with CCDC6-RET fusion. The ORR in patients with KIF5B-RET and CCDC6-RET was 65.3% (95% CI: 59.6-70.7) and 83.0% (95% CI: 73.4-90.1) respectively. Responses in patients with or without prior treatment by fusion partner are shown in Table 1. The median DOR was 20.3 months (95% CI: 17.5-23.9) in patients with KIF5B-RET, while not yet reached in patients with CCDC6-RET (Table 1). Among LIBRETTO-431 patients, 44.0% (70/159) patients in the selpercatinib group and 49.0% (50/102) patients in the control group had KIF5B-RET. In these patients with KIF5B-RET, the median PFS was 19.1 (95% CI: 13.9-24.8) months with selpercatinib compared to 7.4 months (95% CI: 4.9-11.2) with control.

Conclusions: In patients with RET+ NSCLC from LIBRETTO-001 and LIBRETTO-431, selpercatinib demonstrated robust and durable efficacy regardless of fusion partner. PFS in patients with KIF5B-RET from the LIBRETTO-431 control arm was consistent with prior reports of a poorer prognosis in this cohort regardless of treatment; however, clinical outcomes were improved with selpercatinib compared to chemotherapy +/- pembrolizumab. These data further support early and comprehensive genomic testing to identify RET fusions and use selpercatinib as the first-line therapy in patients with advanced RET+ NSCLC.

Introduction: Selpercatinib is a highly selective RET kinase inhibitor that has demonstrated improved progression-free survival (PFS) in patients with first-line RET fusion-positive non-small cell lung cancer (NSCLC). As with other targeted therapies for NSCLC, dose reductions are commonly used for managing selpercatinib toxicity. Given the potent and selective RET inhibition offered by selpercatinib, we hypothesize that outcomes would be maintained even with variable exposures resulting from dose adjustment.

Methods: We studied patients with NSCLC treated with selpercatinib in 2 prospective trials (LIBRETTO-001 and LIBRETTO-431) where patients were started at 160 mg twice daily; dose reductions to 120 mg, 80 mg, and 40 mg twice daily were permitted. Exposure-response models were developed to characterize the relationship between selpercatinib at clinically relevant exposures and efficacy endpoints (overall response rate [ORR] and PFS). Steady-state exposure parameters selected for analysis (area under the plasma concentration-time curve over 24 hours at steady state [AUC24] and maximum and minimum selpercatinib concentrations) were representative of the average selpercatinib exposure over time. Additionally, average exposure over the last 10 doses was considered. Exposure-response analysis was conducted for ORR using a stepwise logistic regression. For PFS, Kaplan-Meier plots were created for each exposure parameter.

Results: Of 504 treated patients with NSCLC (LIBRETTO-431, n=150; LIBRETTO-001, n=354), 266 (53%) underwent dose reduction. Median time to first dose reduction was 2 months. Patients with dose reduction tended to be older (median age [range]: 61 [26-92] vs 59 [23-87] years) and had lower body weight (median weight [range]: 63 [39-148] vs 66 [42-131] kg) and longer time on therapy (median time on treatment [95% confidence interval]: 31.7 [26.2-37.9] vs 21.2 [17.3-25.3] months) versus patients without dose reduction. Aspartate and alanine aminotransferase elevation, QT prolongation, and hypertension were the most common adverse events leading to dose adjustments. Focusing on the 502 patients included in the ORR exposure-response analysis, the response rate was 69% (348 responders); a stepwise multivariate logistic regression showed that probability of response increased with increasing selpercatinib AUC24 (P<0.05). Exploratory analysis of PFS in 504 patients (254 events) by exposure metrics showed no significant relationship with PFS across exposure quartiles.

Conclusions: Our analyses did not find any correlation between drug exposure and PFS but did suggest that higher exposure was associated with better response rates. For patients experiencing toxicity on selpercatinib, dose adjustment to reduce exposure may allow ongoing clinical benefit without a decremental impact on PFS.

Keywords: Exposure-response, Dose adjustments, Selpercatinib

P1.12B.11 ALK Positive Lifestudy

M. Al Achkar[1], N. Thuo[2], S. Sravanam[3], F. Abda[4], W. Chen[5], C. Barton[6], K. Culver[7], [1]Karmanos Cancer Institute, Detroit/MI/USA ,[2]KPMG, Nairobi/MI/USA ,[3]UW, Seattle/MI/USA ,[4]Damascus University, Damascus/SY ,[5]Wayne State University, Detroit/MI/USA ,[6]ALK-positive Inc, Denver/CO/USA ,[7]ALK-positive Inc, other/CA/USA

Introduction: Lung cancer remains the leading cause of cancer-related deaths worldwide. ALK-positive rearrangement, represents a distinct subset. The primary objective of this study is to comprehensively analyze the diagnostic journeys of patients with ALK-positive NSCLC using data from a global registry, focusing on symptomatic presentation of the lung cancer and the time intervals from initial symptom onset to the commencement of treatment.

Methods: A global registry for ALK-positive NSCLC patients was established by ALK Positive Inc, a patient-led advocacy organization to explore their diagnostic and treatment journeys. Our ongoing recruitment process includes direct outreach through various social media, email, and networking channels, along with IRB-approved informed consent procedures. An initial survey collected demographic data, and documented both pre-diagnosis and post-diagnosis phases, completed by patients or their caregivers. This survey covered the first symptoms presented at the clinic, diagnostic tests, referral to lung cancer specialists, time of diagnosis, and treatment initiation, using REDCap for data collection. This approach facilitated a broad spectrum of data collection, including demographics, medical history, specific treatment experiences, and importantly, pre-diagnostic timelines.

Results: As of February 2024, our cohort of 1147 ALK-positive lung cancer patients had a midlife average diagnosis age of 51.9 years, predominantly female (62.9%) and primarily white (76.9%). A substantial number of individuals hold higher education degrees, with 88.4% having attended at least some college. The most common symptoms at diagnosis were cough (56.6%) and shortness of breath (40.1%), followed by general fatigue (30%) and back pain (19.2%). The distribution of cancer stages at diagnosis among patients is as follows: early-stage cancer (Stages I/II) is present in 7% of the cases, with 5.8% at Stage IIIA, 6.4% at Stage IIIB, and 2.4% at Stage IIIC. The majority of the cases are Stage IV, accounting for 70.7%. The diagnostic and treatment timeline showed that from the first visit to the initial test (e.g., chest X-ray), the median time was 17 days, with an interquartile range (IQR) from 0 to 85 days. To see a lung specialist after the first visit, the median time was 31 days, with the IQR spanning 7 to 91 days. The median duration from the first visit to a lung cancer diagnosis was 41 days, with the IQR ranging between 13 and 120.25 days. For patients diagnosed at stage IIC or higher, the median initiation time starting TKI therapy post-diagnosis was 29 days, with an IQR of 16 to 75.9 days.These statistics, based on the largest ALK-positive real-world evidence dataset highlights the variability in patient journey times from initial symptoms to the commencement of TKI treatment.

Conclusions: The creation of a large global registry for ALK-positive lung cancer has allowed us to establish benchmarks for patient journeys from symptom onset to TKI treatment initiation. Utilizing these insights, our objective is to pinpoint critical intervention points to hone strategies that accelerate diagnosis and the delivery of personalized treatments. This ALK Life Study is providing longitudinal data that can enable crucial advances in patient care efficiency and improved clinical outcomes.

Introduction: The current standard of care for limited-stage small cell lung cancer (LS-SCLC) is thoracic radiotherapy with concurrent platinum/etoposide chemotherapy. While most patients respond initially, relapse is common within months after treatment, indicating the need for additional therapies. Tarlatamab is a bispecific T-cell engager (BiTE®) immunotherapy that binds delta-like ligand 3 on the surface of SCLC cells and CD3 on T cells, facilitating T-cell-mediated cancer cell lysis. In phase 1 and phase 2 studies, tarlatamab demonstrated promising antitumor activity with a manageable safety profile in patients with previously treated SCLC. The DeLLphi-306 trial (NCT06117774) will compare the efficacy of tarlatamab versus placebo in patients with LS-SCLC who have not progressed following concurrent chemoradiotherapy.

Methods: DeLLphi-306 is a global, randomized, double-blinded, placebo-controlled phase 3 trial enrolling patients ≥ 18 years of age with histologically or cytologically confirmed SCLC and a diagnosis of LS-SCLC. Patients should have completed 3-4 cycles of platinum-based chemotherapy and concurrent radiation therapy, without progression per RECIST 1.1. Key exclusion criteria include a diagnosis of extensive-stage SCLC, non-small cell lung cancer that has transformed to SCLC, evidence of interstitial lung disease or active, non-infectious pneumonitis, and receipt of sequential (nonoverlapping) chemotherapy and thoracic radiotherapy during chemoradiation. Eligible subjects will undergo 1:1 randomization and receive either tarlatamab, 10 mg Q2W, (N ~ 200) or placebo (N ~ 200) until disease progression, unacceptable toxicity, withdrawal of consent, death, or for a maximum of 12 months (whichever occurs first). Randomization will be stratified by receipt of prophylactic cranial irradiation, disease stage, and the number of cycles of chemotherapy prior to enrollment. The primary endpoint is progression-free survival (PFS) by blinded independent central review (BICR) per RECIST 1.1. The key secondary endpoint is overall survival. Other secondary endpoints include investigator-assessed PFS, investigator and BICR-assessed objective response rate, disease control rate, duration of response, time to progression (all per RECIST 1.1), incidence of treatment-emergent and treatment-related adverse events, serum concentrations of tarlatamab, and incidence of anti-tarlatamab antibody formation. This trial is actively recruiting patients.

P1.13A.02 Tarlatamab Plus Durvalumab as First-Line Maintenance in Extensive-Stage Small Cell Lung Cancer: DeLLphi-305 Phase 3 Trial

M. Perol[1], M-J. Ahn[2], Y. Cheng[3], J. Clarke[4], A-M. Dingemans[5], C. Gay[6], A. Navarro[7], M. Schuler[8], T. Yoshida[9], P. Martinez[10], E.S. Anderson[10], J. Sands[11], [1]Centre Léon Bérard, Lyon/FR ,[2]Sungkyunkwan University School of Medicine, Seoul/KR ,[3]Jilin Cancer Hospital, Changchun/CN ,[4]Duke Clinical Research Institute, Durham/NC/USA ,[5]Erasmus Medical Centre, Rotterdam/NL ,[6]University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[7]Hospital Clinic de Barcelona, Barcelona/ES ,[8]West German Cancer Center, University Hospital Essen, Essen/DE ,[9]National Cancer Center Hospital, Tokyo/JP ,[10]Amgen Inc., Thousand Oaks/CA/USA ,[11]Dana–Farber Cancer Institute, Harvard Medical School, Boston/MA/USA

Introduction: The current standard of care for first-line (1L) therapy for patients with extensive-stage small cell lung cancer (ES-SCLC) is induction with platinum-etoposide (EP) and a PD-L1 inhibitor, such as durvalumab or atezolizumab, followed by maintenance with a PD-L1 inhibitor. In the phase 3 CASPIAN trial, patients with treatment-naïve ES-SCLC were treated with EP plus durvalumab followed by durvalumab maintenance, resulting in a median overall survival (OS) of 12.9 months which was 2.4 months longer compared to EP alone (ESMO Open 2022;7:100408). Despite an improved OS, long-term survival remains poor with a 3-year OS rate of 17.6% in the CASPIAN trial (ESMO Open 2022;7:100408). There remains a need for additional therapies that can delay disease progression and further improve OS. Tarlatamab is a bispecific T-cell engager (BiTE®) immunotherapy that binds delta-like ligand 3 (DLL3) on the surface of SCLC cells and CD3 on T cells, facilitating T-cell-mediated cancer cell lysis. DLL3 expression is detectable by immunohistochemistry in ~85-96% of patients with SCLC. In the phase 2 DeLLphi-301 study, tarlatamab demonstrated durable objective responses with promising survival outcomes and a manageable safety profile in patients with previously treated SCLC (NEJM 2023;389:2063).

Methods: DeLLphi-305 (NCT06211036) is a randomized (1:1), global, open-label, phase 3 study examining tarlatamab (10 mg, Q2W) in combination with durvalumab versus durvalumab alone as maintenance following 1L treatment (EP with durvalumab) in approximately 550 planned patients with ES-SCLC. Key patient inclusion criteria are patients ≥ 18 years of age, histologically or cytologically confirmed ES-SCLC, completion of 3-4 cycles of 1L treatment prior to enrollment without disease progression, Eastern Cooperative Oncology Group performance status ≤ 1, and a minimum life expectancy > 12 weeks. Patients with treated brain metastases are eligible as per protocol. Key exclusion criteria are prior DLL3 pathway-selective inhibitor therapy, active or documented autoimmune or inflammatory disorders per protocol, known human immunodeficiency virus, hepatitis C and/or hepatitis B infections with exceptions according to the protocol, and a history of severe/life-threatening events from immune-mediated therapy. The primary endpoint is OS and key secondary endpoints include progression-free survival, objective response rate, disease control rate, duration of response, safety, and quality of life assessments.

P1.13A.03 MOZART: Phase II Trial of Monalizumab, Durvalumab, and Platinum-based Chemotherapy for First-Line Treatment of Extensive Stage SCLC

H. Mamdani[1], S. Kim[1], R. Gentzler[2], M. Furqan[3], M.D. Shields[4], S.I. Jalal[4], [1]Barbara Ann Karmanos Cancer Institute, Wayne State University, Detroit/MI/USA ,[2]University of Virginia, Charlottesville/VA/USA ,[3]University of Iowa, Iowa City/IA/USA ,[4]Indiana University, Indianapolis/IN/USA

Introduction: Platinum-based chemotherapy in combination with PD-L1 inhibitor is the standard of care first-line treatment for extensive stage small cell lung cancer (SCLC) yielding median overall survival (OS) of slightly over a year. NKG2A/CD94 is an immune checkpoint that is selectively expressed on natural killer (NK) cells and CD8+ T cells in the tumor microenvironment. When engaging with its ligand, HLA-E, NKG2A transduces inhibitory signals that suppress immune-mediated cytotoxicity. Thus, NKG2A blockade enhances anti-tumor immunity by promoting both, NK and CD8+ T cell, effector functions. Monalizumab is a monoclonal antibody targeting NKG2A that enhances NK cell activity against tumor cells and rescues CD8+ T cell function in combination with PD-(L)1 axis blockade. Pre-clinical data have demonstrated that the absence of NK cells substantially enhances metastatic dissemination of SCLC tumor cells in vivo. NK cell function is modulated in response to DNA damage induced by platinum. Post-chemotherapy NK cells display higher expression of NKG2A and is associated with a reduced NK cell mediated anti-tumor activity. Hyperactivation of NK cell activity ameliorates SCLC metastases, an effect that is enhanced when combined with anti PD-1 therapy. Altogether, these data suggest that addition of monalizumab to standard of care first-line treatment may be associated with improved efficacy in patients with SCLC.

Methods: Patients with extensive-stage SCLC with ECOG performance status of 0-2 and adequate organ function are eligible for enrollment on this single-arm phase II study with an initial safety lead-in cohort of 6 patients. Patients may have received one prior cycle of platinum doublet with or without durvalumab and may have treated or untreated asymptomatic brain metastasis. Patients will receive platinum (cis or carbo), etoposide, durvalumab, and monalizumab every 3 weeks for 4 cycles followed by durvalumab and monalizumab every 4 weeks until disease progression or unacceptable toxicity. Primary endpoints include 1-year progression-free survival, safety, and tolerability. Secondary endpoints include objective response rate, 1-year overall survival, and intracranial progression-free survival. Exploratory objectives include analyzing association of treatment efficacy with minimal residual disease status, blood- and tissue-based genomic and transcriptomic signatures, tumor infiltrating immune cells, and peripheral blood NK cell and CD8+ T cell activity. The study has completed safety lead-in phase.

P1.13A.05 Preliminary Results of A Phase II Study of Camrelizumab Combined with Chemotherapy Followed by Concurrent Chemoradiotherapy for LD-SCLC

M. Hu, Y. Zhu, J. Kang, Y. Chen, X. Xu, Q. Xu, J. Ni, Y. Xu, Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Immune checkpoint inhibitors combined with chemotherapy have significant clinical benefits in extensive-stage small cell lung cancer (SCLC). However, for patients with limited-disease SCLC (LD-SCLC), the data on immunotherapy combined with chemoradiotherapy is insufficient.

Methods: In this open-label, multi-center, phase 2 trial, we randomly 1:1 assigned patients with previously untreated LD-SCLC to receive camrelizumab combined with chemotherapy followed by concurrent chemoradiotherapy (CCRT) and camrelizumab consolidation therapy or standard chemoradiotherapy. Patients with ECOG performance status of 0 to 1, and adequate organ function were eligible. For thoracic radiation, 45 Gy in 3 weeks (1.5 Gy, BID) was given on the first day of the third cycle of chemotherapy. An etoposide plus platinum-based regimen was given 4 cycles in total. Patients who had a good response to initial treatment were offered prophylactic cranial irradiation. The primary endpoint was the 1-year progression-free survival rate. We assumed that the 1-year PFS rate in the experimental group was expected to reach 65% compared to chemoradiotherapy alone group 45%, and planned to enroll 112 patients with 56 in each group.

Results: Up to date, we have enrolled 40 patients. The median follow-up was 10.6 months. Safety was evaluated in all treated patients (Table 1). No Grade 5 adverse event was observed. Grade 3 or 4 treatment-related adverse events occurred in 58.8% of the patients in the camrelizumab plus chemoradiotherapy and in 52.9% of those in the chemoradiotherapy alone group. The most frequent grade 3 or 4 adverse events were hematologic toxicities (70.6% vs. 58.8%). Acute esophagitis and pneumonitis of grade 3 occurred in both groups were 1/17 (5.9%) and 1/17 (5.9%), respectively. In the experimental group, only one patient was developed grade 3 immune pneumonia 1/17 (5.9%). The 1-year PFS rate was 54.5% (95% confidence interval [CI] 19.5%-89.6%) with camrelizumab plus chemoradiotherapy and 44.4% (95% CI 3.9%-88.0%) with chemoradiotherapy alone. Among the 17 patients who received camrelizumab, the median PFS time was not reached, as compared with 14.35 (95% CI, 8.15-20.91) months among the 17 patients with chemoradiotherapy alone.

Conclusions: In patients with LD-SCLC, the addition of camrelizumab to chemoradiotherapy did not increase the incidence of adverse events. Camrelizumab plus chemoradiotherapy resulted in an encouraging 1-year PFS rate. Larger sample sizes and longer follow-up times are required to validate our preliminary results. P1.13A.06 Outcomes in LS SCLC Patients with Severe Acute Esophagitis During Chemotherapy and Concurrent Twice-Daily Thoracic Radiotherapy

M. Grønberg[1,2,3], T.O. Halvorsen[2,3], B.H. Grønberg[2,3], K.T. Killingberg[2,3], M. Aanerud[1,4], [1]University of Bergen, Bergen/NO ,[2]Norwegian University of Science and Technology, Trondheim/NO ,[3]St. Olavs hospital, Trondheim University Hospital, Trondheim/NO ,[4]Haukeland University Hospital, Bergen/NO

Introduction: Concurrent platinum/etoposide-chemotherapy and thoracic radiotherapy (TRT) is standard treatment of limited-stage (LS) small-cell lung cancer (SCLC). Twice-daily (BID) TRT is recommended but poorly implemented. 2/3 of patients relapse after chemoradiotherapy and it has been hypothesized that higher TRT-doses improve survival. Radiation induced esophagitis, typically presenting with chest pain and dysphagia after 2-3 weeks of TRT, is the most common radiotoxicity and considered main radiotherapy-dose-limiting toxicity, and major reason for poor implementation of BID TRT. It is, however, not known whether patients who experience severe esophagitis have worse treatment outcomes. We analyzed participants in our randomized phase II trial showing that BID TRT of 60 Gy/40 fractions significantly improved survival compared with the standard 45 Gy/30 fraction schedule (median OS 43.6 vs. 22.6 months; p=0.036) (n=170, NCT02041845) to investigate whether severe esophagitis was associated with more long-term sequelae or inferior PFS or OS.

Methods: Patients with untreated LS SCLC, ECOG PS 0-2, and measurable disease (RECIST 1.1) received four platinum/etoposide-courses and were randomized to receive BID TRT of 45 or 60 Gy. TRT target volumes were restricted to PET/CT positive lesions and modern radiotherapy- techniques (IMRT/VMAT) were allowed. Toxicity was assessed according to CTCAE v4.0. Patients were categorized as experiencing no (CTCAE-grade 0), mild (CTCAE-grade 1-2), or severe acute esophagitis (CTCAE-grade 3-4). Patients reported dysphagia on the EORTC QLQ-C30, a difference in mean scores of ≥10 points was defined as clinically relevant.

Results: 166 patients who commenced TRT were analyzed. Baseline characteristics, treatment, patient reports, long term sequelae and progression free-/overall survival data are listed in Table 1. More patients with severe esophagitis had stage III disease and weight-loss before inclusion. Other baseline characteristics and study-treatment completion rates were similar across esophagitis-categories. All patients had significant increase in dysphagia from baseline until TRT ended. None experienced grade 4-5 esophagitis. Patients with severe esophagitis reported slightly higher maximum and slightly higher mean scores the first 2 years, but proportions needing esophageal stent (3.2% vs. 0-1.4%; p=0.137) or having physician-reported long-term dysphagia (12.9% vs. 4.5-5.8%; p=0.29) were not significantly different. There were no significant differences in PFS (p=0.77) or OS (p=0.88) across esophagitis-groups, nor in multivariable analysis adjusting for sex/PS/disease stage/TRT-schedule (PFS: p=0.713, OS: p=0.882).

Conclusions: Using modern TRT-approaches, severe acute esophagitis was not associated with more long-term sequelae or worse treatment outcomes, indicating that concerns about such toxicity should not prevent LS SCLC patients from receiving BID TRT of 45-60 Gy.

Introduction: The phase III ASTRUM-005 study (NCT04063163) has demonstrated promising antitumor efficacy and well tolerability of first-line serplulimab combined with chemotherapy in patients with extensive-stage small cell lung cancer (ES-SCLC). However, due to the strict eligibility criteria of randomized controlled trials, the practical data of patients with more complex or specific diseases in the real world were lacking. To bridge this knowledge gap, we herein present a 2-year interim analysis drawn from the multicenter, real-world study ASTRUM-005R. This study aims to investigate and supplement the real-world efficacy and safety data of first-line immunochemotherapy regimens incorporating serplulimab with chemotherapy, specifically focusing on ES-SCLC patients in China.

Methods: This cohort study enrolled adult patients with ES-SCLC at 14 institutions in China from April 2022 to April 2024. These patients received at least two cycles of first-line serplulimab combined with chemotherapy and underwent at least one response assessment. The primary endpoint was the investigator-assessed real-world progression-free survival (rwPFS) according to RECIST version 1.1. Secondary endpoints included overall survival (OS), objective response rate (ORR), and safety profiles refer to CTCAE version 5.0.

Results: A total of 538 patients were enrolled and evaluated for both efficacy and safety. The participants had a median age of 63 years (range 57.00-68.75), with 467 (86.80%) being male and 406 (75.46%) having a history of smoking. Most patients (491, 91.26%) had an ECOG PS of 0 or 1. Comorbidities, excluding other primary tumors, were present in 44.05% (237 patients). Liver and brain metastases were observed in 33.09% (n=178) and 21.56% (n=116), respectively. The median number of immunochemotherapy cycles was 4 (range 4-6), with 41.26% (n=222) receiving more than four cycles. The median rwPFS was 9.1 months (95% CI 8.1-9.7), with a 1-year rwPFS rate of 34.6%, surpassing the 1-year PFS rate of 28.2% reported for the Asian in the ASTRUM-005 study. Besides, the 2-year rwPFS rate was shown to be 11.3%. The median rwPFS was 9.7 months (95% CI 8.8-12.8) in patients without liver metastasis, significantly longer than the 7.4 months (95% CI 6.2-8.9) in patients with liver metastasis (P < 0.0001). Patients who received >4 cycles of immunochemotherapy had a median rwPFS of 10.5 months (95% CI 9.3-13.3), which was significantly longer than the 6.7 months (95% CI 6.3-9.1) in patients who received ≤4 cycles (P < 0.0001). Patients without brain metastasis had longer PFS than patients with brain metastasis (9.6 [95% CI 8.9-10.8] vs. 7.3 [95% CI 6.3-8.6] months, p = 0.079), but the difference was not statistically significant. The OS was not yet mature, and the ORR was 71.29%. The occurrence frequency of adverse event of special interest (AESI) was 38.85% (421 events), in which grade ≥3 AESIs occupied 15.43%.

Conclusions: This cohort study reports the real-world survival outcomes of first-line serplulimab-containing immunochemotherapy regimen in patients with ES-SCLC, offering additional empirical evidence to substantiate the therapeutic value of such combinations while complementing the pivotal data to the ASTRUM-005 clinical trial.

P1.13A.08 Biomarker Analysis of Camrelizumab Plus Nab-paclitaxel and Carboplatin as First-Line Treatment for Extensive-Stage Small-Cell Lung Cancer

J. Yu[1], C. Zhou[1], L. Wang[1], T. Jiang[1], A. Xiong[1], J. Yuan[2], W. Shi[2], S. Ren[1], [1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]Hengrui Companey, SHANGHAI/CN

Introduction: This trial aimed to evaluate the efficacy, safety and predictive biomarkers of camrelizumab plus nab-paclitaxel and carboplatin as first-line treatment for extensive-stage small-cell lung cancer (ES-SCLC).

Methods: Camrelizumab plus nab-paclitaxel and carboplatin were administrated every three weeks for up to six cycles, followed by maintenance therapy with camrelizumab until disease progression or intolerable toxicity. The primary endpoint was 6-month progression-free survival (PFS) rate. Secondary endpoints included PFS, overall survival (OS), objective response rate (ORR), disease control rate (DCR) and safety. Integrated analysis of whole-exome and transcriptomic sequencing data were conducted.

Results: 60 patients were enrolled. Primary endpoint was met with 6-month PFS rate of 52.2%. The median PFS and OS was 7.1 and 18.1 months, respectively. The confirmed ORR was 73.3% and DCR was 93.3%. No unexpected adverse events were observed. Biomarker analysis showed that patients with MUC17 alterations or high NEUROG1 expression were associated with significantly shorter PFS and OS. Deeper investigation of transcriptomic data uncovers two subsets with distinct immune features and therapeutic vulnerabilities.

Conclusions: This study showed that camrelizumab plus nab-paclitaxel and carboplatin might be an alternative option of first-line regimens for ES-SCLC. MUC17 alterations or NEUROG1 expression would serve as potential biomarker for this combination.

P1.13A.09 RYZ101 (225Ac-DOTATATE) + Carboplatin + Etoposide + Atezolizumab in Somatostatin Receptor Expressing Extensive-Stage Small-Cell Lung Cancer

S. Puri[1], W. Akerley[1], R. Langdon[2], S. Mehr[2], N. Rivera-Rodriguez[3], J. Berilgen[4], J.M. Rineer[5], C. Mulvey[6], K. Howell[7], A.S. Mansfield[8], E. Parent[9], M. Thakur[10], B. Mancini[11], J. Goldman[12], J. Calais[12], D. Bushnell[13], Y. Yuan[14], J. Li[14], N. Pascale[14], L. Gong[14], D. Ferreira[14], Z. Hao[15], [1]Huntsman Cancer Center, Salt Lake City/UT/USA ,[2]Nebraska Cancer Specialists, Omaha/NE/USA ,[3]PanOncology Trials, San Juan/PR ,[4]Millenium Physicians, Cleveland/TX/USA ,[5]Orlando Health Cancer Center, Orlando/FL/USA ,[6]University of California, San Francisco/CA/USA ,[7]Michigan Health Professionals, Troy/MI/USA ,[8]Mayo Clinic, Rochester/MN/USA ,[9]Mayo Clinic, Jacksonville/FL/USA ,[10]Corewell Health, Grand Rapids/MI/USA ,[11]BAMF Health, Grand Rapids/MI/USA ,[12]University of California, Los Angeles/CA/USA ,[13]University of Iowa, Iowa City/IA/USA ,[14]RayzeBio, San Diego/CA/USA ,[15]Markey Cancer Center, Lexington/KY/USA

Introduction: RYZ101 is a first-in-class, alpha-emitting radiopharmaceutical in development for somatostatin receptor expressing (SSTR2+) solid tumors. Alpha particles (emitted by 225Ac) have a higher linear energy transfer (80-100 keV/µm) and shorter path length (40-100 µm) than beta particles, potentially allowing for improved cancer cell kill rates while limiting off-tumor toxicity. Here we describe preliminary safety data from a single-arm, open-label, phase 1b dose-escalation and dose-expansion trial of RYZ101 in combination with standard of care (SoC) therapy in patients with treatment-naïve SSTR+ extensive-stage small-cell lung cancer (ES-SCLC; NCT05595460).

Methods: Adult patients with histologically/cytologically confirmed SSTR+ ES-SCLC, ECOG PS 0-1, life expectancy ≥12w, and sufficient renal, hepatic, and hematologic function are eligible. Patients are required to have ≥1 SSTR PET imaging-positive RECIST v1.1-measurable disease; ≥50% of measurable lesions must be SSTR2+. Patients may receive up to 1 cycle of SoC before/during screening. Patients with brain metastases are permitted but must be asymptomatic, adequately treated, and on stable/decreasing steroid doses. During dose-escalation, patients receive RYZ101 (IV q6w then q4w) starting at dose level 1 (DL1) of 6.5 MBq with escalation to 8.3 MBq (DL2) and 10.2 MBq (DL3) in the absence of any dose-limiting toxicities (DLTs). Patients also receive SoC: atezolizumab (Tecentriq®, 1200 mg IV d1 q21d, max 4×21-d cycles, then 1680 mg IV q28d); carboplatin (AUC 5-6 IV 60m d1 q21d, max 4×21-d cycles); etoposide (80-100 mg/mm2 IV 60m d1-3 q21d, max 4×21-d cycles). Primary endpoints: safety, maximum tolerated dose/recommended phase 2 dose. Secondary endpoints: efficacy, pharmacokinetics.

Results: As of 17 January 2024, 10 patients were screened and 4 were treated with RYZ101 at 6.5 MBq. Screen failure in all but 1 patient was due to not meeting criteria for SSTR2 PET positivity. Median age was 63y (range 49-79), 50% were female and had ECOG PS 0, all were former smokers with median 30 pack-yrs (range 9-42). All patients received 1 cycle of SoC before/during screening; median duration of treatment and number of RYZ101 doses was 2.6m (range 1.4-4.7m) and 1.5 (range 1-3). Of the 4 patients in DL1, 3 completed the DLT period (42d following first RYZ101 dose). There were no DLTs reported nor any G≥3 AEs related to RYZ101. AEs related to RYZ101 include G1 decreased appetite, G2 dehydration, G1 diarrhea, G1 fatigue, G2 influenza-like illness, G2 nausea, G2 neutrophil count decrease, and G1 vomiting. All SAEs were unrelated to RYZ101 and included pain (n=1), back pain (n=1), hyponatremia (n=1), and syncope (n=1). One patient had G4 neutropenia related to SoC following the 1st cycle of RYZ101, requiring RYZ101 dose reduction, which recovered with supportive care. Preliminary pharmacokinetic findings indicate clearance and half-life comparable to previous studies of RYZ101 and 177Lu-DOTATATE.

Conclusions: There were no DLTs reported at DL1 (6.5 MBq) and the dose of RYZ101 has been escalated to the next dose level. The study is actively enrolling patients to receive RYZ101 at DL2 (8.3 MBq) and additional safety data will be presented once mature.

P1.13A.10 Efficacy and Safety of Lurbinectedin for Small Cell Lung Cancer in a Real-World Setting: Jazz EMERGE 402 Study

B. Halmos[1], P. Lammers[2], G. Liu[3], L. Shunyakov[4], S. Madden[5], S. Kassam[6], M. Patel[7], Y. Ji[8], C. Labbé[9], N. Naveh[10], C. Ndibmun[10], W. Li[10], B. Rengarajan[10], F. Badin[11], [1]Albert Einstein College of Medicine, Bronx/NY/USA ,[2]Baptist Cancer Center, Memphis/TN/USA ,[3]Princess Margaret Cancer Centre, Toronto/ON/CA ,[4]Carrie J. Babb Cancer Center, Bolivar/MO/USA ,[5]Lexington Medical Center, West Columbia/SC/USA ,[6]Southlake Regional Health Centre, Newmarket/ON/CA ,[7]Rochester Regional Health, Rochester/NY/USA ,[8]HealthPartners Cancer Center at Regions Hospital, Saint Paul/MN/USA ,[9]Centre de Recherche de l'Institut Universitaire de Cardiologie et de Pneumologie de Québec – Université Laval, Québec/QC/CA ,[10]Jazz Pharmaceuticals, Philadelphia/PA/USA ,[11]Baptist Health Medical Group, Lexington/KY/USA

Introduction: Lurbinectedin monotherapy is approved in many countries, including the United States (US) and Canada for adults with metastatic (US) or stage 3/metastatic (Canada) small cell lung cancer (SCLC) with disease progression on or after platinum-based chemotherapy. The Jazz EMERGE 402 phase 4 trial is assessing the real-world efficacy and safety of lurbinectedin for patients with extensive stage (ES)-SCLC. Preliminary safety data from this study were previously presented. For the first time, we report efficacy results along with updated safety data.

Methods: This observational, multicenter, single-arm study (NCT04894591) is enrolling patients with ESSCLC according to local approved labels, in the US and Canada.

Results: As of 02Jan2024, 171 patients had received ≥1 cycle of lurbinectedin; 13 (8%) had ongoing treatment and 158 (92%) discontinued with disease progression being the most common reason (n=104 [66%]). The median (range) age was 67 (29-89) years; 37 (22%) patients had an Eastern Cooperative Oncology Group performance status (ECOG PS) of ≥2; and 35 (20%) had central nervous system (CNS) involvement. Baseline characteristics were broadly similar between patients with a chemotherapy free interval (CTFI)<90 days vs ≥90 days. Ninety-two (54%) patients received lurbinectedin monotherapy as second-line (2L) and 59 (35%) as third-line. Median (range) number of lurbinectedin cycles was 4 (1-31) and duration of exposure was 105 (21-694) days. The objective response rate (ORR) in patients assessed by Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 in 2L was 26.1% in the overall population; whereas ORR in 2L was 22.7% and 32.4%, respectively, in patients with CTFI <90 or CTFI ≥90 days (Table 1). Median progression-free survival (mPFS) and overall survival (mOS) in 2L were 3.5 and 7.6 months, respectively, in the overall population; whereas mPFS and mOS in 2L were 4.0 and 11.9 months for patients with CTFI ≥90 days. Similar ORR and mPFS were seen between RECIST and RECIST/non-RECIST evaluated patients. Treatment-related adverse events (AEs) occurred in 64 (37%) patients; AEs of special interest included grade ≥3 anemia (4.1%), neutropenia (6.5%), and thrombocytopenia (5.9%).

Conclusions: Jazz EMERGE 402 has enrolled a broader and sicker SCLC patient population than the phase 2 basket trial leading to lurbinectedin's approval. Patients with CTFI <90 or ≥90 days receiving lurbinectedin in 2L showed higher ORR, mPFS, and mOS than in later lines, and showed comparable mOS and mPFS as the basket trial. The real-world safety profile of lurbinectedin echoed previous reports, with no new safety signals.

Introduction: The IMpower133 clinical trial showed that addition of atezolizumab to carboplatin + etoposide improved overall survival and progression-free survival in patients with extensive-stage small cell lung cancer (ES-SCLC). Despite this milestone in the management of ES-SCLC, most patients eventually experience progressive disease (PD). The understanding of how these tumours metastasize to specific organs in the era of immunotherapy is limited. Here, we carried out an exploratory analysis to delineate disease progression patterns in patients from the IMfirst study (EudraCT: 2019-002784-10), which includes a population that more closely resembles that of the real-world clinical practice in Spain.

Methods: The first reported PD and its corresponding site of progression, assessed by investigators according to Response Evaluation Criteria in Solid Tumours Version 1.1 (RECIST v1.1), was evaluated in the ITT population, as well as in patients with long-term benefit (LTB) or No-LTB. Patients were defined as LTB if they survived for at least 24 months post-randomization or No-LTB if they died within this time period. Percentages of PD are based on the total number of distinct sites (either new or existing). If a patient had multiple lesions at the same site, the site was counted only once.

Results: In total, 155 patients were enrolled in IMfirst study. Median follow-up was 28.4 months (data cut off: 14 December 2022). Of the 118 patients with PD, 115 had detailed reports of sites of progression and were included in the analysis: 85 (73.9%) had PD in existing lesions and 68 (59.1%) in new lesions. The most common sites of existing lesions (≥10% of patients) were lung, lymph nodes, liver, adrenal gland, bone and mediastinum, whereas the most frequent sites of new lesions were brain, liver, lung and lymph nodes. Of the 115 patients with PD included in the analysis, 14 were classified as LTB and 99, as No-LTB (2 patients with PD were censored before 24 months and were excluded from the analysis). PD in existing lesions was observed in 7 (50%) LTB and 77 (77.8%) No-LTB patients, while PD in new lesions was observed in 9 (64.3%) LTB and 57 (57.6%) No-LTB patients. The most common new or existing sites of progression (≥10% of patients) were similar between LTB and No-LTB patients. Regarding the distribution of PD sites, total new or existing lesions were restricted to 6 sites (lung, brain, lymph node, pleura, adrenal gland and liver) in LTB patients, while in No-LTB patients, progression was observed across a wider range of sites.

Conclusions: In this exploratory analysis from IMfirst, patterns of progression are in line with the results reported for IMpower133. These results suggest that No-LTB patients are more likely to experience PD in existing lesions and show a wider range of sites of progression compared to LTB patients. Given the limited sample size, these results should be further validated.

P1.13A.12 Exposure-Response Analyses to Support Ph3 Dose Selection for I-Dxd (Ifinatamab Deruxtecan) in Extensive Stage SCLC Patients

N.M. Midde[1], S. Hennig[2], B.P. Tran[1], M. Qian[1], M. Tang[1], J. Singh[1], S.S. Vaidya[1], Y. Lau[1], [1]Daiichi Sankyo, Inc., Basking Ridge/NJ/USA ,[2]Certara, Inc., Princeton/NJ/USA

Introduction: I-DXd (DS-7300), showed promising efficacy at ≥6.4 mg/kg in heavily pretreated extensive stage small cell lung cancer (ES-SCLC) patients in the ongoing Phase 1/2 study (IDeate-PT01, NCT04145622). Here, we report the exposure response (ER) analysis of I-DXd for safety and efficacy to support dose selection for Phase 3 development in ES-SCLC.

Methods: Interim data from ES-SCLC patients receiving I-DXd (8 or 12 mg/kg IV Q3W) in the dose optimization part of Phase 2 study (IDeate-L01, NCT05280470) and from patients with advanced solid tumors receiving I-DXd (0.8 to 16 mg/kg IV Q3W) in IDeate-PT01 were included in the analysis. Individual exposures for I-DXd and DXd (released payload) were derived based on a developed population pharmacokinetic (PK) model based on the same patients PK data. All patients were included in the exposure-safety (ES) analysis. Only ES-SCLC subjects were considered for exposure-efficacy (EE) analysis. ER analyses were conducted with selected efficacy and safety endpoints that have observed event rates >10% (8 out of 19 prespecified treatment emergent adverse events; TEAEs). Effects of other variables than exposure on the event probability were also evaluated. Modelling was performed using logistics regression analysis for binary endpoints.

Results: As of 25th July 2023, 256 patients were included in the ES analysis. ES analyses identified significant relationships between increased I-DXd exposure (C1 AUC) and any grade gastrointestinal (GI) disorders, and between DXd exposure (C1 or steady state AUC) and any grade and grade ≥3 anemia, any serious adverse event (SAE) and drug interruption. Positive ES relationships were also identified between DXd maximum concentration (C1 Cmax) and any adverse event (AE) grade ≥3 and any grade neutropenia. Geographical region, age, ECOG score, and cancer type were associated with some safety endpoint probability, but further evaluation is needed as the data become mature from these studies. Model projected median event rates at doses of interest, 8 mg/kg and 12 mg/kg were 60.6% and 74.8% for any grade GI disorders, 36.8% and 46.2% for any AE grade ≥3, 26.1% and 39.5% for any SAE, respectively. Difference between projected median event rates was <10% for all other safety endpoints. A total of 110 ES-SCLC patients were included in the EE analysis. EE analysis demonstrated significant relationships between all I-DXd exposure metrics and efficacy endpoints: objective response rate (ORR) and best tumor response. Model projected ORR median event rates at 8 mg/kg and 12 mg/kg were 30.7% and 51.7% respectively. Significant increase in tumor shrinkage is observed with increasing I-DXd exposure. Further EE analyses for progression free survival, duration of response, and overall survival are planned when data with longer follow-up are available. Overall, ER analyses predicted higher rates of efficacy with increasing I-DXd dose. However, frequency of TEAEs only marginally (<14%) increased, with both 8 mg/kg Q3W and 12 mg/kg Q3W showing manageable safety profiles.

Conclusions: Based on overall benefit-risk assessment and ER analyses, 12 mg/kg Q3W was selected as the recommended I-DXd dose for Phase 3 study (IDeate-L02; NCT06203210) and IDeate-L01 extension part for continued development in ES-SCLC.

Introduction: Treatment options are limited for patients with small-cell lung cancer (SCLC) whose disease has progressed on or after platinum-based chemotherapy. Therefore, there is an urgent need for evaluation of novel agents in this setting. Aurora kinase A (AURKA) is a key regulator of mitosis and AURKA expression is associated with worse prognosis in multiple solid tumor types. Alisertib is a highly selective, reversible, ATP-competitive, orally administered, small-molecule AURKA inhibitor under investigation for SCLC. Phase 1/2 clinical trials of alisertib as either monotherapy or in combination with paclitaxel for relapsed/refractory solid tumors (including SCLC) reported response rates of 21-22%. The most common treatment-related grade ≥3 AEs were neutropenia, febrile neutropenia, and leukopenia. Preclinically, greater alisertib sensitivity has been reported in models with high c-Myc expression and/or loss of RB1 function. In a clinical study of alisertib + paclitaxel vs placebo + paclitaxel in SCLC, c-Myc expression or mutations in RB1, RBL1, RBL2, or CDK6 showed strong correlation with an improvement in both PFS and OS in the alisertib arm.

Methods: ALISCA-Lung1 (PUMA-ALI-4201, NCT06095505) is a phase 2 study to determine whether there is a biomarker-defined population of patients with extensive-stage SCLC that derives increased benefit from alisertib monotherapy. The study design is shown in Figure 1. Key inclusion criteria are: ≥18 years of age; progression on or after first-line treatment with platinum-based chemotherapy + anti-PD-L1 immunotherapy; ≥1 measurable lesion per RECIST v1.1; availability of tissue sample for retrospective biomarker evaluation. Key exclusion criteria: prior treatment with AURKA-specific or pan-Aurora-targeted agents; active infection; immunocompromise; unstable brain metastases; inability/unwillingness to swallow tablets. Primary objective: to determine whether any biomarker(s) correlate with increased benefit with alisertib monotherapy. Biomarkers will be assessed by next-generation sequencing, mRNA expression analysis, and immunohistochemistry. Candidate biomarkers include, but are not limited to, RB1 alteration, c-Myc expression, TP53 mutation, AURKA expression, and SCLC molecular subtype. Secondary objectives: to determine investigator-assessed efficacy, survival, safety, and population pharmacokinetics. Eligible patients will receive alisertib 50 mg orally BID d1–7 q21d (including primary prophylaxis with G-CSF) until disease progression, unacceptable toxicity, or withdrawal of consent. All patients will undergo sparse pharmacokinetic sampling. Recruitment is underway and up to 60 patients will be enrolled at approximately 20 centers in the USA. Findings are anticipated to identify a biomarker-defined population that derives the greatest clinical benefit from alisertib. Future development of alisertib in SCLC is anticipated to focus on this biomarker-defined population.

Keywords: Alisertib, Small-cell lung cancer, Aurora kinase A inhibitor

P1.13B.01 Lurbinectedin vs. Platinum Rechallenge in Extensive Stage Small Cell Lung Cancer after Platinum Doublet, A Multicenter Retrospective Study

M. Libre[1], A. Barsouk[2], M. Lu[1], S. Lessans[1], O. Elghawy[2], C. Yu[3], K. Goel[3], J. Wu[1], S. Bhatia[1], A. Cass[1], M. Marmarelis[2], W. Iams[1], [1]Vanderbilt University Medical Center, Nashville/TN/USA ,[2]Abramson Cancer Center, Hospital of the University of Pennsylvania, Philadelphia/PA/USA ,[3]Perelman School of Medicine, Philadelphia/PA/USA

Introduction: Although small cell lung cancer (SCLC) patients typically have a rapid and deep initial response to platinum doublet chemotherapy, relapse can occur quickly. Despite multiple available therapeutic options for patients with progressive disease after first-line therapy, outcomes remain poor and limited evidence exists indicating a preferred second-line treatment approach. Here we present findings from a multicenter retrospective cohort study comparing platinum doublet rechallenge and lurbinectedin in a real-world setting.

Methods: Patient records were identified from Vanderbilt Ingram Cancer Center and the University of Pennsylvania between 2000 and 2023. Study cohorts included extensive-stage (ES) SCLC patients treated with second line lurbinectedin or platinum rechallenge following initial platinum-based chemotherapy. Primary outcomes included overall survival (OS) and real-world progression-free survival (rwPFS).

Results: A total of 81 patients were included, with 45 receiving platinum rechallenge and 36 receiving lurbinectedin. Cohorts were similar for sex, race, comorbidities, and performance status. The platinum rechallenge group skewed younger and had shorter chemotherapy-free interval (CFTI) compared to lurbinectedin (median age 63 [58, 68] vs. 67 [63, 75] p=0.006, and CTFI 2.51 [1.20, 3.59] vs. 9.40 [5.25, 19.34] p<0.001). First line therapy included immunotherapy in 14 (31%) of platinum rechallenge and 28 (78%) of lurbinectedin patients. In the unadjusted dataset comparing platinum rechallenge and lurbinectedin, median rwPFS was 4.56 (1.64, 6.33) and 2.42 (1.36, 3.92) months (p = 0.003) and median OS was 11.14 (4.99, 15.64) and 4.81 (2.62, 7.40) months (p = 0.003), respectively. In a multivariate Cox proportional hazard analysis, OS and rwPFS hazard ratios for lurbinectedin compared to platinum rechallenge were 1.98 (1.15-3.38, p=0.012) and 1.57 (0.93-2.66) (p = 0.094) after controlling for CTFI and concomitant maintenance immunotherapy. CTFI was not independently associated with rwPFS (HR 0.98 (0.97-1.00)) or OS (HR 0.99 (0.97-1.00)) when adjusting for other covariates. When platinum rechallenge vs. lurbinectedin was examined within pre-specified CTFI levels (< 3 months, 3-6 months, or > 6 months) there was no significant difference in OS or rwPFS outcomes between the two strategies. In a secondary analysis of 57 patients from one site (36 platinum rechallenge, 21 lurbinectedin), there was no statistically significant difference in hospitalizations, neutropenic fever (22% platinum rechallenge vs. 5% lurbinectedin, p=0.13), anemia, or transaminitis between groups, although 7 (29%) of platinum rechallenge patients discontinued due to tolerability compared to 0 (0%) with lurbinectedin.

Conclusions: When comparing patients with similar CTFI prior to start of second-line therapy for ES-SCLC (< 3 months, 3-6 months, and > 6 months), there was no significant difference in median OS or rwPFS between platinum rechallenge and lurbinectedin. Drug-related safety events (evaluated in patients from one study site) were similar, although tolerability led to greater discontinuation with platinum-based chemotherapy. These multicenter findings support further research efforts within specific CTFI groupings to identify optimal therapeutic strategies for each patient subgroup in second-line treatment of ES-SCLC.

P1.13B SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS - RELAPSED/REFRACTORY ES-SCLC
SUNDAY, SEPTEMBER 8, 2024 - 12:00 - 14:00

P1.13B.02 Radiation Necrosis in Small Cell Lung Cancer Patients

S. Sherman[1], D. Reinhorn[1], O. Rotem[1], O. Icht[1], D. Limon[1], S. Yust-Katz[1], M. Moskovitz[1], [1]Davidoff Cancer Center, Petah Tikva/IL

Introduction: Immunotherapy (IO) and new radiation therapy (RT) technics such as stereotactic radiosurgery (SRS), advanced the treatment of small cell lung cancer (SCLC) by improving quality of life and lengthening survival. However, attention should be paid to the treatment-related long-term secondary effects. Data from non-small cell lung cancer patients indicate a higher rate of radiation necrosis (RN) in patients treated with IO and cranial RT simultaneously. However, little is known regarding the prevalence of RN in SCLC patients treated with this combination.

Methods: This study focused on patients diagnosed with SCLC and treated in our medical center in the years 2019-2022.

Results: Out of 96 SCLC patients, 47 (49%) had brain metastasis, 34 (72.3%) of which received RT, with the majority (64.7%, n=22) receiving whole brain radiation therapy (WBRT) and the rest (35.3%, n=12) receiving SRS, with 20 patients (58.8%) treated with IO simultaneously or separately from RT. Surprisingly, patients treated with SRS had a shorter median survival of 100 days vs 140 days in the WBRT group. Eight out of 12 (66.6%) patients and 16 out of 22 (72.7%) patients in the SRS and WBRT groups, respectively, survived over 3 months, with only 4 (33.3%) and 8 (36.3%) patients surviving longer than 6 months, respectively. None of the patients was diagnosed with RN during the follow-up period, even with the combination of IO and RT.

Conclusions: These findings demonstrate that SRS is a safe treatment option in SCLC and does not increase the risk of RN, even in combination with IO, although a longer survival was observed in the WBRT cohort.

P2.04A.01 FIRSTLUNG (L301): Cluster Randomized Trial Evaluating the Clinical Utility of DELFI's Blood-Based Lung Cancer Screening Test

L. Cotton[1], C. Cisar[1], P. Bach[1], C. Sheridan[1], N. Trivedi[1], J. Davis[2], [1]Delfi Diagnostics, Baltimore/MD/USA ,[2]Duke University, Durham/NC/USA

Introduction: To optimize the impact of lung cancer screening at the healthcare system level, additional tools are needed to increase the benefits of screening. While low-dose computed tomography (LDCT) has been shown to improve lung cancer detection and reduce mortality, it is not without its risks, such as radiation exposure, false-positive results, and unnecessary interventions often leading to complications. The additional complexity of lung cancer screening is the subpar adherence to LDCT for eligible individuals, which undermines the benefits of screening. Therefore, there is a need for alternative non-invasive methodologies that exploit our understanding of the biology of cancer pathogenesis. This clinical utility study aims to observe how a non-invasive blood-based test impacts physician behavior and LDCT utilization.

Methods: FIRSTLUNG 301 (NCT06145750) is a prospective, cluster randomized controlled trial (RCT) to observe the impact of the DELFI Lung cancer screening test on lung cancer screening utilization in primary care practices. Enrolled practices must meet the eligibility criteria of having a minimum of 50 actively engaged individuals in the practice eligible for lung cancer screening per the 2021 USPSTF criteria. These practices will be randomized 1:1:2 to Arm A1 (control), Arm A2 (control), or Arm B (intervention). Arm A practices will be randomized 1:1 into two groups (A1:A2) to observe the standard of care for lung cancer screening. Practices in A1 will be observed; practices in A2 will receive standard education on lung cancer screening for CME credit. Randomizing within Arms A1 and A2 aims to delineate the impact standard lung cancer screening education may have on utilization. Arm B (intervention) practices will receive education and have access to order the blood-based test for screen-eligible individuals that remained unscreened. The primary study endpoint is the proportion of practice-identified lung cancer screen-eligible individuals receiving a screening CT order and scan during the study period in the entirety of Arm A (control) versus Arm B (intervention). This RCT aims to understand the utilization and impact on lung cancer screening uptake after the DELFI blood-based test intended to inform clinical guidelines and policies focused on improving patient care and health outcomes. Progress: Study initiation on October 31, 2023, with practice randomization. As of April 2024, the study is open for enrollment with 13 practices randomized. The primary study completion date is estimated at December 2025.

Keywords: blood-based test, lung cancer screening, low-dose computed tomography (LDCT)

P2.04A.02 Using an AI Transformer Model to Identify Incidental Pulmonary Nodules (IPN) For Lung Cancer Early Detection

R.L. Myers1, W. Parker2, C. Bartolomeu3, A. Mojibian4, H. Lam3, R. Hung5, S. Lam6

1BC Cancer, Vancouver/BC/CA ,2Vancouver Coastal Health, Vancouver/BC/CA ,3BC Cancer Research Institute, Vancouver, Vancouver/BC/CA ,4Sapien Secure, Vancouver/BC/CA ,5Lunenfeld- Tanenbaum Research Institute, Sinai Health, Toronto/ON/CA ,6BC Cancer, Vancouver, Vancouver/BC/CA

Introduction: Outside a lung screening program, most lung nodules are incidentally found on imaging studies completed for other diagnostic purposes. An estimated 4.8 million Americans have at least one chest CT scan, and 1.57 million have a nodule identified; among these, ~4% received a new lung cancer diagnosis within two years. Chest imaging is increasingly used for various indications, such as cardiac disease detection. The detection of incidental pulmonary nodules (IPNs) will steadily increase. Growing data demonstrates most of the patients with IPNs receive no clinical follow-up, thus missing the opportunity for early cancer diagnosis. Developing an accurate automated IPN identification tool is imperative to ensure appropriate follow-up and ultimately, improve early diagnosis and treatment of lung cancer to complement current lung cancer screening programs.

Methods: As part of the Identifying Early Lung Cancer in A Diverse Population (IDEAL), study, a multi-centre national trial, - the Vancouver study site, is utilizing the Medical Named Entity Recognition Model (NER)- SapienNER v3a, as a screening tool for identifying pulmonary nodules in reports of all lung-in-view CT scans that were done in the Greater Vancouver area. NER is a custom developed, RoBERTa-based transformer model tailored for interpreting unstructured medical reports. All lung-in-view CT imaging studies performed between November 2023 to March 2024 were identified using a list of inclusion and exclusion criteria, based on the specific lexicon of terms used to describe pulmonary nodules in CT reports. The scans were categorized by age ≥ 50 to 74 years, and nodules ≥6 mm. The reports were reviewed by the clinical staff to ensure the nodules were truly incidental.

Results: During a 5-month time period, a total of 14,154 lung-in-view scans were identified in the PACS system. 4363 scans were classified as having a pulmonary nodule, and 1436 of these scans had a nodule size ≥6 mm. Of those, 1072 scans occurred in individuals ages 50-74 yrs. Following clinical review, 131 scans were confirmed to have a truly incidental nodule ≥6mm. Scan type included 44% cardiac (51% with contrast), 45% chest (81% with contrast), 7% CT abdomen, and 3% Head and neck. The majority of scans that were removed from further follow-up were scans that were ordered specifically to track a nodule from a prior imaging study, or for surveillance of lung metastasis in patients with cancer. 74% of patients identified with IPN agreed to be followed-up.

Conclusions: Our study showed a Natural Language Processing (NLP) system can be easily deployed in a large healthcare organization, to reliably and efficiently identify patients with clinically significant IPNs. Our study also identified areas that need further improvement such as comparison with prior imaging studies and extraction of relevant medical history. Implementing a Large Language Model will address these issues and reduce clinician time investment to identify patients with IPN who require follow-up. Advancing our NLP system with LLM capabilities may be the crucial future step required for the complete automation and optimization of follow-up protocols to bolster early lung cancer detection and compliment screening programs.

P2.04A.03 Enhancing Participation in Flemish Lung Cancer Screening: Strategies for Engaging the Hard-To-Reach

C. Theuns1, G. Van Hal1, J. Van Meerbeeck2, J. De Lepeleire3, A. Snoeckx2

1University of Antwerp, Antwerp/BE ,2University of Antwerp / Antwerp University Hospital, Antwerp/BE ,3University of Leuven, Leuven/BE

Introduction: Lung cancer remains one of the most prevalent and deadly cancers worldwide, with late-stage diagnosis significantly contributing to poor prognosis and survival rates. While large randomized screening trials with Low-Dose Computed Tomography (LDCT) have demonstrated effectiveness in reducing lung cancer-specific mortality (NELSON/NLST), reaching and engaging populations at high risk, the “hard-to-reach”, remains challenging. The Council of the European Union, recognizing lung cancer screenings vital role in mortality reduction, recommended in 2022 to explore the feasibility and effectiveness of LDCT for high-risk individuals. This recommendation underscores the necessity to tackle the screening challenges and develop tailored strategies to ensure equity. While lung cancer screening offers significant benefits, it also faces a number of challenges, including stigma, how to address incidental findings, overdiagnosis, false-positive results, workload/capacity issues... One of the most important challenges is the difficulty in reaching and engaging hard-to-reach participants.

Methods: The ZORALCS-study aims to address these challenges through a comprehensive, multidisciplinary approach with a special focus on socioeconomic factors, health literacy, digital literacy and educational factors, involving a wide range of healthcare professionals from various sectors with emphasis on multidisciplinary collaborations (pharmacists, general practitioners, tabaccologists, nurses, occupational therapists, centre for general well-being, public centre for social welfare...). Our study explores and focuses on three key trajectories:

1. Education of healthcare providers and the public: our study emphasizes educating healthcare providers on lung cancer screenings’ benefits and risks, incorporating motivational techniques for active engagement. Addressing lung cancer stigma and providing comprehensive education materials for participants are also central, utilizing mediums like leaflets, radio, TV, and posters in public spaces.

2. Invitation strategy assessment: by examining psychological drivers influencing participation, we assess different invitation methods

to identify the most effective one. Evaluating and scoring these invitations by an external citizens' committee ensures that the most compelling one is utilized.

3. Developing effective recruiting strategies: leveraging the insights from invitation strategy research, we assess various recruiting strategies to identify the most effective for the Flanders region. From community outreach initiatives to leveraging digital platforms, we seek to identify and implement strategies that facilitate access to screening services for hard-to-reach populations.

In conclusion, our implementation study in Flanders highlights the critical need for specific strategies to overcome barriers and enhance participation in lung cancer screening among hard-to-reach populations. By addressing screening challenges and implementing research-backed interventions, our goal is to boost early detection rates and ultimately reduce lung cancer's impact in our community.

P2.04A.04 The Lung Health Check Pilot: Ireland's Flagship Lung Cancer Screening Trial

D.E. O Reilly1,2, S. Roche2, S. Toomey1, B. Hennessy1,2, G.J. Fitzmaurice3, K. Egan2, C. Dowling1, I. Counihan2, E. O Brien2, I. Sulaiman2, R. Morgan2, C. Noonan2, B. Jacob1, A-M. Baird3, S. Cotter4, K. Bennett1, J. Sorensen1, J. Ryan2, P. Redmond1, D.J. Ryan2, J. Naidoo1,2,5

1Royal College of Surgeons of Ireland, Dublin/IE ,2Beaumont RCSI Cancer Centre, Dublin/IE ,3Trinity St. James' Cancer Institute, Dublin/IE ,4Cancer Trials Ireland, Dublin/IE ,5Sidney Kimmel Comprehensive Cancer Centre, Johns Hopkins University, Baltimore/MD/USA

Introduction: The use of low-dose chest CT (LDCT) has demonstrated the ability to detect early stage lung cancer (LC), and improve disease-specific mortality in high-risk individuals. Use of LC risk scores (Prostate, Lung, Colorectal, Ovarian Model; PlCO2012/Liverpool Lung Project; LLPv2) improves the sensitivity, specificity and positive predictive value for LC screening. However, the screen-eligible population remains at 2-4%, and uptake rates are low in existing national programs, particularly in the socially disadvantaged who may benefit most from LC screening. These programs have identified that primary care participation, patient engagement, and improved accessibility may optimize the success of LC screening; as well as provide an opportunity to collect biospecimens from participants, to optimize LC early detection through next-generation biomarker discovery. Currently, there is no national LC screening program in the Republic of Ireland. In the first pilot study of LC screening in Ireland we will: i) investigate the feasibility of a lung cancer screening in a socially disadvantaged area, based on primary care-based participant identification and patient engagement methods, and mobile CT-scanning and ii) investigate novel blood/breath biomarkers in high-risk individuals who participate in the LC screening trial, to identify biologic parameters that may supplement existing risk scores, to maximise LC early detection.

Methods: In a pilot feasibility clinical trial, we will invite 13,933 high-risk participants to a 'Lung Health Check'. This will involve a respiratory disease assessment, baseline spirometry, smoking cessation, a low-dose chest CT, and blood/breath biospecimen collection. Participants will be invited via their primary care practitioner with remote assessment of PLCO2012/LLPv2 scores and eligibility. Eligible participants will be invited to an in-person lung health check at a mobile unit. The primary endpoint is the percentage of high-risk eligible participants who attend (of those invited for the lung health check). A total of 13,933 participants who have ever smoked will be invited to estimate the uptake in the underlying population (Republic of Ireland) with a precision of 1% (i.e. assuming a 95% confidence level ± 1%). Allowing for drop-out, we estimate a sample size of 2183 participants for a baseline lung health check (T0). Participants will attend for a follow-up CT scan at 1 year (T1) if there are no significant findings at T0, while those with lung nodules will be assessed 3 months after T0. Blood and breath samples will be investigated for genomic, proteomic and immunological features associated with a diagnosis of lung cancer, compared with controls (Participants enrolled who are not diagnosed with nodules/LC).

Results:

Conclusions: In this pilot feasibility trial, we will investigate the uptake of lung cancer screening utilising a community-based strategy amongst high-risk participants with additional work focusing on blood/breath biomarkers associated with lung cancer.

P2.04A.05 Providing Tobacco Treatment to Patients Undergoing Lung Cancer Screening at a Large U.S. Health System: A Randomized Trial

K.L. Taylor1, R.M. Williams1, G. Luta1, K. Davis2, J.L. Frey3, T. Lobo1, O. Rostagni1, J. Whealan1, P. Yee1, Z.L. Rashid1, C. Stanton4, R. Niaura5, D. Abrams5, K. Foley6, H.L. Arem7, J. Jayasekera8, J. Slejko9, L.S. Romero1, C.J. Breece10, N. Cobb2, C. Debnam11, V.L. Pham1, E.D. Anderson2

1Georgetown Lombardi Comprehensive Cancer Center, Washington/DC/USA ,2Georgetown University Medical Center, Washington/DC/USA ,3Private Practitioner, Rockville/MD/USA ,4Westat, Inc, Rockville/MD/USA ,5New York University, New York/NY/USA ,6Wake Forest University, Winston Salem/NC/USA ,7MedStar Health Research Institute, Washington/DC/USA ,8National Institutes of Health, Bethesda/MD/USA ,9University of Maryland, College Park/MD/USA ,10Georgetown University Hospital, Washington/DC/USA ,11Community Wellness Alliance, Washington/DC/USA

Introduction: Providing tobacco treatment in conjunction with lung cancer screening is estimated to substantially reduce lung cancer

deaths and increase life-years gained, compared to conducting lung cancer screening alone. Although many organizations recommend that individuals who are currently smoking cigarettes and are undergoing lung cancer screening be offered cessation treatment, there are multiple barriers to treatment delivery. We are conducting a health system-level, pragmatic, randomized trial to compare the effectiveness of two evidence-based treatments for cigarette smoking at MedStar Health, the largest and most diverse health system in the U.S. Mid-Atlantic region. The trial addresses known barriers to tobacco treatment in the healthcare setting, using 'opt out' procedures to contact all eligible patients for enrollment and using centralized delivery of the cessation interventions to address inequities in receipt of cessation treatment.

The goals of this ongoing trial (R01 CA274716) are to improve the evidence-base of cessation treatment for lung screening patients, to improve the systematic uptake of cessation treatment into routine practice, to address barriers to reach and engagement among diverse populations, and to maximize generalizability to other health systems. An economic analysis will evaluate costs, average and incremental cost per quit, and the budget impact of the intervention from the health system's perspective.

Methods: All patients who are currently smoking cigarettes and have received an order for a low-dose CT scan at MedStar Health are identified via the EHR, contacted for trial enrollment using an opt-out approach, and randomized to: 1) E-referral to the Tobacco Quitline (N=594) via the integrated closed-loop system between the EHR and the quitline. The quitline protocol includes proactive outreach and standard phone-based counseling + nicotine replacement; vs. 2) the MedStar Health System (N=594) arm, a centralized, phone-based + nicotine replacement intervention delivered by tobacco treatment specialists (TTS) trained to use motivational interviewing techniques to assist participants in their efforts to reduce or stop cigarette smoking. Using an adaptive design, those who are not abstinent at the 3-month assessment will be randomized a second time, to receive either continued treatment from the TTS vs. a more intensive intervention delivered by a registered nurse and nurse practitioner in which varenicline or bupropion can be prescribed as clinically appropriate. The primary trial outcome is bioverified abstinence from cigarettes at 6-months following randomization. Secondary trial outcomes include self-reported smoking status, quit attempts, and sustained abstinence.

Strengths include testing the effectiveness and economic outcomes of two cessation interventions while simultaneously laying the groundwork for sustainability and future implementation within this and other diverse health systems. Our innovative approach capitalizes on the EHR for recruitment, is focused on accruing diverse populations, and accounts for intervention context to inform future care delivery. Integrating cost effective and broad reaching tobacco treatment interventions into health care systems will maximize the benefits of lung cancer screening.

P2.04A.06 A Multilevel Approach to Address Disparities in Lung Cancer Screening: The PREP Trial

R.M. Williams1, K.L. Taylor1, G. Luta1, A. Sangraula1, P. Yee1, S. Melvin1, T. Lobo1, J. Blumenthal2, S. Mathur2, K. Miller2, L. Adams-Campbell1, K. Foley3, K. Lin4

1Georgetown University Medical Center, Washington/DC/USA ,2MedStar Health Research Institute, Washington/DC/USA ,3Wake Forest University, Winston-Salem/NC/USA ,4Lancaster General Health, Lancaster/PA/USA

Introduction: Lung cancer is the leading cause of cancer-related mortality in the US, with more than 120,000 deaths expected in 2024. Based on the National Lung Screening Trial, which showed that low-dose computed tomography (lung cancer screening) vs. chest X-ray reduced mortality from lung cancer by 20%, the US Preventive Services Task Force recommends annual lung cancer screening for asymptomatic high-risk individuals. Despite this recommendation, utilization is poor (3%-20%). Lung cancer screening may be particularly beneficial for African Americans (AA) because they are more likely to have advanced disease, lower survival, and lower screening rates compared to White individuals. The causes of low uptake of lung cancer screening are multifactorial and consistent with evidence from other cancer screening disparities, pointing to the need for multilevel interventions that simultaneously address multiple barriers to increase screening rates and decrease lung cancer morbidity and mortality in minoritized populations. Guided by NIH's Health Disparities Research Framework, the ongoing study (NCI R00CA256515) is targeting provider and patient behaviors, two key levels of influence in the healthcare setting, to address disparities between AA and Whites in lung cancer screening awareness and utilization.

Methods: We are conducting a quasi-experimental study (pretest-posttest, with a nonequivalent control group) in partnership with four primary care clinics within the MedStar Health system. Sites are matched on CT scanner on site (yes/no) and minority representation (> 40% AA). Individuals eligible for lung cancer screening, defined as 50-80 years old, 20+ pack-years, currently smoking or quit <15 years ago, no history of lung cancer, and who are non-adherent to screening (never screened or > 13 months since last screen), identified via the electronic health record (EHR), are contacted and enrolled (N = 184 in the intervention clinics, N = 184 in the control clinics; total N = 368). Provider participants (N = 21) include those practicing at the partner clinics. To increase provider-prompted discussions about lung cancer screening, an EHR pre-visit planning message will be sent to primary care providers 48 hours prior to scheduled visits with screening-eligible patients. To target patient-level knowledge and promote patient activation about lung cancer screening, an in-reach specialist will educate the patients about screening prior to their visit. Patient participants will be assessed at baseline and 1-week post-visit to measure provider-patient discussion about lung cancer screening, screening intentions, and knowledge. Screening referrals and screening completion rates will be assessed via the EHR 6 months post visit. At the time of this submission, recruitment is ongoing. This multilevel intervention targets important barriers to lung cancer screening. The study will inform future work designed to measure the independent and overlapping contributions of the multilevel implementation strategies to advance equity in lung cancer screening rates.

Introduction: Early detection of lung cancer plays a pivotal role in improving lung cancer survival. Besides screening a high-risk population, detection and follow-up of incidental pulmonary nodules (IPN) is a complementary pathway to detect lung cancer in earlier stages . However, IPN are frequently missed, while follow-up of IPN is regularly absent or non-standardized (1,2). Computer-Aided Detection (CAD) has the potential to increase a radiologists' capability to detect IPN on chest CT scans and aid in identifying patients that need follow-up procedures . Adherence to these follow-up procedures can be improved by implementing a Virtual Nodule Clinic (VNC). In this study, we hypothesize that implementation of CAD and VNC improves clinical management of IPN and therefore induces a stage shift towards earlier lung cancer diagnosis.

Methods: This study is a prospective, observational multicenter study to determine the impact of CAD together with a VNC on IPN detection, follow-up and lung cancer diagnosis. The CAD software supports clinicians in detecting IPN and identify patients that need follow-up procedures according to guidelines of the British Thoracic Society (BTS). A dedicated health care professional will manage the VNC as 'navigator' to ensure all patients adhere to the scheduled referrals and follow-up procedures. Primary outcome is the rate of patients diagnosed with stage I/II lung cancer with curative intent treatment. Secondary outcomes include cost-effectiveness of the program, clinical management with patient outcomes, adherence to guidelines, psychological burden and eligibility for lung cancer screening. Based on an increase in the rate of stage I/II lung cancer diagnosis from 25% in current clinical practice to 60%, one thousand IPN patients have to be recruited in the 8 hospitals across Europe. In addition, we will perform a retrospective study in each participating hospital to further determine the impact of CAD. In this historical cohort generated by Natural Language Processing (NLP), we will re-analyze all chest CT scans with CAD to determine the difference in IPN detection rate and lung cancer diagnosis (Figure 1).

P2.04A.08 Feasibility of Cell-Free DNA Liquid Biopsy in Screening High-Risk Patients for Lung Cancer

D. Raz, A. Ceniceros, A. Akhtar, R. Nelson, S. Gray, L. Erhunmwunsee, N. Nonzee

City of Hope, Duarte/CA/USA

Introduction: Lung cancer screening (LCS) with low dose computed tomography (LDCT) significantly reduces death from lung cancer but is severely underutilized. Despite many U.S. guidelines recommending LDCT for LCS, fewer than 5% of eligible adults are screened. LDCT utilization is even lower for minoritized and low-income populations. Barriers to LCS access and completion are numerous, complex, and multi-level. Innovative strategies that bring LCS to individuals, rather than require travel to health care facilities, are therefore urgently needed. DELFI cell-free DNA (cfDNA) liquid biopsy, which is a low-cost platform and can be collected at home or as point-of-care testing, is a promising LCS-specific blood-based tool that may improve participation in LCS among individuals who face barriers to screening. This study aims to determine the feasibility and acceptability of the DELFI cfDNA test that can be collected at-home or during a community-based healthcare encounter, with a focus on under-resourced populations.

Methods: Feasibility of Cell-Free DNA Liquid Biopsy in Screening High-Risk Patients for Lung Cancer (NCT: NCT05384769) is an investigator-initiated research (IIR) study designed to evaluate the adoption of lung cancer screening when a choice in modality is offered (blood-based test versus LDCT). We plan to recruit 100 participants over a 12-month period through an urban Federally Qualified Health Center (FQHC), a rural LCS program, and a mobile cancer screening clinic in a medically underserved and remote region north of Los Angeles. Participants are eligible to participate if they meet the 2021 USPSTF LCS criteria and are English or Spanish-speaking. After LCS shared-decision making, eligible participants will choose to undergo either a blood-based test (BBT) at home or as point-of-care testing, or standard of care LDCT. Participants undergoing BBT may undergo LDCT at any time after their results are returned. Participants in

both cohorts will complete a baseline and a six-month follow-up survey. The baseline survey will include questions regarding socio-demographics, smoking history, cancer screening history, the LCS Health Beliefs survey, and the Cancer Worry Scale. The six-month follow-up survey will include questions regarding patient satisfaction, the Cancer Worry Scale, cancer diagnosis, and screening follow-up with LDCT. The primary study endpoint is the proportion of participants who agree to undergo lung cancer screening using the BBT versus LDCT, with a feasibility threshold of at least 30% preferring the blood test. Secondary endpoints include the proportion of participants with either Elevated or Not Elevated results subsequently undergo LDCT, and the LCS barriers and sociodemographic characteristics that are associated with the choice to undergo BBT vs. LDCT. Focus groups also will be conducted to assess LB feasibility and implementation. This IIR study will provide insight into the utilization and impact of a blood-based test for lung cancer screening and will inform a larger clinical trial designed to assess the role of this test in improving the early detection of lung cancer in under-resourced communities.

Progress: The study was open to enrollment on March 25, 2024 with an estimated primary study completion date of December 31, 2025.

Introduction: Despite the growing body of high-quality evidence on the effectiveness of the Lung Cancer Screening (LCS) with low dose computed tomography (LDCT) in reducing lung lancer (LC) mortality in high-risk populations,barriers have been reported at both the health provider and target population level4 and low adherence rates. These challenges can be even greater in low-income countries. Several academic associations in Latin America have published recommendations about LCS and promising results in terms of early lung cancer detection and diagnostic accuracy have been described. In this context, we present the first experience of a collaborative registry of LCS in Argentina: LUng CAncer Screening (LuCaS) Project.

Methods: We aim to describe the characteristics of the Argentine LCS Collaborative registry and its participants institutions, with particular reference to adherence to LCS national consensus recommendations at baseline. The LuCaS Project has been designed as an analytical, observational, ambispective, follow-up study on a cohort of individuals with a history of heavy smoking undergoing LCS with LDCT. All institutions that have LCS pilot programs in the country were invited to participate. Individuals are being recruited by each center, all variables are recorded in a common web-based management system. Patient enrolment criteria are current 30 pack-year smokers, or former smokers for a maximum of 15 years, aged between 55 and 74 years. The institutions were questioned about their baseline program characteristics according to the recommendations of the latest LCS national consensus.

Results: Twenty one Argentine institutions have already joined the LuCaS project.Seven of them are funded by the government. Among the 14 private institutions, one has also a government grant (Fig1). Ten programs take place in the city of Buenos Aires. At baseline 20/21 LCS programmes have a multidisciplinary team; 19/21 offer a smoking cessation plan integrated with the LCS programme; 20/21 have pre-established protocols for clinical decision-making about lung nodule management; 15/21 ensure the distribution of educational materials about the benefits and risks of LCS; 19/21 offer cardiovascular risk evaluation; and all have strategies for symptomatic patients care.

Conclusions: LuCas Project is the first Argentine LCS Collaborative registry. Participating institutions have a relatively heterogeneous medical care profile, mostly developed in large urban centers and privately financed. Challenges will remain on how to equate the features of the programs according to the LCS consensus recomendations, recruit more participating institutions, as well as improving the access to LCS to more patients throughout the country.

Keywords: lung cancer screening, early detection, national registry

P2.04B.02 Eight Year Outcomes of a Multidisciplinary Lung Cancer Screening Program at a Large Community Centre in Canada

M. Ossip, G. Sharma, D. Levay, A. Bendzsak, K. Irshad, C. Yeung, K. Bisson, L. Vicente, K. Perdrizet, B. Sheffield, P.K. Cheema

William Osler Health System, Brampton/ON/CA

Introduction: Low-dose chest CT scan (LDCT) lung screening programs reduce lung cancer mortality for high-risk patients. In 2012, William Osler Health System, Canada, a large community centre implemented the longest running multidisciplinary lung cancer screening program in Canada outside of a research/pilot study. We present the real world outcomes of this program.

Methods: Retrospective chart review of screened patients with LDCT (Siemens 120kV, 20 quality reference mAs, Caredose) from February 2012 to December 2019 with follow up to April 2023. Patients were referred by family physicians or specialists. Patients were eligible for annual screening while they met the following criteria: age 55 to 77, minimum of 30-pack-year history of cigarette smoking, no prior lung cancer, no CT scan within 12 months of initial LDCT and former smokers must have quit within the previous 15 years. This multidisciplinary program had standardized radiologist reporting of high risk LDCT. Prior to 2014, a nodule was deemed positive if solid or subsolid and greater than 6 mm in mean diameter on initial study or growing. In 2014. we started transitioning to ACR Lung Rads protocol. All Lung Rads 4 cases were referred to thoracic surgery and seen in a Solitary Pulmonary Nodule clinic.

Results: During the study period, 5460 unique patients were enrolled, with 14,048 high risk LDCT completed (average LDCT/patient was 2.6). Average of 683 new patients entered the program/year, with average annual growth of 27.6%. Median age at program entry was 63 and 61% were males. Of patients screened, 287 (5.3%) had a biopsy by CT guided +/- EBUS/Mediastinoscopy (n=208) or EBUS/Mediastinoscopy alone (n=79). A total of 225 CT guided biopsies were completed of which 118 (52.4%) were malignant, 26 (11.6%) were atypical/suspicious for cancer, 49 (21.8%) were benign, and 32 (14.2%) were non diagnostic. Overall detection rate of cancer including 8 cases of non lung cancer was 4.2% (n=229), and 4.0% (n=221) for lung cancer. Clinical or surgical stage of lung cancers detected was primarily early stage with the following distribution: stage I (61.5%), II (11.8%), III (17.2%) and IV (9.5%). There were 198 surgical resections for 187 unique patients in which the cancer detection rate was 88.8% if they had a pre-surgical biopsy versus 76% if they did not. The pathology of resected cases was lung cancer (85.4%), non lung malignancy (3%) and benign/atypia (11.6%). Majority of surgeries were lobectomies +/- wedge (62.1%), or segmentectomy/wedge (34.8%) with low rates of bilobectomy (1.5%) and pneumonectomy (1.5%). In patients with lung cancer, 60 did not have surgery for various reasons, and patients with surgical resection the stage was as follows: stage I (78.3%), II (13.7%), and III (13.7%).

Conclusions: We report outcomes of the longest running multidisciplinary lung cancer screening program in Canada outside a research protocol with over 5000 patients screened. The collaboration between radiology and thoracic surgery resulted in detection and management of early stage lung cancers which compared favourably to pivotal trials. Our experience provides further evidence supporting lung cancer screening and feasibility of such programs at community centres.

P2.04B.03 Low Cost Low Dose CT Scan for Lung Cancer Screening - Seven Year Experience at a Sub-urban Community Hospital.

D. Sharma1, S. Matthews1, S. Dozier1, G. Dedinsky2, M. Henderson1

1Columbus Regional Health, Columbus/IN/USA ,2Columbus Regional Health/Indiana University Health, Columbus/IN/USA

Introduction: Lung cancer is the largest cause of cancer-related death in U.S. USPSTF recommends annual low dose CT (LDCT) scans for lung cancer screening in high risk population within 50 and 80 years of age, 20 pack years history of smoking and who are either currently smoking or have quit within 15 years. Due to the cost and lack of awareness, most patients are not able to afford LDCT scans and this recommendation has not been widely implemented leading to less than 7% of eligible patients going through the required screening.

Methods: We describe a low-cost approach adopted by Columbus Regional Hospital in conjunction with a multi-specialty physician collaborative. We offered a highly subsidized LDCT screen to high risk patients followed by a multi-disciplinary evaluation for those with Lung rad 3 or 4 findings. The care model utilized evidence-based standards to direct further management including further imaging with LDCT, PET scan or biopsy. We also focused on incorporating the primary care physicians on record to assist with patient follow-up. Aggressive use of patient navigators facilitated care coordination and open communication between providers, patients and family. We hypothesized the cost of initial screens is the most significant barrier and were able to overcome that by offering LDCT at a low price of $25 which at times was further subsidized to $10 and also offered free to 200 patients every year during Lung cancer awareness month. We also hypothesized that Lung cancer was under-diagnosed in our community and convenience and care coordination with a multi-disciplinary care team standardizes the decision making process, promotes primary care and families' inclusivity and shortens the time to treatment. We intensified our efforts to educate the community to promote self directed referrals to obtain LDCT by spreading awareness through many modalities including traditional and social media.

Results: We screened 3095 new patients over seven years. 6646 annual and baseline LDCTs were performed in total. 1180 scans were identified with findings consistent with Lung RADS 3 or 4 requiring further work up. A total of 162 new cancers were identified, of these 135 were lung and 27 were non-lung cancers. 64% of all lung cancers were identified at Stage 1 or 2. We calculated incidence of lung cancer in our population at 4.36% and for all cancers at 5.23%. The incidence dropped to 2.03% and 2.43% for lung cancer and all cancers respectively when adjusted for patient years but still remained significantly higher than the incidence reported in National Lung Cancer Screening Trial.

Conclusions: Low cost screening CT and Multi-Disciplinary approach to report and follow up on findings resulted in more effective screening of the high risk population resulting in more than twice the number of cancers identified compared to traditional lung cancer screening programs. We believe this to be a result of improved implementation of screening program within a high risk rural population due

to low cost, rigorous direct to patient educational efforts and and a multi-disciplinary approach in form of Lung Nodule Review Board.

P2.04B.04 Harnessing EHR/IT to Accelerate Lung Cancer Screening - An American Cancer Society National Lung Cancer Roundtable Initiative

L.S. Rosenthal1, C.C. Thomson2, D.S. Dyer3, T.J. Caverly4, G.L. Branford4, N.T. Tanner5, C.G. Slatore6, P.J. Mazzone7, N. Irani8, J.T. Fathi9, R.A. Smith1, E.A. Kazerooni4

1American Cancer Society, Atlanta/GA/USA ,2Mount Auburn Hospital/Beth Israel Lahey Health, Cambridge/MA/USA ,3National Jewish Health, Denver/CO/USA ,4University of Michigan, Ann Arbor/MI/USA ,5Medical University of South Carolina, Charleston/SC/USA ,6Oregon Health & Science University, Portland/OR/USA ,7Cleveland Clinic, Cleveland/OH/USA ,8University of Kansas Medical Center, Kansas City/KS/USA ,9GO2 For Lung Cancer, Washington/DC/USA

Introduction: Uptake of lung cancer screening (LCS) in the U.S. is low, with approximately 20% of eligible adults reporting recent screening. Following the American Cancer Society National Lung Cancer Roundtable (ACS NLCRT) 2022 Summit, Accelerating Uptake of Lung Cancer Screening, a workshop was held to develop/prioritize tactics to enhance EHR/IT usability and functionality towards increasing screening uptake.

Methods: Eighty individuals (clinicians/researchers/patient advocates) from 58 organizations (professional societies/advocacy organizations/health systems/industry/EHR/IT vendors) attended the workshop to develop recommendations addressing current challenges in using EHR/IT tools to accelerate high-quality LCS uptake. After presentations to create common understanding (LCS workflows, EHR/IT lessons from American College of Radiology LCS Learning Collaborative, intersection of EHR/IT with LCS programs/patients/primary care, and operational and clinical outcomes metrics), nine EHR/IT vendors discussed their current tools. Workshop participants were divided into breakout groups facilitated by two subject matter expert moderators and ACS NLCRT staff: 1) Identifying Individuals Eligible for LCS; 2) Patient Tracking After LCS; 3) Education for Patients, Including Shared Decision Making; and 4) Key Performance Indicators and Quality Measures. Each group reviewed the strategies identified by the 2022 LCS Summit EHR/IT breakout group aligned with their topic and devised tactics that were presented to workshop participants for feedback. The same groups met again, refining tactics and assessing feasibility, after which they re-presented to all participants. Lastly, all attendees ranked their top three priorities anonymously.

Results: Fifteen tactics were ranked (see table). The top 5 tactics were to: 1) Use EHR portals that are standardized and targeted to educate patients about LCS; 2) Develop a national LCS EHR module; 3) Incorporate unstructured data from EHR with natural language processing to improve data capture; 4) Establish a centralized program with IT and navigation to track patients and findings from the point of entry into the LCS program; and 5) Partner with major EHR vendors to make data needed for risk stratification available through a standard data interface. An executive summary details the work: NLCRT-EHR-IT-Executive-Summary_FINAL.pdf

Conclusions: ACS NLCRT developed and prioritized actionable EHR/IT tactics for accelerating screening uptake. Active work underway after the workshop includes: multidisciplinary brain trust launch by one EHR vendor to inform their work; ACS NLCRT-facilitated work with EHR vendors to address the risk factor standard data interface; and ACS NLCRT and American Lung Association funding to develop LCS HEDIS and tobacco history documentation quality measures by the National Committee for Quality Assurance, which are measured through EHR interfaces.

P2.04B.05 Engaging Culturally and Linguistically Diverse Communities to Prepare for Lung Cancer Screening Implementation in Australia.

S. York1, M.L. Yap2, J. Rhee3, L. Pitts4, J.P. Troiani4, B. Stanoevska5, N. Harrison6, R. Dodd7, A. McWilliams8, H. Marshall9, E. Stone10, N. Rankin11

1University of Melbourne, Carlton/AU ,2South Western Sydney Local Health District, Liverpool/AU ,3University of New South Wales, Randwick/AU ,4Illawarra Shoalhaven Local Health District, Wollongong/AU ,5Illawarra Shoalhaven LHD, Wollongong/AU ,6Flinders University, Adelaide/AU ,7University of Sydney, Camperdown/AU ,8Fiona Stanley Hospital, Perth/AU ,9The Prince Charles Hospital, Brisbane/AU ,10St Vincent's Hospital Sydney, Darlinghurst/AU ,11University of Melbourne, Melbourne/AU

Introduction: Lung cancer is the number one cause of cancer death worldwide, including in Australia, where more than 14,000 cases will be diagnosed in 2024. The Australian Population Based Screening Framework stipulates that new screening programs must be: 1)

acceptable to the population, 2) clinically, socially, legally, ethically acceptable to health professionals, consumers and the Australian public and 3) promote equity and access in target groups. Very little Australian research has engaged culturally and linguistically diverse (CALD) communities about lung cancer screening (LCS) to gauge readiness for implementation. In Australia's existing cancer screening programs, unique barriers to participation have been documented amongst some CALD groups. The Australian National Lung Cancer Screening Program (NLCSP) will commence from July 2025. This study was conducted prior to a NLCSP funding announcement. The aims were to identify barriers and enablers to LCS implementation and determine views about LCS acceptability and feasibility.

Methods: This qualitative focus group study used community-based participatory research principles to collaboratively engage CALD stakeholders. The research team worked with highly-experienced program managers, multicultural health workers and bilingual facilitators/translators ('leaders') who provide support and education to Arabic, Macedonian, Italian and Vietnamese communities. The leaders used culturally-appropriate methods to recruit participants, and organised and delivered focus groups with support from the research team. All research study materials were translated into community languages. Participant orientation to lung cancer screening was enabled through a moderator guide to ensure coverage of core topics and a National Health Service England video (used with permission) that featured 'voice-over' translations into community languages. All participants gave written consent. Focus groups were recorded and translated into English by nationally accredited translation services. Thematic analysis is underway to code data to themes.

Results: Nine focus groups were conducted either face to face (n=5) or on Zoom (n=4) with 69 participants across New South Wales, Australia. Six groups were delivered in community languages. Preliminary analysis identified that LCS was perceived as acceptable across all focus groups. Identified barriers included concerns about eligibility criteria exclusions of tobacco use in formats preferred to cigarettes (e.g. shisha) and people who have never used tobacco. Other barriers were significant concerns about the stigma and fear associated with cancer, medical procedures and scans; screening costs and reliance on family or community members to act as interpreters. Participants expressed a preference for recruitment via General Practitioners (GPs) but raised concerns about missing people without a regular GP. Enablers included co-designing complex strategies with communities to disseminate promotion and awareness materials that extend beyond mass media and invitation letters. Community champions were strongly endorsed as a strategy to enhance uptake. Participants reiterated that key program messages must be locally tailored and presented in community languages.

Conclusions: This qualitative study provides crucial foundational evidence from four culturally diverse Australian communities about barriers and enablers prior to NLCSP implementation. The findings are highly informative for other jurisdictions who may be preparing for LCS implementation or need to modify programs to attract more culturally diverse populations to engage in screening.

P2.04B.06 Lung Cancer Screening Program in Serbia: A 3-year- Results and Challenges

J. Djekic Malbasa1,2, T. Kovacevic1,2, D. Dragisic2, G. Stojanovic2,3, B. Zaric1,2, D. Bokan1,2

1University of Novi Sad, Faculty of Medicine, Novi Sad/RS ,2Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica/RS ,3Faculty of Pharmacy, University Bussies Academy Novi Sad, Novi Sad/RS

Introduction: Lung cancer screening aim is to detect high risk subjects and subjects in early stage. The implementation of a lung cancer screening program is very complex. Objective of this study was to present the results and challenges in implementing lung cancer screening program.

Methods: Subjects aged 50-74 years, with a smoking history of 30 pack-years or more and/or 20 pack-years with additional risks (COPD, prior pneumonia, other malignancy, lung cancer hereditary history or exposure to environmental carcinogens) undergone low-dose CT evaluation. Radiological assessment and further evaluation was done per Lung RADS score. Screening was performed at Institute for Pulmonary Diseases of Vojvodina in Sremska Kamenica, and observed period was from October 2020 to December 2023.

Results: Total of 5404 LDCT scans were performed on 2892 screened subjects. The majority were females (58.9%). Females compared to males were often active smokers (87.0% vs 77.8%, p<0.001) with frequently reported positive family history of lung cancer4 (7.3% vs 3.2%, p<0.001), and positive personal history of other solid tumor (7.3% vs 3.2%, p<0.001). Compared to risk perception for lung cancer, male significantly often were not worry at all or were rarely worry about their risk compared to females (82.9% vs. 77.5%, p<0.001). Emphysema was reported in 31.2% (902/2892), with significant differences between males and females (34.2% vs. 29.1%, p=0.004). Lung RADS score positive screens were found in 9.4% (273/2892). The invasive diagnostic was performed in 3.7% (107/2892) of participants, while 0.7% (20/2892) refused invasive procedures. The rate of false positive findings was 1.14% (32/2892). The lung cancer detection rate was 2.3% (67/2892). From total detected lung cancer subjects 87.0% were NCSLC (adenocarcinoma 56.0%, squamous 24.0% and NOS 6.0%) and 11.0% were SCLC. Almost 55.0 % of lung cancer subjects were detected in stage I and II. Significant differences were observed between baseline and follow-up lung cancer stages (32.6 % vs. 52.6% in I, and 36.8% vs. 15.8% in IV stage).The screening respond rate to control LDCT after 12 months (Lung RADS 1 and 2) was 73.9% (1757/2375).

Conclusions: More than 50% of lung cancer subjects detected in screening were in early stages of disease. Innovative approaches, education and a more recognizable campaign are necessary to increase the responds rate among participants with negative baseline LDCT.

P2.04B.07 Impact of Primary Care Initiated Lung Cancer Screening Program: The VANCHCS Experience

G. Kaleka1, D. Liu2, B. Guan3, E.R. Thomas4, S. Chen1, L. Strokecker4, J. Brown-Lambey4, S.K. Shenoy4, B.M. Morrissey4, N.M. Stollenwerk4, C.T. Phan4, D. Cheng4, R.J. Knebel4, L.A. Godoy4, S. Zanfardino4, P. Rajappa4, T. Li4

1University of California, Davis, Sacramento/CA/USA ,2University of California, Davis, Davis/CA/USA ,3VA Northern California Health Care System, Sacramento/CA/USA ,4VA Northern California Health Care System, Mather/CA/USA

Introduction: Despite the known benefits of low dose CT scan (LDCT) in improving the survival of lung cancer patients through early diagnosis, screening rates remain low across the United States. Only 5.8% of eligible Americans were screened for lung cancer in 2021. California and Nevada had the lowest screening rates at 1.0% and 1.3%, respectively. The VA Northern California Health Care System (VANCHCS) serves the 7th largest catchment area in the country with over 385,000 Veterans who reside in 21 different counties. To address the need for improved lung cancer screening (LCS), a primary care-based LCS program was initiated around 2017. We conducted this retrospective study to evaluate the impact of LCS program on the stage of lung cancer diagnosis between 2012 and 2022.

Methods: Eligible Veterans were screened by primary care providers who ordered LDCT scans. A dedicated LCS coordinator reviewed the Lung-RAD reports and coordinated diagnostic workups with relevant specialists. Demographics and stage at lung cancer diagnosis were obtained through the tumor registry. The Chi-square test was conducted to assess the difference in screening rates across all and different race groups.

Results: Between 2012 and 2022, 1073 Veterans were diagnosed with lung cancer at VANCHCS. The distribution of lung cancer stages was as follows: 31.2% stage 1, 8.2% stage 2, 20.6% stage 3, and 40.0% stage 4. While the total number of lung cancer cases diagnosed per year remained stable, there was a notable increase in the proportion of patients diagnosed at stage I and a decrease in stage IV over time.Before 2017, the average percentages of patients diagnosed at stage 1 and stage 4 were 23.6% and 44.1% respectively. However, from 2018 to 2022, the average percentages increased to 38.3% for stage 1 and decreased to 34.8% for stage 4. As of 12/1/2023, 86.9% of 4151 eligible Veterans accepted LCS. Among those who accepted LCS, 71% had been screened with LDCT scan within 1 year. Black and Hispanic Veterans had significantly lower screening rates compared to other ethnicities.

Conclusions: The primary care provider-initiated LCS program at VANCHCS has enhanced the clinical implementation of lung cancer screening.Since 2018, more Veterans have been diagnosed at stage I lung cancer, allowing for potentially curative treatment. Further studies are needed to address the disparities in screening rates, particularly among Black and Hispanic Veterans, and to evaluate the impact of this LCS program on cancer-specific mortality at VANCHCS.

1Ludwig-Maximilians-University of Munich, Thoracic Oncology Centre Munich, Munich/DE ,2Institute for Oncology and Radiology of Serbia, Belgrade/RS ,3Manchester University, Manchester/GB ,4Rescue Lung Society, Boston/MA/USA ,5University of Liverpool, Liverpool/GB ,6Icahn School of Medicine Mount Sinai, New York/NY/USA ,7University of Michigan, Ann Arbor/MI/USA ,8National Korányi Institute for Pulmonology, Budapest/HU ,9American Cancer Society, Atlanta/GA/USA ,10St Bartholomew's Hospital, London/GB ,11University of British Columbia, Vancouver/BC/CA ,12Brock University, St. Catharines/ON/CA

Introduction: To facilitate global implementation of lung cancer (LC) screening and early detection in a quality assured and consistent manner, common terminology is needed. A lexicon with definitions should be used by the entire multidisciplinary team, including primary care physicians, radiologists, respiratory physicians, thoracic surgeons, as well as pathologists, epidemiologists and biostatisticians, and also health care managers and funders, which patients, screening participants and family can understand. Currently, researchers and clinicians within different specialties and professional societies may use the same terms but with different meanings, or different terms for the same intended meanings.

Methods: I n this study, the Diagnostics Working Group of the International Association for the Study of Lung Cancer Early Detection and Screening Committee has analyzed and intensively discussed relevant terms used on a regular basis and suggests recommendations for consensus definitions of terminology applicable in this setting. These recommendations take into account that thoracic imaging includes not only the lungs and airways, but adjacent mediastinal organs including cardiovascular structures, the chest wall and adjacent portions of the lower neck and upper abdomen. The findings should be considered in the context of not only LC but also other potential diseases and comorbidities. Our goal was to understand the basis for differences in definitions and what the impact of these differences might be. We explored how we might reach consensus to define the most common relevant and unambiguous terminology for use by health care

providers, researchers, patients, screening participants and family. Discussions among members were held during regular monthly calls and final recommendations were approved by all members.

Results: Analyzed terms and definitions in use for epidemiological and health-economical purposes included: Standardized incidence and mortality rates, LC specific survival, long-term survival and cure rates, and overdiagnosis, overtreatment, undertreatment. Analyzed terms and definitions in use for defining screening results/findings included: Positive, false positive, negative, false negative and indeterminate screening findings and additional findings and incidental findings. Analyzed terms and definitions in use for describing programme parameters in screening programmes included: Opportunistic vs programmatic LC screening, Screening rounds, interval / interim diagnoses, invasive and minimally invasive procedures. Analyzed terms and definitions in use for shared decision making included: LC screening - possible harms and risks and LC risk (probability of event per defined time) and modifiers prior and posterior to a measure.

Conclusions: Screening programs have been developed in the context of specific health systems and various interdisciplinary settings. Depending on the specific interest, terminology from the fields of epidemiology, health economics and radiology have primarily been used. These terms have their value in the specific discipline and may be necessary for communication in these fields but may have a different meaning in other settings which can cause confusion and may impede the implementation of screening and early detection globally. Therefore, a common set of terminology with standard definitions is recommended when describing clinical LC screening programs to facilitate program uptake, and the discussion about effectiveness and outcomes. The use of the terms should be clearly defined and explained.

P2.04B.09 A Qualitative Evaluation of the Critical Role of Lung Cancer Screening Program Navigators

L. Spalluto1,2, K. Bonnet1, D. Schlundt3, C. Audet1, C. Henschke4, D. Yankelevitz4, S. York1,2, F. Hendler5, D. Moghanaki6,7, R. Dittus1,2, C. Roumie1,2, J. Lewis1,2

1Vanderbilt University Medical Center, Nashville/TN/USA ,2VA Tennessee Valley Healthcare System, Nashville/TN/USA ,3Vanderbilt University, Nashville/TN/USA ,4Icahn School of Medicine at Mt Sinai, New York/NY/USA ,5Louisville VA Medical Center, Louisville/KY/USA ,6University of California Los Angeles, Los Angeles/CA/USA ,7VA Greater Los Angeles Healthcare, Los Angeles/CA/USA

Introduction: Lung cancer screening with low dose computed tomography (LDCT) entails a complex operational process and often relies on navigators who have been shown to improve LDCT utilization and patient experience. Factors influencing these navigators' roles, responsibilities, and ability to impact program outcomes remain incompletely understood. We explored the perspectives of a diverse, national population of Veterans Health Administration (VHA) healthcare team members regarding influences of lung cancer screening program navigators' roles and responsibilities.

Methods: We conducted a cross-sectional qualitative study with healthcare team members involved in lung cancer screening at 10 Veterans Affairs Medical Centers. Semi-structured telephone interviews were conducted from December 2020 to September 2021 with radiologists, pulmonologists, primary care providers, oncologists, surgeons, advanced practice providers, nurses, CT technicians, and administrators. We utilized the Consolidated Framework for Implementation Research for study development and data coding and the Health Systems Science Framework for thematic analysis. The qualitative data was analyzed through an inductive and deductive approach to identify emerging themes.

Results: A total of 30 interviews were conducted and included in the final analytic sample. Participants described the critical role of the navigator in several steps of the lung cancer screening process. Participants described the individual navigator characteristics such as professional background, attending navigator training, dedicated program percent effort and foundational skills as traits that can influence a navigator's impact on the overall program outcomes. Foundational interpersonal skills including teaming, leadership, and commitment to the program were identified as traits that can have profound impact on improving program enrollment and outcomes. Healthcare team interview participants also indicated that VHA organizational structures including adequate program staffing, location of program activities (including virtual and in person and where LDCT examinations are performed), available technology, and financial support for program activities and personnel can be influential in the navigator roles and influence over program activities and outcomes. Sample supporting quotations can be seen in Figure 1.

Conclusions: Lung cancer screening program navigators positively impact lung cancer screening program outcomes. Individual characteristics such as leadership, teaming, training and professional background, and commitment likely influence this impact. This study offers insight into how both healthcare system structure and individual navigator characteristics influence a navigator's impact. As VHA continues to expand lung cancer screening, these data can inform strategies aiming to improve lung cancer screening for Veterans.

P2.04B.10 Leveraging High Mammography Screening Prevalence to Increase Lung Cancer Screening Among Women - A Geospatial Perspective

L. Sahar, V.L.D.L. Douangchai, R.A. Smith

American Cancer Society, American Cancer Society/GA/USA

Introduction: Although lung cancer is a leading cause of mortality among women, screening is still low, below 20% for men and women nationwide. In comparison, national estimates of biennial screening mammography among women 50-74 exceed 70%. That discrepancy, combined with some overlap in the age of eligibility between screening for lung and breast cancer, provides an opportunity to increase awareness, check for eligibility, and schedule or screen women for lung cancer when going for their mammogram. This project focuses on the geographic feasibility and impact of such an approach.

Methods: A geographic approach was developed to assess proximity of lung cancer screening facilities (American College of Radiology lung cancer screening registry facilities) to mammography facilities identified by the FDA MQSA program. Although we examined facilities within growing distances, up to 1 mile, we focused on locations within 0 mile (a.k.a. close proximity, facilities residing within the same plaza/health center). Rural and urban designations were also factored into the analysis. While limited by data availability, we wanted to further estimate the number of women that may be impacted and utilized geospatial analysis of population data (gender and age) as well as estimates of prevalence of mammography.

Results: Most lung cancer and mammography facilities that are in close proximity, are located in urban settings where most women aged 50-74 reside, as well as where most women report having had a mammogram in the past 2-years. There are more facilities in close proximity in the east. Counties with facilities in close proximity are mainly in urban geographies and account for over 30M women aged 50-74 (out of almost 50M women of that age group nationwide). Further analysis utilizing the prevalence of mammography facilities shows a significant number of women who can be identified to discuss lung cancer screening eligibility and then as needed refer to a nearby lung cancer screening facility. Integration of geographic layers of screening facilities within close proximity, lung cancer mortality, and mammography prevalence was done to identify priority locations for interventions.

Conclusions: While limited by data availability, our analysis nonetheless reveals an opportunity to identify women eligible for lung cancer screening when electronic health records and busy primary care providers have been challenged to do so.

P2.04B.11 Factors Associated with Early-Stage Lung Cancer Diagnosis (ESLCD) In Brazil - 2013 - 2019: A Multivariable Analysis.

I. Emmerick1, M. Campos2, D. Castanheiras2, L. Vinhal Faria2, T. Sequeira Valerio2, A. Marques2, J. Muzy2, L. Arueira Chaves3, M.J. Sobreira da Silva4

1UMass Chan Medical School, Worcester/MA/USA ,2Fundação Oswaldo Cruz (Fiocruz), Rio de Janeiro/BR ,3Fundação Oswaldo Cruz (FiocruzUniversidade Federal do Rio de Janeiro (UFRJ), Instituto de Ciências Farmacêuticas, Rio de Janeiro/BR ,4Instituto Nacional de Câncer (INCA), Coordenação de Ensino (Coens) de Janeiro (UFRJ), Instituto de Ciências Farmacêuticas, Rio de Janeiro/BR

Introduction: Lung cancer has the highest mortality rate among the leading deadly cancers worldwide. Despite improvements in tobacco cessation and treatment over the years, disparities in access to care, timely diagnosis, and proper treatment remain prevalent. This study aims to identify the factors associated (FA) with Early-Stage Lung Cancer Diagnosis (ESLCD) in Brazil.

Methods: This retrospective cohort study includes individuals diagnosed with lung cancer from January 2013 to December 2019, registered in the Brazilian hospital-based Cancer Registry (HBCR). Descriptive and bivariate analysis was performed, and T-tests and Chi-square were used to compare early vs late-stage groups. Multivariable backward stepwise logistic regression identified FA with ESLCD at a 95% confidence interval (CI).

Results: The study was conducted with data on 86,558 individuals registered in the HBCR; 56.6% were men, 64 years old on average, and 54.8% were white. We found a high percentage of patients without education information (23.9%), and 70% had completed high school. As for behavioral characteristics, only 20% of the patients had never smoked; the others were current smokers (40%) or former smokers (40%). Almost half of the patients were from the Southeast region of Brazil (44.6%), 27% from the South, 19.9% from the Northeast, 3.9% from the North and 3.9% from the Midwest. The vast majority of the individuals were diagnosed at a late stage (85.6%), while 14.4% were ESLCD. In the bivariate analysis, being less than 65 years old, being female, white, never smoking, having a college degree, and living in the south or southeast regions were associated with ESLCD. In the final multivariable model, the Factors Associated with ESLCD were having less than 65 years (OR=1.28 [95% CI: 1.22-1.34]), of the female gender (OR=1.26 [95% CI: 1.22-1.32]), having education greater than a college degree (OR=1.49 [95% CI: 1.38-1.61]), and living on the southeast (OR=1.22 [95% CI: 1.15-1.30]); and in the south region (OR=1.21 [95% CI: 1.18-1.32]); which are the wealthiest regions in the country.

Conclusions: The education level was the most decisive factor associated with ESLCD. Geographic location played an important role in ESLCD, indicating issues related to wealth and access to health services. Improving access to lung cancer diagnosis, especially for vulnerable populations, can reduce disparities in the rates of early-stage diagnosis and improve overall survival.

P2.04B.12 Respiratory Function as a Prognostic Factor for Lung Cancer in Screening and General Populations

K. Murison1,2, M.T. Warkentin2,3, E. Khodayari Moez2, Y. Brhane2, G. Liu1, R.J. Hung2

1University of Toronto, Toronto/ON/CA ,2Sinai Health System, Toronto/ON/CA ,3University of Calgary, Calgary/AB/CA

Introduction: The role of respiratory function as a prognostic factor among lung cancer patients remains unclear. The objective of this study was to investigate lung function as a prognostic factor for overall survival (OS) in lung cancer patients from a general population-based cohort (UK Biobank, UKB) and a high-risk screening eligible population (National Lung Screening Trial, NLST).

Methods: Patients with an incident lung cancer diagnosis and spirometry-assessed lung function were included. Lung function was measured as the forced expiratory volume in 1-second (FEV1), forced vital capacity (FVC), ratio of FEV1/FVC, and relative FEV1 (observed FEV1 relative to predicted FEV1). OS is time from lung cancer diagnosis to death from any cause or censoring. Multivariable Cox proportional hazards models, adjusted for known prognostic factors selected a priori, were fitted to estimate the effect of lung function on OS in lung cancer patients from populations with different baseline lung cancer risks. We report hazard ratios (HR) and 95% confidence intervals (CI).

Results: 2,690 and 609 lung cancer patients were included in the analysis from the UKB and the NLST, respectively. In the UKB, a higher relative FEV1 and a higher FEV1/FVC ratio were associated with better overall survival after a lung cancer diagnosis with adjusted HR of 0.98 (95% CI: 0.95-1.00, per 10% increase) and 0.95 (95% CI: 0.90-1.00, per 10% increase), respectively. Contour plots illustrate the decreased probability of OS predicted for individuals with decreased lung function. No statistically significant results were found when assessing the NLST data.

Conclusions: Impaired lung function was associated with poorer survival for lung cancer patients diagnosed in a general population, but not in the high-risk screening-eligible population. This highlights the potential clinical importance of respiratory function as a prognostic factor in lung cancer in the general population and presents a possibility for personalized cancer management.

P2.04B.13 Time to Benefit: A Systematic Review and Meta-Analysis of Lung Cancer Screening Trials

E. Kim, I. Cenzer, F.J. Graham, J. Kang, S. Lee, A.S. Rustagi

University of California-San Francisco, San Francisco/CA/USA

Introduction: Lung cancer screening with annual low-dose computed tomography (CT) reduces lung cancer mortality in the long-term but can lead to immediate harms. Guidelines recommend targeting cancer screening to those persons whose life expectancy exceeds the screening test's time to benefit. Therefore, we aimed to estimate the time to benefit from lung cancer screening using low-dose CT to prevent mortality from lung cancer by conducting a systematic review and survival meta-analysis of randomized controlled trials of lung cancer screening.

Methods: We identified randomized controlled trials of lung cancer screening with low-dose CT based on two systematic reviews. We extended one review's search terms/approach to 12/3/2023. We focused on studies that reported lung cancer and all-cause mortality over years of follow-up. For each eligible study, we fit independent Weibull survival curves and generated Markov chain Monte Carlo simulations to estimate the absolute risk reduction at different time points. We determined time to benefit as the time at which specific absolute risk reduction thresholds (ARR=0.0005, 0.001, 0.002) were crossed. We pooled these estimates using random-effects meta-analysis model.

Results: A total of eight randomized controlled trials comprising 88,526 participants were included in the meta-analysis. Enrollment age ranged from 50s to 70s in most studies. Follow-up duration ranged from 7.3 to 12.3 years. For every 500 people screened with low-dose CT, 5.3 years (95% confidence interval 3.9-8.7) passed before one death from lung cancer was prevented (ARR=0.002). The time to prevent one lung cancer death per 1000 persons screened (ARR=0.001) was 3.4 years (95%CI: 2.2-5.1); per 2000 persons screened (ARR=0.0005), 2.2 years (1.4-3.4 years).

Conclusions: Our findings suggest that lung cancer screening with low-dose CT is most appropriate for those with life expectancy greater

than approximately 5.3 years.

P2.04B.14 Barriers to Maximal Screening Impact in Persons Diagnosed with Lung Cancer in a Prospective Cohort.

W. Liao1, J. Goss1, T. Qureshi1, S. Peppers1, A. Harris1, A. Porter1, K. Dortch1, A. Patel1, F. Caro1, J. Roma1, W. Marshall1, C. Fehnel1, A. Mehrotra1, O. Ogbeide1, P. Lammers1, K. Tonkin1, J. Machin1, J. Zhao2, T. Ng2, M. Ray3, M.P. Smeltzer3, R.U. Osarogiagbon1

1Baptist Cancer Center, Memphis/TN/USA ,2Baptist Memorial Hospital, Memphis/TN/USA ,3University of Memphis, Memphis/TN/USA

Introduction: Lung cancer screening (LCS) reduces mortality, but implementation barriers reduce benefit. For maximal benefit, all persons truly at risk should participate in LCS throughout their years of eligibility; persons who smoke should quit. We mapped barriers to maximal benefit of LCS.

Methods: We categorized all persons diagnosed with lung cancer from 2015 to 2023 in three prospective institutional databases (Cohort 1), those who: met USPSTF 2021 LCS eligibility criteria (Cohort 2); had at least one LCS episode (Cohort 3); quit smoking before LCS (Cohort 4); had multiple LCS episodes (Cohort 5). We plotted K-M overall survival for Cohorts 2 to 5. Using Cohort 5 for reference, we compared hazard ratios (adjusted for age, sex, race, insurance and Charlson morbidity score) among LCS-ineligible (Cohort 1 minus Cohort 2), unscreened eligible (Cohort 2 minus Cohort 3), single-episode LCS (Cohort 3 minus Cohort 5), LCS patients who had quit (Cohort 4) versus not quit smoking (Cohort 3 minus Cohort 4).

Results: Of 3,074 patients, 1,686 (55%) were eligible for LCS; 420 (14%) had any LCS; 109 (4%) had LCS after quitting smoking; 131 (4%) had multiple LCS episodes (Figure 1). The survival of patients across Cohorts 2 to 5 differed (Figure 2). With Cohort 5 (screening adherent) as reference, aHR was 2.45(1.62 - 3.70, p< 0.0001) for LCS-ineligible; 2.66(1.76 - 4.00, p < 0.0001) for unscreened eligible; 1.88(1.19 - 2.97, p = 0.0072) for single-episode LCS; and 1.31(0.70 - 2.44, p = 0.3983) for persons who had quit and 2.14(1.68 - 3.44, p = 0.0016) for persons who had not quit smoking before LCS.

Conclusions: Eligibility criteria limitation was the largest barrier to LCS, access for eligible persons was the next largest barrier. Survival was significantly worse in screened patients who actively smoked. Patients with multiple LCS episodes had the best survival.

P2.04B.15 Co-Design of Decision Support Tools for Lung Cancer Screening in Australia

R.H. Dodd1, K. McFadden1, M. Dickson2, S. Sherriff2,3, E. Stone4,5,6, N.M. Rankin6

1The Daffodil Centre, Faculty of Medicine and Health, The University of Sydney, Sydney/AU ,2The Poche Centre for Indigenous Health, Faculty of Medicine and Health, The University of Sydney, Sydney/AU ,3Global Centre for Preventive Health and Nutrition, Institute for Health Transformation, Deakin University, Geelong/AU ,4St Vincent's Hospital Sydney, Sydney/AU ,5School of Clinical Medicine, University of New South Wales, Sydney/AU ,6Centre for Health Policy, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne/AU

Introduction: Lung cancer is the highest cause of cancer death in both men and women, with five-year survival rates 23% in Australia. Mortality rates are substantially higher in regional and remote Australia, in lower socioeconomic groups, culturally and linguistically diverse communities, and among Aboriginal and Torres Strait Islander communities (First Nations). Australia's National Lung Cancer Screening (LCS) Program will commence from July 2025, targeted at people with high risk of lung cancer based on age and smoking history criteria. This study aimed to co-design evidence-based tools to support shared decision-making for LCS by collaborating, including and designing with people that will use these tools.

Methods: Co-design workshops were conducted with potential end-users of decision support tools for LCS: culturally and linguistically diverse consumers (3 workshops; n=21), First Nations communities (4 workshops; n=30) and experts/clinicians (2 workshops; n=9). Workshops included presentations and activities to elicit the most important, convenient, desirable and/or actionable functional

requirements for each group for decision support tools. Cognitive interviews (n=15) were conducted with an independent group of end-users. The resources were designed to align with International Patient Decision Aid Standards and revised iteratively.

Results: The workshop outputs were three decision support tools including a two-page tool, a longer, more detailed decision-aid and a video. Workshop participants outlined key priorities to include in the decision tools as being information about the screening process including the appointment, location of screening services, what treatment might be, screening benefits, the importance of cultural safety, and managing stigma. Consumers wanted a visual representation of the LCS process, testimonials from previous participants of LCS, and found icon arrays to be too statistics focussed. First Nations communities expressed the desire for personalised videos of community members and local health workers, education sessions about LCS, as well as culturally designed t-shirts to help 'get the word out'. Consumers and experts/clinicians were passionate about "getting people in the door" for LCS. Process driven questions were a priority for experts/clinicians, including what the screening involves. Reframing of potential harms of screening as 'other things to consider' was important for both consumers and clinicians. Cognitive interview participants highlighted refinements for each tool regarding comprehension and some design elements. End users found all tools easy to read and understand, and saw the benefit of the different tools for different purposes and audiences.

Conclusions: Co-design workshops identified specific components for shared decision-making tools in LCS appropriate for a range of different communities, including First Nations. These tools have been developed prior to implementation of the National Lung Cancer Screening Program to support those eligible for LCS in making their decision about taking part in screening. Further personalisation and localisation of resources, or information sessions may be beneficial to reach these priority groups. These findings will be highly relevant to other jurisdictions implementing LCS and to inform the development and co-design of these tools with their communities, particularly those with First Nations communities.

P2.04B SCREENING AND EARLY DETECTION - SCREENING IMPLEMENTATION AROUND THE WORLD, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.04B.16 Real-World First Round Results from a Charity Lung Cancer Screening Program in East Asia

A.D.l. Sihoe1, N.K.Y. Fong2, A.S.m. Yam2, M.M.W. Cheng2, D.L.S. Yau2, A.W.L. Ng2

1CUHK Medical Centre, Hong Kong/CN ,2Cancer Information Charity Foundation, Hong Kong SAR, China, Hong Kong/CN

Introduction: Screening with Low Dose Computed Tomography (LDCT) has been proven to potentially reduce the rate of mortality of lung cancer. Lack of real-world data outside of protocolized trials has been cited as an impediment to its more widespread implementation, especially in Asia.

Methods: A single round of LDCT was provided through a community-based charity program in Hong Kong to asymptomatic adults with a family history of lung cancer and/or smoking history. Anonymized data from this program was analyzed.

Results: LDCT was performed for 99 participants, including 98 (99%) who had one or more family members with history of lung cancer, and 70 (71%) who were never-smokers. After a single round of screening, a positive LDCT was noted in 47 participants (47%). A sister with a history of lung cancer (28% versus 8%, p = 0.01) and a multiplex family (47% versus 23%, p = 0.02) were factors associated with a positive LDCT. Lung cancer (all adenocarcinoma) was diagnosed as a direct consequence of positive LDCT findings in 6 participants (6%), of whom 4 had stage I disease and 5 received surgery with curative intent. In the 47 participants with a positive LDCT, having a sister with a history of lung cancer increased the risk of a lung cancer diagnosis (relative risk = 5.23, 95% confidence interval: 1.09 - 25.21). Detected lesions categorized as Lung-RADS 3 or above (odds ratio = 12.08, 95% confidence interval: 1.27 - 114.64) or deemed by an experienced specialist to be suspicious (odds ratio = 63.33, 95% confidence interval: 5.48 - 732.29) weresignificantly more likely to turn out to be a lung cancer.

Conclusions: This real-world data demonstrates that a single round of LDCT screening at a community level in East Asia can detect potentially curable lung cancer at a rate comparable to those reported by protocolized trials. When considering future LDCT screening programs in East Asia, a family history of lung cancer may be a key factor indicating a person for screening, and how features of a LDCT-detected lesion should trigger further intervention warrant further definition.

P2.05A.01 Clinical Presentation, Outcomes, and Anticoagulant Strategies in Patients with Lung Cancer-Associated Isolated Distal Deep Vein Thrombosis

D. Yang1, J. Deng1, S. Huang1, H. He2, C. Dai1, D. Zhao1, C. Chen1

1Department of Thoracic Surgery, Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai/CN ,2Department of Thoracic Surgery, The First Hospital of Lanzhou University, Lanzhou/CN

Introduction: The prognosis and anticoagulation strategies for isolated distal deep vein thrombosis (iDDVT) remain controversial. Currently, no studies have analyzed lung cancer-associated iDDVT (LC-iDDVT) in different subtypes, namely axial venous thrombosis (AVT) and muscular venous thrombosis (MVT).

Methods: The study included 593 patients with LC-iDDVT and 260 patients with lung cancer-associated proximal DVT (LC-Proximal DVT). LC-iDDVT was further classified into AVT (112 patients) and MVT (481 patients). Short-term (90-day) outcomes were assessed using logistic regression (odds ratio [OR]; 95% confidence interval [CI]), and long-term (1-year) outcomes were evaluated using survival analysis (hazard ratio [HR; 95% CI]).

Results: At the 90-day follow-up, patients with MVT had a lower adjusted risk of pulmonary embolism (PE; OR=0.18 [0.07-0.52], P=0.001) or venous thromboembolism (VTE) recurrence (OR=0.51 [0.30-0.85], P=0.010) than patients with LC-Proximal DVT. Similar results were observed at the 1-year follow-up. However, there was no significant difference in the 90-day and 1-year adjusted risk of PE (OR=0.75 [0.27-2.13], P=0.594; HR=0.87 [0.42-1.78], P=0.700) and VTE recurrence (OR=0.97 [0.51-1.87], P=0.935; HR=0.99 [0.63-1.56], P=0.970) between patients with AVT and those with LC-Proximal DVT. Among patients with LC-iDDVT, those receiving anticoagulation had a lower risk of VTE recurrence (HR=0.57 [0.35-0.95], P=0.030) and DVT deterioration (HR=0.28 [0.13-0.60], P=0.001) compared to those without anticoagulation. Moreover, patients with AVT receiving >3 months of anticoagulation had a lower risk of VTE recurrence compared to those with ≤3 months of anticoagulation (HR=0.23 [0.03-0.92], P=0.038).

Conclusions: Unlike patients with MVT, patients with AVT have a prognosis similar to that of patients with LC-Proximal DVT. Furthermore, patients with LC-iDDVT should receive anticoagulation therapy, and anticoagulation strategies should be optimized in patients with AVT.

P2.05A.02 Incidence of Pneumonitis in Asian Patients with Non-Small Cell Lung Cancer: A Systematic Literature Review and Meta-Analysis

C. Pierce1, K. Zu1, D. Xing1, Y. Kuang2, J. Uyei2, O. Sanni2, Y. Wang2, A. Liu1

1Merck & Co., Inc., Rahway/NJ/USA ,2IQVIA, San Francisco/CA/USA

Introduction: Pneumonitis is a well-documented adverse event (AE) of certain treatments for non-small cell lung cancer (NSCLC), including PD-1/PD-L1 inhibitors and thoracic radiation. However, it remains unclear whether there are racial/ethnic differences in the risk of pneumonitis. Several recent studies, such as the PACIFIC study, have reported a higher rate of post-chemoradiation pneumonitis in Asian compared with non-Asian patients with NSCLC, therefore, understanding the unique susceptibility and risk of pneumonitis in Asian patients is crucial for optimizing therapeutic efficacy and safety in this population. The objective of this study was to quantify the incidence of pneumonitis in patients treated for NSCLC in East and Southeast Asian countries.

Methods: A systematic literature review and meta-analysis was performed and reported in accordance with PRISMA guidelines. MEDLINE, Embase, Cochrane Central Register, and five local language databases in Chinese, Japanese, and Korean were searched from 1/1/2014-8/2/2023. Records were screened for eligible randomized-controlled trials (RCTs), single-arm trials, and non-randomized trials evaluating pharmacological or radiation therapy in lung cancer patients. Trials were included if conducted in East or Southeast Asian countries, or if their results were stratified by these regions. Random-effects meta-analyses were performed to assess the incidence of all-grade (grade 1-5), grade 1-2, and grade 3-5 pneumonitis using generalized linear mixed models in R 4.3.3.

Results: Among 4,280 records identified from the search, 202 studies on Asian patients with NSCLC met the inclusion criteria. A total of 189 studies (23,173 patients) were included in the meta-analysis, comprising 108 single-arm trials, 76 RCTs, and 5 non-randomized trials. Most studies were conducted within a single country, with Japan (n=89), China (n=72), and South Korea (n=12) being the most frequently reported study sites. While there was variation across studies in NSCLC subtype, line of treatment, outcome reporting, and follow-up duration (median range: 8.2-81 months), this variation was deemed acceptable. Targeted therapy (n=81), chemotherapy (n=41), and chemoradiation (n=37) were the most extensively studied treatments among the included trials. Across all types of treatments, the pooled incidence of all-grade, grade 1-2, and grade 3-5 pneumonitis in Asian patients was 5.42% [95% confidence interval (CI): 4.25-6.89], 3.58% [95% CI: 2.54-5.03], and 1.34% [95% CI: 1.06-1.70], respectively. Among patients that received radiation-containing treatments, the pooled incidence of pneumonitis was estimated to be 34.12% [95% CI: 25.11-44.45] for grade 1-2 events and 2.96% [95% CI: 2.12-4.12] for grade 3-5 events, whereas among patients that did not receive radiation-containing treatments, the pooled incidence of grade 1-2 and 3-5 pneumonitis was 1.74% [95% CI: 1.33-2.27] and 1.00% [95% CI: 0.76-1.32], respectively.

Conclusions: This study quantifies the background risk of pneumonitis among East and Southeast Asian patients receiving any treatment for NSCLC. Pneumonitis incidence markedly increases in Asian patients receiving radiation-containing treatments, , primarily in grade 1-2 pneumonitis. This increase in radiation-induced pneumonitis among Asian patients is much larger than what is reported in the literature for non-Asian populations (22-24%). Results from this study help to contextualize the safety data from trials combining other therapies with thoracic radiation.

P2.05A.03 Regional Disparities in Distant Metastatic Lung Cancer Patients and Overall Survival in Norway. A Nationwide Population Study

J. Berg1, R.H. Tilseth2, V.D. Haakensen3, B. Møller4, Y. Nilssen4

1Tønsberg Hospital Trust, Tønsberg/NO ,2Førde Hospital Trust, Førde/NO ,3Oslo University Hospital, Oslo/NO ,4Cancer Registry of Norway, Oslo/NO

Introduction: The incidence of lung cancer with distant metastases (stage IV) in Norway has remained stable at 40% since 2013 and varies between 32% and 56% in different health trusts. The aim of this project was to examine the situation of lung cancer patients in the two health trusts with the highest proportion, Vestfold and Førde, were formerly heavily industrialized places. Nevertheless, the proportion of daily smokers and the incidence of lung cancer were at the national average.

Methods: We included 16 953 patients diagnosed with non-small cell lung cancer (NSCLC) or small cell lung cancer (SCLC) in Norway between 2018 and 2022. Data from the Cancer Registry of Norway were analyzed. Descriptive statistics on age, sex, stage, performance status (ECOG) and morphological distribution were performed. Relative survival was estimated using the Pohar-Perme estimator, and a health trust specific lifetable stratified by age, sex and calendar period.

Results: Lung cancer characteristics in Førde and Vestfold matched the national average for age and morphological distribution. However, Vestfold patients exhibited poorer health, and functional status (Figure 1). More lung cancer patients in Førde and Vestfold than in the rest of the country were diagnosed based on severe symptoms (Figure 2). Fewer incidental findings were noted in Førde and Vestfold for local stage disease. Norway's overall survival rate from 2018-2022 was 28%, with regional disparities ranging from 23.6% to 35.9%. Førde demonstrated a comparatively higher survival rate of 32%, whereas Vestfold reported a slightly lower rate of 27%.

Conclusions: Lung cancer patients in Vestfold and Førde, health trusts with the highest proportion of advanced disease in Norway, experienced delayed access to specialized healthcare with severe symptoms, compared to those elsewhere. Besides cancer stage, factors like comorbidity and functional status also affect survival.

P2.05A.04 Does the Treating Physician's Specialty-Oncology or Pulmonology-Affect Clinical Outcomes and Survival in Lung Cancer Patients?

J. Berg1, R.H. Tilseth2, V.D. Haakensen3, B. Møller4, Y. Nilssen4

1Tønsberg Hospital Trust, Tønsberg/NO ,2Førde Hospital Trust, Førde/NO ,3Oslo University Hospital, Oslo/NO ,4Cancer Registry of Norway, Oslo/NO

Introduction: Up to 75% of lung cancer patients at the time of diagnosis or relapse have advanced disease with distant metastasis (stage IV) and need palliative treatment, which is a systemic life-prolonging treatment involving radiotherapy, chemotherapy, immune checkpoint inhibitors or targeted therapy, sometimes in combination with radiotherapy.Lung cancer patients with stage III or IV disease who require palliative treatment are treated by either oncologists or pulmonologists, depending on the practices used in different countries. There is still a lack of information on how physician specialty affects clinical outcomes and survival and whether there are any differences; professional discussions are ongoing on this subject.The aim of this study was to investigate whether there are any differences in lung cancer outcomes between treatments administered by oncologists and pulmonologists.

Methods: All lung cancer patients with a stage IV registered at the Cancer Registry of Norway in the period 2018-2022 were included. Based on the patients' place of residence, and the clinical specialty available, each health trust was categorized as either 'oncologist' or 'pulmonologist'. Time from date of diagnosis to treatment with either palliative radiotherapy or immunotherapy, and one-year overall survival were assessed according to specialty categories

Results: A total of 6,724 patients were included, 51.4% of whom were treated by pulmonologists and 48.6% by oncologists. No significant differences were observed between the groups in relation to age, sex, histology, stage, palliative radiotherapy, or PD-L1 expression.There was no difference in the proportion of patients who received palliative radiotherapy (34.6% [pulmonologists] vs 35.5% [oncologist], p=0.41). Patients treated by an oncologist came to palliative radiotherapy sooner after the time of diagnosis than patients treated by a pulmonologist (35 vs. 41 days, p= 0.10). Significantly more patients treated by a pulmonologist received immunotherapy than patients treated by an oncologist (45.6 and 38.3%, p<0.01), (Figure 1). The wait time to start immunotherapy was significantly shorter for pulmonologist-treated patients, median 21 vs. 28 days (p=0.04), (Figure 2). The 1-year overall survival was slightly longer among patients treated by a pulmonologist compared to those treated by an oncologist (30.8% [28.7%-31.8%] and 27.8% [26.2%-29.4%]).

Conclusions: Our results suggest that more patients treated by pulmonologists received immunotherapy with shorter wait time and had a tendency of improved survival than patients treated by oncologists. A likely reason for this is that the transition between departments is time-consuming and delay the treatment onset.

P2.05B.01 How Reliable Is PET/CT in T1A and T1B Non-Small Cell Lung Cancer for Mediastinal Staging?

G. Özcibik Isik1, &. Sarbay2, B. Kiliç1, E. Erşen1, V. Kara1, M.K. Kaynak1, A. Turna1

1Istanbul University-Cerrahpassa Cerrahpasa, ISTANBUL/TR ,2Sinop State Hospital, Sinop/TR

Introduction: TNM staging is used in non-small cell lung carcinomas.For preoperative clinical mediastinal staging, PET/CT is utilized; for pathological mediastinal staging, EBUS, mediastinoscopy, and VAMLA are employed.Staging also benefits from systematic lymph node dissection following lung resection.In our study, we aimed to evaluate accuracy of PET-CT in T1a and T1b NSCLC non-small cell lung cancer patients.

Methods: Those who received lung resection, systematic lymph node dissection, and videomediastinoscopy or video-assisted mediastinoscopic lymphadenectomy(VAMLA) for non-small cell lung cancer in our clinic between January 2002 and January 2022 were included.Tumors with a tumor diameter larger than 2 cm were excluded from the study.A total of 224 patients were included.Clinical mediastinal staging status and pathological staging status were noted.The groups were evaluated in terms of demographic characteristics, biochemical parameters, tumor characteristics and survival.

Results: Of the 196 patients with clinical(c) T1A-BN0 underwent VAMLA, 173 were pathologically found to have N0(88.2%), whereas occult N1 rate was 7.1%.Occult N2 rate was 4.7%. Of 17 patients with cT1aN2 NSCLC, 10 (58.8%) and 4 (23.5%) were found to have pN2 and pN1 disease whereas only 3 patients (17.7%) were found to have pN2.The sensitivity of PET/CT in the evaluation of N0 and N1-2 was 91%, specificity was 32.3%, and accuracy was 82.1%.The sensitivity of PET/CT in the evaluation of N0-1 and N2 was 98.4%, specificity was 78.5%, and accuracy was 88.8%.The area under the curve(AUC) for the prediction of N0, N1 and N2 by PET-CT were 0.639(95% CI: 0.517-0.761) 0.614 (95% CI: 0.425-0.803) and 0.641 (95% CI: 0.488-0.794) respectively(Figure 1-3).

Conclusions: The low accuracy observed when PET/CT indicates N0 for mediastinal staging of non-small cell lung carcinomas smaller than 2 cm should not be overlooked. Therefore, it is advisable that comprehensive mediastinal staging is essential to accurately detect N1-2 involvement.VAMLA could be considered the reference staging procedure for staging cT1A-BN0-2 NSCLC.

P2.05B.02 Automated Extraction of Key Entities from Thorax CT Reports Using NER with Prompt Engineering

Z. Akcali, M. Kocak, A. Farzaliyeva, F. Guven, M.N. Ramazanoglu, E. Hasdemir, B. Yagdiran, A. Oguz, M. Agildere, O. Altundag

Baskent University, Ankara/TR

Introduction: Medical records have undergone dramatic transformations over the past decades. Traditionally, patient information was documented and stored in paper files, posing challenges in terms of accessibility, organization, and analysis. The advent of Electronic Medical Records (EMRs) revolutionized healthcare data management, enabling efficient storage, retrieval, and sharing of patient information. However, EMRs often contain vast amounts of unstructured data, particularly within radiology reports, making it difficult to efficiently extract and utilize key clinical findings. This is where Artificial Intelligence (AI) comes into play. AI-powered tools, such as Natural Language Processing (NLP) and Named Entity Recognition (NER), can automatically analyze and extract relevant information from unstructured medical texts. This has the potential to significantly improve workflow efficiency for healthcare professionals, facilitate large-scale data analysis for research, and ultimately contribute to better clinical decision-making and patient care. Medical NLP models are mainly available in English, with limited options for other languages.

Methods: In this study, we explore the use of NER with chat prompts to automatically extract key entities from anonymized thorax CT reports, demonstrating the potential of AI in transforming how we interact with and utilize medical data. This study investigates the feasibility of using Named Entity Recognition (NER) with chat prompts to automatically extract key entities from anonymized thorax CT reports, ensuring patient privacy is protected in accordance with HIPAA regulations. We trained and tested the model on a dataset of 53 and 50 reports respectively, focusing on six entities: anatomy (ANAT), impression (IMP), outsider words (O), and observation presence (OBS-P), absence (OBS-A), and uncertainty (OBS-U).

Results: Evaluation on the test set yielded promising results, with an overall accuracy of 97% and macro-averaged F1 score of 0.96. Notably, ANAT and OBS-A achieved F1 scores of 0.99, demonstrating high precision and recall in identifying anatomical structures and absent observations (Table-1). The model also performed well in recognizing other entities, with F1 scores exceeding 0.91 for IMP, O, and OBS-U.

Conclusions: These findings suggest that NER with chat prompts can be a valuable tool to extract key information from thorax CT reports.

This approach can potentially improve workflow efficiency for radiologists, facilitate data analysis and research, and ultimately contribute to enhanced patient care. Further research will explore the model's performance on larger datasets and investigate its generalizability to other types of radiology reports. We aim to refine the chat prompt design and explore different NER models to potentially improve performance further.

P2.05B PULMONOLOGY AND STAGING - IMAGING, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.05B.03 A Novel Lung Nodule Localize Method: Topographic Map Dyeing Model for Target Vessel Watershed Boundary

Z. Chen, Z. Guo, Q. Liang, Q. Nie, W-z. Zhong

Guangdong lung cancer institute, Guangzhou/CN

Introduction: Blind spots quite often occurred in the surgical localization of pulmonary nodules, and complex process and various complications makes nodules localization difficult. We found that segment boundary during Expansion and collapse method or ICG dyeing after target vessel blocked or stumped is irregular, If the boundary texture can be accurately simulated before surgery, it can be used as an optional localization method

Methods: Retrospective collection of cases of lung segment, subpulmonary segment, or watershed wedge resection with indocyanine green boundary display as a training cohort, including preoperative thin-layer chest CT collection and intraoperative use of 3D fluorescence endoscopic recording. Preoperative CT was delineated manually and delivered to deep learning to establish an automated AI 3D reconstruction model. Use fluid thermal diffusion algorithm to delineate the target area of reconstructed blood vessels, and perform constant correction by comparing the real staining boundaries inside the endoscope through machine learning, iterating to obtain the most suitable parameter formula. Prospective watershed staining validation was conducted in three medical centers in China.

Results: For 1/3 of peripheral pulmonary nodules, the accuracy of drainage wedge resection was 95%, AUC0.914 95% (0.875-0.953), and the accuracy of puncture localization wedge resection was 95%, AUC0.857 95% (0.804-0.910), p=0.0898; For 2/3 of pulmonary nodules, the accuracy of watershed wedge resection is 91%, AUC0.841 95% (0.779-0.903), watershed wedge resection accuracy is 95%, AUC0.620 95% (0.524-0.716) P=0.0001;

Conclusions: The watershed method has no significant difference in efficacy and puncture localization of 1/3 peripheral pulmonary nodules, and can be used as an alternative solution; For internal 2/3 nodules, it is significantly better than traditional segmental resection surgery. It is feasible to use artificial intelligence to automatically reconstruct the boundaries of pulmonary blood vessels and target blood vessels, and simulate staining, which is highly consistent with the contour of staining boundaries in real endoscopes. These findings have the potential to further develop preoperative planning and intraoperative navigation system technology, enabling real-time non-invasive localization and precise resection of pulmonary nodules during the surgical process.

P2.05B.04 Development of a CT Image-Based Virtual Atelectasis Simulation Model and Noninvasive Lung Nodule Localization System

J. Hwang1, I. Hwang2, S. Ham2, C. Kim1

1Korea University Ansan Hospital, Ansan/KR ,2Healthcare Readiness Institute for Unified Korea, Korea University College of Medicine, Seoul/KR

Introduction: This study aimed to develop a computed tomography-based virtual atelectasis simulation system for noninvasive lung nodule localization to improve the precision of presurgical planning for pulmonary nodule resections.

Methods: Contrast-enhanced computed tomography images of the lungs of 20 patients diagnosed with pulmonary nodules at Korea University Ansan Hospital between June 2021 and February 2024 were acquired, and image data were converted into three-dimensional models using 3D slicer. The mesh points extracted from these lung models were then manipulated to simulate the effects of gravity, by adjusting the lung shapes and nodule positions to align with the respective surgical postures. Subsequently, we assessed the similarity of the simulation by comparing the resulting deformed lung shape and nodule locations with the corresponding perspectives observed in the surgical videos.

Results: Overall, the average volume of the entire lung was 2,226 cm3 (±588) and the lung shrinkage rate was 48.6% (±12.9). Evaluations of an average of 15 pairs of images per case revealed significant conformity between atelectasis simulation images and surgical video snapshots, with average Dice and Jaccard similarity coefficient values of 90.28 and 88.25, respectively. Furthermore, the alignment of nodule positions between the simulations and surgical anticipation demonstrated notable accuracy, with an average Hausdorff distance of 6.39mm.

Conclusions: We developed a simulation of lung atelectasis based on preoperative computed tomography scans. The integration is anticipated to enhance the accuracy of locating nodules contributing to efficient and precise surgical planning.

Figure. a.DICOM data from 20 patients were used to create a 3D model. The model was adjusted accordingly. The chest cavity shape was captured using the drape function, and mesh points were adjusted to match the concave sternum. Texture was applied for realism, and the model was presented in real-time. Evaluation involved comparing the simulated lung shape with images from the surgical video.

P2.05C PULMONOLOGY AND STAGING - PATHOLOGY ASSESSMENT, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.05C.01 Pathologic Nodal Staging Reporting Quality: A Multi-Center Assessment of NSCLC Trends Over Time & Key Reporting Parameters

H. Tupper1, J. Santhakumar2, K. Burapachaisri2, R. Jackson2, Z. Islas3, K.C. Banks4, V. Sarovar5, A. Sun6, R.K. Wile2, K.E. Barnes2, L.C. Sakoda5, J.B. Velotta7

1UCLA, Los Angeles/CA/USA ,2University of California San Francisco, San Francisco/CA/USA ,3Kaiser Permanente, Pasadena/CA/USA ,4University of California, San Francisco East Bay, Oakland/CA/USA ,5Kaiser Permanente Northern California, Oakland/CA/USA ,6University of California, Berkeley, Berkeley/CA/USA ,7Kaiser Permanente Oakland, Oakland/CA/USA

Introduction: Non-small cell lung cancer (NSCLC) staging, treatment and survival data are collated nationally to draw conclusions about optimal management. Nodal staging quality is associated with improved NSCLC survival, but there is significant variability in pathologic reporting. This multi-center retrospective study evaluates the quality of pathologists' nodal staging in early-stage NSCLC patients, assessing key reporting parameters and trends over time.

Methods: We evaluated adult patients with clinical stage I-II NSCLC who underwent upfront resection between 2009-2019 whose surgical pathology report indicated a negative (N0) or unclear (Nx or unreported) nodal stage. Patient characteristics, treatment variables and key pathologic reporting parameters, including presence of nodal tissue in specimens, pathologist-reported nodal number and stage, and surgical lymph node adequacy (>3N2 & 1N1) were ascertained through chart review. Key outcomes were the appropriateness of pathologist-designated N0 or Nx stage. Tumor specimens staged N0 with incomplete nodal specimens (<3N2 & 1N1) were designated "i-N0," while those completely lacking nodal tissue that were inappropriately staged N0 were designated "X-N0." Specimens with complete nodal specimens (>3N2 & 1N1 nodes) inappropriately staged as Nx were designated "X-Nx." Associations between patient characteristics, treatment variables and pathologic reporting parameters were evaluated using Kruskal-Wallis, Chi-square and Fisher's exact tests. Staging trends over time were analyzed using a Wilcoxon-type rank-sum test and key outcomes were analyzed with multivariate logistic regression.

Results: Among 2356 patients, N stage was unreported in 103 (4.4%), Nx in 120 (5.1%) and N0 in 2133 (90.5%). There was a clear trend in pathologist-designated N stage by reporting year (p<0.0001) with a decrease in unreported N stage after 2011. 15.6% (n=348) of pathology reports with lymph nodes lacked a node count and most of these (67.0%, n=233) involved nodal fragments. Among 2133 N0-designated specimens, 59.9% (n=1278) were "i-N0" and 0.8% (n=17) were "X-N0." Each additional year predicted decreased odds of "i-N0" (OR 0.94 [95% CI: 0.09-0.97]), as did pre-operative receipt of invasive mediastinal staging (OR 0.71 [95% CI: 0.53-0.95]). Care in Region D (vs. A, B, or C) predicted increased odds of "i-N0" (OR 2.34 [95% CI: 1.58-3.45]). Similarly, each subsequent surgery year, anatomic resection (vs. wedge), and care in Region B were associated with decreased odds of "X-N0" (OR 0.61 [95% CI: 0.45-0.84]; OR 0.06 [95% CI: 0.01-0.28]; OR 0.05 [95% CI: 0.004-0.43], respectively). Among 120 Nx-designated specimens, 17.5% (n=21) were "X-Nx." No factors with associated with "X-Nx."

Conclusions: Data quality limits our ability to identify optimal treatment and survival patterns. Standardized reporting template uptake has propelled significant advances in pathologic reporting, but room for improvement remains with notable variability between centers. A pathologic-reporting indicator for an "incomplete" surgical nodal harvest and a standardized approach to quantifying lymph node fragments may be warranted to improve pathologic data quality.

P2.05C PULMONOLOGY AND STAGING - PATHOLOGY ASSESSMENT, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.05C.02 Does the Proposed 9th TNM Offer Improved Prognostic Accuracy after Lung Carcinoma Resection? Preliminary Analysis Results

P.H. Kaluzynski1, M. Knetki-Wroblewska2, A. Szpechcinski1, P. Rudzinski1, M. Pawlica3, R. Langfort1, T. Orlowski1, M. Szolkowska1

1The Institute of Tuberculosis and Lung Diseases, Warsaw/PL ,2The Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw/PL ,3Medical University of Warsaw, Warsaw/PL

Introduction: The proposed 9th TNM for lung carcinoma provides for the division of the N2 category into subgroup N2a and N2b - according to number of positive nodal stations. Following the changes in the N2, a revision of the TNM IIA-IIIB stage groups was proposed.

The aim of this study was to compare overall survival (OS) and disease-free survival (DFS) in stage groups defined according to the 8th and proposed 9th TNM in the real population.

Methods: For this retrospective study, a group of patients who underwent lung resection for primary lung carcinoma between 2012 and 2013 were selected. Information about disease, treatment and follow-up was obtained from the institutional databases of two hospitals. The stage was determined according to the 8th and proposed 9th TNM. The number and stations of resected lymph nodes were recorded. The date of death was obtained from the Central Informatics Center Data Sharing Team in Poland. OS and DFS were determined according to Kaplan-Meier survival analyses.

Results: So far, of the 944 patients identified in the databases, the medical histories and histopathology reports of first 200 patients operated on in 2012 have been analyzed in detail. This group included 132 men (66%) and 68 women (34%), aged 34 to 85 years (median 64). The majority of patients had adenocarcinoma (47.5%) and squamous cell carcinoma (36%), mostly in stages IB, IIB and IIIA. In 96% of patients the R0 resection was achieved, in 8 patients the surgical margin was positive (R1: 7; 4% and R2: 1, 0.5%). Adjuvant radiotherapy or chemotherapy was used in 41 patients (21%). Thirty-eight patients (19%) were lost to follow-up after surgery. In 59 patients, disease recurrence was registered between 0 and 138 months (median 20) from the date of surgery. By the date of the study, 130 patients had died (65%) between 0 and 143 (median 66) months after surgery; the exact cause of death could not be determined in most cases. Reclassification from the 8th to the proposed 9th TNM resulted in a change of staging group in 17 cases (9%).OS for stages IIA, IIB, IIIA and IIIB determined according to the 8th vs. proposed 9th TNM showed no statistically significant differences (P = 0.73; 0.93; 0.81; 0.49, respectively). Similarly, there were no significant differences in DFS between the groups (IIA: P=0.41; IIB: P=0.59 IIIA: P=0.51; IIIB: P=0.18).

Stratification of staging groups determined according to the 8th TNM showed difference for OS (P = 0.0066) and for DFS (P = 0.0031). Stratification of staging groups determined according to the proposed 9th TNM showed weak difference for OS (P = 0.0391) and no difference for DFS (P = 0.09).

Conclusions: Preliminary analysis showed that in our group of patients with surgically treated lung carcinoma, the 8th TNM more clearly separated the prognostic staging groups for OS and DFS than the proposed 9th edition. This may be related to the small number of cases analyzed and the need for multivariate analysis. The study will continue.

Keywords: 9th TNM, Overall Survival, Disease Free Survival

P2.07A EARLY-STAGE NON-SMALL CELL LUNG CANCER - DEVELOPMENTS IN EGFR MUTATED EARLY STAGE NSCLC, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.07A.01 Clinicopathological vs. Molecular Models in Predicting Adjuvant EGFR-TKI Benefit in Stage I NSCLC

Y. Jiang, Y. Lin, W. Fu, R. Zhong, H. Liang, J. He, W. Liang

The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Adjuvant EGFR-TKIs show promising outcomes in early-stage NSCLC with EGFR mutations, but accurately identifying patients who would derive the greatest benefit remains a clinical challenge. We compared the predictive performance of clinicopathological factors and the 14-gene assay to assess postoperative prognosis and predict the potential benefit of adjuvant EGFR-TKIs in stage I NSCLC.

Methods: From March 2013 to February 2019, patients with completely resected stage I NSCLC (8th TNM staging) and EGFR mutation were included. The 14-gene assay, assessed through quantitative PCR, was developed and subsequently validated across diverse international cohorts. Clinicopathological high-risk factors include any feature indicating a higher risk of recurrence based on NCCN guidelines. The primary endpoint of this study was the 5-year disease-free survival (DFS) rate.

Results: Diagnostic values were evaluated in 180 stage I NSCLC patients. The 14-gene assay demonstrated superior performance compared to clinicopathological factors in predicting recurrence events, with a larger AUROC (C-index of 0.73 vs. 0.57; P<0.001). Patients with molecular high-risk, rather than clinicopathological high-risk factors, showed a more favorable response in predicting the benefit of adjuvant EGFR-TKIs. Specifically, adjuvant EGFR-TKIs benefited molecular high-risk patients over not using EGFR-TKIs, regardless of clinicopathological high-risk (DFS rate increased from 65.9% to 95.0%, P=0.016) or low-risk subgroups (80.0% to 100%, P=0.044). Patients with molecular low risk did not show any benefit from EGFR-TKIs, regardless of clinicopathological high-risk (DFS rate increased from 95.5% to 100%, P=0.460) or low-risk subgroups (94.1% to 100%, P=0.630).

Conclusions: The 14-gene assay proved to be superior to clinicopathological factors, offering valuable guidance for adjuvant EGFR-TKIs decisions in stage I NSCLC.

Introduction: The use of adjuvant osimertinib for epidermal growth factor receptor (EGFR) mutants is expected to expand to earlier stage I in the future, potentially competing with the current standard of care, oral tegafur/uracil (UFT), in Japan. However, the effect of EGFR mutation status on the therapeutic effect of UFT remains unclear. This study was conducted as an exploratory analysis of a retrospective observational study that investigated the real-world data of postoperative adjuvant chemotherapy in Japan (CSPOR-LC03).

Methods: Between 2008 and 2013, 1812 patients with completely resected adenocarcinoma diagnosed as pathologic stage I (T1 > 2 cm, TNM classification sixth edition) were included. This study exclusively enrolled physically low-risk patients—namely, those who have maintained organ function, and no history of other cancers. Additional gene analysis was performed using surgical specimens for patients whose EGFR mutation statuses were unknown. The primary endpoint was the 5-year disease-free survival (DFS) rate, and the secondary endpoint was the 5-year overall survival (OS) rate. We compared these survival rates between four groups classified based on the administration of adjuvant UFT and EGFR mutation status. We performed univariable and multivariable analyses using a Cox proportional hazards model to identify prognostic factors for recurrence and death using clinicopathological factors including the administration of adjuvant UFT and EGFR mutation status.

Results: The median duration of follow-up of participants was 5.8 years (interquartile range [IQR]: 5.0–7.1 years). Of the 1812 patients, 831 (46%) were men, and the median preoperative age was 67 years (IQR: 61–72 years). Of the 933 (51%) patients with EGFR mutations, 394 underwent adjuvant UFT therapy. Of the 879 (49%) patients without EGFR mutations, 393 underwent adjuvant UFT therapy. The 5-year DFS of UFT+/ EGFR+ and UFT-/EGFR+ patients were 82.0% and 87.1%, respectively, and those of UFT+/ EGFR- and UFT-/EGFR- patients were 80.0% and 86.9%, respectively. DFS was significantly worse in the UFT+ group than in the UFT- group (P = 0.015). In OS analysis, no significant difference was observed between the four groups (P = 0.125). In the multivariable analysis for DFS, male sex (HR, 1.333; P = 0.014), pleural invasion positive (HR, 1.538; P = 0.004), lymphatic permeation positive (HR, 1.371; P = 0.017), vascular invasion positive (HR, 2.173; P < 0.0001), and nodule with GGO (HR, 0.570; P < 0.0001) were significant, however, adjuvant UFT therapy was not an independent prognostic factor for DFS. Univariable and multivariable analyses restricted to the higher-risk subgroups, without GGO and tumor diameter >3 cm, also showed no effect of UFT, regardless of EGFR mutation. In OS, EGFR mutation-positive was significant predictive factors in the univariable analysis (HR, 0.716: P = 0.024), however, the significance disappeared in the multivariable analysis.

Conclusions: In pathologic stage I (>2 cm) lung adenocarcinomas with EGFR mutation, the survival benefit of adjuvant chemotherapy using UFT was not observed.

Introduction: Despite the established evidence regarding the epidermal growth factor receptor (EGFR) mutation status as a biomarker for EGFR tyrosine kinase inhibitor (EGFR-TKI) treatment in patients with advanced lung adenocarcinoma (LUAD), the prognostic implications of EGFR mutation status in surgically resected LUAD remain unclear, especially concerning uncommon EGFR mutations (UCM). This study aims to clarify the prognostic differences between UCM and common EGFR mutations (CM) in completely resected LUAD patients.

Methods: A multicenter retrospective observational study was conducted at 21 centers in Japan, involving 4,181 LUAD patients who underwent pulmonary resection between 2015 and 2018. Patients with EGFR mutation negativity or unavailability, wedge resection, and incomplete resection were excluded, resulting in the evaluation of clinicopathological and prognostic characteristics of 1,636 patients with CM and UCM.

Results: Among eligible patients, 1,441 (88.1%) had CM and 195 (11.9%) had UCM. Clinicopathological features were similar between the two groups, except for a higher prevalence of smoking history and lower incidence of nodules with ground glass opacity on CT findings in patients with UCM, who also underwent mediastinal lymph node dissection more frequently compared to those with CM. Recurrence-free survival (RFS) did not exhibit significant differences between CM and UCM groups (Figure 1A). However, overall survival (OS) was notably shorter in patients with UCM compared to those with CM. In a multivariable analysis of OS, UCM independently predicted poor prognosis (hazard ratio [HR] 1.538, 95% confidence interval [CI] 1.003-2.359) (Figure 1B). Furthermore, this association was notably pronounced when focusing on patients with pathological stage II-III disease (HR 2.007, 95% CI 1.195-3.370). Median survival after recurrences was significantly shorter in patients with UCM compared to CM (46.7 vs 59.0 months, P= 0.001). Although the administration rate of first-line treatment after recurrences was comparable between UCM and CM groups (73.2% and 78.4%, respectively), the use of EGFR-TKIs was significantly lower in UCM compared to CM (44.1% vs 76.6%).

Conclusions: Patients with surgically resected EGFR-mutated LUAD harboring CM and UCM demonstrated similar recurrence risk; however, those with UCM exhibited significantly shorter OS compared to CM. Further advancement of post-recurrent and perioperative management for patients with UCM is imperative.

Introduction: In the perioperative treatment for lung adenocarcinoma (LUAD), biomarkers like programmed cell death-ligand 1 (PD-L1) expression and epidermal growth factor receptor (EGFR) mutation are utilized. However, the clinical relevance of PD-L1 expression in surgically resected EGFR-mutant LUAD remains uncertain.

Methods: We made a real-world dataset collecting LUAD patients who underwent surgical resection across 21 centers in Japan from 2015 to 2018. We explored the relationship between PD-L1 expression, EGFR mutations, and prognosis.

Results: In total, 4,181 LUAD patients were registered. Of them, we excluded the patients who underwent wedge resection (N=391) or R1 resection (N=29) and the patients with unknown PD-L1 expression (N=2,914). Eventually, 847 LUAD patients were included in the analysis. Among them, 429 patients (51%) had negative PD-L1 expression (tumor proportion score [TPS]<1%) and 418 patients (49%) had positive PD-L1 expression (275 and 143 patients with weakly positive [TPS=1-49%] and strongly positive [TPS≥50%], respectively). EGFR mutations were detected in 331 (39%) LUADs. High PD-L1 expression correlated with unfavorable recurrence-free survival (RFS) in both EGFR-mutant (N=330, P=0.0001) and EGFR-wild (N=515, P=0.0001) LUADs (Figure 1). Additional analysis according to the type of EGFR mutation showed that high PD-L1 expression showed an association or a trend with poor RFS in exon 19 deletion (N=135, P=0.0024) or exon 21 L858R mutation (N=148, P=0.0516), respectively (Figure 2). In contrast, high PD-L1 expression correlated with poor OS only in EGFR-wild LUADs (P=0.0293) but not in EGFR-mutant LUADs (P=0.2535). Multivariable analysis elucidated that high PD-L1 expression was an independent factor of unfavorable RFS but not OS.

Conclusions: High PD-L1 expression could predict poor RFS independent of EGFR mutation status or type of EGFRmutation. Further investigation is warranted to elucidate whether EGFR-mutant LUAD patients expressing high levels of PD-L1 require an additional adjuvant strategy to prevent disease recurrence.

P2.07A.05 Synchronous Super Multiple Primary Lung Cancers Prefer High-Frequency BRAF and Low-Frequency EGFR Mutations in MAPK Pathway

H. Li1, Z. Huang1, C. Guo1, Y. Wang1, S. Wang2, N. Bai2, N. Liang1, S. Li1

1Peking Union Medical College Hospital, Beijing/CN ,2Nanjing Geneseeq Technology Inc., Nanjing/CN

Introduction: Recently, the detection rates of multiple primary lung cancer (MPLC) are increasing. In clinical practice, we found some patients with a large number of lesions. Continuing our series of research published in 2020 and 2022, we defined lung cancer with five or more confirmed primary lesions as super MPLCs. Elucidating the genomic characterization of the special MPLC subtype can help reduce disease burden and understand tumor evolution.

Methods: We removed and identified most of the potentially malignant lesions in 18 patients with super MPLCs. Whole-exome sequencing was performed on the 130 resected malignant specimens.

Results: In our cohort of synchronous super early-stage MPLCs (PUMCH-ssesMPLC), we found that BRAF mutations, rather than EGFR mutations, predominate in super MPLCs. The mutations of super MPLCs were enriched in PI3k-Akt and MAPK signaling pathways. By comparing with a total of 11 control cohorts for 3 types, we found that in the MAPK pathway, super MPLCs have a significantly higher BRAF mutation frequency (31.5%) than MPLCs with fewer lesions and early-stage single-lesion lung cancer, while the EGFR mutation frequency (13.8%) is significantly lower. Combined with our previous research, we found that as the mean lesion number of MPLCs increases, BRAF mutations gradually become dominant. Class II mutation (48.8%) is the predominant BRAF mutation subtype. Also, with lesion invasiveness increasing, the mutation pattern more inclines to the classic pattern of super MPLCs. Follow-up also confirms that super-MPLC patients who underwent surgery only have a good prognosis.

Conclusions: In the study, we provided a comprehensive genomic landscape of super MPLCs. High-frequency BRAF mutations, especially class II BRAF mutations, and low-frequency EGFR mutations determine the limited effectiveness of targeted therapy in super-MPLC patients. Combined with follow-up, the importance of surgery is further emphasized.

P2.07B EARLY-STAGE NON-SMALL CELL LUNG CANCER - EVOLVING SURGICAL APPROACHES, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.07B.01 Single Versus Multiple Segmentectomies: A Comparison of Short- And Long-Term Outcomes

F. PEZESHKIAN1, M. McAllister1, F. Hooshmand1, A. Singh1, J. Herrera-Zamora1, R. Leo1, E. Sugarbaker2, R. Ribeiro Barcelos1, M.M. Rochefort1, H.A. Khalil1, R. Bueno1, P.A. Ugalde Figueroa1, M.T. Jaklitsch1, S.J. Swanson1

1Brigham and Women's Hospital, Boston/MA/USA ,2Baylor College of Medicine, Houston/TX/USA

Introduction: Segmentectomy can provide equivalent oncologic outcomes as lobectomy in well-selected patients with early-stage non-small cell lung cancer (NSCLC). However, differences in indication and outcomes of single compared to multiple segmentectomy remain unclear. We compared short- and long-term outcomes of single versus multiple segmentectomies.

Methods: Patients who underwent segmentectomy for NSCLC from 08/2005-05/2023 were identified using a prospectively maintained institutional database. Patients who had positive clinical nodal disease or received neoadjuvant therapy were excluded. Patients were not excluded based on tumor size. Patients with ≥6 months of follow-up data were included in survival and recurrence analyses. Survival was estimated using Kaplan-Meier models and compared using log-rank tests. Cumulative incidence of recurrence was modeled with death as a competing risk for recurrence and compared with Gray's test. Cox and Fine-Gray models were constructed to evaluate cause-specific and subdistribution hazard ratios (CSHR and SDHR) for recurrence.

Results: Of 693 segmentectomy patients meeting study criteria: 354(51.1%) were single and 339(48.9%) multiple segmentectomy. Statistically significant differences were observed in median nodule size on imaging (1.6cm vs. 1.8cm, p=0.002) and pathologic lesion size (1.6 cm vs. 1.9 cm, p<0.001) for single vs. multiple segmentectomies, respectively. Median number of resected lymph nodes was higher in multiple segmentectomies (6 vs. 5; p=0.002). Other pathologic features did not differ between groups, nor did the incidence of postoperative complications, 30-or 90-day mortality. The 5-year overall survival was 72.8% (95%CI= 66.7-79.4) after single and 75.9% (95%CI=69.8-82.6) after multiple segmentectomy, respectively; this difference was not statistically significant (p=0.28). The 5-year cumulative incidence of locoregional recurrence was higher after single (17%, 95%CI=12-22%) than multiple (10%, 95%CI=6.4-15%) segmentectomies (p=0.03). After adjusting for high-risk pathologic features and tumor size, multiple segmentectomy remained associated with a lower risk of locoregional recurrence than single segmentectomy (CSHR=0.39, 95%CI=0.22-0.70; SDHR=0.40, 95%CI=0.22-0.73). Parenchymal margins were reported in 540 (77.9%) cases. In subgroup analyses adjusting for margin length and pathologic features, multiple segmentectomies remained associated with reduced risk of locoregional recurrence, but effect size was reduced (CSHR=0.55, 95%CI=0.31-0.98; SDHR=0.56, 95%CI=0.31-1.02).

Conclusions: Our results suggest that multiple segmentectomy may provide superior locoregional control compared to single segmentectomy without increasing perioperative morbidity by ensuring adequate margins. However, the disparity in locoregional recurrence was not reflected in significantly poorer overall survival after either procedure. Further study of indications and high-risk features for single and multiple segmentectomy will improve procedure selection and surgical decision-making for patients with early-stage NSCLC.

P2.07B.02 Is Wedge Resection Really Enough for the Treatment of Patient with Stage I Non-Small Cell Lung Cancer? A SEER Database Analysis.

L. Ventura1, S. Tenconi1, J. Rao1, W. Pradeep1, A. Kar1, J. Edwards1, W. Fang2, D. Waller3

1Sheffield Teaching Hospital NHS Foundation Trust, Sheffield/GB ,2Shanghai Chest Hospital, Jiao Tong University, Shanghai/CN ,3Thorax Centre, St. Bartholomew's Hospital, London/GB

Introduction: The recent results of the CALGB140503 studies suggested a role for sublobar resection,including wedge resection,for the treatment of early-stage NSCLC.We aimed to investigate the role of wedge resection by comparing this technique's survival and perioperative outcomes to lobectomy in all stage I NSCLC.

Methods: We retrospectively analysed the Surveillance,Epidemiology and End Results(SEER) database of stage I NSCLC(≤4cm in size) patients who underwent either lobectomy or wedge resection from 2000 to 2017.We performed propensity score matching(PSM) to adjust for selection bias(1:1 matching, calliper:0.01, variables matched:age,gender,ethnicity,tumour location,size,histology and number of lymph nodes sampled).The primary endpoint was overall survival(OS) and lung cancer specific survival(LCSS),the secondary endpoints were 30-day and 90-day mortality.Univariate and multivariate Cox proportional hazard regression were applied to evaluate the effects on prognosis of both lobectomy and wedge resection.Results were presented as hazards ratio and 95% confidence interval(HR and 95%CI).

Results: Overall,32673 patients treated by lobectomy and 9073 patients treated by wedge resection were included in the analysis. After PSM,4764 patients in each group were considered and,except for stage IA1,OS and LCSS was greater after lobectomy than wedge resection(OS-Stage IA1-HR:0.88(0.74-1.04),p-value: 0.125-Stage IA2 -HR:0.82(0.76-0.89),p-value: <0.001-Stage IA3-HR:0.65(0.58-0.73), p-value: <0.001-Stage IB-HR:0.80(0.72-0.88), p-value: <0.001.LCSS-Stage IA1-HR:0.80(0.64-1.01),p-value: 0.065-Stage IA2- HR:0.72(0.64-0.81),p-value: <0.001-Stage IA3-HR:0.64(0.55-0.75),p-value: <0.001-Stage IB-HR:0.77(0.66-0.88),p-value: <0.001)(Fig.1-2).If a similar number of LN were removed during surgery(10 or more lymph nodes),the survival benefit of lobectomy disappeared until stage IA2,remaining superior to wedge resection for stage IA3 and IB(data not shown).The 30-day mortality was significantly higher after wedge resection(2.3%vs1.4%, p=0.01)but there was no significant difference in 90-day mortality(4.5%vs3.7%,p=0.10).

Conclusions: Although CALGB140503 showed similar benefits for wedge resection and lobectomy in NSCLC≤2cm, our study can confirm a similar outcome only in stage IA1.While in stage IA2 we may argue that survival may be the same after a proper lymph node dissection,in stage IA3 and IB lobectomy may still be the treatment of choice.

P2.07B.03 Simultaneous Bilateral Video-Assisted Thoracic Surgery Is Safe and Feasible for Multiple Primary Lung Cancers

L. Yang

Peking Union Medical College Hospital, Beijing/CN

Introduction: The treatment for bilateral synchronous multiple primary lung cancers (MPLC) remains challenging. Simultaneous bilateral video-assisted thoracic surgery (VATS) may be an optimal treatment with curative intent, but its safety and feasibility are controversial.

Methods: One hundred and fifty-eight patients who underwent simultaneous bilateral VATS (simultaneous group) and 79 who underwent two-staged bilateral VATS (two-staged group) were included in this study. Their medical records were retrospectively reviewed and analyzed.

Results: The majority of patients were female and non-smokers. Forty-one percent of patients underwent lobectomy and contralateral wedge resection. There was no significant difference in the postoperative complication rate between the simultaneous groups and two-staged group (13.3% vs 11.4%, p=0.73). Patients who underwent simultaneous bilateral resection had shorter hospital stays, shorter anesthesia time and less chest drainage compared with those who underwent two-staged resection. Male, current smoker, respiratory comorbidities and advanced TNM stage were risk factors for postoperative complications in simultaneous bilateral VATS (figure 1). Patients in two groups had similar overall survival and disease free survival (figure 2 p=0.2).

Conclusions: Simultaneous bilateral VATS for bilateral lung nodule resection is as safe and feasible as two-staged bilateral VATS. Patients who underwent simultaneous bilateral resection had similar or even better outcomes compared to that of the two-staged group. Simultaneous bilateral VATS is potentially an optimal treatment option based on appropriate patient selection.

P2.07B.04 Comparative Effectiveness of Sub-Lobar Resection vs Lobectomy for Medically Operable Stage I NSCLC: A VACCR Analysis

M. Snider, J.K. Salama, M.J. Boyer

Duke University School of Medicine, Durham/NC/USA

Introduction: Lobectomy is standard of care surgical management for early-stage, non-small cell lung cancer (NSCLC), with sub-lobar resection reserved for patients lacking sufficient pulmonary reserve or who have small, peripheral tumors. Outside of a clinical trial, the role of sub-lobar resection for early-stage NSCLC irrespective of tumor location is not well defined. This study sought to compare overall survival (OS) and lung cancer-specific survival (LCSS) following lobectomy or sub-lobar resection in patients treated for Stage I NSCLC in an open access healthcare setting.

Methods: Patients diagnosed with Stage I NSCLC between 2000-2020 from the Veterans' Affairs Health System with an FEV1 or DLCO > 60% of predicted treated with lobectomy or sub-lobar resection were identified. OS and LCSS were compared using log-rank and Kaplan-Meier analyses, with hazard ratios calculated. Multivariable Cox regression analysis via stepwise approach included age, diagnosis period, sex, race, smoking status, FEV1, DLCO, tumor histology, and clinical T stage as covariates. Surgery type was included ad hoc for clinical suspicion.

Results: Overall, 1,267 patients were included. Patients were predominantly male (97%) and white (75%). 73% of patients had a Charlson comorbidity index of 0. Most sub-lobar resection patients underwent wedge resection (79%). Sub-lobar resection patients were older (mean age 68 vs 66, $p < 0.001$) and had worse lung function (mean predicted FEV1: 84% vs 91%; DLCO: 77% vs 85%, $p < 0.001$ for both) compared to lobectomy patients, respectively. Median follow-up was 5.6 years and 5-year OS was 58% (95% CI 56-61%). 90-day mortality rates were equivalent between lobectomy and sub-lobar resection (2.6% vs 2.4%, $p > 0.05$). Multivariable analysis showed no significant difference in OS and LCSS between surgery types (Table 1). Age, diagnosis period, and DLCO were significant predictors of OS and LCSS. Sex and smoking status were additionally found to be significant predictors of OS. When considering surgery type and these demographic factors, DLCO appears to be a predictor of mortality after surgery, while FEV1 does not.

Conclusions: In medically operable patients undergoing sub-lobar resection or lobectomy for Stage I NSCLC, there is no difference in OS

and LCSS on multivariable analysis, indicating the two are equivalent in this real world, open access healthcare setting. With recent phase III trials JCOG0802/WJOG4607L and CALGB 140503 supporting the use of sub-lobar resection for small peripheral tumors, this data supports future studies investigating the role of sub-lobar resection in an expanded population of medically operable patients.

P2.07B.05 Prospective Comparative Study of Postoperative Respiratory Function after Lobectomy Versus Segmentectomy

C. Takemura, M. Yotsukura, Y. Yoshida, S-i. Watanabe

National Cancer Center Hospital, Tokyo/JP

Introduction: Preservation of postoperative respiratory function is one of the important indicators for expanding the indications for segmentectomy. In a recent Japan Clinical Oncology Group (JCOG) 0802 trial, the difference in the median reduction of forced expiratory volume in 1 second (FEV1) between lobectomy and segmentectomy at 12 postoperative months was only 3.5%. As there have been few reports comparing postoperative respiratory function by resected lobes or segments, we conducted this prospective non-randomized study at our institution.

Methods: Patients who underwent segmentectomy or lobectomy for lung cancer between January 2021 and March 2023 were included in this study. Respiratory function tests were scheduled preoperatively, and at 6 and 12 months postoperatively. Differences in the median FEV1 reduction rate (FEV1 Red) between segmentectomy and lobectomy were evaluated.

Results: The study included 537 patients (241 lobectomies and 296 segmentectomies). The median FEV1 Red after lobectomy/segmentectomy was 13.9%/8.3% at 6 months ($p < 0.001$) and 12.3%/7.6% at 12 months ($p < 0.001$).The median FEV1 Red at 6 months after lobectomy/segmentectomy were 14.0%/7.5% for right upper lobe (RUL) ($p < 0.001$), 20.4%/9.8% for left upper lobe (LUL) ($p < 0.001$), 9.0%/8.3% for right lower lobe (RLL) ($p = 0.199$), and 16.0%/8.9% for left lower lobe (LLL) ($p = 0.012$), respectively. The median FEV1 Red at 12 months after lobectomy/segmentectomy were 11.9%/6.6% for RUL ($p = 0.002$), 18.0%/8.8% for LUL ($p < 0.001$), 11.4%/6.3% for RLL ($p = 0.053$), and 12.8%/10.6% for LLL ($p = 0.060$), respectively. Among segmentectomy patients, the maximum FEV1 Red was observed in left S9+10 segmentectomy, with median FEV1 Red of 12.5%/12.5% at 6/12 months, respectively. The minimum FEV1 Red was observed in right S3 segmentectomy, with median FEV1 Red of 6.9%/6.6% at 6/12 months, respectively.

Conclusions: Compared to lobectomy, segmentectomy tended to preserve postoperative respiratory function. While significant differences were observed in the median FEV1 Red between lobectomy and segmentectomy for RUL and LUL, no significant differences were observed in RLL and LLL. The degree of preservation of postoperative respiratory function may vary depending on the site of resection, which might be one of the key criteria when choosing the candidate for segmentectomy.

P2.07B.06 Segmentectomy for cIA1-2 Lung Cancer in the Lower Lobe with Solid-Predominant Opacity: Impact on Recurrence and Survival Rates

M. Endo1, J. Suzuki2, H. Watanabe2, S. Takamori1, K. Sato2, T. Sasage2, M. Nakatsuka1, K. Hoshijima2, K. Abe2, A. Niwa1, S. Shiono2

1Yamagata Prefectural Central Hospital, Yamagata/JP ,2Faculty of Medicine, Yamagata University, Yamagata/JP

Introduction: The JCOG0802/WJOG4607L trial revealed that segmentectomy is more advantageous in terms of overall survival for non-small cell lung cancer less than 2 cm. However, when it comes to the lung lobe, there is no significant difference in overall survival between lobectomy and segmentectomy. Depending on the location of the segment, lobectomy may be favored over segmentectomy. This study aims to understand better the surgical outcomes of segmentectomies in the lower lobe, which can be pretty intricate in surgical technique.

Methods: We conducted a study to analyze the survival rates and factors related to survival in patients with non-small cell lung cancer who underwent segmentectomy at two institutions in Yamagata Prefecture, Japan, between 2010 and 2022. The study focused on patients undergoing segmentectomy in the lower lobe for tumors with a maximum size of 2 cm and a consolidation to maximum tumor diameter (C/T) ratio of 0.5 or greater.

Results: Of the 493 patients who underwent segmentectomy, 89 underwent segmentectomy in the lower lobe, excluding basal segmentectomy, with 48 undergoing segmentectomy in the right lower lobe and 41 in the left lower lobe. The patients were divided into two groups: the S6 group (43 patients who underwent S6 segmentectomy) and the non-S6 group (46 patients who underwent other than S6 segmentectomy). The median follow-up was 5.2 years. The study found that the 5-year survival rate was 79% in the S6 group and 94%

in the non-S6 group ($p < 0.01$), while the 5-year recurrence-free survival rate was 74% in the S6 group and 87% in the non-S6 group ($p = 0.04$). On multivariate analysis, low FEV1 and omitted mediastinal nodal dissection were identified as poor prognostic factors for overall survival, while omitted mediastinal nodal dissection was a poor prognostic factor for recurrence-free survival. The study also found that there were five recurrences in the S6 group (2 ipsilateral lymph nodes, three lung metastases, one disseminated tumor, and one distant organ metastasis) and two in the non-S6 group (1 resection margin and one distant organ metastasis). The causes of death were 10 cases in the S6 group (4 deaths from primary disease, 2 from other cancers, three from other diseases, and one unknown) and 2 cases in the non-S6 group (1 from other cancers and one from other diseases).

Conclusions: The findings of our retrospective analysis indicate that among segmentectomies performed in the lower lobe, the prognosis of S6 segmentectomy is significantly worse than that of non-S6 segments. Therefore, we recommend that segmentectomy be carefully considered and indicated for lung cancer cases affecting the S6 segment. While our findings should be interpreted with caution due to the retrospective nature of the study, they provide important insights into the management of lung cancer and the potential risks associated with different types of segmentectomies.

Introduction: Segmentectomy for non-small cell lung cancer (NSCLC) smaller than 2 cm is well-supported by robust evidence and is being further explored in clinical trials for tumors 2 to 3 cm, where some supportive evidence already exists. This study investigates segmentectomy for NSCLC larger than 3 cm, which present challenges in achieving adequate surgical margins, and focuses on its potential to expand treatment options for these patients.

Methods: We retrospectively analyzed 1208 patients diagnosed with cN0 NSCLC >3 cm who underwent anatomical complete resection at three institutions from 2010 to 2022.Propensity Score Matching (PSM) was utilized to compare clinicopathologic characteristics and outcomes between segmentectomy (S) and lobectomy (L) groups.

Results: The study included 118 patients in the S group and 1090 patients in the L group; the median age of the S group was 74 years, 79 (66%) were male, and 83 (70%) had smoking history. The median radiological size of the tumors in the S group was 3.5 cm, the median diameter of the solid component was 3.1 cm, and the median value of SUVmax was 2.9.The most common surgical procedures were left upper segmentectomy in 30 cases (25%), right S6 segmentectomy in 18 cases (15%), left S1+2 segmentectomy in 16 cases (13%), and other complex segmentectomy were also observed. The major histological type was adenocarcinoma in 94 cases (79%), pathological whole tumor size was 3.4 (2.8-4.1) cm, 13 cases (11.0%) were positive for lymph node metastasis, and pStage 0-1, II, and III were 81, 15, and 10 cases, respectively. In the S group, the 5-year overall survival (5yOS) rate was 76.4% and 5-year recurrence-free survival (5yRFS) rate was 72.4%.After adjusting with PSM and analyzing 108 matched pairs, a higher incidence of adenocarcinoma and larger pathological tumor diameters were noted in the L group. However, no significant differences were observed in pT, pN, or pStage. The 5yOS rates were 75.9% for the S group versus 78.0% for the L group, with a p-value of 0.69 (Figure). Similarly, the 5yRFS rates were 68.0% for the S group compared to 79.0% for the L group, with a p-value of 0.10, indicating no significant differences (Figure).

Conclusions: Segmentectomy for NSCLC >3 cm might yield outcomes comparable to lobectomy if patient selection is well controlled. This finding implies the potential for expanding indications for segmentectomy and improving patient outcomes in NSCLC therapeutic strategies.

P2.07B.08 Outcome Comparison Between Left Upper Lung Lobectomy and Split Lobe Segmentectomy for Clinical Stage I Lung Cancer

T-N. Kao1, X-H. Chiang2, H-H. Hsu2, M-W. Lin2, J-S. Chen2

1National Taiwan University Hospital, Taipei City/TW ,2National Taiwan University Hospital, Taipei/TW

Introduction: The left upper lobe (LUL) can be divided into the upper division - proper segment (segment 1-3) and lingula segment (segment 4-5), akin to the segments in the right upper lobe and middle lobe. Does split-lobe segmentectomy for early lung cancer in the apical lung or lingula segment yield similar oncological outcomes to LUL lobectomy? While previous studies, like those by the Japan Clinical

Oncology Group (JCOG), have focused on smaller tumors (<2cm), we aim to assess if split-lobe segmentectomy is a viable approach for clinical stage I non-small cell lung cancer (NSCLC) patients with tumors between 2-4 cm, maintaining oncological efficacy comparable to LUL lobectomy.

Methods: From 2011 to 2021, we retrospectively included 377 clinical staged I NSCLC patients receiving LUL lobectomy, LUL S1-3 tri-segmentectomy, or LUL S4-5 lingular segmentectomy. Subsequently, we categorized them into two groups based on tumor size: 0-2 cm and 2-4 cm, enabling us to conduct subgroup analyses. To ensure comparability in preoperative demographics, a 1:1 propensity score matching procedure was implemented. Following matching, we obtained 42 patients in the 0-2 cm group and 146 patients in the 2-4 cm group. We systematically gathered retrospective data pertaining to clinical, pathological, perioperative, and oncological outcomes for these matched patient cohorts.

Results: The study focuses on the 2-4 cm group. Before matching, disparities existed between the two groups (split-lobe lobectomy and LUL lobectomy) in age, comorbidities (Charlson Comorbidity Index, CCI), and CT tumor diameters. After 1:1 propensity score matching based on age, CCI, tumor total diameters, and solid diameters, demographics and clinicopathological features showed no significant difference. Disparities persisted in operative times (p=0.001), postoperative hospital stays (p=0.001), and durations of ICU stay (p=0.023), suggesting comparable or superior perioperative outcomes with split-lobe segmentectomy. No significant differences in progression-free survival (PFS) (p=0.594) or overall survival (OS) (p=0.843) were found after matching, with a mean follow-up exceeding 4 years (figure). Split-lobe segmentectomy poses no heightened risks of cancer progression or mortality. The 0-2 cm group had similar outcomes as well. Multivariate analysis showed that surgical method was not a significant factor for survival (p=0.053).

Conclusions: We had presented the most recent and large matched comparative analysis in such topic in the recent 20-year literature. Left upper lobe split-lobe segmentectomy emerges as a secure and feasible surgical option for clinical stage I NSCLC, demonstrating comparable PFS and OS outcomes to LUL lobectomy, but with equivalent or even improved perioperative outcomes.

P2.07B.09 Real-World Validation for Impact of Sublobar Resection Over Lobectomy on Lung Cancer Survival and Frailty Using SEER-Medicare

E. Choi1, C.C. Su2, Y. Shi1, L.K. Groner1, B.B. Pua1, R. Crupi1, J. Mao1, H-Y. Jung1, C.A. Garcia1, L.C. Pinheiro1, E.T. Sholle1, Y. Shieh1, R. Tamimi1, A. Sedrakyan1, S.S. Han2, N. Altorki1, J. Mandelblatt3

1Weill Cornell Medicine, New York/NY/USA ,2Stanford School of Medicine, Palo Alto/CA/USA ,3Georgetown University and the Georgetown Lombardi Institute for Cancer and Aging Research, Washington, DC/DC/USA

Introduction: Lung cancer is a disease of older adults with a median age at diagnosis of 71 years. While lobectomy is effective for treating early-stage lung cancer, older patients may be vulnerable to complications from this surgical procedure due to limited lung function and a high chronic disease burden. Recent phase-3 clinical trials indicate that sublobar resection may be non-inferior to lobectomy in terms of disease-free and overall survival in patients with early-stage non-small cell lung cancer (NSCLC). However, selection biases and younger patients in the trials can limit generalizability to real-world populations of older patients from different clinical and socioeconomic backgrounds. Furthermore, the long-term consequences of sublobar resection vs. lobectomy on subsequent development of an aging-related syndrome, such as frailty, has never been evaluated. To address this evidence gap, we used target trial emulation to provide real-world validation of non-inferiority of sublobar resection vs. lobectomy on lung cancer-specific survival and frailty.

Methods: Using data from SEER cancer registries linked to Medicare fee-for-service (SEER-Medicare) insurance claims, we identified 8,093 eligible patients (age≥65 years) with stage T1aN0 NSCLC (tumor size≤2 cm) diagnosed between 2008-2015 and followed through 2019 for trial emulation. Patients were excluded if they had not been continuously enrolled in Medicare Parts A and B from the year before diagnosis through 2019 or death, had received chemotherapy or radiotherapy before surgery, or were frail at the time of diagnosis. Frailty was defined by a validated claims-based frailty index (cFI) ranging from 0 to 1, with cut-points of non-frail (<0.25), or frail (≥0.25). The cFI assesses the accumulation of 93 aging-related deficits using diagnosis and procedure codes in Medicare Parts A and B claims annually over a 12-month look-back period.The primary outcome was the 5-year lung cancer-specific and overall mortality by different clinical and socioeconomic factors (i.e., 5-year age groups, histology, race/ethnicity, and neighborhood socioeconomic status [nSES]). The secondary outcome was the time to development of frailty. Target trial emulation based on the clone-censor-inverse probability weight method was used to minimize immortal time bias, mitigate selection bias and confounding, and mimic per-protocol analysis of the target trial via a discrete hazard model, which was approximated using a pooled logistic regression.

Results: To emulate the target trial of comparing sublobar vs. lobar resection within 3 weeks of diagnosis, 8,093 patients (75.4 median age at diagnosis; 40% male; 61.2% with adenocarcinoma; 5.7% Black; 4.2% Asian) from SEER-Medicare were analyzed. Those with sublobar resection (vs. lobectomy) had similar lung cancer-specific mortality (adjusted-weighted odds-ratio [awOR] 1.04 [0.81-1.33], p=0.73) and overall mortality (awOR=1.05 [0.89-1.23], p=0.57). This non-inferior result was observed across patient subgroups by age, histology, race, and nSES. Patients undergoing sublobar (vs. lobectomy) had a significantly lower risk of becoming frail over time (awOR=0.63 [95% CI: 0.44-0.89], p=0.01).

Conclusions: Clinical trials and our real-world emulated trial data show comparable survival benefits between sublobar resection and lobectomy. The lung cancer patients with sublobar resection were less likely to develop frailty, suggesting that thoughtful treatment decisions could support healthy aging while reducing cancer burden.

P2.07B.10 Should Lymph Node Dissection Be Routinely Undertaken for Patients with Small-Sized Solid-Dominant Non-Small-Cell Lung Cancer?

N. Oka, M. Yotsukura, Y. Yoshida, Y. Yatabe, S-I. Watanabe

National Cancer Center Hospital, Tokyo/JP

Introduction: Sublobar resection for early-stage non-small cell lung cancer (NSCLC) is expected to become increasingly common. We investigated the prognosis and incidence of lymph node metastasis and recurrence in patients with clinical stage IA small-sized (≤2 cm) NSCLC based on the presence of ground-grass opacity (GGO) components.

Methods: Consecutive 903 patients who underwent lobectomy, segmentectomy, or wedge resection for clinical stage IA (≤2 cm diameter and consolidation-to-tumor ratio [CTR] >0.5) NSCLC from 2017 to 2022 were included in this study. The patients divided into two groups based on the presence of GGO components (solid tumor group with CTR = 1 [S group] [n = 595] and part-solid tumor group with 0.5< CTR <1 [PS group] [n = 308]) and identified differences in incidence of nodal involvement and recurrence, and long-term prognosis.

Results: Adenocarcinoma was the most common histologic type in both groups and more frequently observed in PS group (74.6% vs. 99.0%, p <0.001). There was no significant difference in overall survival (OS) between the S and PS group (5-year OS rate, 89.0% vs. 93.3%; p = 0.134). However, recurrence-free survival (RFS) was better in PS group (5-year RFS rate, 75.1% vs. 91.1%; p <0.001). Nodal involvement (pN1-2) was more often detected in S group (9.7% vs. 0.6%, p <0.001). Furthermore, nodal recurrence and/or metastasis were observed in 85 (14.3%) in S group, which was significantly higher than 6 (1.9%) in PS group (p <0.001) (Table 1). In S group, the survival after wedge resection was significantly worse than after segmentectomy (5-year OS rate after lobectomy/segmentectomy/wedge resection, 86.6%/97.0%/82.2%, p <0.001; 5-year RFS rate, 72.6%/81.3%/72.8%, p = 0.039). However, in PS group, no significant difference was identified based on the extent of lung resection (5-year OS rate, 91.2%/96.2%/88.8%, p = 0.459; 5-year RFS rate, 84.2%/95.3%/88.8%, p = 0.080).

Conclusions: In patients with small-sized part-solid NSCLC, nodal involvement and recurrence were rarely observed, and mediastinal lymph node dissection can be omitted. In addition, due to the favorable prognosis and no survival difference based on the extent of lung resection, it may be possible to expand the indications for wedge resection without mediastinal lymph node dissection.

P2.07B.11 Delays to Lung Cancer Surgery by Biopsy Technique

J. Zhu, T. Holton, S. Kantor, R. Yip, C.I. Henschke, D.F. Yankelevitz

Mount Sinai Health System, New York/NY/USA

Introduction: Excessive time-to-treatment initiation (TTI) for early-stage lung cancer remains a challenge for healthcare providers and patients. Recent literature found that for patients who undergo surgical resection for clinical stage I/II NSCLC, increased time from diagnosis to surgery is associated with a higher chance for pathological upstaging, as well as decreased overall survival. At our healthcare institution, over 90% of clinical stage I lung cancer patients undergo biopsy prior to surgery. Biopsy occurs either via percutaneous needle biopsy or bronchoscopy. As the biopsy contributes to delay, we sought to determine whether there was a significant difference in delays depending on technique. Additionally, we compared the TTI of patients who received biopsy versus those who received surgical biopsy. A secondary aim of this research was to quantify how much added delay there was from biopsies that did not yield results suggestive of malignancy.

Methods: We reviewed all participants of the prospective cohort study, Initiative for Early Lung Cancer Research on Treatment (IELCART), from 2016-2024. We included patients who received surgical resection for clinical stage I (T1a-c, T2a) lung cancer (TNM 8th edition modified). Using the methodology from our prior research, time intervals measuring days from suspicious imaging to biopsy, biopsy to surgery, and suspicious imaging to surgery were compared across groups for significant differences.

Results:

39 (<.001)

Data are presented as median(category 1) - median(category 2) (P-value). P-values are adjusted using the Bonferroni correction; P≤0.05 indicates statistical significance.

TTI from biopsy to surgery (84 vs 40; p<0.001) and TTI from suspicious imaging to surgery (139 vs 87; p<0.001) is significantly higher for biopsies that yielded non-malignant findings versus malignant findings.

Conclusions: Bronchoscopies resulted in lower TTI than needle biopsies, though they were less likely to confirm a malignant diagnosis. Surgical biopsies had a significantly lower TTI than either biopsy technique but has the disadvantage of potentially operating on benign lung nodules. Biopsies that did not confirm a malignant diagnosis added 52 days to delay.

Introduction: We examined the prognostic value of SUVmax change on clinical outcomes following neoadjuvant atezolizumab (anti-PD-L1) treatment in patients with resectable NSCLC from the LCMC3 study (NCT02927301).

Methods: LCMC3 was a Phase II, open-label, single-arm study in patients with resectable stage IB-IIIA or select IIIB NSCLC. Patients were aged ≥18 years, had an ECOG performance status of 0 or 1 and received neoadjuvant atezolizumab 1200 mg IV every 3 weeks for

2 cycles followed by surgery. Patients in the primary efficacy population were EGFR/ALK negative or unknown status. This post hoc analysis examined a subset of this population that had major pathologic response assessment and paired PET-CT scans before and after neoadjuvant atezolizumab treatment, prior to surgery. 18F-FDG uptake was quantified using SUV, with the highest pixel value within the primary tumor defined as SUVmax. P values were nominal and not adjusted for multiple comparisons.

Results: This analysis included 183 enrolled patients (2 patients were excluded as ineligible), 159 of whom had surgical resection; 119 patients (65%) had a major pathologic response assessment and were evaluated with pre- and post-atezolizumab PET-CT. The SUVmax from pre- to post-neoadjuvant atezolizumab decreased in 77 patients and increased in 42. Baseline and disease characteristics were generally balanced between these 2 groups, except that the decreasing vs increasing SUVmax group had a numerically greater median decrease in tumor size (−10% vs 0%) and a numerically greater prevalence of high (TPS ≥50%) PD-L1 expression (36% [28/77] vs 26% [11/42]; Table). All 5 patients in the analysis with pathologic complete response had decreasing SUVmax (P=0.160). Three-year disease-free survival improved by 16% in individuals with decreasing SUVmax (P=0.071; Table). Patients with decreasing vs increasing SUVmax demonstrated a significantly higher major pathologic response rate (30% [23/77] vs 7% [3/42]; P=0.005) and 3-year overall survival (88% vs 72%; P=0.043; Table).

Conclusions: Decreasing vs increasing SUVmax following neoadjuvant atezolizumab treatment was associated with improved clinical outcomes, including a trend toward longer DFS and significant improvements in major pathologic response and overall survival. These results suggest that assessment of SUVmax may be a valuable tool for clinicians that should be further evaluated for pre-surgery prognostic stratification of patients with resectable NSCLC.

P2.07C.02 Prognostic Impact of Adjuvant Immunotherapy in Patients with Non-Small Cell Lung Cancer Following Neoadjuvant Immunotherapy

Y. Dong, L. Xu, H. Si, J. Wu, T. Chen, J. Wen, H. Xie, Y. She, D. Zhao, C. Chen

Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Whether adjuvant immunotherapy can bring further survival benefits for resectable non-small cell lung cancer (NSCLC) after neoadjuvant chemoimmunotherapy still remains unknown. This study aims to evaluate the prognostic impact of adjuvant immunotherapy and identify potential factors associated with prognostic benefits from adjuvant immunotherapy.

Methods: A total of 439 patients, diagnosed with an IB-IIIB NSCLC, receiving neoadjuvant chemoimmunotherapy or immunotherapy between August 2019 and October 2022 at Shanghai Pulmonary Hospital were enrolled in our study, with a median follow-up time of 24.8 months. To minimize the influence of potentially prognostic confounders, propensity-score matching (PSM) was adopted between patients following adjuvant immunotherapy and non-adjuvant immunotherapy groups with a 1:1 ratio. Recurrence-free survival (RFS) was estimated using Kaplan-Meier methods and tested by log-rank test, and unstratified Cox proportional hazards models fitted to the subgroups.

Results: In the entire cohort, we reported that 29.61% of patients (n=130) reached pathological complete response (pCR). Patients with a pCR had significantly better RFS than those without (p<0.001) (Figure 1A). After PSM between patients following adjuvant immunotherapy and non-adjuvant immunotherapy groups, there were 110 patients in each matched set and the median number of cycles of adjuvant immunotherapy in the adjuvant immunotherapy group was 10. Patients who received adjuvant immunotherapy experienced survival benefits over those who did not (hazard ratio [HR]: 0.51, 95% confidence interval [CI]: 0.28-0.94, p=0.012) (Figure 1B). We noted that patients who did not achieve pCR (HR: 0.54, 95% CI: 0.28-1.05, p=0.066) were more likely to benefit from adjuvant immunotherapy compared to the pCR subgroup (HR: 0.35, 95% CI: 0.07-1.80, p=0.188) (Figure 1C). The forest plot of subgroup analysis showed that patients with squamous cell carcinoma and patients without lymph node involvement were significantly benefit from adjuvant immunotherapy (HR:0.40, 95% CI: 0.18-0.89; HR:0.34, 95% CI: 0.12-0.997) (Figure 1D).

Conclusions: To our knowledge, our result is the first to demonstrate the addition of adjuvant immunotherapy to neoadjuvant chemoimmunotherapy is significantly associated with improved RFS for patients with resectable NSCLC and patients with squamous cell carcinoma and patients without lymph node involvement experienced significant benefits from adjuvant immunotherapy. We validated that pCR would translate into prognostic superiority, but we also found that the non-pCR subgroup tended to benefit more from adjuvant immunotherapy, which suggests that the extent of pathologic response observed at surgery could guide adjuvant treatment escalation or de-escalation strategies.

P2.07C.03 Limited Efficacy of Immunochemotherapy in Pulmonary Invasive Mucinous Adenocarcinoma and Mucoepidermoid Carcinoma as Neoadjuvant Setting

Z-b. Qiu1,2, Z. Xu2,3, H-J. Li2, J-H. Yan2, J-Y. Ding2, C. Zhang2, Y-L. Wu2, W-Z. Zhong2

1Schoole of Medicine, South China University of Technology, Guangzhou/CN ,2Guangdong Provincial People's Hospital, Guangzhou/CN ,3National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Recently, clinicians have successfully integrated immune checkpoint inhibitors (ICIs) alongside chemotherapy into perioperative regimens for locally advanced lung cancer. However, the specific efficacy of chemoimmunotherapy in addressing invasive mucinous adenocarcinoma (IMA) and mucoepidermoid carcinoma (MEC), characterized by mucinous cell presence, remains to be comprehensively elucidated.

Methods: We retrospectively review patients diagnosed with IMA and MEC at Guangdong Provincial People's Hospital (GDPH) and Cancer Hospital Chinese Academy of Medical Sciences (CAMS). Inclusion criteria comprised patients who underwent surgery following induction chemoimmunotherapy. Driver gene mutation status was determined via NGS before therapy. Otherwise, EGFR and ALK status were assessed using ARMS and Ventana methods, respectively. PD-L1 expression (Dako 22C3) was quantified using tumor proportion score (TPS). Event-free survival (EFS) was defined as the duration from initial surgery to recurrence or metastasis.

Results: A total of 14 patients (12 IMA and 2 MEC) were included. Among them, 6 had KRAS mutations, 2 had HER2 mutations, and 1 had RET mutations; no patients exhibited EGFR mutations or ALK alternation. Overall, low-level PD-L1 expression was observed, with only one case showing a TPS of 10%, and the rest at 0 or ≤1%. All patients underwent 2-4 cycles of neoadjuvant chemoimmunotherapy, with 13 (92.9%) achieving R0 resection. The sole patient with R2 resection received adjuvant radiotherapy post-surgery. Only one exhibited a partial response (-30.38%), while the remaining 13 maintained stable disease following neoadjuvant therapy. In terms of pathological assessment, none had achieved MPR or pCR (defined as 0% and <10% viable tumor cell). Totally 5 patients experienced postoperative recurrence or metastasis, resulting in one mortality, after a median follow-up period of 19.6 months (Fig A). The median EFS time was 16 months, with all five patients experiencing their first relapse as intrapulmonary metastases (Fig B).

Conclusions: Limited efficacy of chemoimmunotherapy in the neoadjuvant setting for resected IMA and MEC was observed. Only one case exhibited radiological partial response, with no partial or complete pathological responses observed. However, further validation on a larger scale is still on going.

P2.07C.04 Surgical Complexity of Anatomical Lung Resections after Induction Immunotherapy for Locally Advanced or Metastatic Non-Small Cell Lung Cancer

R.S. Werner, K. Chiffi, D. Schneiter, S. Hillinger, O. Lauk, I. Opitz

University Hospital Zurich, Zurich/CH

Introduction: Neoadjuvant immunotherapy has become an integral part of the multimodal treatment in advanced NSCLC. However, an increasing procedural complexity after neoadjuvant immunotherapy is described by many surgeons. We therefore aim to score the surgical complexity of anatomical resections after induction immunotherapy.

Methods: We performed a single-institutional retrospective review of patients with clinical stage IIIA-IVB NSCLC who underwent anatomical lung resection and mediastinal lymphadenectomy after neoadjuvant immunotherapy. Surgical complexity and hilar fibrosis were scored according to the proposed scoring system by Rusch et al. (https://doi.org/10.1016/j.jtcvs.2022.10.007).

Results: 25 patients met the inclusion criteria, among which 4 (16%) were treated with neoadjuvant immunotherapy alone, 18 (72%) with neoadjuvant immunochemotherapy and 3 (12%) with neoadjuvant immunotherapy and chemoradiotherapy. Clinical UICC-stages were IIIA in 8 (32%), IIIB in 2 (8%), IVA in 9 (36%) and IVB in 6 patients (24%). Surgical access was primarily open in 13 (52%), RATS in 5 (20%) and VATS in 7 patients (28%). Resections included 15 lobectomies, 4 bilobectomies, 5 pneumonectomies and 1 segmentectomy. Conversion from minimally invasive to open approach was required in 5 patients (2 VATS and 3 RATS cases), all due to extensive hilar fibrosis. A hilar fibrosis score of 2 was present in 15 cases and a score of 0 was only seen in 4 patients. The presence of a high fibrosis score was not associated with an increased risk for perioperative complications (p=0.66), but patients with a fibrosis score of 2 showed a longer median length of hospital stay (9.4±3.9 versus 6.7±1.8 days), although not statistically significant (p=0.056).

Conclusions: Surgical complexity after neoadjuvant immunotherapy for advanced NSCLC can be objectified by a hilar fibrosis score. The prognostic relevance of the hilar fibrosis score for early outcomes such as perioperative complications and length of stay needs to be assessed in larger prospective cohorts.

P2.07C.05 Perioperative (Neoadjuvant Plus Adjuvant) Immunotherapies for Resectable NSCLC:A Systematic Review and Meta-Analysis of Phase 3 Trials

W. Chen, C. Zhang, H. Liu

Cancer Hospital of Dalian University of Technology, Liaoning Cancer Hospital & Institute, Shenyang/CN

Introduction: Meta-analysis based on phase III trials which investigated the efficacy and safety of perioperative (neoadjuvant plus adjuvant) immunotherapies in resectable non-small cell lung cancer (NSCLC) patients are lacking. In addition, existing phase III studies have described inconsistent results of perioperative immunotherapies in some important subgroups of patients and requires further investigation.

Methods: PubMed, Embase and Cochrane Library were systematically searched for phase III trials of perioperative immunotherapies in resectable NSCLC patients before March 23, 2024. The pooled hazard ratios (HR) were determined through the generic inverse variance methods model, the pooled risk difference (RD) derived through the inverse variance method. Random-effect model was applied depending on the heterogeneity. The protocol of this study was registered with the International Platform of Registered Systematic Review and Meta-analysis Protocols (INPLASY202440003).

Results: We identified 5 trials (N=2855) that met eligibility criteria, with 1420 and 1435 patients receiving perioperative (neoadjuvant plus adjuvant) immunotherapies and perioperative chemotherapy, respectively. Pooled event-free survival (HR: 0.58; 95%CI: 0.51-0.65), pathological complete response (RD: 21%; 95%CI: 15-27) and major pathological response (RD: 29%; 95%CI: 21-37) favored perioperative immunotherapies over perioperative chemotherapy. No clinically meaningful differences were observed between perioperative immunotherapies and perioperative chemotherapy across the incidence of any grade TRAE (RD: 1%; 95%CI: -1-3), grade≥3 TRAE (RD: 5%; 95%CI: 2-8), surgical resection rate (RD: 3%; 95%CI: 1-6) and R0 resections rate (RD: 4%; 95%CI: 2-6). For subgroup patients, perioperative immunotherapies provide more efficacy benefits compare with perioperative chemotherapy regardless of disease stage, histology and PD-L1 expression (Table).

Conclusions: This meta-analysis demonstrated that perioperative (neoadjuvant plus adjuvant) immunotherapies was associated with prolonged EFS, higher pCR and MPR rates compare with perioperative chemotherapy across disease stage, histology and PD-L1 expression, with no increased safety risk and no impact on the feasibility and completeness of surgery. The study supports the use of perioperative immunotherapies for patients with resectable NSCLC.

Introduction: Patients with advanced non-small cell lung cancer (NSCLC) without targetable driver alterations or those who become resistant to targeted therapy have limited treatment options after progression on platinum-based chemotherapy or immune checkpoint blockade. Hence, there is a need for effective therapies in the late-line setting. Human epidermal growth factor receptor 2 (HER2) expression detected by immunohistochemistry (IHC; range 1+-3+) occurs at a higher frequency than activating HER2 mutations and has been reported in approximately 50% of lung cancers (Uzunparmak 2023). Patients with tumors that express HER2, including HER2-low (IHC 1+ or IHC 2+/in situ hybridization-negative) tumors, may be targeted with HER2-directed antibody-drug conjugates (ADCs). Disitamab vedotin (DV; RC48-ADC) is an investigational ADC comprising a fully humanized HER2-directed monoclonal antibody, disitamab, conjugated to monomethyl auristatin E (MMAE) via a protease-cleavable mc-vc linker. DV elicits antitumor activity through multimodal mechanisms of action, including MMAE-mediated direct cytotoxicity, bystander effect, and immunogenic cell death. Disitamab targets different epitopes of the HER2 receptor, with a higher molecular affinity for HER2, than trastuzumab. DV monotherapy has shown promising clinical activity across several HER2-expressing advanced solid tumors (Xu 2021, Peng 2021, Sheng 2023, Wang 2021). Available data from

these studies suggest DV may be a potential treatment option in previously treated advanced NSCLC with HER2 expression.

Methods: DV-005 (NCT06003231) is a phase 2, multicohort, multicenter, open-label basket trial assessing DV monotherapy for the treatment of patients with previously treated advanced solid tumors that express HER2 (≥1+ determined by local IHC). Patients with HER2 mutations will be eligible. In this multicohort study, Cohort 2 will enroll patients with metastatic or locally advanced unresectable NSCLC. DV will be administered intravenously every 2 weeks until disease progression, unacceptable toxicity, death, termination of study, or withdrawal of consent. Patients with NSCLC enrolled in Cohort 2 must have progressed during or after platinum-based therapy or within 6 months of platinum-based adjuvant, neoadjuvant, or concomitant chemoradiotherapy for early or locally advanced-stage disease. Patients must have also received prior anti-programmed cell death receptor 1 (PD-1)/programmed cell death ligand 1 (PD-L1) therapy unless contraindicated. Those patients with known EGFR, ALK, ROS1, or other actionable alterations must have received targeted therapy. Prior HER2-directed therapy is permitted, including HER2-directed ADCs. All patients must have measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 and Eastern Cooperative Oncology Group performance status 0 or 1. Patients are ineligible if they have received MMAE-based therapy or have clinically significant cardiopulmonary disease, chronic liver disease, or uncontrolled central nervous system metastases. The primary endpoint is overall response rate, defined as confirmed complete or partial response per RECIST v1.1, as assessed by the investigator. Secondary endpoints include safety and tolerability, disease control rate, duration of response, progression-free survival, overall survival, incidence of antidrug antibodies, and pharmacokinetic parameters. Enrollment is ongoing in the US and Canada.

P2.10A.02 Phase 1/1b Trial of MBRC-101, An Anti-EphA5 Monomethyl Auristatin (MMAE) Antibody Drug Conjugate, In Advanced Refractory Solid Tumors

M. Gubens1, S. Sen2, M.A. Salkeni3, A. Vandross4, N. Gandhi5, W.J. Edenfield6, R. Aggarwal1, K. Parsons7, I. Chen7, J. Powderly5

1University of California San Francisco, San Francisco/CA/USA ,2NEXT Oncology, Dallas/TX/USA ,3NEXT Oncology, Fairfax/VA/USA ,4NEXT Oncology, Austin/TX/USA ,5Carolina BioOncology, Huntersville/NC/USA ,6Prisma Health Cancer Institute, Greenville/SC/USA ,7MBrace Therapeutics, San Diego/CA/USA

Introduction: EphA5 receptor is a member of the Ephrin receptor tyrosine kinase (RTK) family. Several lines of robust nonclinical evidence indicate EphA5 is a novel and selective target for solid tumor-directed therapy. Expressed only minimally in normal tissues, it is highly expressed in non-small cell lung carcinoma (NSCLC) and other malignancies. MBRC-101 is a novel antibody drug conjugate (ADC) composed of an anti-EphA5 antibody conjugated to an MMAE payload (drug-to-antibody ratio of 4) through a valine citrulline cleavable linker. In pre-clinical testing against a variety of cell-derived (CDX) and patient-derived (PDX) xenograft solid tumor models, MBRC-101 demonstrated robust anti-tumor activity against NSCLC and other EphA5-expressing malignancies.

Methods: This first-in-human, Phase 1/1b, multicenter, open-label study is examining the safety and efficacy of MBRC-101 in patients with advanced metastatic solid tumors refractory to standard treatment. Phase 1 will identify potential optimal biologically relevant doses (OBRD) and the maximum tolerated dose (MTD) of MBRC-101 at one or more dosing regimens. Phase 1b will evaluate the safety and preliminary clinical activity of MBRC-101 at potential OBRDs. Phase 1 will enroll patients (n ≈ 30) with advanced or metastatic solid tumors. A modified toxicity probability interval (mTPI-2) method will guide dose escalation using a pre-specified decision matrix. The primary endpoints are MTD, dose limiting toxicities (DLTs), treatment emergent adverse events (TEAEs), and clinical laboratory tests. Phase 1b will enroll patients (n ≈ 60) into 3 expansion cohorts (n ≈ 20 per cohort): Cohort A, NSCLC; Cohort B, triple negative or HR+/HER2- breast cancer; and Cohort C, pancreatic adenocarcinoma, gastric adenocarcinoma, hepatocellular carcinoma, ovarian adenocarcinoma, and squamous cell carcinoma including primary malignancies of the head and neck, esophagus, cervix, and skin. The primary endpoints are TEAEs, clinical laboratory tests, and investigator-assessed objective response rate (ORR) by RECIST v1.1 and clinical evaluation. Secondary endpoints for Phase 1 and 1b include PK analytes and EphA5 expression as determined by immunohistochemistry (IHC). Expression of EphA5 in primary or metastatic tumor tissue will not be required for enrollment into Phase 1 or 1b but will be assessed retrospectively. A Safety Review Committee will monitor safety at each dose escalation in Phase 1 and at regular intervals throughout Phase 1b.

Results: As of April 1, 2024, n = 13 patients (n =2 with NSCLC) had been enrolled. No DLTs were observed through 3 escalating dose levels.

Conclusions: This Phase 1/1b trial is evaluating MBRC-101, a novel ADC composed of an anti-EphA5 antibody and MMAE payload, in patients with NSCLC and other advanced refractory solid malignancies.

P2.10A.03 RESOLUTION: Phase II Study of Disitamab Vedotin in Combination with Tislelizumab and Bevacizumab in Patients with HER2 Alteration Advanced NSCLC

J. Chen, C. Su

Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Nowadays, there are limited approved targeted therapies for metastatic non-small cell lung cancer (mNSCLC) with HER2 alterations. Disitamab vedotin (RC48) is a novel antibody-drug conjugate (ADC) that carries a tubulin inhibitor targeting the HER2 protein on the surface of tumor cells, specifically recognizing and killing these tumor cells. It has demonstrated considerable anti-tumor effects in solid tumors. The synergy between ADCs and immunological or anti-vascular agents holds promise for enhancing the efficacy of treating HER2-altered NSCLC. Consequently, further investigation into the potential of combination therapy for NSCLC harboring HER2 alterations is warranted.

Methods: RESOLUTION (Clinical Trial Number: ChiCTR2300077938) is a dual-cohort, phase 2 study. 56 eligible patients who have locally advanced or metastatic NSCLC with HER2 alterations will be enrolled. There are two cohorts: (1) Patients who have previously received ≥1 line of systemic therapy (2) Cohort 2: patients with locally advanced or metastatic NSCLC who have not received prior systemic therapy.The primary endpoint is objective response rate (ORR). Secondary study endpoints are progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and duration of response (DOR). Disease response will be assessed by investigator according to RECIST 1.1. Patients enrollment is ongoing.

Keywords: HER2 alteration, ADC

P2.10A.04 Valemetostat and Datopotamab Deruxtecan in Previously Treated, Advanced, Unresectable, or Metastatic Non-squamous NSCLC

A. Spira1, N. Yamamoto2, A. Mohapatra3, J. Sands4

1Virginia Cancer Specialist, Fairfax/VA/USA ,2National Cancer Center Hospital, Tokyo/JP ,3Daiichi Sankyo Inc., Basking Ridge/NJ/USA ,4Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Valemetostat tosylate (valemetostat) is a novel, potent, and selective dual inhibitor of enhancer of zeste homolog (EZH)2 and EZH1. Valemetostat 200 mg/day PO has demonstrated clinical efficacy and favorable tolerability in multiple hematologic malignancies. EZH2 controls the expression of multiple genes, including those involved in the DNA damage response, like DNA/RNA helicase Schlafen 11 (SLFN11). In response to DNA damage, SLFN11 binds to chromatin, causing a replication block and inducing apoptosis. Expression levels of SLFN11 indicate sensitivity to DNA-damaging agents (DDAs) in lung cancer and are downregulated in chemotherapy-resistant tumor cells due to trimethylation of histone H3 at lysine 27 at the SLFN11 gene locus. EZH2 inhibition by valemetostat is expected to upregulate SLFN11 and sensitize tumor cells to DDAs. Topoisomerase inhibition causes DNA strand breaks, which may synergize with valemetostat. Datopotamab deruxtecan (Dato-DXd) is a novel, investigational trophoblast cell surface protein 2 (TROP2)-directed antibody-drug conjugate (ADC) composed of a humanized anti-TROP2 IgG1 monoclonal antibody covalently linked to a potent topoisomerase I inhibitor payload (DXd) via a plasma-stable tetrapeptide-based cleavable linker. In the phase 3 TROPION-Lung01 trial, Dato-DXd significantly improved progression-free survival (PFS) vs standard chemotherapy in previously treated, locally advanced, or metastatic non-small-cell lung cancer (NSCLC). This study is structured as a Master Protocol trial evaluating the clinical activity and safety of valemetostat in combination with DXd-ADCs, including Dato-DXd and the human epidermal receptor 2 (HER2)-directed ADC, trastuzumab deruxtecan (T-DxD), in patients with NSCLC or other solid tumors, respectively.

Methods: This global, phase 1b, multicenter, two-part, open-label Master Protocol study will enroll ~ 70 patients per sub-protocol in multiple regions including the US and Japan. The NSCLC sub-protocol will enroll adult patients with 2L+ locally advanced, unresectable, or metastatic non-squamous NSCLC with or without actionable genomic alterations (Figure). A preliminary dose-escalation part will assess escalating valemetostat doses of 50-200 mg PO QD with fixed-dose Dato-DXd 6.0 mg/kg IV Q3W, to determine the valemetostat recommended dose for expansion (RDE). A subsequent dose-expansion part will evaluate the efficacy of valemetostat (at the RDE) + Dato-DXd. Primary endpoints of this study are safety and tolerability of valemetostat in Part 1 and objective response rate in Part 2. Secondary endpoints include duration of response, PFS, overall survival and pharmacokinetics. An interim futility analysis will be performed when 20 patients have been enrolled and completed ≥ 6 months of follow-up. Clinical trial information: NCT06244485.

1University of Kansas Medical Center, Kansas City/KS/USA ,2University of Kansas, Lawrence/KS/USA ,3University of Iowa Carver College of Medicine, Iowa City/IA/USA ,4University of Kentucky Markey Cancer Center, Lexington/KY/USA

Introduction: For advanced/metastatic non-small cell lung cancer (NSCLC) patients who do not have targetable driver mutations, either immunotherapy using immune checkpoint inhibitors alone or in combination with platinum-based chemotherapy is now a standard of care. However, many patients do not derive benefit due to primary, adaptive, or acquired resistance, as well as immune-related adverse effects (irAEs), necessitating the discovery of novel therapeutics to benefit patients who have failed or are intolerant to first-line immunotherapy. Here, we propose a multi-center phase II study to use ipatasertib, an AKT1 inhibitor, in combination with docetaxel, based on the following rationales: 1) Aberrant activation of the PI3'K-AKT pathway due to either the hyperactivation of oncogenes and/or loss-of-function of tumor suppressors occurs in more than half of NSCLC patients; 2) Hyperactivation of the PI3'K-AKT pathway also confers a suppressive tumor immune microenvironment; 3) The combination of ipatasertib and taxane has demonstrated safety and efficacy in earlier studies.

Methods: Eligible patients must have advanced/metastatic NSCLC and have failed or are intolerant to first-line anti-PD1/PD-L1, either single-agent or in combination with chemotherapy and/or anti-CTLA4. Patients who were treated with concurrent chemoradiation therapy followed by durvalumab, upon progression on or after durvalumab, will also be eligible if there is no other systemic anti-cancer treatment given. In addition, patients who are qualified for FDA-approved targeted therapy may be eligible if they have failed at least one line of such targeted therapy, followed by the failure or intolerance to only one line of anti-PD1/PD-L1 therapy, either single-agent or in combination with chemotherapy and/or anti-CTLA4. Participants will receive ipatasertib 400 mg PO daily on days 1-14 plus docetaxel at 75 mg/m2 intravenously on day 1 of each 21-day cycle. G-CSF support is started from cycle 1. The primary endpoint is progression-free survival (PFS). Secondary endpoints include objective response rate (ORR), overall survival (OS), and safety. The exploratory endpoints include the correlation of PFS with cfDNA, PTEN status, microbiome, and ex vivo testing using tumor organoids. Using PFS ~4.6 months in this population as a comparison, we hypothesize that this proposed therapy will yield a 50% increase in median PFS (6.9 vs. 4.6 months). Assuming that PFS follows an exponential distribution, we will need to enroll 45 participants in order to have 80% power to detect a 50% improvement in median PFS using a type I error of 5% with a one-sided test. Allowing for a 25% censoring rate, we therefore plan to enroll 60 evaluable participants. This study is currently ongoing.

Introduction: Trophoblast cell-surface antigen 2 (TROP2), a cell surfaceglycoprotein involved in the regulation of tumor growth and invasion, isbroadly expressed and upregulated in several cancers, including NSCLC. Sacituzumab tirumotecan (sac-TMT; also known as MK-2870/SKB264) is an antibody-drugconjugate (ADC) composed of the humanized anti-TROP2 monoclonal antibody, ahydrolytically cleavable linker, and the cytotoxic drug KL610023. Sac-TMT has demonstratedencouraging antitumor activity and manageable toxicity in phase 1 and 2 studiesof patients with solid tumors, including heavily pretreated EGFR-mutant NSCLC.We describe the design of the ongoing phase 3 TroFuse-004 study (NCT06074588) thatwill evaluate the efficacy and safety of sac-TMT vs chemotherapy for previouslytreated advanced or metastatic nonsquamous NSCLC with EGFR mutations orother genomic alterations.

Methods: The global, randomized,open-label, phase 3 TroFuse-004 studywill enroll ~556 patients, including 456 with exon 19del or L858R EGFRmutations, and 100 with other genomic alterations. Eligible patients are aged≥18 years with histologically or cytologically documented advanced (stage IIInot eligible for resection or curative radiation) or metastatic nonsquamousNSCLC with exon 19del or exon 21 L858R EGFR mutations or other genomicalterations in ALK, ROS1, BRAF V600E, NTRK, METexon 14 skipping, or RET and those with less common EGFRmutations (exon 20 S768I, exon 21 L861Q, and/or exon 18 G719X). Patients must have progressive disease on or after 1 or 2lines of prior tyrosine kinase inhibitor therapy and a platinum-based therapy(may contain anti-PD-[L]1), measurable disease per RECIST v1.1, an availabletumor sample, and adequate organ function. Prior EGFR tyrosine kinaseinhibitor therapy must include a third-

generation tyrosine kinase inhibitor forpatients with T790M EGFR-mutant NSCLC. Patients with active centralnervous system metastases or carcinomatous meningitis are ineligible, althoughthose with previously treated and untreated stable brain metastasis are eligiblefor enrollment. Patients will be randomized (1:1) to sac-TMT 4 mg/kg Q2W onDays 1, 15, and 29 of every 6-week cycle, or chemotherapy (docetaxel 75 mg/m2Q3W or pemetrexed 500 mg/m2 Q3W) on Days 1 and 22 of every 6-weekcycle. Randomization will be stratified by EGFR mutations with priorthird generation tyrosine kinase inhibitor vs EGFR mutations with noprior third generation tyrosine kinase inhibitor vs other genomic alterations,brain metastasis (yes vs no), and TROP2 expression (low vs medium vs high). Dualprimary endpoints are PFS (per RECIST v1.1 by blinded independent centralreview) and OS in patients with EGFR-mutant NSCLC. Key secondary endpointsinclude PFS and OS in all patients with NSCLC, ORR, DOR, patient-reportedoutcomes (PROs), and safety. Health-related quality oflife PROs will be measured using the EORTC QLQ-C30 and EORTC QLQ-LC13. Enrollmentstarted in November 2023 and is currently ongoing.

Introduction: Sacituzumab tirumotecan (sac-TMT; also known as MK-2870/SKB264) is an antibody-drug conjugate composed of a humanized anti-trophoblast cell-surface antigen 2 (TROP2) monoclonal antibody, a hydrolytically cleavable linker, and the cytotoxic topoisomerase I inhibitor KL610023. TROP2 is a cell-surface glycoprotein associated with cancer growth and invasion and is overexpressed in several cancers, including non-small-cell lung cancer (NSCLC). Phase 1 and 2 studies of sac-TMT, including in patients with heavily pre-treated EGFR-mutated NSCLC, have shown encouraging antitumor activity and manageable toxicity. We describe the design of the phase 3 TroFuse-009 study (NCT06305754), which will evaluate the efficacy and safety of sac-TMT vs platinum-based doublet chemotherapy in patients with EGFR-mutated locally advanced or metastatic nonsquamous NSCLC with disease progression following prior EGFR tyrosine kinase inhibitor (TKI) therapy.

Methods: This global, randomized, open-label, phase 3 study will enroll approximately 520 patients aged ≥18 years with histologically or cytologically confirmed stage III not eligible for resection or curative chemoradiation or stage IV nonsquamous NSCLC with one of the following tumor-activating EGFR mutations: exon 19del, L858R, G719X, S7681, or L861Q. Patients must have experienced disease progression on prior EGFR TKI therapy (those who previously received a first- or second-generation EGFR TKI as first-line therapy must have documentation of the absence of EGFR T790M mutation on a biopsy sample obtained after disease progression; if T790M mutation was acquired after receiving a first- or second-generation EGFR TKI, the patient must have subsequently received a third-generation EGFR TKI before enrollment). Patients must also have a tumor tissue sample for biomarker analysis (TROP2 expression will be assessed centrally by immunohistochemistry), measurable disease per RECIST version 1.1, and ECOG PS of 0 or 1. Patients with known central nervous system metastases and/or carcinomatous meningitis are ineligible, except those with previously treated brain metastases (if clinically stable for ≥2 weeks, with no evidence of new/enlarging brain metastases and no steroids within 3 days before study treatment) or known untreated, asymptomatic brain metastases. Patients will be randomized 1:1 to receive either sac-TMT 4 mg/kg every 2 weeks or pemetrexed 500 mg/m2 plus carboplatin AUC 5 mg/mL/min every 3 weeks for 4 doses followed by pemetrexed 500 mg/m2 every 3 weeks until disease progression or unacceptable toxicity. Randomization will be stratified by brain metastases at baseline (yes vs no), TROP2 expression (no or low vs medium vs high), and type of EGFR TKI received in first line (third-generation vs first- or second-generation, including those with third-generation in second line). Tumor imaging will be performed every 6 weeks from randomization through week 48 and every 12 weeks thereafter. Safety will be assessed from the time of randomization through 30 days after discontinuation of study treatment; AEs will be graded according to National Cancer Institute Common Terminology Criteria for Adverse Events version 5.0. Dual primary endpoints are progression-free survival (per RECIST version 1.1 by blinded independent central review) and overall survival. Secondary endpoints include objective response rate, duration of response, patient-reported outcomes, and safety. Enrollment in this study will begin in May 2024.

P2.10B.01 Exploratory Analyses of Tusamitamab Ravtansine vs Docetaxel in Previously Treated Non-squamous NSCLC Patients: CARMEN-LC03

B.C. Cho1, J. Cadranel2, M. Chadjaa3, S. Yoruk4, P.A. Dennis5, A. Seluzhytsky5, L. Charbonnier3, L. Wu6

1Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul/KR ,2Department of Pulmonology and Thoracic Oncology, Tenon Hospital, Assistance Publique - Hôpitaux de Paris and Sorbonne University, Paris/FR ,3Sanofi, Vitry-Sur-Seine/FR ,4Sanofi, Istanbul/TR ,5Sanofi, Cambridge/MA/USA ,6Department of Thoracic Oncology, Hunan Cancer Hospital, Changsha/CN

Introduction: CARMEN-LC03 was a phase 3, open-label, randomized (1:1), multicenter study that evaluated tusamitamab ravtansine (tusa rav), an antibody-drug conjugate with a microtubule-destabilizing payload (DM4), vs docetaxel in patients with advanced nonsquamous non-small cell lung cancer (NSCLC) previously treated with chemotherapy and immunotherapy and whose tumors highly expressed CEACAM5 (defined as ≥2+ intensity in ≥50% of tumor cells assessed by immunohistochemistry [IHC]). The primary analysis showed that tusa rav did not improve progression-free survival (PFS), showed a trend towards improved overall survival (OS), favorable safety, toxicity profile, and patient-reported outcomes (PROs). Here we present results from post-hoc exploratory analysis of PFS and OS.

Methods: Patients were randomized to receive tusa rav 100 mg/m2 Q2W IV or docetaxel 75 mg/m2 Q3W IV. The two primary endpoints of PFS and OS were analyzed by stratified Cox regression model to estimate the hazard ratio (HR) and 95% confidence interval (CI) of tusa rav versus docetaxel in all randomized participants (intent-to-treat [ITT] population). Post-hoc exploratory analyses were performed for several subgroups of interest, including different cut-off for CEACAM5-IHC expression, actionable genomic alterations (AGA), and prior taxane use (using unstratified Cox-regression model).

Results: As of September 22, 2023, 194 patients were randomized to tusa rav and 195 to docetaxel. Median age was 64 years; 59.6% were male. In patients without AGAs (that needed immunotherapy) and no prior taxanes (overlapping mechanism of action with tusa rav payload), OS favored tusa rav versus docetaxel with a HR (0.71 [0.52-0.97]), while PFS was not affected (HR=1.00 [0.73-1.38]). Both PFS (HR=0.87 [0.60-1.26]) and OS (HR=0.71 [0.49-1.03]) favored tusa rav in participants with CEACAM5 ≥2+ in ≥80% tumor cells compared to population with CEACAM5 ≥2+ in 50-79% tumor cells (PFS: HR=1.38 [0.92-2.07], and OS: HR=1.02 [0.69-1.50]). Dividing patients into terciles of CEACAM5 expression showed that patients with >90% achieved the greatest benefit (PFS, OS, and PROs) with tusa rav. Further analysis revealed that median OS substantially improved with increasing CEACAM5 expression, irrespective of treatment. In the post-hoc exploratory analyses, the greatest relative clinical benefit with tusa rav was observed among patients with CEACAM5 >90%, median OS (tusa rav vs docetaxel) was 18.63m vs 15.24m, respectively (HR=0.65 [0.39-1.08]; Table).

Conclusions: These exploratory analyses identify patients likely to derive clinical benefit from tusa rav and suggest a previously unknown prognostic role for CEACAM5 in NSCLC. Additional research is needed to corroborate these findings.

P2.10B.02 Cutoff Determination for C-met Protein Overexpression by VENTANA MET (SP44) IHC to Determine Teliso-v Eligibility in NSCLC

N. Zhang, Y. Sun, P.J. Ansell, A.T. Mistry, M.M. Li, A.G. Hotson, C.K. Ratajczak, D. Smith

AbbVie Inc., North Chicago/IL/USA

Introduction: c-Met (also known as MET protein) overexpression occurs in approximately 25% of patients with advanced epidermal growth factor receptor wildtype non-squamous non-small cell lung cancer (EGFR WT NSQ NSCLC) and is associated with poor prognosis. Telisotuzumab vedotin (Teliso-V) is a first-in-class, c-Met protein-directed antibody-drug conjugate that has shown efficacy in patients with c-Met protein-overexpressing advanced EGFR WT NSQ NSCLC. The VENTANA MET (SP44) immunohistochemical (IHC) assay measures c-Met protein expression on formalin-fixed paraffin-embedded tumor samples. This study aimed to determine the optimal cutoff values for c-Met protein overexpression to identify patients with EGFR WT NSQ NSCLC who are most likely to benefit from treatment with Teliso-V.

Methods: Tumor samples from patients with EGFR WT NSQ NSCLC enrolled in an ongoing first-in-human study of Teliso-V (NCT02099058) were retrospectively analyzed for c-Met protein expression using the VENTANA MET (SP44) IHC assay. The membrane staining intensity and the percentage of c-Met staining positivity on tumor cells were assessed and their association with best objective response to Teliso-V treatment was evaluated. Receiver operating characteristic (ROC) analysis was used to determine the membrane staining intensity threshold (ie, 1+, 2+, or 3+) that best associated with best objective response. Statistical analyses, including sensitivity, specificity, positive predictive value, negative predictive value, and Fisher's exact test p-value were performed for each of the prespecified candidate cutoffs to determine the percentage of tumor cells indicating c-Met positivity: 10%, 25%, 50%, 75%, 90%, and 100%. Statistical outcome evaluation and comparison of Fisher's exact test p-values and the Youden index were used to determine the optimal cutoff value of c-Met protein overexpression to identify eligibility for Teliso-V treatment. Reported p-values are nominal.

Results: Best objective response rates above and below each potential threshold for each intensity were compared in 30 patients. Among evaluated staining intensities and candidate cutoffs, 25% c-Met positivity with 3+ staining intensity on tumor cells was identified as the most optimal cutoff and intensity, with best objective response rates of 56% and 10% for those above (n=9) and below (n=21) the cutoff

(p=0.0139) and an area under the ROC curve of 0.736 for the staining intensity. A threshold of 50% cell positivity with 3+ staining intensity resulted in best objective response rates of 67% and 12% for those above (n=6) and below (n=24) the cutoff (p=0.0157).

Conclusions: A cutoff value of 25% c-Met-positive tumor cells with 3+ intensity was selected to determine positivity of c-Met protein overexpression in patients with EGFR WT NSQ NSCLC eligible for Teliso-V treatment. A cutoff value of 50% was selected to determine high expression of c-Met protein.

Keywords: c-Met, NSCLC, Teliso-V

Introduction: Platinum doublet chemotherapy is a standard of care option for treatment of patients with epidermal growth factor receptor mutation-positive (EGFR+) advanced non-small cell lung cancer (aNSCLC) after disease progression on osimertinib. Evidence for second-line (2L) platinum chemotherapy after osimertinib from a pragmatic clinical trial is lacking.

Methods: OCELOT (NCT04335292) is a multicentered phase II open-label multi-cohort investigator-initiated study of osimertinib for the third-line treatment of EGFR+ aNSCLC (Cohort A), following first-line (1L) treatment with osimertinib then 2L treatment with platinum-pemetrexed chemotherapy, and (Cohort B) 1L treatment of EGFR+ aNSCLC for patients with uncommon EGFR mutations. Patients in Cohort A were enrolled at the time of 2L chemotherapy and patients in Cohort B were enrolled prior to 1L osimertinib. We analyzed response rate as per RECIST 1.1 and survival outcome of patients with EGFR+ aNSCLC treated prospectively in both cohorts of OCELOT clinical trial with platinum-pemetrexed chemotherapy (in 2L) after progression on osimertinib. The chemotherapy dosing was at the investigator's discretion. The primary outcome of this analysis was objective response rate (ORR). The secondary outcome was progression free survival (PFS) and time to treatment failure (TTF).

Results: At data cut off for this analysis, a total of 29 patients received 2L treatment with platinum pemetrexed. 52% (n = 15) of patients were male. The median age was 63 years (range, 36-87 years). 22 had evaluable disease. The ORR in the whole cohort was 31.8% and the disease control rate (DCR) was 81.8% (partial response in 7, stable disease in 11 and progressive disease in 4 patients). The ORR and DCR among six patients having uncommon EGFR mutations was 50% (n = 3) and 83% (n = 5) respectively. The median PFS in the whole cohort was 6.6 months and 6-month PFS was 50% (the results for PFS are the same when restricted to common mutations). The median TTF was 7.0 months and the 6-month TTF was 53.3%. OS data are immature.

Conclusions: The response rate and progression free survival of patients with EGFR+ aNSCLC treated with 2L platinum pemetrexed after progression on osimertinib is comparable to published literature. This supports that the benefit of platinum pemetrexed translates for a pragmatic population receiving chemotherapy dosed at the investigators' discretion.

Introduction: Paclitaxel liposome is paclitaxel encapsulated by liposomes made from lecithin and cholesterol. Paclitaxel liposome reduces the incidence of drug-induced toxicity especially hypersensitivity reactions compared with solvent paclitaxel formulation because

polyethoxylated castor oil is not used. This study aimed to evaluate the real-world effectiveness and safety of paclitaxel liposome-based chemotherapy plus immunotherapy as first-line treatment among Chinese patients with advanced non-small cell lung cancer (NSCLC).

Methods: The data for this study were sourced from the "Efficacy and Safety of Immunotherapy in NSCLC Patients: A Multi-Center Observational Study" project within the real-world lung cancer database initiative launched by the Lung Cancer Special Committee of the China Medical Education Association, with a specific focus on the use of paclitaxel liposome plus immunotherapy. Patient data was drawn from an online hospital platform. The study evaluated advanced NSCLC patients who underwent first-line treatment with paclitaxel liposome-based chemotherapy and immunotherapy in nine Chinese hospitals between April 2020 and November 2023. The primary outcome was progression-free survival (PFS), with objective response rate (ORR) and safety as secondary outcomes.

Results: Among 200 patients who met the criteria, 188 were male with an overall median age of 66 (range: 59 to 69). Of all patients, 163 (81.5%) were squamous cell carcinoma, 10(5.0%) were adenocarcinoma, and 27 (13.5%) were NSCLC where specific pathological subtypes were not recorded. 27% of the patients were at stages IIIB-IIIC, and 73% were at stage IV. The percentage of patients with and without EGFR mutations were 1.0% and 69.0% respectively, with 31.0% had unkown status. The median treatment cycles for first-line paclitaxel liposome-based chemotherapy and immunotherapy were 4. The immunotherapy agents used included tislelizumab (n=120), pembrolizumab (n=30), sintilimab (n=29) and others (n=21). All patients were co-administered platinum with 92.5% receiving carboplatin. The median duration of follow-up was 9.5 months. The median PFS was 11.4 months (95% CI: 9.8-13.3). The 1-year PFS rate was 44% (95% CI: 36-54). Multivariate analysis identified treatment cycles of paclitaxel liposome as independent risk factors for PFS (P<0.05), with patients received >3 cycles having better PFS. Out of the 164 patients evaluated for effectiveness, 11 achieved a complete response, 86 demonstrated a partial response, 52 had stable disease, and 15 experienced progressive disease. The overall ORR was 59.1%, and the DCR was 90.9%. Adverse events of all grades were recorded in 59% of the patients, with 16.5% were of grade 3 or higher. It should be noted that the non-laboratory adverse events were based on analyses of patient-reported outcome(PRO) data. The most common adverse events included bone marrow suppression, gastrointestinal reactions, and liver function abnormalities. The adverse events observed in > 10% of the patients were decreased neutrophil count and anaemia. 16 deaths were recorded till the cut-off date of 29th February 2024.

Conclusions: Paclitaxel liposome-based chemotherapy plus immunotherapy demonstrated substantial effectiveness and safety for advanced NSCLC in the real-world setting. The study is currently ongoing.

P2.10B.05 Renal Toxicity in Patients with Non-Small Cell Lung Cancer Receiving Maintenance Therapy with Pemetrexed and Pembrolizuma

U.M. Weber, A.G. Nicklawsky, B.A. Yoder, E.L. Schenk, P.A. Bunn, D.R. Camidge, T. Patil

University of Colorado School of Medicine, Aurora/CO/USA

Introduction: Both pemetrexed and pembrolizumab have been associated with renal toxicity but there are limited data comparing the rates of renal toxicity in patients with metastatic non-small cell lung cancer (NSCLC) who receive maintenance therapy with pemetrexed, pembrolizumab, or both.

Methods: A retrospective analysis of patients with metastatic NSCLC who were treated at the University of Colorado Cancer Center from 2019-2023 with at least 4 cycles of platinum, pemetrexed, and pembrolizumab followed by at least 1 cycle of maintenance therapy with pemetrexed, pembrolizumab, or both was conducted. Baseline characteristics were collected at the time of treatment initiation. Patients were defined as having one of the co-morbidities of interest if they had been assigned a corresponding ICD-10 code at the time of treatment initiation. The outcome of interest was renal events that occurred while patients were on maintenance therapy. A renal event was defined as having any ICD-10 code corresponding to abnormal results of kidney function studies, acute kidney injury (AKI), or chronic kidney disease (CKD) assigned while on maintenance therapy. CKD was only counted as a renal event if it was not present at baseline. Differences between cohorts were evaluated with the Kruskal-Wallis rank sum test for continuous variables, the Chi-square test for categorical variables, and the Fisher Exact test for categorical variables with low cell counts.

Results: A total of 166 patients were included in this study of whom 58 received maintenance pemetrexed, 30 received maintenance pembrolizumab, and 78 received maintenance pemetrexed/pembrolizumab. The baseline characteristics of the patients are summarized in Table 1.

There was a trend towards increased incidence of any renal event in the pemetrexed (19.0%) and pemetrexed/pembrolizumab (21.8%) cohorts compared to the pembrolizumab cohort (3.3%, p=0.07). This was driven by a significantly higher incidence of AKI in the pemetrexed (17.2%) and pemetrexed/pembrolizumab (17.9%) cohorts compared to the pembrolizumab cohort (0%, p=0.02). There was no significant difference in the incidence of abnormal results of kidney function studies or CKD between the cohorts.

Conclusions: In this retrospective analysis, no AKIs were observed in patients with metastatic NSCLC who received maintenance therapy with pembrolizumab, while AKIs were observed at a significantly higher rate in patients who received maintenance therapy with pemetrexed with or without pembrolizumab. There was a trend towards less renal events in general with pembrolizumab maintenance therapy. These data suggest that pembrolizumab does not add significant risk of renal toxicity in the maintenance treatment of metastatic NSCLC.

P2.10B.06 Improvements in Survival Outcomes of Large Cell Carcinoma Over Past Two Decades (2000-2020)

A. Sood1, J. Elengickal2, A. Sangari3, S.H. Peketi4, L. Hou1, W. Aung1, M. Locke1, X. Zou1, N. Seetharamu1

1Northwell Health, Manhasset/NY/USA ,2Prisma Health, Columbia/SC/USA ,3Emory University School of Medicine, 100 Woodruff Circle/NY/USA ,4Nassau University Medical Center, East Meadow/NY/USA

Introduction: Large cell carcinoma (LCC) is an aggressive subtype of lung cancer, characterized by poor prognosis. Little has been done to explore the long term trends in improvement of Large Cell carcinoma over time. This study aimed to assess trends in 5-year survival rates for LCC patients diagnosed from 2000 to 2015, examining improvements trends.

Methods: We utilized data from the Surveillance, Epidemiology, and End Results (SEER) database, focusing on Large Cell Carcinoma (LCC) spanning from 2000 to 2020. This dataset included year of diagnosis and treatment modalities encompassing radiation therapy, and chemotherapy for a cohort of 16,175 patients. To assess the impact of various factors on survival, we employed a Cox proportional hazards model. This model specifically examined the influence of the year of diagnosis, and detailed treatment modalities such as the type and receipt of chemotherapy and radiation therapy, alongside surgical interventions. The objective was to quantify their effects on survival months, providing insights into the evolving effectiveness of lung cancer treatment practices.

Results: We looked at survival rate by 5 year cohort, as well as effect of chemotherapy and radiation therapy on survival outcomes. There

was a slight improvement in survival in 2005-2009 (HR 0.95, p = 0.007), compared to 2000-2004, while 2010-2014 showed a HR of 0.97 (p = 0.38), suggesting marginal improvement. For 2015-2019, the HR was 0.83, demonstrating significant 17.4% improvement in survival outcomes (p <0.0001). Chemotherapy led to a 21.3% improvement in survival outcomes (HR of 0.79, p <0.0001). Declination of radiation therapy resulted in 47% decrease in survival outcomes (HR of 1.47, p = 2.04e-06).

Conclusions: Overall, we identified an improvement of survival trends over time in patients with LCC. This analysis emphasizes the notable progress in cancer treatment post-2015, aligning with survival improvements. Chemotherapy's role in substantially reducing the hazard rate is confirmed, underscoring its importance in treatment protocols. The adverse outcomes associated with refusing radiation therapy stress the necessity of following recommended treatments. A limitation of our analysis is the impact of data censoring for patients diagnosed from 2015 to 2019, whose follow-up does not cover the full five-year period due to the dataset concluding in 2020. Although survival analysis techniques accommodate censored data, this constrains our insights into the definitive long-term outcomes for these recent cohorts. Further, we were missing staging data to control for severity of disease process.

P2.10B.07 Chemotherapy in Combination with Anti-PD1 in PD-L1-Negative Non-Small Cell Lung Cancer Patients: A Single-Center Experience

J. MARCHAL CABRERA1, S. SEQUERO LÓPEZ1, E.I. MORCILLO CALERO1, Ó. VALLE CÁRCEL1, E. MAÑAS MORA1

1HOSPITAL SAN CECILIO, GRANADA/ES

Introduction: Non-small cell lung cancer (NSCLC) represents a significant burden in Western countries. In this study, we aim to examine the clinical course of patients diagnosed with PD-L1-negative adenocarcinoma and metastatic squamous cell carcinoma of NSCLC, specifically focusing on their response to first-line treatment combining chemotherapy and anti-PD-1 therapy.

Methods: A retrospective study was designed, including patients diagnosed with adenocarcinoma and squamous cell carcinoma without actionable mutations and negative for PD-L1, who were treated with chemo-anti-PD1 from 2019 to the present. Demographic variables were collected, with particular interest in those related to tumor presentation characteristics, progression-free survival (PFS), and overall survival (OS) time.

Results: We collected data from a total of 45 patients with a median age of 68 years (range: 49-78 years). Approximately 20% of our patients presented with brain metastases, liver metastases, or both (9 cases), with pulmonary metastases being the most common at diagnosis (51.1%). This was followed by bone metastases (37.8%), lymph node involvement (26.7%), brain metastases (11.1%), and liver metastases (6.7%). Tumor progression was observed in 48.9% of patients, with the lungs being the most frequently affected organ. Among the 5 patients diagnosed with brain metastases, 40% (2 patients) were eligible for radiosurgery, while the remaining patients received whole-brain radiotherapy. Following first-line progression, only 20% of patients (9 patients) underwent subsequent chemotherapy. Mutation data were obtained using Next Generation Sequencing (NGS) techniques, revealing that 42% of tumors were negative for mutations, while 17% harbored KRAS mutations, and 4% had MET mutations. The median PFS for our population is 7 months (95% CI 0-14.3), and the median OS is 8 months (95% CI 4.2-11.8). Currently, 48.8% (22 patients) are still alive. The median PFS for adenocarcinoma and squamous cell carcinoma was 6 months (95% CI 3.3-8.7) and 5.3 months (95% CI 2.4-8.2), respectively. The median OS was 8 months (95% CI 3.5-12.4) and 6 months (95% CI 2-11.5), respectively.

Conclusions: The combination of chemo-anti-PD1 therapy shows promise in enhancing the survival outcomes of these patients. However, our study reveals that this patient population exhibits a higher tumor burden and is of more advanced age compared to the cohorts in pivotal trials. Moreover, only a minority of our patients were eligible for second-line treatment following disease progression. It is anticipated that with the expansion of patient cohorts in future studies, we will be able to better characterize this population and delineate specific strategies to improve current outcomes.

P2.10B.08 Opportunities for ADC Development in 2L NSCLC Leveraging Predictive Biomarkers

J. Pérez-Granado, B. Larvol, M. Gramling

The Larvol Group LLC, San Francisco/CA/USA

Introduction: Despite advances in 2L treatment options for metastatic Non-Small Cell Lung Cancer (mNSCLC), these have limited

benefits and substantial toxicity. The recent approval of Antibody-drug conjugates (ADCs) has spurred advancements in these treatments combining monoclonal antibodies with cytotoxic payloads. The complex structure of ADCs makes it critical to identify biomarkers that predict response.

Methods: A systematic review in LARVOL CLIN, an outcomes database of 100,000 trials, was conducted to identify trials comparing ADC versus non-ADC treatments in 2L+ mNSCLC. Predictive biomarkers of response to ADCs assessed in those trials were verified using LARVOL VERI, a precision oncology database.

Results: Four P2/3 trials comparing ADC to non-ADC treatments in 2L+ for mNSCLC have published outcome data (Table 1 and Image 1). DESTINY-Lung01 and DESTINY-Lung02 led to HER2-targeting trastuzumab deruxtecan (T-DXd) approval. TROP2-targeted datopotamab deruxtecan (Dato-DXd) tested in non-squamous NSCLC showed significant PFS over chemotherapy, but OS is pending final assessment. HER3-targeting patritumab deruxtecan (HER3-DXd) has been evaluated in HERTHENA-LUNG01 for EGFR-mutated NSCLC.

Biomarkers predicting response in NSCLC are emerging from the data for Dato-DXd and HER3-DXd. In the P1b TROPION-LUNG02 trial, Dato-DXd combined with pembrolizumab proved effective regardless of PD-L1 expression. HER3-DXd used in the presence of EGFR and HER2 mutations indicates its efficacy isn't dependent on wild-type HER3 heterodimerization. In contrast, HER2-targeting T-DXd response has yet to be accurately correlated with HER2. While T-DXd is effective in HER2 overexpressing NSCLC (DESTINY-Lung01), it showed superior efficacy in HER2-mutated NSCLC (DESTINY-Lung01/2).

Conclusions: Dato-DXd and HER3-DXd would be the first non-HER2-targeting ADCs approved for mNSCLC 2L+, targeting TROP2 and HER3, respectively. While T-DXd and HER3-DXd have been tested in HER2 and EGFR mutated cohorts, respectively, Dato-DXd use has not shown to be impacted by any specific biomarker. These results indicate the need to identify predictive biomarkers of response for improved patient population selection.

P2.11A.01 Racial/ethnic Differences in Real-World Adverse Events and Survival Among Patients on Immunotherapy for Advanced NSCLC

G.G. Ho1,2, O. Mbah1, X. Wang1, K. Schwed1,3, A. Dolor1, Q. Zhang1, D. Donnelly1,4, K. Magee1, P. Yerram1, C.A. Ryals1

1Flatiron Health, New York/NY/USA ,2University of California, Berkeley, Berkeley/CA/USA ,3Memorial Sloan Kettering Cancer Center, New York/NY/USA ,4Cornell University, Ithaca/NY/USA

Introduction: Incidence of immune-related adverse events (irAEs) has been linked to improved clinical outcomes among patients with advanced non-small cell lung cancer (advNSCLC) receiving immunotherapy (IO), but this trend may differ across racial/ethnic groups. Prior studies have also documented higher rates of irAEs among White patients relative to Latinx and Black patients, but were limited by single institution bias and/or small sample size. We examined associations between real-world adverse events (rwAEs) and survival by race/ethnicity in a large IO-treated advNSCLC cohort.

Methods: We used the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database. Patients with advNSCLC who initiated IO between January 1, 2015 and October 31, 2023 were included. Real-world adverse events (diarrhea, kidney toxicity, liver toxicity, colitis, rash, adrenal insufficiency, hyperthyroidism, pneumonia, cough, dyspnea, hyperglycemia) occurring during IO treatment were extracted from unstructured clinician documentation in the EHR using machine learning. We employed Cox proportional-hazard models to assess racial/ethnic differences in rwAE incidence, and its association with survival outcomes, adjusting for age, sex, performance status, mono-/combination therapy, line of therapy, stage, and diagnosis year.

Results: The study cohort included 33,943 patients (3.4% Latinx, 10.3% non-Latinx [NL] Black, 2.1% NL-Asian, 67.0% NL-White patients, 17.0% Other/Unknown/Not documented). On average, Latinx (75.1%) and NL-Black (83.0%) patients were less likely than NL-White (85.0%) patients to have documentation of any of the selected rwAEs (adjusted Hazard Ratio [HR], 0.74; 95% CI, 0.69-0.79; HR, 0.90; 95% CI, 0.87-0.94 respectively), while incidence of any rwAE was similar for NL-Asian (85%) and NL-White patients (HR, 1.07; 95% CI, 0.99-1.16). In adjusted analysis, Latinx (HR, 0.90; 95% CI, 0.83-0.97), NL-Black (HR, 0.89; 95% CI, 0.86-0.93), and NL-Asian patients (HR, 0.79; 95% CI, 0.71-0.87) exhibited longer survival compared to NL-White patients. We observed similar trends for PFS, except for NL-Asian patients who had similar survival relative to NL-White patients (HR, 0.99; 95% CI, 0.91-1.08). Overall, presence of at least one rwAE was associated with better OS (HR, 0.46; 95% CI, 0.44-0.47) and PFS (HR, 0.63, 95% CI, 0.61-0.65). When stratified by race/ethnicity, the rwAE-survival benefit was similar among groups except for Latinx patients for whom we observed a smaller OS (HR, 0.84; 95% CI, 0.70-1.00) and no PFS (HR, 0.90; 95% CI, 0.76-1.07) benefit compared to NL-White patients.

Conclusions: Latinx, NL-Black, and NL-Asian patients exhibited fewer rwAEs and better survival outcomes relative to NL-White patients. Notably, within each race/ethnicity group, except Latinx, the presence of rwAEs conferred strong survival benefits. This study supports previous work demonstrating that equitable access to IO can mitigate survival inequities among patients with NSCLC and furthermore, underscores the importance of diversity in oncology IO trials. Future research should examine mechanisms underlying associations between adverse events and survival among racially/ethnically diverse patients receiving IO.

P2.11A.02 Proteomics-Based Target Identification for Optimizing Bispecific Antibody Use in NSCLC

A.A. Khosla1, E. Lin2, M.S. Kumar3, J. Deshane4, K. Goliwas4, S. Ponnazhagan4, I. Jaiyesimi1, A. Desai4

1Corewell Health William Beaumont University Hospital, Royal Oak/MI/USA ,2Mayo Clinic, Rochester/MN/USA ,3St Vincent Hospital, Boston/MA/USA ,4University of Alabama at Birmingham, Birmingham/AL/USA

Introduction: Bispecific antibodies (BsAbs) are designed to bind two different antigens, redirecting and activating T cells against tumor cells, thus augmenting tumor cell elimination and treatment efficacy. BsAbs have attained approval as standard-of-care interventions for several malignancies, notably primary lung adenocarcinoma (LUAD). With the continued exploration of BsAbs in clinical trials targeting various tumor antigens, it is imperative to elucidate their specific targets to optimize drug development strategies tailored to LUAD.

Methods: We examined the expression of BsAbs targets in a cohort of 110 primary LUAD patients and 101 normal adjacent lung tissue controls in a prior study. BsAbs targets of interest in this study included MET, EGFR, EpCAM, PD-L1 (CD274), CTLA4, BCMA (TNFRSF17), TIGIT, HAVCR2, LAG3, HER2 (ERBB2), HER3 (ERBB3), DLL3, DLL4, VEGFR1 (FLT1), PSMA (FOLH1), B4GALNT1, ALK, CD226, PVR, PDCD1, CD3E, CD19, CD20 (MS4A1), IL3RA, TNFRSF8, CEACAM5. Proteomic analysis of these samples was performed using TMT 10-plex isobaric labeling coupled with LC-MS/MS. Protein abundance was assessed through TMT ratios relative to a common reference sample, and hierarchical clustering was employed to identify tumor subsets with similar BsAbs target expression profiles.

Results: After quality control of the proteomic data, the expression could be assessed for MET, EGFR, EPCAM, PD-L1, ERBB2, ERBB3, FLT1, PVR, CD3E, MS4A1, IL3RA, and CEACAM5. Hierarchical clustering robustly segregated tumors from normal lung tissue samples (Figure 1). Normal lung tissue was associated with increased expression of FLT1 isoform 1 as well as IL3RA. Tumor subsets clustered according to three distinct BsAbs proteomic profiles: 1) CEACAM5 overexpression, 2) MS4A1 with CD3E overexpression, and 3) B7H3, MET, or EPCAM overexpression. Mutual exclusivity was most notable between the overexpression of CEACAM5, MS4A1, and PDL1.

Conclusions: In conclusion, our proteomics-based evaluation identified actionable target signatures of LUAD for the application of existing BsAbs. Despite notable intertumoral heterogeneity, these profiles stratify into three predominant patterns of BsAbs target expression. Our findings underscore the significance of biomarker-guided strategies for effective BsAbs selection and the rationale for combinatorial BsAbs therapy in NSCLCs.

P2.11A.03 Association of LIPI with Patterns of Response, Resistance, and Survival in Patients with Metastatic NSCLC Treated with PD(L)-1 Blockade

E. CABALLE1, L.A. Cabrera-Miranda1, M. Ramos-Ramirez1, N. Hernandez-Pedro1, J. Lucio-Lozada1, C. Castillo-Ruiz1, D. Davila-Dupont1, C. Izquierdo-Tolosa1, D. Flores-Estrada1, P. Soberanis-Piña1, A.F. Cardona2, L.E. Raez3, O. Arrieta1

1INSTITUTO NACIONAL DE CANCEROLOGIA, MEXICO CITY/MX ,2Luis Carlos Sarmiento Angulo, Cancer Treatment and Research Center (CTIC), Bogota, Colombia/CO ,3Memorial Cancer Institute/Florida Atlantic University, Miami FL/FL/USA

Introduction: While immune checkpoint inhibitors (ICIs) have revolutionized the treatment landscape for non-small cell lung cancer (NSCLC), a significant proportion of patients still experience primary resistance (PR) to PD-(L)1 blockade, and half of individuals eventually develop acquired resistance (AR) within 12-24 months after the initial response. Despite these challenges, predictors of resistance remain poorly understood. Recent insights have highlighted the role of persistent inflammation in resistance to PD-(L) 1 blockade. The Lung Immune Prognostic Index (LIPI), a novel and readily accessible score reflecting systemic host inflammation, has been identified as an independent adverse prognostic factor in patients with NSCLC undergoing ICI treatment. Therefore, LIPI may serve as a predictive tool for discerning response and resistance patterns in patients with NSCLC undergoing PD-(L)1 blockade therapy

Methods: This retrospective study included 153 patients with metastatic NSCLC treated with PD-(L)1 blockade alone or in combination with chemotherapy. We investigated the association between LIPI and primary resistance (PR), defined as progressive or stable disease lasting less than 3 months, and AR, characterized by an initial complete or partial response followed by disease progression. We further categorized AR into oligo-(≤3 distinct sites of progression) or systemic (>3 sites) resistance patterns. Additionally, we explored the patterns of response, distinguishing between long-term response (LTR) (≥24 months) and early progressive disease (progression ≤6 months), as well as progression-free survival (PFS) and overall survival (OS). We assessed the relationship between the LIPI and clinical outcomes using multiple logistic and Cox regression models.

Results: Based on the LIPI category, 50 patients (32.7%, [95% confidence interval [CI], 25.3 - 40.7%]) were classified as good risk, 68 (44.4%, [95% CI, 36.4 - 52.7%]) as intermediate-risk, and 35 (22.9%, [95% CI, 16.5 - 30.4%]) as poor-risk LIPI. Good-LIPI was significantly associated with LTR (adjusted odds ratio [aOR] 5.13, 1.36-19.33, p=0.015), AR (aOR 3.27, 1.34-7.97, p=0.001), and oligo-AR (aOR 3.51, 1.13-10.85, p=0.03). Similar positive associations for good-LIPI were observed for progression-free survival (PFS) (mPFS 12.4 months [95% CI 8.5 - 16.3], adjusted hazard ratio [aHR] 0.64, [95% CI, 0.43 - 0.96]; p=0.029) and overall survival (mOS 25.6 months [95% CI 19.8 - 31.4], aHR 0.48, [95% CI, 0.30 - 0.75]; p=0.002).

Conclusions: LIPI serves as a valuable predictive tool for discerning distinct response and resistance patterns to PD-(L)1 blockade and supports the negative role of systemic host inflammation in patients with ICI-based therapy. Further prospective studies are necessary to validate these findings.

Introduction: Dynamic changes in cell-free DNA (cfDNA) may represent a biomarker of response to immune checkpoint inhibitor-based therapy (ICI) in non-small cell lung cancer (NSCLC). While the majority of plasma cfDNA is not tumour-related (circulating tumour DNA), exhaled breath is acellular and cfDNA within exhaled breath condensate (EBC) may be more representative of tumoural changes. We sought to explore the hypothesis that molecular response (MR) in cfDNA detected in EBC is associated with a clinical benefit to ICI+/- chemotherapy for participants with advanced NSCLC.

Methods: Participants due to commence ICI+/- chemotherapy for newly diagnosed advanced NSCLC were eligible. Patient demographics and tumour features were collected. Baseline EBC (R-TubeTM) and peripheral whole blood were collected from participants pre-treatment, and at 3, 6 and 12 weeks following commencement of systemic ICI+/-chemotherapy. The QIAamp Circulating Nucleic Acid kit (Qiagen) was used to extract cfDNA from all samples, while the RNaseP Real-Time digital droplet PCR assay was used to quantify cfDNA. MR was defined as >=50% reduction in cfDNA in EBC at 3 or 6 weeks following commencement of therapy. The association between MR in cfDNA of the

EBC and response to treatment at 3 months was assessed using standard statistical methods. Response to treatment was determined by clinician-assessed radiographic/clinical assessment at 3 months.

Results: At the time of this interim analysis, a total of 47 participants were enrolled with available EBC and response assessments. Four participants were excluded due to insufficient EBC (absence of baseline/follow-up EBC samples for analysis). The median age was 67 years (range: 48 - 81) , and 68% of (32/47) participants were male. The majority of participants (30/47, 63%) received ICI + chemotherapy which consisted mainly of pembrolizumab plus chemotherapy (28/30, 94%). The remainder (17/30, 27%) received pembrolizumab monotherapy. Amongst 43 evaluable participants, a MR was identified in 37% (16/43) at 3 and/or 6 weeks. In those with a MR, 81% (13/16) had a response to treatment at 3 months, while 19% (3/16) had clinical progression at this timepoint. Dynamics of cfDNA in the EBC in those who did not achieve an MR will be presented descriptively. Comparing the proportions of those with clinical benefit/progression in those with and without MR was associated with a trend towards significance (Chi2=3.28, p = 0.07).

Conclusions: In this interim analysis, we identify that dynamic changes in cfDNA are detectable in the exhaled breath condensate of participants with advanced NSCLC, treated with ICI+/-chemotherapy. Our interim results indicate a trend towards significance that a 'molecular response' in the exhaled breath at 3 weeks and/or 6 weeks[JN1] [DO2] is associated with a radiographic response at 3 months. Future work will focus on those who have clinical benefit but do not sustain an MR, completion of the analysis in a larger cohort (n=108) of participants, an analysis including blood-based circulating tumour DNA and longer clinical follow-up.

P2.11A.05 The Impact of Tumor Molecular Features and Smoking History on Survival with Chemo-Immunotherapy in EGFR-Mutant NSCLC

J.N. Bodor, Y. Zhou, M. Cheung, H. Borghaei, M.L. Clapper, J. Treat

Fox Chase Cancer Center, Philadelphia/PA/USA

Introduction: Recent phase III trials evaluating anti-PD-1 with platinum-based chemotherapy in patients with EGFR-mutant NSCLC failed to demonstrate a significant improvement in progression-free survival versus (vs.) chemotherapy alone. While these studies were negative, there is a small subset of patients with EGFR-mutant tumors that derive durable benefit from chemo-immunotherapy. However, markers for predicting checkpoint inhibitor response in this patient population are lacking. Prior data from retrospective cohorts suggest the presence of uncommon EGFR alterations (e.g. G719X mutations, exon 20 insertions), high PD-L1, or a smoking history may be predictive of single-agent checkpoint inhibitor response in patients with EGFR disease. Limited research has been performed evaluating such markers in patients with EGFR-mutant NSCLC treated with chemo-immunotherapy. In addition, little attention has been given to the impact of TP53 alterations on the immunogenicity of EGFR-mutant NSCLC; a co-mutation correlated to greater benefit with checkpoint inhibitors in other oncogene-driven tumors. Our study used real-world data to determine real-world progression-free survival (rwPFS) in patients with EGFR-mutant NSCLC treated with chemo-immunotherapy and evaluated differences in outcomes by EGFR subtype, smoking history, tumor PD-L1 expression, and co-mutations in TP53.

Methods: The Flatiron Health-Foundation Medicine clinicogenomic database, a nationwide de-identified EHR-derived database linked to comprehensive genomic profiling, was used to evaluate patients with advanced NSCLC bearing EGFR alterations treated with pembrolizumab plus carboplatin/pemetrexed. The de-identified data originated from 280 US cancer clinics (~800 sites of care). Kaplan-Meier curves estimated rwPFS (based on clinician documentation of progression) and accounted for left truncation in cases where molecular profiling occurred after start of treatment. Median rwPFS in months (m) was determined and comparisons were assessed using univariate Cox regression.

Results: In our analysis of 127 patients with EGFR-mutant NSCLC treated with chemo-immunotherapy, median rwPFS (5.8 m, 95% CI 5.2-7.0) mirrored findings reported in prior phase III trials. Smoking history (yes vs. no), PD-L1 positivity (≥1% vs. <1%), and PD-L1 high (≥50% vs. <50%) were not predictive of greater rwPFS. However, patients with a tumor co-mutation in TP53 had longer rwPFS (6.6 m, 95% CI 5.5-8.4) as compared to patients without this mutation (4.3 m, 95% CI 3.0-7.8, p=0.02). In our cohort, 58 patients had tumors bearing exon 19 deletions, 45 had L858R mutations, and 24 had uncommon EGFR alterations. Uncommon alterations included exon 20 insertions, G719X, L861Q, or S768I mutations. Median rwPFS did not significantly differ between patients with exon 19 deletion (5.8 m, 95% CI 4.6-7.0) and L858R (5.4 m, 95% CI 4.7-10.2, p=0.68), and uncommon (8.4 m, 95% CI 2.8-15.8, p=0.69) alterations. Percent PFS at 12 m was similar for exon 19 deletion (19.1%), L858R (21.1%), and uncommon (22.6%) EGFR-mutant tumors.

Conclusions: Findings suggest that smoking history, the subtype of EGFR, and tumor PD-L1 expression do not aid in identifying patients with EGFR-mutant NSCLC that obtain greater benefit from chemo-immunotherapy. The co-occurrence of TP53 mutations in EGFR-driven disease warrants further study as a potential biomarker of immunotherapy response.

P2.11A.06 Tumor-Informed ctDNA Status Guiding 1st-line Immuno-Chemotherapy in Advanced NSCLC: CHOICE-01 Retrospective Analysis

Z. Wang1, J. Zhong1, J. Xu1, R. Wan1, H. Bai1, J. Duan1, X. Mi2, W. Xie2, Y. Xu2, C. Li2, G. Wang2, S. Cai2, J. Wang1

1State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN ,2Medical Department, Burning Rock Biotech, Guangzhou, China/CN

Introduction: Predictive biomarkers are needed to identify patients who are suitable for immune checkpoint inhibitors (ICIs) plus chemotherapy in treatment-naïve advanced non-small cell lung cancer (NSCLC). Circulating tumor DNA (ctDNA) status has the potential to indicate tumor burden and immunogenicity to select suitable patients.

Methods: From a randomized phase III trial of first-line toripalimab plus chemotherapy (ICI-chemo) versus chemotherapy in advanced NSCLC (the CHOICE-01 study), 393 patients with sequencing data of both pre-treatment cancerous tissue (whole-exome sequencing) and ctDNA (targeted capture panel) were included. Tumor-informed ctDNA positivity was defined as the presence of tissue-derived variants in plasma. In addition, dynamic ctDNA statuses for treatment efficacy of ICI-chemo of 91 patients were further evaluated at the first day of the third cycle (C3D1). The mechanisms were investigated between patients with tumor-informed ctDNA positivity or negativity.

Results: In the CHOICE-01 study, ICI-chemo prolonged progression-free survival (PFS, HR=0.45 [95% CI: 0.34-0.60], P<0.001) and overall survival (OS, HR=0.66 [95% CI: 0.49-0.88], P=0.0048) in patients with positive tumor-informed ctDNA rather than those with negative results (PFS, HR=0.74 [95% CI: 0.46-1.21], P=0.23; OS, HR=1.13 [95% CI: 0.58-2.23], P=0.72). The neoantigen, weighted Genome Instability Index (wGII), loss of heterozygosity (LOH), and ploidy were significantly increased in the ctDNA-positive group compared to the ctDNA-negative group (P<0.05). In the ICI-chemo arm, patients who had a positive status of tumor-informed ctDNA at baseline and achieved ctDNA clearance at C3D1 exhibited longer PFS and OS compared with those without clearance (P<0.05). Patients who were progressed from chemotherapy received ICI crossover showed longer OS than those received non-ICI crossover in the tumor-informed ctDNA positive group (P<0.05).

Conclusions: These results suggested that ICI-chemo was associated with improved outcomes compared with chemotherapy in patients with tumor-informed ctDNA positivity. Our study highlights the potential of tumor-informed ctDNA as a valuable tool in guiding first-line treatment decisions in advanced NSCLC patients.

P2.11A.07 Selected Shared Neoantigens for Personalized Tumor Neoantigen Peptide Vaccine in the Treatment of Advanced Tumors

Y. Zhang1, W. Dai2, F-M. Kong1,2

1University of Hong Kong-Shenzhen Hospital, Shenzhen/CN ,2The University of Hong Kong, Hong Kong/CN

Introduction: Tumor neoantigens are derived from immunogenic mutated epitopes that are specific to tumor tissue. Previous research has demonstrated that these neoantigens are highly individualized and heterologous, so immunotherapy based on neoantigens can be personalized. However, the development of neoantigen vaccines is time-consuming and labor-intensive. Furthermore, the complex condition of advanced tumors poses challenges in the application of individually tailored neoantigens. The discovery of shared neoantigens holds promise for the development of neoantigen vaccines. The purposes of this study were to investigate the feasibility to discover shared tumor neoantigens through panel gene sequencing form advanced tumor patiens to personalized neoantigen peptide vaccine.

Methods: Advanced tumor patients with panel gene sequencing results form 520-gene NGS panel and 680-gene NGS panel were eligible. Paired plasma, white blood cells and tumor biopsy tissue (if available) were obtained and tested by commercial vendors. Tumor neoantigens were selected by the binding affinity of mutant peptides to patient-specific HLA, with a threshold of less than less than 500 nM using ImmuneMirror. The correlations among TMB, bTMB, and total neoantigen load (TNN) were assessed by Pearson's corelation. Significance on patient survivals were analyzed by multivariate Cox regression models with significance set at P < 0.05.

Results: We recruited 115 lung cancer patients with panel gene sequencing data from 3 industrial venders. Total 85 tissue samples and 86 ctDNA were collected. A total of 17 mutant genes with mutation frequency greater than 10% were detected, with TP53 [Normally, mutation EGFRc.2573T>G (p.L858R) can be labelled as EGFRT2573G in the form of gene or EGFRL858R as a protein.] mutation frequency reaching 50% (520-gene NGS panel) and 57.3% (680-gene NGS panel). TMB, bTMB and TNN were highly correlated with each other. Three shared candidate neoantigens namely TP53c.818G>A (p.R273H), EGFRc.2573T>G (p.L858R), and KRASc.34G>T (p.G12C) were identified based on the both panel gene sequencing.

Conclusions: Tumor neoantigen prediction based on both independent gene panel sequencings proved to be feasible and reliable, particularly for shared neoantigens. This study opens the possibility of utilizing panel gene sequencing for neoantigen-based personalized immunotherapy. Notably, we identified TP53 p.R273H, KRAS p.G12C and EGFR p.L858R- derived neoantigens, which may improve prognostic evaluation and provide a promising treatment option for patients with resistance to conventional targeted therapy or immunotherapy.

Introduction: Immunotherapy is firmly established as a treatment regimen in various solid tumors, driven by its exceptional benefits in a selected group of patients. Despite widespread adoption of immune checkpoint blockade (ICB) across diverse solid tumors, the quest for a clinically informative biomarker for long-term benefit remains unmet.

Methods: A total of 49 patients with metastatic NSCLC treated with ICB were included. Long-term (LTR) and short-term responders (STR) were defined as those with a response to ICB lasting more than 24 months or less than 6 months, respectively. Longitudinal blood specimens were collected before ICB treatment initiation and early-on treatment. Plasma ctDNA next-generation sequencing panel (NGS) and serum proteomics were performed. GeoMx DSP on baseline tumor tissue was performed in a subset of patients.

Results: Our analysis revealed specific characteristics of LTR compared with STR, namely higher PD-L1 in tumor cells (p=0.005) and higher incidence of irAEs (p=0.001). Genomic features associated with lack of benefit from ICB included co-occurring mutations in KRAS/STK11 and TP53/KMT2D (p<0.05). At a baseline LTR patients exhibited higher serum levels of proteins related with apoptosis (CASP8, PRKRA), chemotaxis, immune proteasome, processing of MHC class I (S100A4, PSMD9, RNF41) and immune homeostasis (HAVCR1, ARG1) (p<0.05). Protein spatial profiling of tumor samples showed higher levels of proteins linked with the presence of immune cells (CD45), T cells (CD8), antigen presentation (HLA-DR) and immune regulation proteins (PD-L1, IDO1) within the tumor and tumor microenvironment (p<0.05) in LTR patients. Serum longitudinal analysis identified a set of proteins that presented distinct dynamics in LTR compared to STR, making them interesting candidates to evaluate as early predictors of treatment efficacy.

Conclusions: Our multimodal analysis of patients with metastatic NSCLC treated with ICB identified clinicopathological and immunological features associated with long-term benefit. The presence of pre-existing antitumor immunity emerged as a strong predictor of long-term benefit providing insights for potential biomarkers and therapeutic strategies for enhancing ICB outcomes in metastatic NSCLC.

P2.11A.09 Survival Outcomes of Lung Adenocarcinoma with Intestinal Differentiation in the Era of Immunotherapy

M.S. Tratt1, A. Bandhlish2, K. Eaton1, L. Deng1

1Fred Hutchinson Cancer Center, Seattle/WA/USA ,2University Of Washington, Seattle/WA/USA

Introduction: Lung adenocarcinoma with intestinal differentiation (LAID) comprises a rare and heterogeneous non-small cell lung carcinoma subgroup. LAID can display distinct morphological patterns including mucinous, enteric, and colloid. In the era of chemotherapy, LAID have been associated with a poorer prognosis compared to other lung adenocarcinomas. However, outcome data for these tumors compared with other adenocarcinomas is unknown in the immunotherapy era. Leveraging the National Cancer Database (NCDB), which includes data for approximately 70% of lung cancers diagnosed in the United States, we compared survival outcomes of LAID to other lung adenocarcinoma (LUAD) subtypes based on treatment type in the modern era.

Methods: The National Cancer Database (NCDB) was queried for histologically confirmed stage IV adenocarcinoma patients diagnosed from 2016 to 2019. LAID was defined as invasive mucinous adenocarcinoma, colloid adenocarcinoma, or enteric adenocarcinoma according to the 2015 WHO lung cancer classification. A log-rank test was used for survival analysis and adjusted by Cox multivariate regression for age, gender, race, disease grade, treating facility type, insurance status, and comorbidity. Overall survival (OS) was defined as the time from the treatment initiation date to the date of death or the last follow-up. P < 0.05 was considered to be statistically significant. All statistical tests performed were two-tailed.

Results: A total of 52,393 patients were identified, including 51,355 LUADs and 1,038 LAIDs (729 colloid adenocarcinoma, 300 invasive mucinous adenocarcinoma and 9 enteric-type adenocarcinoma). 7.5% of LAID patients received immunotherapy alone, 48% received chemoimmunotherapy combination, and 45% of patients received chemotherapy alone. Compared with LUAD, LAID had significantly shorter overall survival (median = 13.45 months vs median = 10.18 months, HR 1.22 95% CI [1.14 - 1.31], respectively). LAID was associated with poorer survival compared to other adenocarcinomas across all treatment regimens (immunotherapy alone: HR 1.38, 95% CI [1.04 - 1.84] chemoimmunotherapy combination: HR 1.19, 95% CI [1.07 - 1.34], and chemotherapy alone: HR 1.21, 95% CI [1.08 - 1.35]). Among LAID,

chemoimmunotherapy combination is associated with improved survival compared to chemotherapy alone (HR 0.77, 95% CI [0.66 - 0.90]). The sample size of patients LAID patients receiving immunotherapy alone was small and thus underpowered to draw conclusions (HR 0.87, 95% CI [0.65- 1.18]) compared to chemotherapy alone.

Conclusions: Our study represents the first time the NCDB has been leveraged to compare outcomes of LAID versus LUAD in the era of immunotherapy. Compared with other LUAD, LAID remains associated with poorer survival in the era of immunotherapy. However, combined chemoimmunotherapy appears to be associated with improved survival compared to chemotherapy alone in this rare subgroup.

P2.11A.10 Impact of Baseline Glucocorticoid Use on the Efficacy of Immunoradiotherapy in NSCLC Patients with Brain Metastases

Y. Peng, J. Xiong, W. Shi, Y. Zhang, Z. Yang

The Second Affiliated Hospital of Chongqing Medical University, Chongqing/CN

Introduction: Glucocorticoids (GCs) plays an important therapeutic role for the cerebral edema due to radiative acute brain injury or brain metastases, but it also poses negative impact on the efficacy to immunotherapy. Our study focuses on the patients with NSCLC brain metastases treated by immunotherapy combined with intracranial radiotherapy and analyses the influence of different doses of baseline GCs use on the control of intracranial lesions, PFS and OS of the patients.

Methods: 62 patients with NSCLC brain metastases who received immunotherapy combined with intracranial radiotherapy (interval between immunotherapy and intracranial radiotherapy is less than 28 days) were collected, all of whom had received baseline (28 days before and after the first cycle of immunotherapy) GCs during concurrent therapy. The patients were divided into three groups according to the purpose of GCs administration (low GCs use: receiving GCs doses less than 30mg; median GCs use: receiving GCs doses greater than or equal to 30 mg and less than 100 mg; high GCs use: receiving GCs doses greater than or equal to 100 mg). Survival outcomes (iPFS, PFS and OS) were analyzed and Propensity score matching (PSM) was used to balance the variables that were significantly different at baseline in different groups of dose stratification of GCs.

Results: The median iPFS of patients in the group of high GCs use was significantly shorter than the group of median GCs use and low GCs use (5.23 months vs 12.70 months vs 16.43 months, p<0.001). However, there was no significant difference between the group of median GCs use and the group of low GCs use in their median iPFS (12.70 months vs 16.43 months, p=0.362). As for median OS and median PFS among the three groups of patients, we observed results consistent with median iPFS. The propensity score matching proved that the group of high GCs use still had significant differences in median iPFS (5.23 months vs 8.93 months, p=0.023), median PFS (4.33 months vs 8.10 months, P=0.046) and median OS (7.47 months vs 14.63 months, P=0.033) comparing with the patients of median GCs use and low GCs use (Figure1).

Conclusions: The application of GCs often increased in patients with NSCLC brain metastases receiving immunotherapy combined with intracranial radiotherapy and the baseline high dose GCs use (GCs≥100mg) will reduce the efficacy of the combination therapy and impair the survival outcomes.

P2.11A.11 Impact of Proton Pump Inhibitor Use on Faecal Microbiome in Patients with NSCLC Treated with Immune Checkpoint Inhibitor

Y. Huang1, J. Lee2, C.K. Sim3, J.J. Zhao3, K. Sooi1, A. Wong1, S.H. Tay2, Y.Y. Soon1, F. Aminkeng4, B.C. Goh1, D.S. Tan1, R.A. Soo1

1National University Cancer Institute Singapore, Singapore/SG ,2National University Hospital, Singapore/SG ,3National University of Singapore, Singapore/SG ,4Medical College of Wisconsin, Milwaukee/WI/USA

Introduction: Emerging data suggests that concomitant medications, such as proton pump inhibitors (PPI) influence immune-related adverse events (irAE) and the host gut microbiome. We aim to study the microbiome taxonomic and functional features associated with PPI and development of irAE in patients with non-small cell lung cancer (NSCLC) treated with ICI-based therapy.

Methods: Stool samples were obtained from patients with Stage III or IV NSCLC treated with ICI from September 2016 to August 2023. DNA from stool samples was extracted using FastDNA Spin Kit (MP-Biomedicals). Metagenomic libraries were constructed using TruSeq3 (Illumina) and sequenced on NovaSeq6000 2x 150PE platform (Illumnia), targeting ~2.5Gb of sequences per aliquot. Metagenomic taxonomic and functional profiles were generated using the bioBakery meta'omic workflow v4. IrAEs were characterized and graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) v5.

Results: Of the 36 patients enrolled, the median age was 63 years, the majority male (86.1%), Chinese (83.3%), smokers (83.3%), ECOG PS 0-1 (52.8%), stage IV at diagnosis (72.2%), and adenocarcinoma histology (77.8%). PD-L1 TPS was ≥50% in 41.7% of patients. Nineteen percent of patients had concomitant chemotherapy with ICI. The commonest ICIs used were pembrolizumab (55.6%), durvalumab (22.2%) and atezolizumab (13.9%). Half of the patients developed irAEs, of which skin (30.6%), liver (11.1%), endocrine (8.3%) and pulmonary toxicities (8.3%) were the commonest. Some 58% of patients (n=21) received PPI whilst on ICI with two-thirds of patients on PPI (n=14) subsequently developing irAEs. PPI use was associated with occurrence of irAE (OR 5.5 (95%CI 1.28 - 23.7, p=0.02). Stool analysis identified 13 and 8 significant microbial species, as well as 35 and 86 microbial enzymes associated with PPI use and subsequent irAE, respectively. Of note, both the use of PPI and subsequent irAE were associated with increased abundance of Collinsella sp (i.e. SGB4121) and decreased abundance for microbial potential for tropinesterase (EC 3.1.1.10).

Conclusions: Use of PPI was associated with IrAE and resulted in gut microbiome dysbiosis. To our knowledge, this is the first study to describe the association between PPI, irAE and faecal microbiome changes. Future larger studies with longitudinal sampling are required to study the impact of PPI on outcomes of NSCLC patients on ICI.

P2.11A.12 Machine Learning-Based Clinicogenomic Prediction of Response to PD-(L)1 Inhibition in KRAS Altered Non-Small Cell Lung Cancer

D. Boiarsky1, L. Hong2, B. Ricciuti3, A. Cooper4, M. Saad2, A. Elkrief5, A. Di Federico6, M. Aminu2, W. Rinsurongkawong2, J. Lewis2, A. Vaporciyan2, X. Le2, J.J. Lee2, J. Luo3, J. Wu2, M. Negaro2, D. Gibbons2, J. Heymach2, F. Skoulidis2, A. Schoenfeld4, M. Awad3, J. Zhang2, N. Vokes2

1Yale Cancer Center, New Haven/CT/USA ,2University of Texas MD Anderson Cancer Center, Houston/TX/USA ,3Dana-Farber Cancer Center, Boston/MA/USA ,4Memorial Sloan Kettering Cancer Center, New York/NY/USA ,5Universite de Montreal, Montreal/QC/CA ,6Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: KRAS altered non-small cell lung cancer (NSCLC) is characterized by comutations which confer differential sensitivity to immune checkpoint inhibitors (ICI). Further studies are needed to disentangle the predictive effects of known biomarkers and to identify novel biomarkers to help guide treatment selection.

Methods: Patients with EGFR/ALK-negative metastatic NSCLC who received PD-(L)1 inhibitor therapy at three institutions were included, and patients with (KRASa) and without (KRASwt) KRAS alterations (mutations and amplifications) were analyzed separately. Clinical progression-free survival (PFS) and overall survival (OS) were compared between patients with previously untreated metastatic PDL1+ NSCLC and ECOG 0-1 who received ICI alone (ICI-mono) or with chemotherapy (ICI-chemo). Inverse propensity weighting (IPW) for clinical characteristics was used to control for differences in treatment selection. Among patients with complete clinical and genomic annotation, we trained elastic-net regularized logistic regression models to predict complete or partial response from stable or progressive disease. An 80/20 split was used to separate the training and testing cohorts. Repeated (n=10) stratified 10 fold cross-validation was performed to optimize hyperparameters for area under the receiver operating characteristic curve (AUROC).

Results: A total of 3864 patients (51% female, median age 67, KRASa 1652, KRASwt 2212) were identified. Among KRASa patients, those treated with ICI-chemo vs ICI-mono had similar PFS but worse OS (unadjusted: HR=1.1, p=0.018, IPW-adjusted: HR=1.5, p=1.4e-7) in unadjusted and IPW-adjusted analysis. Among KRASwt patients, those treated with ICI-chemo had increased PFS on unadjusted (HR=0.8, p=0.088) and adjusted analysis (HR=0.5, p=0.0033), whereas OS was increased on IPW-adjusted (HR=1.3, p=0.00098) but not unadjusted analysis. Next, we developed integrated clinico-genomic models that outperformed PDL1 in predicting response to ICI (KRASa: AUROC 0.65 vs 0.54; KRASwt: AUROC 0.74 vs 0.64). In both models, features predictive of response were PDL1>=50%, TMB>50th percentile, ICI-chemo treatment, and TP53 alterations; features predictive of non-response were ECOG>=2 and higher line of therapy. In the KRASa model, alterations in NTRK3, KIT, TP53 were predictive of response while alterations in KEAP1, STK11, and SMARCA4 were predictive of non-response. In the KRASwt model, alterations in WT1 were predictive of response and PDL1<1% was predictive of non-response. Among previously untreated patients with ECOG<2 and co-occurring alterations in KRAS and STK11, PFS and OS were improved among patients with alterations in NTRK3 (PFS: HR=0.5, p=0.035; OS: HR=0.5, p=0.047) and KIT (PFS: HR=0.3, p=0.027; OS: HR=0.3, p=0.056).

Conclusions: In this study, we found that among PDL1+ patients, treatment with PD-(L)1 monotherapy versus in combination with chemotherapy was associated with improved OS regardless of KRAS status, but improved PFS in patients without but not with KRAS alterations. Additionally, we developed models to predict response to ICI which outperformed PDL1, and identified independently predictive biomarkers of response to ICI therapy in patients with and without KRAS alterations.

P2.11A.13 Cytokine Release Syndrome from Dual Immune Checkpoint Blockade in Non-Small Cell Lung Cancer: FAERS Analysis

Y. Fujiwara1, Y. Nishimura2, B.G. Fitzgerald1, S. George1, I. Puzanov1, G.K. Dy1

1Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA ,2University of Hawaii, Honolulu/HI/USA

Introduction: Combining immune checkpoint blockade (ICB) agents mainly targeting PD-1/PD-L1 and CTLA-4 has been established as a standard of care for several cancer types including non-small cell lung cancer (NSCLC). Cytokine release syndrome (CRS) rarely occurs with ICB monotherapy but recent studies suggest CRS may arise in a particular population receiving dual ICB in NSCLC. This study aims to comprehend the clinical characteristics of CRS from dual ICB therapy.

Methods: We searched the US Food and Drug Administration Adverse Events Reporting System (FAERS) using the term "Cytokine release syndrome" to identify CRS cases with NSCLC treated with ICB labeled as "suspect product active ingredients". Clinical and demographic characteristics were analyzed and compared between the dual ICB and the ICB monotherapy group using Fisher's exact test. We also performed a systematic review to elucidate the clinical factors of CRS associated with dual ICB, including patient characteristics, timing of the CRS onset, levels of C-reactive protein (CRP) at the onset of CRS, and treatment details such as the dose of glucocorticoid and other immunosuppressants.

Results: In the FAERS database, 8615 CRS cases were analyzed, and 195 solid tumor cases of CRS associated with ICB were identified. Among these cases, 81 patients were diagnosed with NSCLC (Dual ICB: n=58, ICB monotherapy: n=23). In the dual ICB group, the median age was 68 years (Interquartile range [IQR] 61-75) and 41 patients (70.7%) were male. In the ICB monotherapy group, the median age was 69 years (IQR 64-71) and 12 patients (52.2%) were male. In the dual ICB group, 67.2% (n=39/58) and 32.8% (n=19/58) of patients received dual ICB alone and dual ICB with chemotherapy, respectively. In the ICB monotherapy group, PD-1 and PD-L1 blockade were used in 60.9% (n=14/23) and 39.1% (n=9/23). In 85 patients with NSCLC, most of the CRS cases came from Asia for both dual ICB (96.6%, n=56/58) and ICB monotherapy (56.5%, n=13/23). For treatment outcomes of CRS, our systematic review identified 12 articles comprising 15 with solid tumors with clinical course of CRS. In 15 cases, NSCLC was most common (66.7%, n=10/15). The median age of patients with NSCLC was 67 years (IQR 55-70). Median onset of CRS in NSCLC was 47.5 days (IQR 22.5-90.25) after dual ICB therapy, and median CRP levels at the CRS onset were 12.6 mg/dL (IQR 10.4-15.1). Excepting two cases where patients died soon after dual ICB therapy, all patients required high or pulse-dose glucocorticoids, and one case required tocilizumab administration.

Conclusions: This pharmacovigilance study found that CRS from ICB occurs in patients with NSCLC predominantly from Asia, particularly with dual ICB, which merits further investigation on risk factors and immune homeostasis in these patients. Most cases required pulse-dose glucocorticoids and thus, establishment of early detection and treatment strategies is needed.

P2.11A.14 Research of the Predictive Role of Immune Cells and Intestinal Flora on Immune-related Adverse Event in Lung Cancer

M. Lin, J. Chen

The Second Hospital of Dalian Medical University, Dalian/CN

Introduction: Immune checkpoint inhibitors (ICIs) have opened a new direction in the treatment of unresectable advanced lung cancer by targeting tumour cells through the immune system. However, use of ICIs disrupts the normal mechanisms of immune tolerance, leading to immune-related adverse event (irAE), which carries the risk of drug discontinuation, drug switching, and deterioration of the patient's condition. It is necessary to find effective biomarkers for predicting irAE in lung cancer patients.

Methods: Unresectable primary stage III-IV lung cancer patients who were treated with at least one of the ICIs and attended the Second Affiliated Hospital of Dalian Medical University from 01 May 2021 to 30 September 2023 were included. Peripheral blood and stool samples were collected at baseline (before receiving the first treatment) and before receiving each cycle of treatment. Peripheral blood immune cells were tested using flow cytometry. Stool samples were tested through metagenomics and untargeted metabolomics. Treatment efficacy and irAE during treatment were assessed.

Results: A total of 88 patients were included, with 41 in the group developing irAE. The median onset time of irAE was 118 days. 1. Characteristics of the peripheral blood immune cells in patients with irAE: (1) patients who developed irAE had a higher percentage of baseline CD8+ T cell PD-1 expression compared to patients who did not develop irAE. (2) patients who developed irAE had lower peripheral blood B-cell counts and higher percentage of activated CD4+ T cells, activated CD8+ T cells, early activated CD8+ T cells, late activated helper T cells, late activated suppressor T cells and Th2 cell when developing irAE compared to baseline. 2. Characteristics of the intestinal flora of patients with irAE: the most significantly enriched groups of flora at baseline in the patients who developed irAE (Group N) was Micrococcus, while the group that did not develop irAE(Group NI) was enriched with Phocaeicola coprocola and Oscillibacter. There were significant differences in baseline gut flora metabolites and metabolic pathways between patients with or without irAE. Calcitriol and L-Isoleucine may serve as a biomarker that is predictive of the development of irAE (Figure 1).

Conclusions: In lung cancer patients who developed irAE after immunotherapy, baseline peripheral blood immune cells and intestinal flora differed from those who did not develope irAE and changed significantly during progression of irAE, and monitoring changes in these indicators may help to predict irAE and guide better treatment.

P2.11A.15 Gut Metatranscriptomics Predict Survival in Anti-PD Immunotherapy Treated Advanced-Stage Non-Small Cell Lung Cancer

D. Dora1, P. Kiraly2, C. Somodi1, B. Ligeti3, D. Edit2, G. Galffy2, Z. Lohinai1

1Semmelweis University, Budapest/HU ,2Pulmonary Hospital Torokbalint, Torokbalint/HU ,3Pázmány Péter Catholic University, Budapest/HU

Introduction: Emerging evidence highlights the gut microbiome's role in modulating the efficacy of anti-programmed death (PD) immunotherapies (ICI) in different cancers. However, more knowledge is needed to understand their functional activity using metatranscriptomics (MTR). We aim to analyze the association between the gut microbiome MTR signatures and ICI treatment outcomes in advanced-stage non-small cell lung cancer (NSCLC) patients.

Methods: We applied a De Novo Assembly-based MTR analysis on fecal samples from 29 advanced-stage NSCLC patients who received anti-PD ICI therapy. We categorized patients based on progression-free survival (PFS) into long (>6 months) and short (≤6 months) PFS groups. Through RNA sequencing, we employed the Trinity pipeline for assembly, MMSeqs2 for taxonomic classification, and DESeq2 for differential gene expression (DEG) analysis. We constructed principal component analysis (PCA), Random Forest (RF), and Support Vector Machine (SVM) machine learning algorithms and comprehensive microbial profiles. Clinicopathological variables such as Age, Gender, Histology, PD-L1, Stage, Smoking pack year (PY), Chronic obstructive pulmonary disease (COPD) comorbidity, and Body Mass Index (BMI) were included as clinical confounders.

Results: We identified 7849 protein-coding gene transcripts. Significant microbial composition variances were observed between the two PFS groups. Notably, Actinomycetota was significantly overrepresented in patients with short PFS (vs. long PFS, 36.7% vs. 5.4%, p<0.001), as was Euryarchaeota (1.3% vs. 0.002%, p=0.009). At the same time, Bacillota showed higher prevalence in the long PFS group (vs. short PFS, 66.2% vs. 42.3%, p=0.007). The 120 significant DEGs identified were analyzed using the UniProtKB and UniRef90 databases to determine their functional annotations and potential protein matches. A cluster analysis of the top 120 protein-coding transcripts revealed a subgroup of patients showing a homogeneous profile associated with longer PFS and another, more heterogeneous group associated with shorter PFS. This finding was further confirmed using PCA, which separated the PFS groups. We confirmed the predictive role of n=6 Trinity IDs with multivariate analysis, including Bacterial surface antigen and domain-containing proteins. RF and SVM machine learning models verified the microbial signatures' predictive effect with accuracies of 78.1% and 75.6%, respectively. Furthermore, multivariate analyses incorporating clinical variables, including PD-L1 expression and chemotherapy treatment, underlined the impact of multiple RNA-based microbial biomarkers on PFS.

Conclusions: Specific gut microbiome MTR signatures predict survival in ICI-treated advanced NSCLC. Specific gene clusters and species' MTR gene expression might differentiate short vs. long PFS. Our data warrant further research to validate these MTR associations and explore their clinical implications.

P2.11A.16 Categorizing Steroid-Response Types in Checkpoint Inhibitor-Related Pneumonitis

C. Zhou, Y. Yang, X. Lin, S. Li

The First Affiliated Hospital of Guangzhou Medical University, National Center for Respiratory Medicine, National Clinical Research Center for Respiratory Disease, State Key Laboratory of Respiratory Disease, Guangzhou Institute of Respiratory Health, Guangzhou/CN

Introduction: Glucocorticoids (GCs) are the first-line treatment of checkpoint inhibitor-related pneumonitis (CIP). However, there is a large heterogeneity in the response efficiency to GCs in different CIP patients, and its efficacy assessment requires enhancement. Herein, based on the effectiveness of GCs at different times, we proposed a novel steroid-response typing of CIP and explored their different characteristics.

Methods: In this retrospective cohort study, we analyzed 98 CIP patients, categorizing them as steroid-sensitive, refractory, dependent, or resistant based on GC efficacy. We explore the incidence and interplay of these types and associated features, including clinical characteristics, cytokine levels, immune-cell counts, and autoantibody levels.

Results: In this study, 80 patients (81.6%) showed steroid-sensitive status, and 18 (18.4%) were steroid-refractory. Among those with three-month follow-ups, 42.5% of steroid-sensitive patients relapsed without ICI stimulation; 66.7% were steroid-dependent, and 33.3% were steroid-resistant. Steroid-refractory patients had three patients relapses: one steroid-dependent and two steroid-resistant. Both steroid-refractory and -resistant types had higher CIP severity and poorer performance status when they began to use immunotherapy (P < 0.050) than sensitive and dependent groups. Steroid-resistant cases had more combined other immune-related adverse events (P =

0.030) than steroid-dependent types. Cytokine analysis showed higher IL-8 in steroid-resistant CIP (58.4 vs. 18.9 pg/mL, P = 0.034), and steroid-refractory patients had lower CD4+ T-cell counts (70.0 vs. 181.0 /UL, P = 0.023). However, there was no significant difference in autoantibody levels among different steroid types. Lastly, steroid-refractory and -resistant patients tended to have shorter overall survival than steroid-sensitive or -dependent cases.

Conclusions: CIP steroid-response categorization includes four types: sensitive, refractory, dependent, and resistant. Refractory and resistant types exhibit higher mortality rates and shorter survival. Severe grades of CIP, concurrent irAEs, peripheral blood IL-8, and T-cell counts are related to steroid-response types.

P2.11A.17 Impact of Mutation Class and Smoking Status in BRAF-Mutant Non-Small Cell Lung Cancer (NSCLC) Treated with Immune Checkpoint Inhibitors (ICI)

J.A. Marin-Acevedo1, S.V. Bandikatla2, R. Thapa2, S. Puri2, D-T. Chen2, K. Hicks2, J. Gray2

1Indiana University, Indianapolos/IN/USA ,2Moffitt Cancer Center, Tampa/FL/USA

Introduction: Oncogenic BRAF mutations are found in ~4% of NSCLC. These mutations are subdivided into class I and non-class I (i.e., class II and III) and are frequently associated with smoking. We previously reported the efficacy of frontline ICI in the treatment of BRAF-mutant NSCLC. It is unclear, however, if the mutation class and/or smoking status impact the response and outcomes to therapy.

Methods: We conducted a retrospective analysis of individuals with BRAF-mutant NSCLC using next-generation sequencing or genotyping methods from January 1, 2012 through August 4, 2023. Patient demographics, smoking status, and disease stage were collected through electronic medical record review. PD-L1 expression (22C3 or SP263) was also assessed. Overall survival (OS) and progression-free survival (PFS) were calculated using the Kaplan-Meier method with log-rank test. A p-value ≤0.05 was considered significant.

Results: Among 110 individuals with BRAF-mutant NSCLC, 54% were females (n=59), 92% were white (n=101), 95% had adenocarcinoma (n=104), 82% were current/former smokers (n=90), 51% had non-class I (n=25 class II, n=31 class III), 75% had PD-L1 ≥1%, and 57% had PD-L1 ≥50%. There were 88 evaluable individuals with advanced disease treated with systemic therapy: 49 received frontline ICI, 19 received chemotherapy, and 20 received targeted therapies (e.g., anti-BRAF/MEK). Among those treated with frontline ICI, there were no significant differences in PFS between class I and non-class I (9.2 vs. 10.8 months, respectively; p 0.53); however, there was a trend towards improved OS for class I versus non-class I (42.6 vs. 18.5 months; p 0.28). Current/former smokers had significantly better PFS than never-smokers, while never-smokers with class I mutations had significantly better OS compared to those with non-class I (Table 1). Current/former smokers with non-class I mutations and no brain metastasis also had an improved OS compared to their never-smoker counterparts (24.6 vs. 8.8 months, respectively; p 0.024). There was an improved OS among individuals with PD-L1 ≥1%, current/former tobacco users, or those with class I mutations treated with frontline ICI compared to chemotherapy. PFS was also significantly better for those with non-class I mutations, current/former smokers, and there was a trend towards improved OS amongst never-smokers (Table 2).

Conclusions: Individuals with BRAF mutations treated with frontline ICI had improved OS and PFS compared to those treated with chemotherapy. OS benefit was particularly pronounced for never-smokers and for those with class I mutations.

P2.11A.19 Invasive Lymph Node Patterns and Prognosis in Lung Adenocarcinoma

S. Lao1, z. Chen2, W. Wang1

1The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,2Affiliated Qingyuan Hospital of Guangzhou Medical University, Qingyuan/CN

Introduction: Tumor-draining lymph nodes (TDLNs) are usually the first station of tumor metastasis in lung cancer. TDLNs+ have distinct pathomorphologic and tumor microenvironment (TME)-compositional patterns, which still need to be thoroughly investigated in lung adenocarcinoma (LUAD).

Methods: Here, we enrolled 312 LUAD patients with TDLNs+ from our institution between 2015 and 2019. 3DHISTECH was used to scan all of the TDLNs+. Based on morphologic features, TDLNs+ patterns were classified as polarized-type or scattered-type, and TME-compositional patterns were classified as colloid-type, necrosis-type, specific-type, and common-type.

Results: Multivariate analysis revealed an increased risk of early recurrence associated with scattered-type (HR 2.37, 95%CI:1.06-5.28), colloid-type (HR 1.95, 95%CI:1.03-3.67), and necrosis-type (HR 2.21, 95%CI:1.13-4.89). NanoString transcriptional analysis revealed an immunosuppression and vascular invasion hallmark in scattered and necrosis patterns and an immunoactivated hallmark in polarized and common patterns. According to imaging mass cytometry (IMC), the scattered and necrosis patterns revealed that germinal centers (GC) were compromised, GCB cell and T cell proliferation were deficient, tumor cells had the potential for proliferation, and the immune attack may be weaker.

Conclusions: In this study, we present evidence that LUAD patients have distinct patterns and immune hallmarks of TDLNs+ related to their prognosis.

Keywords: lymph node metastasis, pathomorphologic pattern, lung adenocarcinoma

P2.11A.20 Metformin Enhances Immune Checkpoint Inhibitor Response in Overweight Lung Cancer Patients: A Retrospective Cohort Study

S. Kalvapudi1, S. Bawek2, Y. Vedire1, A. Pachimatla1, P. Jain1, S. Yendamuri1

1Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA ,2University at Buffalo, The State University of New York, Buffalo/NY/USA

Introduction: Metformin has shown potential benefits in conjunction with immune checkpoint inhibitors (ICIs) in preclinical studies. However, the results from retrospective clinical studies and prospective trials for non-small cell lung cancer (NSCLC) are inconsistent. We aimed to investigate whether metformin's efficacy varies based on patients' body mass index (BMI).

Methods: We conducted a retrospective review of NSCLC patients treated with ICIs between 2015-2023. Patient response was assessed using Recist 1.1 coding and chart review to determine progression-free survival (PFS). Patients were categorized based on BMI into overweight (BMI ≥ 25) and non-overweight (BMI < 25) groups. Cox proportional hazards modeling was used to evaluate univariate and multivariable PFS with metformin. Multivariable analysis was adjusted for age, sex, smoking status, histology, and first-line regimen.

Results: In the final cohort (n=480; overweight = 292, non-overweight = 187), a higher proportion of overweight patients had a history of regular metformin use compared to non-overweight patients (22% vs. 11%, p = 0.003). Univariate analysis revealed a trend towards better PFS among metformin users in the overweight group (Hazard Ratio [HR] = 0.68; 95% Confidence Interval [CI] = 0.457 - 1.011, p = 0.057), whereas the opposite trend was observed in the non-overweight group (Figure 1). Multivariable analysis showed significantly improved PFS for patients with history of metformin use, as compared to those without (HR = 0.629, 95% CI = 0.418 - 0.947, p = 0.027) (Table 1).

Conclusions: We demonstrate that combining metformin with ICI may enhance PFS in overweight but not in non-overweight NSCLC patients. These findings suggest that BMI could serve as a predictive factor for the response to ICI therapy in patients receiving metformin. They also offer guidance for patient selection in clinical trials investigating metformin in NSCLC, with a particular focus on overweight/obese individuals.

Keywords: Metformin, Immune Checkpoint Inhibitor, BMI

P2.11A.21 CCL4 Attenuated the Efficacy of Immunotherapy via Regulating the Phenotype and Function of Treg in EGFR-TKI Resistant NSCLC

S. Liu, W. Liang, J. He

the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: The efficacy of immune checkpoint inhibitors (ICI) in advanced NSCLC patients with sensitive EGFR mutation was controversial. Our previous study demonstrated that those with acquired resistance to EGFR-TKI responded worse to ICIs, but the mechanism is unclear.

Methods: Advanced NSCLC patients with resistance to EGFR-TKIs and received ICI treatment from January 2016 to June 2021

were retrospectively analyzed. single cell sequencing and flow cytometry were conducted to explore the cell components in tumor microenvironment. In vitro experiments were carried out to clarify the efficacy of CCL4 regulating the phenotype and function of Tregs. Western blot, RT-PCR, flow cytometry and co-culture system were adopted to uncover the possible mechanisms.

Results: Fifty-eight NSCLC patients with EGFR sensitive mutation and treated with anti-PD-(L) 1 based immunotherapy were enrolled. Those with acquired resistance to EGFR-TKI showed significantly higher frequency of primary resistance to immunotherapy. Flow cytometry analysis revealed significantly increased CD39+ Treg and decreased CD8+ T cells infiltration in the tumor microenvironment. Bulk RNA sequencing analysis showed that differently expressed genes between EGFR-TKI acquired resistance cohort versus primary resistance cohort were significantly enriched in chemokine signaling pathway, and CCL4 was highly expressed in EGFR-TKI acquired resistance patients. Single-cell RNA sequencing demonstrated that it was tumor cells, not immune cells or fibroblasts, highly expressing CCL4 after a long-term treatment with EGFR-TKI. And this finding was further verified in vitro experiments as that cell lines with resistance to EGFR-TKI (H1975, PC9GR, PC9OR) expressed higher CCL4 than those without (PC9, L858R). In vitro experiments verified that exogenous supplementation of CCL4 could significantly improve the expression of CD39 on Tregs. Additional CCL4 to the co-culture system of Tregs with CD8+ T cells could decrease the production of IFN-— and granzyme B, attenuating the cytotoxicity of CD8+ T cells, and previously added anti-CD39 inhibitors to the co-culture system could offset this effect. The effects from exogenous CCL4 could be replaced by co-culturing with EGFR-TKI resistant cell lines.

Conclusions: NSCLC tumor cells with acquired resistance to EGFR-TKI upregulated the expression of CD39 on Tregs by secreting CCL4 in tumor microenvironment, attenuating the cytotoxicity of CD8+ T cells, ultimately affecting the efficacy of anti-PD-(L) 1 immunotherapy.

Keywords: EGFR-TKI resistance, immunotherapy, CCL4

P2.11A.22 Higher Blood TMB/Tissue TMB Ratio as an Inferior Prognostic Biomarker for Survival in Advanced Stage NSCLC

L. Kim1, S. Yoo2, J. Kim2, Y.K. Chae2

1Ascension Saint Francis Hospital, Evanston/IL/USA ,2Northwestern University Feinberg School of Medicine, Chicago/IL/USA

Introduction: High tumor mutation burden, calculated from tissue next-generation sequencing (tTMB), is known to have predictive value for favorable survival outcomes with immune checkpoint inhibitor treatment (ICI) in certain cancers. Blood-based TMB (bTMB) is increasingly utilized as an alternative to tTMB, primarily due to challenges in obtaining tissue samples for sequencing. However, the prognostic significance of bTMB in relation to tTMB is not well understood.

Methods: Patients treated for advanced-stage non-small cell lung cancer (NSCLC) with both available pre-treatment tTMB and bTMB results (blood NGS collected from October 2020 to February 2024) were included in the analysis. Survival outcomes according to bTMB (High defined as ≥ 16 Mut/Mb, Low defined as <16 Mut/Mb), tTMB levels (High defined as ≥ 10 Mut/Mb, Low defined as <10 Mut/Mb), and bTMB/tTMB ratio were analyzed. The Spearman's rank correlation coefficient was used to assess the concordance between bTMB and tTMB.

Results: Among 84 patients, 32 (38%) received ICI monotherapy, 30 (35%) received ICI and chemotherapy combination therapy, 17 (20%) received cytotoxic chemotherapy, and 15 (18%) received targeted therapy. The median tTMB was 6.3 (Q1: 3.2, Q3: 11.5), and the median bTMB was 11.5 (Q1: 7.8, Q3: 21.1). The median interval between tTMB collection and bTMB collection was 20 days (Q1: 12 days, Q3: 105 days, range 0-1540 days). The median bTMB/tTMB ratio was 1.99 (Q1: 0.98, Q3: 3.48). The median interval between bTMB collection and treatment initiation was 14 days (Q1: 7 days, Q3: 28 days, range: 0-134 days), with 67 patients (80%) having an interval of <30 days. There was no difference in PFS and OS of patients who received immunotherapy between groups with high and low tTMB. Similar findings were observed with bTMB. When patients were divided into two groups according to bTMB/tTMB tertiles (1st and 2nd tertile vs 3rd tertile), the third tertile group had a significantly inferior OS in both all regimen group (84 patients, p 0.002, HR 2.70, 95% CI 1.26-5.77) and immunotherapy group (62 patients, p 0.03, HR 2.43, 95% CI 0.97-6.13) (figure 1). However, no significant difference in PFS was observed for all regimen group and immunotherapy group.

Conclusions: A higher blood TMB/tissue TMB ratio can serve as an inferior prognostic biomarker for survival of patients with advanced stage NSCLC. A high bTMB/tTMB ratio may be indicative of increased tumor heterogeneity and/or higher metastatic tumor burden. Further studies are warranted to explore the role of bTMB/tTMB ratio.

P2.11A.23 Fecal Microbiota Transplantation Plus Rechallenging Immunotherapy in Patients with Advanced Non Small Cell Lung Cancer: An

Exploratory Study

M.J. Huang1, Y.j. Du1, Y. Li1, M. Yu1, Y. Yu1, Y. Zhang1, Y. Lu1, L. Li1, J. He2, Y. Gong1, J. Zhu1, B. Zou1, Y. Liu1

1Division of Thoracic Tumor Multimodality Treatment and Department of Medical Oncology, Cancer Center, West China Hospital, Sichuan University., Chengdu/CN ,2Xiamen Treatgut Biotechnology Co., Ltd., Xiamen, China., Xiamen/CN

Introduction: Previous studies have associated the gut microbiota with response to immunotherapy and fecal microbiota transplantation (FMT) has been applied as an effective tool for reestablishing gut microbiota. However, whether FMT could reverse immunotherapy resistance in patients with non small cell lung cancer (NSCLC) has not been investigated.

Methods: Here, we conducted a clinic trial to detect the safety and efficacy of healthy donor FMT plus PD-1 blockade re-challenging therapy in 7 patients with advanced NSCLC who have progressed after initial response to immunotherapy.

Results: During the follow-up, a total of 66 adverse events (AEs) were reported (Grade 1: 69.7%, Grade 2: 22.7%, Grade 3: 7.6%) and no serious adverse event above grade 3 was identified. Treatment related AEs were mainly associated with immunotherapy, only Grade 1 FMT-related AEs (nausea, diarrhea, bloating, constipation etc.) were reported. Additionally, the disease control rate (DCR) was 28.6%, including one partial responses (PR) and one stable disease (SD) with PFS of 14.6 months and 8.1 months, respectively. The median progression-free survival (PFS) was 1.5 months (95% CI: 1.24 - 1.75) and the overall survival (OS) was 12.1 months (95% CI: 0.3 - 23.9) for all patients. Moreover, the composition of the intestinal flora in all patients was modulated after treatment. At genus level, most of species decreased while two original species (Prevotella_9 and Veillonella) increased and two new species (Megamonas and Alloprevotella) appeared post-treatment. And the alpha diversity increased in responders, whereas it decreased in non-responders. Additionally, 73 metabolites elevated and 41 metabolites reduced in stool specimens of recipients ($p<0.05$ VIP>1).

Conclusions: The combined therapy of FMT and anti-PD-1 antibody has a tolerable safety profile and preliminary therapeutic effect, warranting further investigation.

P2.11A.24 Characterization of Circulating Tumor-Associated and Immune Cells in Advanced-Stage NSCLC

V. Yaghoubi Naei1, W. Mullally2, M. Warkiani3, K. O'Byrne2, A. Kulasinghe1

1The University of Queensland, Brisbane/AU ,2Princess Alexandra Hospital, Brisbane/AU ,3University of Technology Sydney, Sydney/AU

Introduction: Non-small cell lung cancer (NSCLC) is the most prevalent form of lung cancer and the leading cause of cancer-related deaths globally. There is an increasing need to better understand biomarkers that may be predictive of clinical outcomes which can be assessed using non-invasive means.

Methods: Our study sought to investigate circulating peripheral blood cells in NSCLC, including epithelial, immunological, tumour-associated and hybrid subtypes. We performed enrichement of blood samples using spiral microfluidic technology, followed by comprehensive characterisation of the enriched cell fraction in n=50 NSCLC patient blood samples prior to commencement of therapy. Peripheral blood assessments were measured against clinical endpoints (response to therapy, overall survival).

Results: We identified a distinctive class of tumor-associated macrophages (TAMs) that exhibits a unique morphology and cell size, in addition to homotypic circulating tumour cell clusters, heterotypic clusters and single CTCs. Our study reveals a heterogeneous landscape of circulating tumor cells and clusters, underscoring the complexity of cell types found in the circulation of NSCLC patients.

Conclusions: Our study sheds light on the diverse landscape of circulating tumor cells and associated macrophage populations in NSCLC patients. We have detected various cell subpopulations, including tumour-associated macrophages and CTC clusters that exhibit varied cell compositions. Notably, the presence of TAMs correlates with late disease stages and poor clinical outcomes, highlighting their potential roles in tumor progression and metastasis.

Keywords: circulating tumour cells, macrophages, liquid biopsy

Introduction: Immune checkpoint inhibitors (ICIs) can achieve durable responses in non-small cell lung cancer (NSCLC) patients without EGFR/ALK driver alterations. However, primary or acquired resistance is common, occurring in over half of patients, and mechanisms of resistance are poorly understood.

Methods: The GEMINI database was queried to identify metastatic NSCLC patients without targetable EGFR/ALK alterations who were treated with ICI alone or in combination with chemotherapy (ICI-chemo). Mutational profiling was performed on tissue or blood using targeted NGS. Radiographic response was assessed using RECIST guidelines (version 1.1).

Results: A total of 1914 patients with NSCLC treated with PD-(L)1 blockade were identified, of whom 641 (33.5%) had progressive disease (PD) at their first on-treatment scan evaluation (primary resistance: Pres) and 465 cases (24.3%) achieved initial response (complete or partial response; CR/PR). Acquired resistance (AR) was common, occurring in 57% (265 out of 465) of initial responders. The onset of AR was variable, occurring within 6 months in 26 (9.8%) patients (AR_S), 179 (67.5%) in 6-24 months (AR_M), and 60 (22.6%) > 2 years (AR_L). Squamous cell histology, liver metastasis, and ICI-chemo combination therapy were enriched in the AR_S group compared to other AR and Pres groups. High PD-L1 expression was enriched among patients with AR > 6 months compared to Pres and AR_S groups. An elevated peripheral blood derived neutrophil-to-lymphocyte ratio (dNLR) was observed in the Pres and AR_S groups compared to the other AR groups (p=0.01). A total of 145 patients had paired tissue or blood sequencing at baseline and at ICI progression. The mean level of PD-L1 expression decreased at the time of progression compared to the baseline level (p=0.02). Genes related to PI3K/AKT/mTOR (PIK3CA) and RAF/MEK/ERK (ARAF, BRAF) signaling pathways, as well as the ErbB family genes (EGFR, ERBB2 and MET), were more abundant in the post-ICI set than the pre-ICI set.

Conclusions:

Liver metastases and dNLR associate with earlier time to acquired resistance. The genomic profile at resistance in NSCLC patients is heterogeneous. A deeper understanding of the mechanisms of resistance evolution is needed to optimize sequential or combinatorial treatment strategies to overcome resistance.

Introduction: A high neutrophil/lymphocyte ratio (NLR) has a reported association with poor prognosis in non-small cell lung cancer (NSCLC) patients, but data are limited on the potential contribution of other immune cells such as monocytes and eosinophils in modulating the systemic immune response. The aim of this analysis was to validate the prognostic importance of the NLR and other peripheral myeloid cells, including monocytes and eosinophils, in patients with NSCLC treated with cemiplimab in the EMPOWER-Lung 1 (NCT03088540) and EMPOWER-Lung 3 (NCT03409614) phase 3 trials. We also aimed to develop a nomogram derived from the joint Cox model enabling physicians to predict 1- and 2-year outcomes based on individual characteristics of patients with NSCLC treated with the programmed cell death-1 (PD-1) inhibitor, cemiplimab.

Methods: Overall survival (OS) was assessed in patients from the full analysis set with an available blood differential test at baseline that included monocyte, lymphocyte, and neutrophil measurements. For hypothesis testing and cut-point derivation, data were randomly split into training (70%) and testing (30%) cohorts using random sampling. The multivariable model developed in the training set was validated in the testing set using Harrell's concordance index to estimate discrimination and calibration plots to visualize model calibration. A graphical representation of the individual effect sizes from a statistical regression model, and their relationship with predicted probability of the dependent variable, was provided using a nomogram, enabling estimation of the predictive probability of 1-year and 2-year OS for any given patient.

Results: In the testing cohort our model (Figure) yielded a concordance index of 0.61, indicating a modest predictive performance. Calibration curves between observed and predicted probabilities of death indicated that for higher-risk individuals above a 1-year mortality probability of 30%, the model is mis-calibrated and underestimated the 1-year mortality probability. However, most patients had a predicted 1-year mortality below 30%, with few patients above 75%.

Conclusions: This analysis shows that peripheral blood cell count parameters, including putative immunosuppressive neutrophils and monocytes as well as protective lymphocytes and eosinophils, may predict outcomes with anti-PD-1 therapy in patients with advanced NSCLC. While the variables in the nomogram were statistically significant and enhanced the ability to discern difference over the baseline model, overall discrimination was moderate, indicating that more data are needed to better predict clinical outcomes in this setting.

Introduction: Radiomics have shown promise in improving prognostication in metastatic non-small cell lung cancer (mNSCLC) subjects treated with immunotherapy (IO). However, ensuring generalizability across different centers still represents an open challenge to clinical adoption. We sought to develop and test the generalizability of a radiomics model aimed at predicting risk of progression in IO treated subjects with mNSCLC.

Methods: Pretreatment CT scans of IO treated mNSCLC subjects and with known outcome data were collected from a single institution (Discovery cohort) to develop the model. Radiomics features were extracted from the segmentation of the largest lung tumor lesion. The 8 most predictive radiomics features were selected using a least absolute shrinkage and selection operator (LASSO) cox regression and combined using a survival random forest algorithm. The radiomics risk model was trained via cross-validation using censored progression-free survival (PFS) data. To determine what learned features were predictive of IO outcome, we tested the model in a cohort of mNSCLC subjects treated with 1L chemotherapy (Chemo cohort). To test model generalizability, we used a publicly available retrospective cohort of pretreatment CT scans of mNSCLC treated with IO and with known PFS data from an independent institution (External cohort). Risk models were evaluated by splitting the data into high and low risk groups, and evaluating the hazard ratios (HR) and log rank test p-values between the predicted risk groups.

Results: The Discovery cohort included 108 mNSCLC subjects who received IO as 1L therapy. Sixty-seven (62%) subjects received a combination of IO and chemotherapy. The cohort (51% female) had a median age of 68 (range 25->89) years and a median PFS of 11.5 (95% CI 8.3-15.8) months. The chemo-cohort of 55 patients (45% female) had a median age of 65 (range 45-82) years and a median PFS of 10.3 months (95% CI 5.3-12.9). The External cohort included 174 mNSCLC subjects (52% female) who underwent IO as first (33%), second (54%) or subsequent (13%) line of therapy. Nine (5%) subjects received IO combination therapies. These subjects had a median age of 68 (range 38->89) years and a median PFS of 2.7 (95% CI 2.2-3.6) months. The model cross-validated on the discovery cohort produced a HR of 1.79 (95% CI 1.08-2.95), p-value=0.024. In the Chemo-cohort, the HR was of 1.93 (95% CI 1.07-3.47), p-value=0.026. On the independent test cohort the HR was of 1.45 (95% CI 1.04-2.03), p-value=0.029. When focusing on subjects treated with IO as 1L therapy, the HR was of 1.74 (95% CI 0.92-3.32), p-value=0.089.

Conclusions: The derived radiomics model showed promising risk stratification and generalizability capabilities in IO treated subjects. However, results from the Chemo cohort suggest the model might be predictive of overall risk of disease progression rather than response to IO therapy.

Introduction: Treatment management in patients with metastatic non-small cell lung cancer (NSCLC) who are eligible for systemic therapy lacks reliable biomarkers to choose from approved first-line treatments. Currently approved biomarkers include PD-L1 expression scores and tumor mutational burden, which provide only a limited view of the tumor immune environment. The PROphet NSCLC test was recently developed in a multicenter observational trial (ClinicalTrials.gov identifier: NCT04056247) of NSCLC patients undergoing PD-1/PD-L1 inhibitor-based therapy to address clinical needs. The PROphet NSCLC test combines pretreatment plasma proteomics and machine learning to assist first-line treatment management and provides treatment considerations based on the levels of 388 plasma proteins, termed resistance-associated proteins (RAP). In this study, the biological mechanisms underlying RAPs were analyzed. Notably, biological analysis of plasma proteins in cancer patients presents a challenge given the intricate interplay between the tumor, immune system, and other tissues. Advanced analysis methods were employed to decipher the biological mechanisms associated with RAP, resulting in six distinct groups of RAP proteins related to the immune system, tumor, and other tissues that can be linked to resistance mechanisms.

Methods: Biological analysis was performed on 388 RAP proteins measured in plasma samples obtained from 206 advanced-stage NSCLC

patients before PD-1/PD-L1 inhibitor treatment initiation. A correlation matrix was constructed for all 388 RAPs across 206 patients, assuming that proteins exhibiting similar expression levels may correlate and be involved in the same biological process. Subsequently, a weighted graph was constructed based on the correlation matrix. In this graph, every node corresponds to a protein, and the strength of the correlation between the two proteins is depicted by the weight of the edge connecting their respective nodes. Finally, a correlation strength threshold was applied to the weighted graph, whereby only edges above the threshold were considered. This threshold was determined to optimize the occurrence of clusters containing multiple proteins, while minimizing the presence of isolated proteins. Enrichment analysis was performed for each protein cluster using standard enrichment databases.

Results: The RAP protein correlation analysis resulted in nine clusters containing 114 of the 388 RAP, of which the two most significant clusters included 46 and 30 RAP. In contrast, the smallest clusters contained only two RAP proteins. Significant enrichment of cellular compartments and tissues was observed in the six clusters. Notably, no significant enrichment was observed when all 388 RAPs were included in the analysis because of the mixture of signals derived from various biological mechanisms. The largest cluster, comprising 46 RAP proteins, predominantly comprised extracellular proteins associated with the acute-phase response, whereas the other large cluster of 30 RAP proteins comprised proteins enriched in nuclear and alveolar cells. The different clusters were enriched in proteins related to the extracellular matrix, endoplasmic reticulum, liver, and intracellular ferritin complexes.

Conclusions: Our study provides valuable insights into the biological processes associated with the clinical benefits of immunotherapy. This underscores the potential of plasma proteomics to identify mechanisms related to therapy resistance and biomarkers for clinical outcomes.

P2.11B.02 Genomic Correlates of Response to Chemoimmunotherapy in STK11MUT and KEAP1MUT Metastatic Non-Small Cell Lung Cancer

A. Saini1, A. Elkrief2, L. Hong3, B. Ricciuti1, E. Garbo1, F. Pecci1, M. Makarem1, A. Di Federico1, M.M. Gandhi1, M. AIdea1, M. Nishino1, L.M. Sholl1, N.I. Vokes3, A.J. Schoenfeld2, M.M. Awad1

1Dana-Farber Cancer Institute, Boston/MA/USA ,2Memorial Sloan Kettering Cancer Center, New York/NY/USA ,3The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: Mutations in STK11 and KEAP1 are associated with primary and acquired resistance to immune checkpoint inhibition (ICI)-based regimens in patients with advanced non-small cell lung cancer (NSCLC). However, STK11 and KEAP1 mutations are highly heterogenous, and a fraction of NSCLCs harboring these mutations retain sensitivity to (ICI)-based regimens. We aimed to characterize the determinants of response to chemoimmunotherapy among these patients.

Methods: Clinicopathologic and genomic data were collected from patients with advanced NSCLC treated with chemoimmunotherapy and whose tumors underwent genomic profiling at three academic centers. Cox-proportional hazards models were used to understand outcomes to chemoimmunotherapy in the mutational NSCLC cohorts.

Results: Among 1492 patients with advanced NSCLC treated with chemoimmunotherapy, 329 (22.1%) and 246 (16.5%) harbored mutations in STK11 and KEAP1, respectively, and the objective response rates (ORR) were 28.3% and 30%, respectively. Among the 443 patients with metastatic NSCLCs with either STK11 and/or KEAP1 mutations, the median age was 68 (range 40-92), 96.6% had a history of tobacco use, 87.8% had adenocarcinoma histology, 86.5% had a ECOG performance status 0-1, the median PD-L1 was 0 (range 0-95), and 97.7% received chemoimmunotherapy in the first-line setting. In both STK11MUT and KEAP1MUT NSCLC, those with a tumor mutational burden (TMB) percentile ≥90% had a higher ORR, and longer median progression free survival (mPFS), and longer median overall survival (mOS) than those with a TMB percentile <90% (Table). In both mutational subgroups, absence of a concurrent mutation in KRAS was associated with a longer mPFS compared to those with a concurrent mutation in KRAS. In KEAP1MUT NSCLC, PD-L1 ≥1% was associated with a higher ORR and longer mPFS compared with a PD-L1 <1%; in STK11MUT NSCLC, there was no association between PD-L1 and response or survival to chemoimmunotherapy; however, these analyses may be limited by the overrepresentation of patients with low/negative PD-L1 levels in this cohort. NSCLCs harboring STK11 missense mutations had a longer mPFS and mOS compared to those with non-missense mutations; by contrast, there was no significant difference in mPFS or mOS in NSCLCs harboring KEAP1 missense vs non-missense mutations. Patients with mutations in STK11 or KEAP1 alone had a higher ORR and longer mPFS and mOS compared to those with concurrent mutations in STK11 and KEAP1 (Table).

Conclusions: Among NSCLCs with STK11 and/or KEAP1 mutations, various pathologic and genomic factors, including PD-L1 expression, TMB, KRAS status, and missense vs non-missense mutation subtype, impact the efficacy of chemoimmunotherapy.

Introduction: Hyperprogressive disease (HPD) has been described in –14% of pretreated non-small cell lung cancer (NSCLC) patients upon single-agent PD-1/PD-L1 inhibitors (SA-ICI) and has not been reported upon platinum-based chemotherapy (PCT) and ICI combinations. So far, no predictive biomarkers are available for HPD early detection.

Methods: In NSCLC patients treated with 1st line single-agent ICI or PCT-ICI, HPD was defined as delta tumor growth rate (TGR) >50% and/or TGR ratio ≥2. Circulating low density neutrophils (LDNs) were assessed by flow cytometry on peripheral blood mononuclear cells (PMBCs). LDNs were defined as CD66b+CD15+ cells among CD11b+ PBMCs and immature subtypes as CD10- LDNs. The LDNs predictive role was assessed by Youden's test. Single-cell RNA-sequencing was performed on 14 PBMC samples (6 HPD, 8 PR) using Seurat and harmony R packages. Cell types were identified both though AUCell R package and manual curation. The differentiation in trajectories within the HPD cell dataset was described with Monocle3.

Results: 144 NSCLC patients were included: 75 treated with SA-ICI, 69 with PCT-ICI. In the SA-ICI cohort, HPD occurred in 8 (11%) patients. Immature circulating CD10- LDNs were significantly higher at baseline in HPD [median: 39.3, interquartile range (IQR): 28.7] compared to progressive disease [median: 7.4, IQR: 14.9, p<0.01] or partial response (PR) [median: 3.7, IQR: 12.6, p<0.01]. Circulating CD10- LDNs were associated with HPD [odds ratio (OR): 1.17, 95% CI: 1.06; 1.29], with a good prediction capability [cross-validated AUC 0.97 (95%CI: 0.94;1.00)]. A 30.5% cut-off value for CD10- LDNs was identified to discriminate HPD from others. In the PCT-ICI cohort, 14 patients had circulating CD10- LDNs ≥30.5%, being at high risk of HPD. However, no HPD was observed with PCT-ICI and dynamic evaluation in HPD high risk patients showed 52.3% (IQR: 28.4) reduction in CD10- LDNs upon PCT-ICI, suggesting that PCT prevents HPD by reducing immature LDNs. At a single-cell level, neutrophils from HPD patients had increased expression of IL-1 receptor type-II (IL1R2) compared to PR (log2FC=0.7, p<0.01), in line with an emergency granulopoiesis occurring in HPD. Furthermore, higher proportion of senescent T-cells was observed in HPD versus PR (log2FC=0.65, p<0.01), and genes associated with T-cells senescence were significantly modulated along the pseudotime trajectory (p<0.01) (Figure).

Conclusions: In HPD an opposite maturation drift occurs in circulating neutrophils compared to T-lymphocytes. In particular, immature neutrophils and senescent T-cells identify patients at high risk of HPD, who should be addressed to 1st line PCT-ICI combinations.

1SAN RAFFAELE HOSPITAL, MILAN/IT ,2Federico II, University of Naples, NAPLES/IT ,3University of Pavia, Pavia/IT ,4HARVARD UNIVERSITY, BOSTON/MA/USA ,5IRCCS MARIO NEGRI, MILAN/IT ,6AORN Ospedali dei Colli, NAPLES/IT

Introduction: Acquired resistance (AR) has been defined as radiological progression after response to PD-1/PD-L1 inhibitors. Although the addition of platinum-based chemotherapy (PCT) to PD-1/PD-L1 inhibitors (ICI) is able to reduce primary resistance, the effect of PCT on AR is unclear.

Methods: Randomized clinical trials (RCTs) testing ICI alone (mono-ICI) or in combination with PCT (ICI+PCT), CTLA-4 inhibitors (combo-ICI) or both of them (combo-ICI+PCT) in metastatic NSCLC were searched in electronic databases (Medline, EMBASE, CENTRAL Cochrane) until 03/2024. RCTs with available Kaplan Meier (KM) curves of duration of response (DOR) and/or patients at risk at 12 months were eligible. AR rate was computed by patients at risk at 12 months from DOR curves. Primary endpoint was to indirectly compare the AR rate with PCT-containing versus PCT-free regimens. Aggregate data were reported with risk ratio (RR) and pooled by random effect model. Time to event outcomes were retrieved from KM curves through the individual patient data (IPD)-from-KM method and compared by log rank test.

Results: 16 RCTs (3915 patients, main characteristics and PD-L1 status in the Figure 1) were included. The addition of PCT significantly increased AR rate compared to PCT-free regimens both for ICI+PCT versus mono-ICI comparison (RR: 1.46, 95% CI 1.21-1.76) and for combo-ICI+PCT versus combo-ICI comparisons (RR: 1.48, 95% CI 1.07-2.05). Median DOR was significantly shorter with ICI+PCT compared to mono-ICI [11.8 months (95%CI 10.5-12.7) versus 16.2 months (95%CI 14.8-20.5), p=0.0001] and with combo-ICI+PCT compared to combo-ICI [11.6 months (95%CI 8.7-17.4) versus 18.4 months (95%CI 15.8-23.3), p=0.0005] (Figure 2).

Conclusions: In NSCLC the addition of PCT to immunotherapy (anti-PD-(L)-1 +/- anti-CTLA-4) significantly increases the rate of AR and reduces the DOR. These data highlight the need to identify biomarkers to better select patients who may benefit from a first-line PCT-sparing regimen, in order to reduce the risk of AR.

P2.11B.05 Effect of Dysbiosis-Inducing Drugs on the Response to Immune Checkpoint Inhibitors in Patients with NSCLC

S. Lopes1, B. Bertrand1, P. Lucile1, Q. Creusot1, B. Mennecier1, G. Pamart1, C. Matau1, E. Pancreach1, M. Beau-Faller1, A. Dory1, C. Mascaux1

1Strasbourg University Hospitals, Strasbourg/FR

Introduction: Immune checkpoint inhibitors (ICIs) have significantly improved overall survival (OS) in patients with metastatic non-small cell lung cancer (NSCLC). However, only 30% of patients actually benefit from this costly treatment, which is not without side effects. Better patient selection prior to treatment is therefore essential. To this end, the search for new biomarkers more effective than PD-L1 expression is in progress. Among these, the composition of the gut microbiota appears to be closely correlated with response to ICIs. Many drugs can alter the composition of the microbiota and theoretically reduce therapeutic response of ICIs. In this study, we analyzed the impact of drug interactions in clinical practice.

Methods: We retrospectively collected clinical, biological and pharmacological data from ICI-treated patients with NSCLC followed at a university hospital between 2015 and 2022. Only resistant patients (progression-free survival (PFS)<3 months) and long responders (PFS>1 year) were included. Treatments associated with dysbiosis were systematically reviewed up to 90 days prior to ICI initiation. The treatments included were: corticosteroids >10mg/d, antibiotics (ATBs), proton pump inhibitors (PPIs), satins, non-steroidal anti-inflammatories, opioids, laxatives, metformin, anti-vitamin K, L-thyroxine, cholecalciferol, phloroglucinol, anti-H1 and H2, tricyclic antidepressants, serotonin reuptake inhibitors, antiarrhythmics and probiotics.

Results: This study included 369 patients, of whom 193 were resistant and 176 long-responders. Overall survival (OS) was significantly reduced in the corticosteroid group (p=0.0033; HR=2.4 (CI95% [1.1-5]), median OS 10.1 vs 29.2 months), PPI (p<0.0001; HR=2.6 (CI95% [1.7-4.1]), median OS 8.6 vs 36.4 months) and opioids (p=0.011; HR=1.7 (CI95% [1.1-2.6]), median OS 12.9 vs 30.4 months). PFS was negatively impacted in case of prescription of corticosteroid (p=0.0015, HR=2.7 (CI95% [1.1-6.7]), median PFS 1.6 vs 12.6 months), PPI (p<0.0001; HR=3.4 (CI95% [2-5-7]), median PFS 2.0 vs. 20.0 months), opioids (p=0.016; HR=1.8 (CI95% [1.1-3]), median PFS 2.4 vs. 13.9 months) and anti-H1 (p=0.014; HR=3.1 (CI95% [1.04-9.1]), median PFS 1.9 vs. 12.4 months). In multivariate analysis, only PPIs were associated with a reduction in OS (HR=3.5 (CI95% [2.1-5.9]) and PFS (HR=3.1 (CI95% [1.9-4.9])).

Conclusions: PPIs are associated with reduced efficacy of ICIs in NSCLC patients. The indication for gastric antisecretory agents should be reassessed before initiating immunotherapy.

P2.11B.06 BIRC5 Expression Correlated with Immunosuppressive Phenotype and Predicted Inferior Response to Immunotherapy in LUAD

S. Yang1, X. Liu1, S. Mao1, C. Shao1, X. Li1, C. Zhao1, Y. Wang1, Q. Fang1, B. Chen1, F. Wu1, X. Chen1, X. Chen2, J. Yu1, S. Ren1

1Shanghai Pulmonary Hosptial, Shanghai/CN ,2Fujian Cancer Hospital, Fuzhou/CN

Introduction: BIRC5, also known as survivin, is the smallest but functionally most complex member of the inhibitor of apoptosis protein family. BIRC5 plays a pivotal role in shielding cells from both intrinsic and extrinsic apoptotic pathways, primarily by indirectly inhibiting caspase 9 activation and physically preventing direct interactions with apoptosis-promoting molecules.BIRC5 is highly expressed in most cancers and correlated with tumor growth, recurrence, chemotherapy resistance, and poor prognosis. However, a comprehensive analysis of BIRC5 expression in lung adenocarcinoma and its prognostic value for immunotherapy has not yet been investigated.

Methods: Clinical and transcriptomic data of 535 lung adenocarcinoma samples, 59 normal lung, and 54 patients with non-small cell lung cancer received immunotherapy were analyzed. Deconvolution analysis was conducted to uncover the relationship between tumor microenvironmental features and BIRC5 expression level. The predictive and prognostic values of BIRC5 was also evaluated with Log-rank test and Cox regression analysis.

Results: Lung adenocarcinoma had a significantly higher BIRC5 expression level than normal lung tissues. The elevated BIRC5 expression was markedly associated with unfavorable clinical outcomes. Transcriptomic and single-cell sequencing data analysis revealed that tumors

with high BIRC5 expression was correlated with multiple pathways' enrichment. Deconvolution analysis indicated a negative correlation between BIRC5 expression and infiltration levels of CD8+ T cells, dendritic cells, and NK cells in LUAD, but a positive correlation was observed between BIRC5 expression and regulatory T cells (Tregs) infiltrations. Importantly, lung adenocarcinoma patients received immunotherapy with high BIRC5 expression had dramatically shorter progression-free (1.2 vs. 4.5 months; P = 0.012) and overall survival (3.1 vs. 12.7 months; P = 0.005) than those with low BIRC5 expression.

Conclusions: These findings suggested that high BIRC5 expression was associated with DNA damage/repair, cell invasion and proliferation related pathways enrichment and increased Tregs infiltration, which would result in inferior outcomes in lung adenocarcinoma patients.

P2.11C.01 With Eyes on the Future: Prospective Evaluation of Immune-Related Adverse Events in Patients with Lung Cancer

L. Kiel1, R. Kaufman1, M. Horiguchi1, D. Haradon1, M. Sanchez1, R. Lederman1, F. Amaral Duarte2, K. Meza3, C. Mantz1, T. Nguyen1, S. McDonald1, E. Sharon1, N. Florez (Duma)4

1Dana-Farber Cancer Institute, Boston/MA/USA ,2Hospital das Clinicas UFMG, Belo Horizonte/BR ,3Baylor University, Houston/TX/USA ,4Dana-Farber Cancer Institute/Harvard Medical School, Boston/MA/USA

Introduction: Immune checkpoint inhibitors (ICIs) bear unique, time-dependent immune-related adverse events (irAEs). However, limited data exist regarding tolerability in real-world populations. We report interim, non-sex stratified results of the first study prospectively evaluating ICI tolerability in patients with lung cancer (LC) in a real-world setting.

Methods: Recruitment began in July 2023 and is ongoing. The electronic Patient-Reported Outcomes version of the Common Terminology Criteria (PRO-CTCAE) was utilized to assess patients' irAEs. Patients (pts) complete up to 6 questionnaires throughout their treatment plus an end of treatment evaluation. Inclusion criteria includes pts ≥18 years, with LC stage I to IV, receiving single-agent ICI at Dana-Farber Cancer Institute. Descriptive statistics summarized patients' demographics, clinical characteristics, and symptoms.

Results: 36 pts were enrolled in the study as of January 23, 2024. 35 pts have completed their first PRO-CTCAE questionnaire; the median number of completed questionnaires was 2 (range: 1-6). Due to the current sample size, results reported reference pts' first PRO-CTCAE assessment. 53% of pts identified as female, 92% identified as White, and 6% as Black (Table 1). 56% of pts (19/34) reported having shortness of breath (SOB), most of whom (63%; 12/19) reported having moderate to severe SOB that often (somewhat to very much; 42%; 8/19) interfered with daily activities; 21% of them (4/19) stated that the SOB had worsened since starting ICIs. Similarly, of the 54% (19/35) with a cough, 42% (8/19) reported a moderate to very severe cough and 16% (3/19) reported its worsening since ICI initiation. 14 pts reported anorexia secondary to treatment, with most of them (57%; 8/14) reporting that it interfered with daily activities. Most pts (79%; 27/34) noted some degree of lack of energy. Rates of skin toxicity were low, with only 6% (2/35) experiencing a rash after beginning ICIs. Many pts did not experience nausea, abdominal pain, or unexpected sweating (80%; 28/35, 83%; 29/35, 77%; 27/35). However, of the pts reporting nausea and abdominal pain, high severity of these symptoms was noted (43%; 3/7, 50%; 3/6). Other low frequency irAEs included diarrhea, dry mouth, and dysgeusia.

Patient Characteristics

Conclusions: SOB and cough were the most common symptoms experienced with high severity in this ongoing prospective evaluation of irAEs in pts with LC. Though nausea and abdominal pain were less common, when present, these symptoms were reported with high severity. Future data from this study will elucidate patient experiences with irAEs throughout their treatment course.

P2.11C.02 Incidence of Hematological Toxicity with Use of Immunotherapy and Chemotherapy in Advanced NSCLC: A Network Meta Analysis

W. Fu1, Y. Jiang1, W. Ye1, W. Liang2

1The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,2The First Affiliated Hospital of Guangzhou Medical University, Department of Thoracic Surgery and Oncology/CN

Introduction: Numerous randomized controlled trials (RCTs) have explored the effectiveness and safety of diverse treatments for advanced non-small cell lung cancer. However, the specific hematologic toxicity risks linked to these different therapies are still not well-defined.

Methods: We defined the primary outcome as the incidence of hematologic toxicity of ≥3 Grades, and the secondary outcomes included the incidence rates of all grades of hematologic toxicity events. Random-effects models were used for network meta-analysis, focusing on subgroup analyses for first-line/post-line treatments and different chemotherapy regimens. Besides, single-arm meta-analyses were performed for all interventions using a random-effects model.

Results: We reviewed 4657 articles and included 38 eligible RCTs involving 13 interventions and 24,951 patients. Compared with conventional chemotherapy, CTLA-4+Chemo (OR=1.68, 95%CI: 0.42, 6.68) increased the risk of ≥3 Grades anemia; PD-1+CTLA-4+Chemo (OR=1.33, 95%CI: 0.5, 3.55) and PD-1+Chemo (OR=1.13, 95%CI: 0.95, 1.35) increased the risk of ≥3 Grades decreased neutrophil count; PD-1+VEGF+Chemo (OR=2.18, 95%CI: 1.11, 4.3) and PD-1+Chemo (OR=1.34, 95%CI: 1.04, 1.81) increased the risk of ≥3 Grades decreased platelet count; PD-1+CTLA-4+Chemo (OR=2.72, 95%CI: 0.53, 24.08) increased the risk of ≥3 Grades decreased white blood cell count (Figure 1). Similar trends were observed in terms of overall hematologic toxicity of all grades. Subgroup analysis was consistent with the overall outcome. Figure 2 shows the incidence of hematologic toxicity across various interventions as determined by single-arm meta-analysis.

Conclusions: Our research indicates that combining immune checkpoint inhibitors with chemotherapy may increase the risk of hematologic toxicity beyond the levels seen with either treatment alone. This implies a multifaceted, synergistic interaction, potentially altering immune cell function, angiogenesis regulation, and the direct impact of chemotherapeutic agents on blood-forming cells. Further studies are needed to decipher the underlying molecular mechanisms and to identify risk factors and markers for this enhanced toxicity in combined Immunotherapy and Chemotherapy regimens.

,4Genentech, Inc.,, South San Francisco/CA/USA ,5AItos Labs, Redwood City/CA/USA

Introduction: Patients receiving immune checkpoint inhibitors (ICIs) may develop immune-related adverse events (irAEs). While irAEs carry obvious risks for the patients, recent studies suggest a relationship with improved overall survival (OS) in patients experiencing irAEs. However, the association between specific irAEs and treatment benefit is not well understood. Here, we investigate the association of OS with immune-related pneumonitis (IRP) and immune-related hepatitis (IRH) - two common irAEs in Chinese lung cancer patients treated with ICIs.

Methods: A real-world retrospective cohort study design was conducted based on the Lung Cancer Tracking Cohort (LCTC) comprising EHR data from Hunan Cancer Hospital presenting between January 2018 to December 2023. Clinical data of 3,261 lung cancer patients treated with ICIs were included and analyzed. The relationship between IRP or IRH and survival was assessed using multivariate Cox-proportional hazard models with time-varying covariates and landmark analyses to address immortal time bias. The covariates that we adjusted for include gender, age, stage, smoking status, history of alcohol, line of therapy, treatment strategies, pathological type, ECOG score, local therapy, brain metastases and liver metastases.

Results: IRP and IRH were among the most prevalent irAEs observed. The median follow-up time of the 3261 patient cohort was 24.9 months (range from 0.2 - 90 months). Among all patients, 248 (7.6%) developed IRP, of which 23 (0.7%) experienced grade 3 or higher, and 380 (11.7%) developed IRH, of which 62 (1.9%) experienced grade 3 or higher. The median time to onset for IRP and IRH was 5.9 months and 2.1 months, respectively. We observed a significantly longer OS in patients developing IRH (HR = 0.76, 95%CI: 0.64 - 0.91, p = 0.002) in multivariate cox-proportional hazard models with time-varying covariates. However no such effect was found for IRP (HR = 1.10, 95%CI: 0.90 - 1.33, p = 0.325) and neither mild nor severe IRP showed an association with OS. When comparing the effect of mild (grade 1 or 2) and severe (grade 3 or higher) IRH on OS, mild IRH was significantly associated with longer OS (HR = 0.76, 95%CI: 0.63 - 0.91, p = 0.003). Severe IRH showed a similar though not significant association (HR = 0.79, 95%CI: 0.53-1.18, p = 0.262). Landmark analyses support these results.

Conclusions: This study, which to our knowledge is the largest analysis of specific irAEs and ICIs effectiveness in Chinese lung cancer patients and demonstrated a significant and positive association between IRH and longer OS. These findings highlight the importance of considering IRH as a potential indicator of better treatment outcomes in lung cancer patients. Additionally, this emphasizes the need to manage irAEs in order to optimize the benefit/risk balance for patients receiving ICIs. Further efforts are ongoing to assess the potential for genetic markers and/or signatures associated with the occurrence of IRH and IRP.

P2.11C.04 Enhancing Multidisciplinary Clinicians' Ability in Identifying and Managing irAEs in the Emergency Setting Through Online CME

M.A. Worst1, A. Small1, A. Furedy1, M. Yuan1, S. Bahra1, M. Wattana2, J. Brahmer3

1Medscape LLC, Newark/NJ/USA ,2The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,3Johns Hopkins Kimmel Cancer Center, Baltimore/MD/USA

Introduction: Despite immune checkpoint inhibitors (ICIs) potential for generating durable responses and survival benefits, ICIs can induce a spectrum of immune-related adverse events (irAEs), ranging from mild to severe or life-threatening. Clinicians in the emergency department (ED) may be the first point of contact for patients with non-small cell lung cancer (NSCLC) experiencing an irAE, but may not have specialized training, thus demonstrating a need for collaborative workflows to reduce morbidity and mortality. The objective was to determine if online continuing medical education (CME) could improve ED physicians', oncologists', nurse practitioners' (NPs), and physician assistants' (PAs) ability to collaboratively treat irAEs in patients with NSCLC who present to the ED.

Methods: The educational initiative consisted of a 15-minute video discussion between two multidisciplinary faculty. Educational impact was measured with a repeated pre-/post-assessment including multiple choice competence questions and a 5-point Likert scale confidence question. Data from all ED physicians, oncologists, and NPs/PAs who completed pre- and/or post-education assessments were aggregated and stratified by learning theme and demographic question responses. Relative changes in percentage of correct responses and clinicians who were confident (value of 4 or 5) were used to measure improvement. A McNemar's test assessed significant levels of changes reported with P values <.05 considered statistically significant. The activity launched July 2023; data were collected until February 2024.

Results: ED physicians', oncologists', and NPs'/PAs' had statistically significant improvements in competence and confidence after education (N=38 to 64), including stratifications by practice setting and institutional protocol availability.

Conclusions: Participating clinicians realized statistically significant improvements in their ability to identify and treat irAEs in the ED. Clinicians' gains may correspond with real-world improvement in clinical care, thus enhancing patient outcomes and experiences. Findings suggest that additional educational activities can help address residual gaps and improve ability in this dynamic clinical setting.

P2.11C.05 Correlation Between Gut Microbiome and Immune-Related Adverse Reactions for Lung Cancer

X. Han, J. Chen

The Second Affiliated Hospital of Dalian Medical University, Dalian/CN

Introduction: As a new immunotherapy method, immune checkpoint inhibitors are currently a hot topic in the treatment of lung cancer. However, while immunotherapy brings curative effects, it also brings immune-related adverse reactions(irAEs). irAEs is the most common reason for the withdrawal of immunotherapy, which will undoubtedly affect the efficacy and quality of life of lung cancer patients. Therefore, reducing the occurrence of immune-related adverse reactions is an urgent problem to be solved. Gut microbiome plays an important role in maintaining the balance between human health and disease. Many studies have proved that gut microbiome can regulate human immunity, and thus play a certain role in the immunotherapy of lung cancer patients. The relationship between gut microbiome and irAEs is currently unclear.

Methods: We enrolled 16 NSCLC patients who developed irAEs during immunotherapy from May 1, 2021 to December 31, 2022. Collect baseline fecal samples from all patients (Q group) and fecal samples at the time of irAEs (H group), and perform metagenomic sequencing to compare differences in gut microbiome abundance and functional diversity between the two groups.

Results: Our analysis shows significant differences in the composition of gut microbiome between the two groups of patients. When irAEs occur, the abundance of Firmicutes and Proteobacteria in the patient's gut is higher, while the abundance of Bacteroidetes and Actinobacteria is lower. At the genus level, there was no significant change in the abundance of each dominant bacterial genus, but the abundance of Bacteroidetes and Prevotella in patients with irAEs was slightly lower than baseline. Compared to the baseline of irAEs patients, the most significantly associated bacterial species with irAEs are Ligilactobacillius_salivarius, Veillonella'atypoca, Veillonella_parvula, Veillonella_dispar, Streptococcus_parasanguinis. There were also significant differences in the gut microbiome function between the two groups of patients. When irAEs occur, the patient's gut microbiome plays a greater role in physiological functions such as nucleotide and lipid metabolism, intracellular trafficking, secretion, vesicular transport, and extracellular structure. In carbohydrate metabolism, when irAEs occur, the patient's gut microbiome plays a greater role in glycoside hydrolases.

Conclusions: This study suggests that lung cancer patients with irAEs have unique gut microbiome characteristics, which may serve as potential biomarkers for diagnosing and predicting irAEs.

P2.14A.01 Clinicopathological Characteristics and Treatment Outcomes of Patients with Advanced SMARCA4-Deficient Non-Small Cell Lung Cancer

h. liu, Q. Hong, L. Cai

Sun Yat-sen University Cancer Center, Guangzhou/CN

Introduction: SMARCA4/BRG1-deficient non-small lung cancer (SD-NSCLC) has distinct clinicopathological and genomic features from classical NSCLC with high invasiveness and poor prognosis, which is associated with primary resistance to standard treatment, especially in late-stage patients. Therefore, we designed this retrospective study focusing on stage III/IV and supposed to clarify the profiles and find the treatment response effects from immunotherapy and local treatment for these SD-NSCLC patients.

Methods: 53 SD-NSCLC patients in stage III/IV with follow-up time longer than 6 months from 110 consecutive patients diagnosed with SAMRCA4/BRG1 deficiency by immunohistochemistry at Sun Yat-sen University Cancer Centre from May 2019 to May 2023 were included in this study. We assessed the clinicopathological features of the patients and grouped them based on their treatments: ICIs (n=39) and non-ICIs(n=14), or with local treatment (including radiotherapy or surgery) (n=23) and without local treatment (n=30). Further, we conducted stratified analysis according to TNM stage to compare prognostic differences between groups.

Results: 94.3% (50/53) of the patients were male, with an average age of 59.3 years. 71.7% (38/53) of them had a smoking history, and 54.7% (29/53) were stage IV. Histologically, 84.9% (45/53) of the patients exhibited poorly differentiated carcinomas, 50.9% (27/53) were NSCLC not otherwise specified and 45.3% (24/53) were adenocarcinomas. 62.5% (20/32) of the patients had positive PD-L1 expression and 71.4% (15/21) had high tumor mutation burden (>=10 mut/Mb). Next-generation sequencing (NGS) was performed in 39.6% (21/53)of the patients. The most common mutations included TP53 (85.7%, 18/21), followed by SMARCA4(61.9%, 13/21), LPR1B (52.4%, 11/21), KEAP1 (23.8%, 5/21), STK11(19.0%, 4/21). Regimens containing ICIs significantly improved median progression-free survival (mPFS) than non-ICIs in

the stage IV SD-NSCLC patients (7 vs. 3 months, P=0.021), the median overall survival (mOS) also showed a longer trend (not reached vs. 15 months, P=0.107). While in stage III and overall patients, the mPFS and mOS did not differ significantly (P>0.05). Patients in stage III who received local treatment had a significantly longer mPFS than those who did not (9 vs. 2 months, P=0.012), although the difference in mOS did not reach significance (27 vs. 17 months, P=0.753). In stage IV and overall patients, local treatment did not markedly improve mPFS and mOS (P>0.05).

Conclusions: Combination therapy with ICIs may be an effective strategy for advanced SD-NSCLC patients and local treatment also has certain significance for locally advanced patients.

P2.14A.02 Assessment of Immunohistochemical Panel Utilization in Thymic Carcinoma Diagnosis: Real World Experience Insights

N. KATARIA, I. VEYTSMAN

MedStar Washington Hospital Center, Washington/DC/USA

Introduction: Thymic tumors originate from the thymic epithelium and exhibit aggressive tumor invasiveness and a high potential for metastasis. These Thymic Epithelial Tumors (TETs) display distinct biological functions, histological findings, and genomic profiles. Thymic carcinomas represent approximately 20% of all TETs. Among the various histologic subtypes recognized by the World Health Organization (WHO), Thymic Squamous Cell Carcinoma (TSCC) is the most prevalent, accounting for 70-80% of cases. Despite advancements, the mortality rate of thymic cancer remains in the top 10 among chest tumors. Although clinical, radiological, and morphological features can aid in distinguishing between thymic carcinomas and Non-Small Cell Lung Cancers (NSCLCs), differentiation can sometimes pose challenges. Instances arise where shared histologic and radiological features blur the lines between NSCLC and thymic carcinoma. Surgical resection is the preferred treatment for TETs where feasible. However, inoperable cases necessitate accurate preoperative diagnosis for appropriate treatment decisions, such as chemotherapy. Immunohistochemistry (IHC) plays a crucial role in diagnosing small biopsied specimens, with the WHO recommending a specific IHC panel: Positive immunostaining for CD5, KIT (CD117), FOXN1, and/ or CD205. This study aims to explore the utilization of the recommended IHC panel by pathology departments across the Hospitals of the MedStar Network, considering that it is not routinely performed and is conducted only upon request from treating physicians.

Methods: Data collection for this study utilized the MedStar Georgetown Cancer Centre Network registry. Two Electronic Health Record (EHR) software platforms, namely MedConnect and Centricity, were employed to extract data. Initially, all patients diagnosed with thymic tumors between January 1, 2003, and December 31, 2023, were included. Subsequently, ICD-9 (164) and ICD-10 (C37) codes were utilized to identify cases of TSCC. Specific immuno-histochemical markers pertinent to TSCC, including CD-5, CD-117, p-63, and p-40, were further retrieved and subjected to analysis.

Results: A total of 364 cases of thymic tumors of any pathology were identified within the designated time frame using the MedStar Georgetown Cancer Centre Network registry database. Among these, only 29 patients received a confirmed diagnosis of TSCC. Notably, the IHC marker p-63 was tested in 21 out of 29 patients, CD-117 in 13 out of 18, CD-5 in 14 out of 20, and p-40 in 6 out of 16 cases of TSCC where testing was indicated. FOXN1 and CD 205 were not tested in any.

Conclusions: Despite WHO recommendations for testing all thymic carcinomas for specific IHC profiles, our study reveals that only a fraction of tumors undergo testing for these specific panels. Moreover, this testing is not standard practice among pathologists in our institutions and is conducted solely upon request from treating physicians. This practice may lead to misdiagnosis of lung cancer or missed diagnoses of thymic carcinoma, emphasizing the critical importance of accurate diagnosis due to the variability in treatment regimens for different cancers. Our next steps involve engaging with the pathology department to institute reflex testing based on suspicion of thymic cancer.

1Royal Brompton and Harefield Hospitals, London/GB ,2Royal Marsden NHS Foundation Trust, London/GB ,3Mount Vernon Cancer Centre, London/GB

Introduction: 9th edition of TNM classification (TNM9) for thymic epithelial tumours has been proposed. The primary aim of this study is to develop a predictive model for post-surgical recurrence by incorporating routinely available clinicopathological parameters and TNM9. The secondary aim of the study is to identify a subpopulation of patients with very low risk of recurrence.

Methods: This is a single institutional, retrospective study including all thymic epithelial tumours underwent surgical resection with curative intent during a 31-year period (1991-2022), regardless of the resection status. Variables related to the clinical (age, sex), histopathological (histological subtype, lymphovascular invasion, tumour necrosis, resection status), staging (TNM9 final stage) and peri-operative treatment domains were retrieved from an institutional thymoma database. Survival analysis was performed using univariate and multivariate Cox regression, and variables predictive of recurrence with P<0.05 in univariate setting were included in multivariate analysis. Variables predictive with P<0.05 in multivariate analysis were used to develop a point-based predictive model, and the weight of each individual variable was based on its effect size in the former.

Results: This study includes a total of 436 cases, with a documented recurrence rate of 12.6% (55/436). Thymoma, thymic neuroendocrine tumour and thymic carcinoma comprise 90.8% (396/436), 3.4% (15/436), 5.7% (25/436) of cases respectively. In univariate setting, age (≤65 years), histological subtypes other than type A/AB/metaplastic or multinodular thymoma with lymphoid stroma (MNT), presence of lymphovascular invasion or tumour necrosis, TNM9 final stage II-IV, incomplete resection (R1/R2) and the administration of neoadjuvant or adjuvant therapy were associated with higher rates of recurrence. In multivariate setting, histological subtype, tumour necrosis, TNM9 final stage and resection status were independent predictors of recurrence. A four-tier recurrence risk group derived from these four independent variables stratified patients into very low (1.0%), low (6.7%), intermediate (28.1%) and high (44.1%) risks of recurrence, with AUC of 0.859 (95% CI 0.812-0.906, P<0.001). These risk groups also showed statistically significant associations with recurrence free survival. Patients with very low risk of recurrence represented just under half of the study population (47.5%), with estimated 5-year and 10-year recurrence free survival rates of 100% and 98.2% respectively.

Conclusions: In this study, we developed a practical predictive model of post-surgical recurrence for thymic epithelial tumours and refined the proposed TNM9 classification by identifying a very low risk group. This model permits risk-based patient stratification, post-surgical management and follow-up, and potentiates de-escalation strategies. Independent validation of our findings is warranted.

P2.14A.04 Mapping the Distribution of Ectopic Thymus Through Flow Cytometry Analysis of CD3mediumTCRvßmediumCD4+CD8+ T Cells

Y. Ao1, J. Gao1, J-h. Jiang1, S. Wang1, C. Jin2, H. Wang3, J. Ding1

1Zhongshan Hospital Fudan University, Shanghai/CN ,2Changhai Hospital Naval Medical University, Shanghai/CN ,3University of Chinese Academy of Sciences, Shanghai/CN

Introduction: Accurately mapping the distribution of ectopic thymus (ET) is crucial for determining the appropriate extent of surgery for myasthenia gravis (MG). However, traditional histological methods for identifying ETs have significant limitations, including time-consuming procedures, inadequate specimen yield, and a risk of false negative results. This study aims to evaluate the effectiveness of flow cytometry in detecting ETs in patients undergoing total thymectomy.

Methods: A total of 864 samples from 103 patients were assessed at our center using flow cytometry analysis and Hematoxylin and eosin (H&E) staining. Tissues showing the presence of CD4+CD8+ T cells in flow cytometry or Hassall's corpuscles in H&E staining were considered ETs. We calculated the prevalence of ETs and conducted comparisons between different patient groups based on various clinical characteristics.

Results: In the discovery set, flow cytometry was able to identify ETs in 69.2% of samples, while standard histological methods only detected 23.6%. Our validation set revealed a higher incidence of ETs in MG patients compared to non-MG patients (73.5% vs. 58.0%, p < 0.0001), as well as in patients with thymic epithelial tumors compared to those with a normal thymus (68.1% vs 58.1%, p = 0.0088). We also found that MG patients had a higher prevalence of active ETs, characterized by a high proportion of CD4+CD8+ T cells indicating robust thymopoiesis. Furthermore, ETs were more frequently observed in the cervical region than the mediastinum region (75.0% vs. 60.8%, p = 0.0012), and in patients aged ≤ 40 years compared to those over 40 years old (73.0% vs. 60.6%, p = 0.0027).

Conclusions: Our findings emphasize the reliability of flow cytometry as an alternative method for detecting ETs, overcoming the limitations of traditional histological examination. Moreover, we provide a novel distribution map of ETs based on this approach, offering valuable insights to enhance surgical decision-making in MG treatment.

P2.14A.05 Validity of Simple Thymomectomy for Clinical Stage I Thymoma without Myasthenia Gravis: A Propensity Score-Matched Analysis

T. Hishida, T. Suzuki, S. Omura, Y. Okubo, K. Masai, K. Kaseda, K. Asakura

Keio University School of Medicine, Tokyo/JP

Introduction: Total thymectomy (TT) has been traditionally recommended as a standard mode of resection for thymic epithelial tumors. In recent years, simple thymomectomy (ST) has been growing trend in early-staged thymomas without myasthenia gravis (MG). However, due to no completed prospective trials, current international guidelines still recommend TT for all thymomas. The aim of this study is to access the surgical outcomes and the validity of ST in comparison with TT for clinical stage I non-myasthenic thymoma.

Methods: We conducted a retrospective analysis of clinicopathological data from 119 patients who underwent either ST or TT for non-myasthenic thymoma with clinical stage I disease (cT1N0M0 in the 8th edition of TNM staging system) between 2003 to 2018 at our institution. The mode of resection was determined by a multidisciplinary treatment board, with recent trend favoring ST for tumors measuring 5 cm or less. Surgical outcomes following each resection were evaluated, and a one-by-one propensity score (PS)-matched analysis was performed to reduce potential biases.

Results: Among the cohort, 50 patients (42%) underwent ST, while 69 patients (58%) underwent TT. The ST group more frequently received thoracoscopic approach (62% vs. 14%). Additionally, the ST group showed shorter operative times (median, 86 vs. 175 minutes) and lower rates of operative morbidity (CTCAE ≥grade 2, 2% vs. 9%) compared to the TT group. Median postoperative follow-up duration was 7.0 years (range, 0.1 to 19.2). Recurrence-free and overall survival (RFS and OS) did not significantly differ between the two groups (5-year RFS: 93.3% in ST and 95.2% in TT, p = 0.518; 5-year OS: 93.2% in ST and 98.5% in TT, p = 0.289). PS-matched analysis involving 40 patients in each group revealed comparable RFS (p = 0.342) and OS (p = 0.540) (Fig 1). Recurrence was observed in 3 patients from each group, and all of whom had tumor of ≥5 cm on preoperative CT scans. In the subgroup with tumor ≥5 cm tumor, the ST group had a higher recurrence rate (38% vs. 10% in the TT group). Postoperative autoimmune disease including MG did not occur in the ST group.

Conclusions: ST is less invasive alternative to TT and is deemed acceptable for clinical stage I thymoma without MG, considering both oncological and immunological aspects. However, caution should be exercised regarding the increased risk of recurrence in case of large tumors (>5cm) following ST. Further prospective studies are needed to confirm the present findings.

P2.14A.06 Diaphragmatic Plication in Surgery for Complex Mediastinal Tumor

Y. Yuan

Shanghai Jiao Tong University School of Medicine, Shanghai General Hospital, Shanghai/CN

Introduction: Complex mediastinal tumor (CMT) referred to tumor that invades important mediastinal structures such as major blood vessels and nerves. In patients with CMT invading the phrenic nerve, some may present with preoperative diaphragmatic elevation, the other may suffer phrenic nerve damage during surgery, resulting in diaphragmatic elevation, which can lead to severe respiratory distress. For these patients, diaphragmatic plication can effectively lower the diaphragm.

Methods: We use endoscopic linear cutter stapler for diaphragmatic plication. First, we clamp the diaphragmatic apex to elevate it, and use another clamp to push down the abdominal contents. Following this, 6cm staplers are used for diaphragmatic plication, with a minimum width of 2cm and an average length of 10-20cm. For patients with thin diaphragms or oozing of blood, a 4-0 polypropylene suture is used for reinforcement.

Results: From 2020 to 2024, a total of 49 patients with CMT underwent intraoperative diaphragmatic plication by our team. There were 33 males and 16 females, with an average age of 49.9 years old. All patients underwent radical resection of mediastinal tumors. The main reason for intraoperative diaphragmatic plication was the inseparability or injury of the phrenic nerve, which accounted for 41 cases. Additionally, 13 patients had preoperative imaging findings of diaphragmatic elevation. Regarding the safety, no patient underwent reoperation during postoperative period. There were 6 postoperative deaths and 5 patients who experienced postoperative complications. The occurrence of postoperative complications and deaths was mainly associated with surgery for CMT, not with diaphragmatic plication. In terms of effectiveness, 11 patients with preexisting elevated diaphragm returned to normal. For other 34 patients, diaphragmatic plication was performed as a preventive measure due to the inseparability or injury of the phrenic nerve during surgery, and there was no postoperative diaphragmatic elevation observed. Therefore, a total of 45 patients were considered effective (91.8%). Among these 45 patients, 9 patients had recurrent diaphragmatic elevation during follow-up (20%). Furthermore, we performed remedial diaphragmatic plication for 3 patients with postoperative diaphragmatic elevation and respiratory distress followed by CMT surgery, and the effect was remarkable.

Conclusions: Diaphragmatic plication was safe and feasible for patients underwent surgery for CMT, although there was a certain chance of recurrence.

P2.14A.07 Learning Curve Analysis of Near-Infrared Fluorescence-Guided Robotic-Assisted Minimally Invasive Esophagectomy with Indocyanine Green Dye

Y.S. Patel, J. Agzarian, W.C. Hanna

McMaster University, Hamilton/ON/CA

Introduction: Robotic-Assisted Minimally Invasive Esophagectomy (RAMIE) using near-infrared fluorescence (NIF)-guided perfusion analysis with indocyanine green dye (ICG) is a novel technique for esophagectomy. We aimed to determine the number of cases required to reach technical proficiency at the first Canadian centre.

Methods: Patients with esophageal cancer who were candidates for esophagectomy were enrolled from 03/2022-03/2024 at one site in this prospective single-arm feasibility trial. Participants underwent RAMIE via a two-stage approach: abdominal stage via 5-port robotic approach, and thoracic stage via 5-port robotic approach. NIF-guided perfusion analysis with ICG was used to verify the course of the right gastro-epiploic artery in the abdominal stage, and to confirm the optimal location and perfusion state of the anastomosis in the thoracic stage. The anastomosis was constructed with a hand-sewn 2-layer technique. The learning curve was evaluated using the cumulative sum (CUSUM) method, with operative time as the quantitative metric.

Results: Of 18 patients enrolled, 11.11%(2/18) were withdrawn: one RAMIE was aborted due to hemodynamic instability; and the other due to conversion to laparotomy because of intra-abdominal adhesions. Median age was 68.5(IQR:58-71.5) and 93.75%(15/16) were men. Mean procedure time was 384.38(SD:57.10) minutes. ICG was used successfully in 100%(16/16) of cases: perfusion was detected with a green hue by NIF in both stages of the operation with clear identification of poorly perfused segments of the conduit. CUSUM analysis did not reveal an inflection point (Figure 1). Median length of stay was 8(IQR:7-11) days. Grade IVa complications occurred in 3 patients (3/16;18.75%): one patient experienced hemorrhagic shock; a second had a tracheoesophageal fistula within 90 days; and a third had an anastomotic leak requiring readmission to hospital.

Conclusions: CUSUM analysis of the first 16 cases did not reveal an inflection point, meaning the number of cases required to attain proficiency has not been reached yet.

Introduction: Thymic epithelial tumors (TETs) are rare malignant tumors with limited treatment options. No standard 2nd-line treatment is available following the preferred 1st-line chemotherapy, resulting in limited outcomes and poor prognosis. This study aimed to evaluate the efficacy of tyrosine kinase inhibitors (TKIs) in Latin America as well as some prognostic factors for advanced TETs.

Methods: A retrospective study was conducted using data from a CLICaP real-world database. Patient demographics, tumor genomics, and treatment outcomes were analyzed. Survival analyses were performed to assess progression-free survival (PFS) and overall survival (OS). Clinicobiological features and treatment outcomes with TKIs alone or in combination with immunotherapy were evaluated.

Results: 34 patients with confirmed histological diagnosis of thymic carcinoma were included. Median age at diagnosis was 52 years with a female representation of 35% (n=12). 32 patients (94%) presented symptoms at diagnosis with 6 (19%) experiencing myasthenia gravis. Furthermore, 20 individuals (59%) had familial history of cancer. With regards to staging, one patient (3%) was diagnosed at stage IIIB, 10 at IVA (29%) and the remainder at IVB (63%). Regarding pathological characteristics, CD117 immunohistochemistry was performed in 24

cases of which 16 (66%) were positive. Molecular characteristics revealed a mean TMB of 2.4 mut/Mb and PD-L1 expression >1% in 53% of cases. Mutations were identified in 24 cases. The most commonly mutated gene was TP53 in 16 (67%). Other mutations were identified in TET (n=2, 8%), PIK3CA (n=2, 8%) and KIT(n=2, 8%). CNV in the form of amplifications was found for CCND2 (n=2, 8%), AKT3 (n=2, 8%), and FGF (n=3,13%), whereas deletions were detected in MTAP (n=3,13%), and CDK4 (n=2, 8%). Considering treatment, Lenvatinib was administered to 21 patients (62%), sunitinib to 10 (24%), Lenvatinib pembrolizumab in 2 (6%), and everolimus to one (3%). TKI was offered as a second line in 21 patients (62%), a third in 7 (21%), and a fourth in 6 (17%). The best responses were partial in 5 patients, with an overall response rate of 15%. All responders were given TKIs as a second-line treatment. 19 achieved disease stabilization (56%). Regarding PFS, a median of 5.88 months (95%CI 4.73-7.47 months) was reached. Median OS was 53,7 months (95%CI 34 months-NR). Earlier treatment lines favored better PFS, with patients treated with TKI as a fourth line reaching a median of 1.28 months compared to 5.97 months as a second and 6.33 months as a third line (p<0.001).

Conclusions: These findings suggest that TKIs are efficacious as second or post-line treatments and represent a viable treatment option for Hispanic patients with advanced TETs.

P2.14A.09 Adaptive Reprogramming of Arginine Biosynthesis is an Attractive Target for Modulating the Response to WEE1 Inhibition in Pleural Mesothelioma

S. Yin1, R.A. Schmid2, R-W. Peng2, D. Xu1, Y. Shu1

1The First Affiliated Hospital of Nanjing Medical University, Nanjing/CN ,2Bern University Hospital, Bern/CH

Introduction: Pleural mesothelioma is a rare but highly aggressive thoracic malignancy with an extreme shortage of treatment options. Platinum-based chemotherapy has long been the first-line therapy for patients with advanced pleural mesothelioma. Our previous study revealed that chemotherapy resistance in pleural mesothelioma is closely related to high WEE1 expression. Moreover, subsequent whole-genome CRISPR-Cas9 screening indicated that WEE1 may be a genetic vulnerability for pleural mesothelioma. However, our preliminary results revealed heterogeneity in the drug sensitivity of mesothelioma cell lines to WEE1 inhibitors, highlighting the importance of uncovering the underlying mechanisms of WEE1 inhibitor resistance.

Methods: In this study, we first selected pleural mesothelioma cell lines (H28 and MSTO-211H) sensitive to WEE1 inhibition based on a cell viability assay and induced drug resistance by chronic exposure to AZD1775 (MK-1775), a WEE1 kinase inhibitor, for 3 months. Moreover, unbiased transcriptomics and metabolomics profiling were applied to both parental and resistant mesothelioma cell lines. Furthermore, joint pathway analysis via transcriptomics and metabolomics assays was performed to decipher the molecular basis underlying WEE1 inhibitor resistance. In parallel, subsequent in vitro functional studies were performed to validate the biological function of the above-identified molecular alterations.

Results: Intriguingly, we showed that the adaptive reprogramming of arginine biosynthesis, a characteristic metabolic phenotype of pleural mesothelioma, is the major molecular alteration in resistant mesothelioma cells. Further exploration revealed that chronic exposure to a WEE1 inhibitor increased circulating arginine levels but was accompanied by significant downregulation of arginosuccinate synthase 1 (ASS1), which generally lacks the ability to convert citrulline back to arginine. Consistent with these findings, subsequent functional validation confirmed that the depletion of arginine in culture medium improved the drug response to WEE1 inhibition in mesothelioma cell lines through the induction of extensive DNA damage and apoptosis.

Conclusions: Our work thus provides the molecular basis for WEE1 inhibitor resistance while providing targetable metabolic vulnerability to enhance the antitumor response to WEE1 inhibition in patients with pleural mesothelioma.

P2.14A.10 Real-World Evidence of Ipilimumab Plus Nivolumab Combination Therapy in Patients with Malignant Pleural Mesothelioma

T. Kondo, T. Otsuki, M. Kato, T. Murata, M. Mori, H. Ota, H. Wakita, T. Kandori, J. Kiyota, T. Higashiyama, M. Tokuda, A. Tada, Y. Negi, D. Horio, D. Fujimoto, K. Mikami, R. Takahashi, T. Minami, K. Kuribayashi, T. Kijima

Hyogo College of Medicine, Nishinomiya city, Hyogo prefecture/JP

Introduction: Recent clinical studies have demonstrated the efficacy of immune checkpoint inhibitors (ICIs) for malignant pleural mesothelioma, and the ipilimumab plus nivolumab combination therapy was approved as standard therapy in Japan in 2021, following the approval of nivolumab in 2018. Thus, immune checkpoint inhibitors are expected to play a central role in the treatment of MPM. However, the safety and effectiveness in actual clinical practice consisting of many patients with poor tolerance to anticancer drugs, have not been fully investigated due to the limited number of the cases.

Methods: We retrospectively analyzed 55 patients with MPM who treated with ipilimumab plus nivolumab combination therapy at our institution from June 2021 to March 2023. Objective response rate (ORR) and disease control rate (DCR) were evaluated by modified RECIST ver 1.1. Survival curves were plotted with the Kaplan-Meier method and compared using the log-rank test. Adverse events were graded according to the CTC-AE ver 5.0.

Results: Patients' backgrounds were as follows: the median age was 72 years (range 45-88), the number of male/female was 42 / 13 and patients with ECOG performance status (PS) grade of 0-1 / ≥2 was 53 / 2. The respective number of the patients with epithelioid / sarcomatoid / biphasic / desmoplastic subtype was 35 / 13 / 6 / 1. Immune-related adverse events (irAEs) were observed in 38 patients. Regarding the effectiveness, the median progression free survival (PFS) was 12.4 months and overall survival (OS) was not reached to the median. ORR and DCR were 40.0% and 81.8% respectively. Regarding PFS of the patients, no significant difference was observed in ages (> 75 years old vs < 75 years old) and histological subtypes (epithelioid vs non-epithelioid). On the other hand, it was significantly longer in the patients with better PS (P≤0.0001) or in those who developed irAEs of any grade (P=0.01).

Conclusions: Ipilimumab plus nivolumab combination therapy was a safe and effective treatment for the entire patient population of MPM with good PS in real-world clinical practice.

P2.14A.11 Real-World Immunotherapy Use in Pleural Mesothelioma: Insights & Immunological Landscape

X. Xu1, J. Shou2, D. Wang3, L. Ye4, Y. Fang2, M. Fang3, W. Mao5

1Shanghai Pulmonary Hospital, Shanghai/CN ,2Sir Rung Rung Shaw Hospital, Hangzhou/CN ,3Zhejiang Cancer Hospital, Hangzhou/CN ,4Wenzhou Medical University, Hangzhou/CN ,5Chinese Academy of Sciences, Hangzhou/CN

Introduction: Pleural mesothelioma (MPM), a malignancy arising from the pleural tissue, represents a rare yet aggressive tumor. While immunotherapy has shown considerable efficacy in this disease, its real-world utilization remains inadequately characterized. Moreover, there is a paucity of knowledge regarding the precise effects of immunotherapy on specific cellular subpopulations within the immune microenvironment.

Methods: We collected data from over 10 centers nationwide, comprising information from 287 patients, among whom 47 received either single-agent or combination immunotherapy. Clinical pathological information and survival data of malignant MPM patients undergoing immunotherapy were gathered. Immunological changes within the tumor tissues and normal pleura were assessed using multiplex immunofluorescence in 21 MPM patients, focusing on dendritic cells (DCs) , macrophages, lymphocytes, and immune checkpoints such as LAG3 and TIGIT. Additionally, single-cell sequencing was performed on tissue samples from three MPM patients before and after immunotherapy resistance.

Results: The median overall survival time for the 47 patients who received immunotherapy was 19.93 months, significantly higher than survival times reported in previous eras of chemotherapy (Figure 1). Additionally, we developed an organoid model to simulate immune resistance following immunotherapy (Figure 1). The number of DCs in the tumor microenvironment of MPM significantly decreased (P<0.05). Among them, ten patients had specific tissue samples before and after immunotherapy resistance, with multiplex immunofluorescence revealing a marked reduction in DCs and macrophages (P<0.05). Furthermore, comparative single-cell sequencing of tissue samples from three MPM patients before and after immunotherapy demonstrated a significant decrease in DCs and NKT following the development of resistance (P<0.05).

Conclusions: Hence, we consider the efficacy of immunotherapy in real-world settings for MPM patients satisfactory, recommending the proactive application of immunotherapeutic agents. During immunotherapy, DCs and other immune cells play crucial roles, warranting in-depth mechanistic research.

for Medical Genomics, Indianapolis/IN/USA ,6Department of Biostatistics and Health Data Science, Melvin and Bren Simon Comprehensive Cancer Center, Indiana University School of Medicine, Indiana Bioscience Research Institute, Indianapolis/IN/USA

Introduction: Chemotherapy has been the standard of care for mTET in the past few decades. Herein, we aimed to develop a stepwise pipeline to identify potential cell surface targets suitable for immune-based therapy in mTETs.

Methods: From 2015 to 2020, 21 patients with stage IV TETs underwent clinical CLIA-based RNA sequencing (Discovery cohort). Using transcriptomic data from discovery cohort, we employed an integrated cell surface computational platform that predicts cell surface protein expression. To overcome the limitations of bioinformatic prediction, the expression of potential candidate proteins was validated through immunohistochemistry (IHC) in a tissue array of 97 mTETs and 35 normal tissues.

Results: Through RNA-Sequence of discovery cohort, we identified highly expressed transcripts in mTET. Among 60,908 transcriptomic pools screened, 10 potential targets were identified through a stepwise process. Final targets had expression in both thymoma and thymic carcinoma and no expression in vital organs in the proteomic database. In validation cohort, IHC of the targets, which included ABCG1, ANO9, CLDND1, COL17A1, and GRAMD1A revealed that COL17A1 had the highest protein expression in 66% of TETs and no significant expression in vital organs. Patients with COL17A1 expression had significantly worse overall survival compared to patients with negative TETs (n=90, HR 6.2, p<0.001). The spatindicatesriptomic analysis of a separate cohort showed moderate co-localization of T-cell markers with COL17A1 indicating the potential immunogenic nature of this protein.

Conclusions: We identified several highly expressed transcripts in mTET, among which COL17A1 protein stands out as a potential candidate. COL17A1 transcriptomic and proteomic profile, coupled with its impact in clinical outcome and immunogenicity makes it an attractive target candidate for therapeutic intervention.

P2.14A.13 Discovery and Clinical Application of Potential Prognostic Genes for Clinical Outcome in Malignant Pleural Mesothelioma

T. Kato, S. Okado, H. Huang, Y. Imamura, Y. Nomata, H. Watanabe, Y. Kawasumi, Y. Kadomatsu, H. Ueno, S. Nakamura, T. Mizuno, T.F. Chen-Yoshikawa

Nagoya University, Nagoya/JP

Introduction: Malignant pleural mesothelioma (MPM) is a disease with a very poor prognosis. Although we have experienced cases of long-term survival after surgery, some cases are difficult to treat surgically due to the large invasiveness. Recently, the results from the MARS 2 trial comparing the efficacy of surgery versus no surgery in the treatment of MPM were presented, and there was no significant difference in survival time between the two groups. Here, through comprehensive genetic analysis, we attempted to identify new prognosis-related genes to consider the indications for surgical treatment.

Methods: Gene expression and survival data of TCGA MPM dataset (n=85) were used. We applied a Cox proportional hazards model with overall survival and performed multiple testing (FDR 1%) on all 20,532 genes to obtain prognostic genes. Using the identified genes, we performed cluster analysis, Kaplan-Meier analysis, and gene ontology analysis to examine the clinicopathological significance of prognostic genes. To validate the relationship between selected gene expression and prognosis, we performed an immunohistochemical (IHC) analysis in 23 specimens from surgically treated patients with MPM who achieved macroscopic complete resection in our hospital.

Results: Cox multivariate analysis identified 1246 out of 20532 genes as prognostic genes. The 85 cases were divided into two clusters by consensus clustering based only on the expression level data of the above genes. Median survival times for each cluster were 31.2 and 12.7 months, with significant differences determined by log-rank test ($P < 0.001$). Comparison of histological subtypes between 2 groups revealed significant differences between groups ($P = 0.009$), however, the poor prognosis group also included many epithelial types. Analysis of the worse prognostic genes showed that the highest-ranked statistical enrichment was associated with the GO mitotic cell cycle ($Log10(P) = -67.03$). On the other hand, for the better prognostic genes, the terms list showed that the highest-ranked enrichment was associated with the GO defense response to the virus ($Log10(P) = -9.66$). From the comprehensive survival analysis, we identified CHST4 gene as a potential predictor of favorable overall survival for patients with MPM. We performed IHC using CHST4 for 23 MPM specimens and the median overall postoperative survival was 107.8 months in the high-expression-group and 38.0 months in the low-expression-group ($P = 0.044$, Figure)

Conclusions: Comprehensive analysis of TCGA MPM dataset made it possible to identify prognostic gene groups, suggesting the possibility of creating a new disease type classification and deciding the indication of surgical treatment.

Introduction: Studies have demonstrated survival benefit of immune checkpoint inhibition (ICI) compared to chemotherapy (chemo) for the management of unresectable mesothelioma. CheckMate 743 established ipilimumab/nivolumab (I/N) as the front-line standard of care. There is a need to integrate real-world data with clinical trial data to further understand patient outcomes outside of clinical trials.

Methods: We conducted a multi-center retrospective analysis of characteristics and outcomes of patients diagnosed with mesothelioma between 1/1 2016 - 8/30/2023 and treated with I/N in the front-line setting (FL) or after progression (PL). Clinical endpoints included progression free survival (PFS), overall survival (OS), overall response rate (ORR) and ICI related adverse events (IrAEs) defined using CTCAE 5.0.

Results: We identified 126 patients who received I/N (FL=90, PL=36). The median (m) age in the FL and PL groups was 73 yrs and 65 yrs respectively. Most patients were male (FL=81%, PL=69%), white (94%), and with an ECOG performance status of 0 or 1 (FL=83%, PL=97%). Most patients had pleural (FL=91%, PL= 75%) or peritoneal (FL= 8%, PL= 25%) mesothelioma. Histological subtypes were epithelioid (FL= 59%, PL= 83%), biphasic (FL=21%, PL=8%) and sarcomatoid (FL 19%, PL= 6%). BAP1 loss was identified by either IHC or NGS in 34% (FL) and 39% (PL) of patients. There was no significant difference in PFS between the two groups (mPFS, FL= 7.9 months (mos), PL= 8.4 mos; HR= 0.94; 95% CI, 0.59-1.5; p=0.67). No significant difference in OS between two groups was found (mOS, FL= 14.83 mos, PL= 28.90 mos; HR=0.51; 95% CI, 0.28-0.92; p=0.49). When comparing PFS of patients receiving 1st line chemo (n=33) to the FL group, no difference was noted (mPFS, chemo= 4.5 mos, FL= 7.9 mos; HR=0.31; 95% CI, 0.49-1.18; p=0.14). Among patients with evaluable responses, the ORR was 44% (35/80) and 42% (13/31) in the FL and PL groups respectively. IrAEs were observed in 44% and 56% of the FL and PL groups respectively. Grade 3/4 IrAEs accounted for 25% and 40% of toxicities in the FL and PL groups respectively. The treatment discontinuation rate due to IrAEs in the FL group was 21% and was 25% in the PL group.

Conclusions: No statistically significant differences in survival outcomes were noted between FL vs PL groups. However, more irAEs including grade 3 or 4 toxicities were noted in the PL group bringing to light the potential benefit of upfront I/N rather than upon progression on systemic chemo in-terms of tolerability. This is the first real world study conducted in the US evaluating the outcomes of patients with unresectable mesothelioma.

P2.14B.01 [DREAM] Double Lung Transplant Registry Aimed for Lung-limited Malignancies - A Prospective Registry Study for Medically Refractory Cancers

Y.K. Chae, L.I-Y. Chung, T. Demir, C. Moloney, B. Sanson, R. Dwyer, C.M. Jung, R. Tomic, A. Bharat

Northwestern University, CHICAGO/IL/USA

Introduction: Adenocarcinoma in situ (AIS) and minimally invasive adenocarcinoma (MIA) are listed as 'special circumstances' for lung transplantation according to a consensus document from the International Society for Heart and Lung Transplantation (ISHLT). Five studies have reported on lung transplantation in carefully selected subsets of patients with multifocal lung adenocarcinoma. The 5-year survival rate of bilateral sequential lung transplantation was estimated at over 50% in patients with multifocal BAC, invasive adenocarcinoma, and NSCLC. Moreover, there is an unmet need for patients who have lung-limited metastasis after successful treatment for primary tumors such as sarcomas or colorectal cancer (CRC). As with liver transplantation for CRC patients who have liver-confined metastases, the applicability of lung transplantation in lung-limited metastatic patients should be explored. There is also an unmet need for patients with respiratory failure with a history of cancer in the last 5 years.

Methods: This is a prospective registration trial to evaluate outcomes of patients who undergo double lung transplantation for the treatment of the select groups of medically refractory cancers (primary lung cancers or metastatic cancers in lungs). Overall survival (OS), disease-free survival (DFS), allograft rejection (AR) and allograft survival (AS) as well as molecular and genetic biomarkers will be studied. The study duration will be 10 years including surveillance. The goal is to enroll 125 participants through the Northwestern Medicine Clinical Programs. Essential Criteria: 1. The tumor should be without any extrapulmonary metastasis as determined by standard of care diagnostic and staging workup. 2. All standard of care or experimental oncological treatments known to improve survival should have failed or deemed infeasible 3. Patients should meet the general criteria for lung transplant evaluation and listing Study cohorts: • Cohort A: Primary lung cancers - Examples include, but not limited to, invasive mucinous/non-mucinous non-small cell lung cancers and multifocal carcinomas. • Cohort B: Metastatic cancers to the lung only - Examples include, but not limited to, germ cell tumors, head & neck tumors, colorectal tumors, renal cell tumors, testicular cancers. • Cohort C: Respiratory failure with a history of cancer in the last 5 years- Examples include, but not limited to interstitial lung disease (ILD), pulmonary fibrosis (idiopathic or secondary), advanced chronic

obstructive pulmonary disease (COPD), bronchiectasis, emphysema, cystic fibrosis (CF), emphysema due to alpha-1 antitrypsin deficiency, and pulmonary arterial hypertension (PAH) Clinical trial registry number : NCT05671887. Enrollment began November 16, 2022. Trial is open and continues to enroll participants as of April 5, 2024.

Keywords: Lung Cancer, Double Lung Transplantation, Lung Transplantation

P2.14B.02 Application of Chemokine Receptor 4 Targeted 68Ga Pentixafor in Evaluation of Thymic Epithelial Tumors (TETs): A Prospective Study

X. Gao, R. Wang, X. Peng, X. Zhou, C. Guo, S. Li, Z. Zhu, Y. Chen

Peking Union Medical College Hospital, Beijing/CN

Introduction: Recently the correlation between C-X-C chemokine receptor 4 (CXCR4) overexpression with poor prognosis in thymic epithelial tumors (TETs) with myasthenia gravis has been reported. This pilot study was designed to evaluate the use of 68Ga-Pentixafor PET/CT, which targets CXCR4, in the non-invasive diagnosis of TETs.

Methods: With institutional review board approval and informed consent (NCT06086327), a total of 22 patients with suspected TETs (mean age ± SD, 53 ± 12.8 y; 8 men) were enrolled in this prospective pilot study up to now. All patients underwent 68Ga-Pentixafor PET/CT scans at 37 ± 9.5 minutes after injection of approximately 3.7 ± 0.8 mCi of 68Ga-Pentixafor, and the PET/CT outcomes were compared with operation pathology. The expression level of CXCR4 gene was analyzed using bulk RNA-seq in TETs and normal thymus tissues. Cellular localization of CXCR4 was evaluated using single nuclei RNA sequencing (snRNA-seq) analysis.

Results: 21 patients underwent surgery and one patient was followed up after PET/CT scan. 11 patients were diagnosed with TETs (4 Type AB, 1 Type B1, 3 Type B2, 1 Type B3, 1 MNT, and 1 thymic carcinoma) and 11 patients were diagnosed with other tumors (6 thymic cysts, 1 MALT, 1 bronchogenic cyst, 1 pulmonary cyst, 1 haemangioma and 1 mature teratoma). 68Ga-Pentixafor identified all patients with TETs (11/11, 100%), and the mean SUVmax uptake value in all 11 lesions of TETs was 13.9 ± 9.0, which was significantly higher than that in non-TETs (2.2 ± 0.7) ($p < 0.001$). Bulk RNA-seq analysis of 6 TETs and 6 normal thymic tissues reveal that the gene expression of CXCR4 was elevated significantly. Single-cell analysis demonstrated CXCR4 was mainly distributed in immune cells including T_NK cell, B cell, proliferating B cell, plasma, and Macrophage. The distribution of CXCR4 positive cell demonstrated the uptake of CXCR4 targeted 68Ga-Pentixafor mainly enriched in the stroma region of TETs.

Conclusions: The preliminary study indicates the diagnostic utility of 68Ga-Pentixafor in TETs and the differential diagnostic ability of 68Ga-Pentixafor in TETs. Further investigation of the value of differentiating subtypes of TETs and predicting prognosis using 68Ga-Pentixafor in larger clinical trials is warranted.

P2.14B.03 A Phase II Parallel Arm Study of Sacituzumab Govitecan-Hziy in Patients with Advanced Thymoma and Thymic Carcinoma

J.A. Marks1, S. Agarwal1, J. Ahn1, J.E. Reuss1, M. Altan2, C. Nabel3, M.E. Gutierrez4, M.C. Garassino5, G.J. Riely6, H. Wakelee7, S.V. Liu1, C. Kim1

1Georgetown University, Washington/DC/USA ,2The University of Texas MD Anderson Cancer Center, Houston/TX/USA ,3Massachusetts General Hospital, Boston/MA/USA ,4Hackensack University Medical Center, Hackensack/NJ/USA ,5University of Chicago, Chicago/IL/USA ,6Memorial Sloan Kettering Cancer Center, New York/NY/USA ,7Stanford University, Stanford/CA/USA

Introduction: Thymic epithelial tumors (TETs), including thymoma and thymic carcinoma, are rare thoracic tumors of the anterior mediastinum. For those with advanced disease, platinum-based chemotherapy is used as first-line treatment. However, there is no standard regimen established for TET at progression after initial therapy, and treatment options for advanced/recurrent TETs are limited. Trop-2, a transmembrane glycoprotein, is overexpressed in solid tumors including thymomas and thymic carcinomas. Sacituzumab govitecan-hziy, a Trop-2-directed antibody-drug conjugate, has shown efficacy and safety in several tumors including breast cancer and urothelial cancer. The overexpression of Trop-2 in TETs and the clinical efficacy in other malignancies provide rationale for exploring its use in thymoma and thymic carcinoma.

Methods: This open-label, single-arm, parallel cohort, multi-center study assesses the safety and efficacy of sacituzumab govitecan-hziy in patients with advanced thymoma (cohort A) and thymic carcinoma (cohort B) who have received at least one prior line of systemic

therapy. The study employs a Simon optimal two-stage design, enrolling patients with adequate performance status, measurable disease, and adequate organ function. Sacituzumab govitecan-hziy is administered at a fixed dose of 10 mg/kg weekly on Days 1 and 8 of 21-day cycles until disease progression or unacceptable toxicity. Follow-up continues every 6 months for 2 years post-discontinuation. Archival tissue is obtained prior to initiation of study treatment with an optional biopsy at the time of progression. In cases where archival tissue is not available, a fresh biopsy is obtained at baseline. Blood samples for correlative studies are collected at baseline, on day 1 of cycle 3, and at the time of progression. The primary endpoint is investigator-assessed response using Response Evaluation Criteria in Solid Tumors v1.1 criteria, with tumor imaging assessments every 2 cycles during the first 3 months and every 3 cycles thereafter. Secondary endpoints comprise adverse events by Common Terminology Criteria for Adverse Events v5.0, median and 6-month progression-free survival, duration of response, and overall survival. For each cohort, 9 patients will be enrolled. If 0 of the 9 achieve a response, no further patients will be enrolled in that cohort. If 1 or more of the first 9 patients has a response, accrual will continue until a total of 17 patients have been enrolled in that cohort.

Results: Not applicable

Conclusions: Not applicable

P2.14B.04 Tislelizumab Plus Standard Chemotherapy as First-Line Treatment in Advanced Thymic Epithelial Tumors(TETs): A Prospective, Single-Arm Trial

L. Zhang, S. Li, J. He, W. Gao

The First Affiliated Hospital of Nanjing Medical University, Nanjing/CN

Introduction: Thymic epithelial tumors (TETs) ,classified as either thymoma (T) or thymic carcinoma (TC), have a poor prognosis, and treatment options are limited. Chemotherapy remains the standard treatment for advanced TETs. However, Chemotherapy yielded limited benefits with response rates of 20%-30% reported in previous clinical trials. With the exploration of Immunotherapy, PD-1 and PD-L1 inhibitors are gaining momentum as new options for various malignancies. High PD-L1 expression on TETs suggests that anti PD-1/PD-L1 agents could be a promising alternative treatment option for these tumors. Completed clinical trials have shown an encouraging efficacy of Pembrolizumab as a second-line therapeutic strategy for TETs ,despite the high rate of immune-related adverse events(irAEs). Notably, irAEs seem more common in patients with thymoma (T). Therefore, Immunotherapy for TETs is highly controversial. More safety and effective treatment options for TETs need to be explored. There is increasing evidence suggesting that compared with a PD-(L)1 inhibitor alone, a combination with chemotherapy for the first-line treatment may decrease the rates of most irAEs. Tislelizumab is a novel engineered anti-PD-1 monoclonal antibody with high affinity , which was specifically engineered to minimize Fc-–receptor (Fc–R) macrophages binding in order to avoid antibody-dependent phagocytosis. Tislelizumab has shown preliminary anti-tumor effects in various solid tumors. Here, We initiate a prospective trial to explore the feasibility, efficacy and safety of Tislelizumab plus standard Chemotherapy as first-line therapy in unresectable or recurrent TETs.

Methods: Eligible participants must be age ≥18 years with histologically confirmed T or TC not amenable to potentially curative treatments or recurrence after operation; have an Eastern Cooperative Oncology Group (ECOG) performance status of ≥1; and without prior system anticancer therapy after diagnosed with this disease. Key exclusion criteria include patients with immunosuppression, active autoimmune disease or documented history of clinically severe autoimmune disease. Patients with Thymoma will receive Tislelizumab(200mg,d1) in combination with standard Chemotherapy (Cisplatin 50 mg/m2,day1 and Doxorubicin 50 mg/m2 day1 and Cyclophosphamide 500 mg/m2 day1) ,q3w,for 4-6 cycles. Patients with Thymic carcinoma will receive Tislelizumab(200mg,d1) in combination with paclitaxel(200mg,d1) and Carboplatin (AUC=5,d1) ,q3w,for 4-6 cycles. Tislelizumab was administered intravenously at a fixed dose of 200 mg every 3 weeks until disease progression, death, unacceptable toxicity, withdrawal of consent, or at the discretion of the investigators. The survival outcomes, efficacy and safety profile will be investigated. Primary outcome measures will be the overall response rate (ORR) and progression-free survival (PFS). Secondary measures will explore overall survival (OS), duration of response (DOR) ,disease control rate(DCR) and safety. This study is registered with chinadrugtrials.org.cn, ChiCTR2400081177.

Results: From October 2023 to April 2024, this study has enrolled 8 TETs patients(5 with TC and 3 with T) .Median age was 61 years(range: 54-72) and 50% were male. By the cutoff day (April 5th,2024), none of them developed disease progression and 5 patients can be evaluated. Confirmed partial response (PR) were achieved in 2 patients and Stable disease (SD) in 3 patients, resulting in DCR of 100%. The PFS and OS were not reached. One enrolled patient was diagnosed with type A Thymoma with malignant lesions involved the superior vena cava and right atrium. The edema caused by superior vena cava syndrome significantly reduced after systemic treatment. Of the 8 enrolled patients, the most frequently observed adverse events of any grade, regardless of their causality to Tislelizumab, was myelosuppression (5/8). One patient with Thymoma (1/8) experienced immune-related adverse events(irAEs) grade 3 immune-related pneumonia. No immune-related Grade 4-5 AEs were reported and all AEs were manageable with supportive measures.

Conclusions: Tislelizumab plus standard Chemotherapy as first-line treatment showed encouraging antitumor activity and tolerable safety profile.Larger prospective randomized studies are warranted.This study is ongoing and more data will be released. Further ploration of biomarkers is also underway to identify potential benefit populations.

Introduction: Recent phase 3 studies in patients with unresectable pleural mesothelioma (PM) have demonstrated a significant improvement in median overall survival (OS) for anti-programmed cell death-1 (PD-1) antibodies in combination with standard chemotherapy (CCTG IND.227) or cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) inhibition (CheckMate 743). No trials to date have investigated the treatment of PM using a combination of chemotherapy with inhibition of both PD-1 and CTLA4 using immunotherapy, in comparison to standard-of-care dual immunotherapy alone or chemotherapy alone (depending on histology). Volrustomig (MEDI5752) is a monovalent, PD-1/CTLA-4 bispecific, humanized IgG1 monoclonal antibody engineered to specifically inhibit PD-1, with increased CTLA-4 blockade on PD-1+ activated T cells compared to PD-1- resting peripheral T cells. This mechanism of action may allow enhanced CTLA-4 blockade at tolerable doses beyond those achieved with current PD-1/CTLA-4 combinations. In a first-in-human phase 1/2 study (NCT03530397), first-line volrustomig + carboplatin + pemetrexed showed promising efficacy with acceptable tolerability in non-small-cell lung cancer. Building upon these findings, the phase 3, open-label, multicenter, global eVOLVE-Meso study will evaluate whether first-line volrustomig in combination with chemotherapy improves efficacy compared with current standard-of-care regimens in patients with unresectable PM (NCT06097728).

Methods: Key eligibility criteria include age ≥18 years, WHO/ECOG PS of 0 or 1, adequate organ and bone marrow function, PM with known histology (epithelioid or non-epithelioid including biphasic or sarcomatoid), no prior systemic therapy for PM, and no active or prior autoimmune or inflammatory disorders (Figure). Approximately 600 patients will be randomized in a 1:1 ratio to volrustomig + carboplatin + pemetrexed; or investigator's choice of (a) nivolumab + ipilimumab until PD, unacceptable toxicity or for up to 2 years, or (b) for epithelioid histologies only, pemetrexed + carboplatin or cisplatin. Randomization will be stratified according to tumor histology (epithelioid vs non-epithelioid), sex (male vs female), region (Americas vs Europe vs Asia), and investigator's choice of planned regimen (nivolumab + ipilimumab vs platinum + pemetrexed). The primary endpoint is OS in patients with epithelioid histology. Secondary endpoints include OS in all randomized patients; investigator-assessed progression-free survival in patients with epithelioid histology and in all randomized patients, objective response rate, and duration of response determined by modified RECIST 1.1; time to second progression or death; and safety. Pharmacokinetic and exploratory biomarker analyses will also be conducted. Enrollment opened in November, 2023.

Introduction: To reduce the gap about the relevant heterogeneity of molecular testing and cancer care across Europe, Women Against Lung Cancer in Europe (WALCE) promoted the European Program for ROutine testing of Patients with Advanced lung cancer (EPROPA) and providing a free-of-charge molecular profiling platform for non-small cell lung cancer sample characterization with the aim of increasing the detection of targetable drivers and improving patients' access to clinical trials.

Methods: From January 2021 to December 2023, 20 centres located at 5 different European countries (Greece, Slovenia, Romania, Albania and Italy) joined EPROPA, with 555 advanced NSCLC patients registered into the program. Anonymized patients' clinical-pathological data were shared through the EPROPA web platform and tissue samples were collected to the Molecular Pathology Unit of the Reference Center (University of Turin) for molecular analyses. A comprehensive genomic profiling by targeted next-generation sequencing approach has been performed and molecular reports have been discussed within the molecular tumour board (MTB) in order to assess patients' eligibility for clinical trials.

Results: The average turnaround time was 8 days, with only 30 out of 555 (6%) tissue samples not suitable for molecular analysis. Among the 525 analyzed samples, a total of 570 molecular alterations have been identified, including 264 pathogenic targetable oncogenic alterations and 113 cases with co-occurring mutations, while no molecular alterations have been detected in 41/525 (8%) of cases. A total of 18 molecular alterations with potential germline and hereditary cancer syndrome implications have been reported. The identification of a clinical trial was considered for 205 patients. After MTB discussion, 30 patients were enrolled and treated in clinical studies available in Europe; no clinical trials were available for 122 patients while 53 patients were not clinically eligible.

Conclusions: This data confirmed the feasibility and usefulness of the program in the real-world practice scenario, supporting the implementation of NGS-based molecular characterization of advanced NSCLC samples, in order to reduce the unequal access to tests, drugs and clinical trials in Europe.

1University of Illinois Chicago Medical Center, Chicago/IL/USA ,2LUNGevity, Davis/CA/USA ,3Center for Business Models in Healthcare, Glencoe/IL/USA ,4Northwestern University Feinberg School of Medicine, Chicago/IL/USA ,5Jesse Brown Department of Veterans Affairs Medical Center, Chicago/IL/USA ,6Johns Hopkins Kimmel Cancer Center, Baltimore/MD/USA ,7Grady Cancer Center, Atlanta/GA/USA ,8Southern Ohio Medical Center, Portsmouth/OH/USA ,9Northwestern Medicine, Chcicago/IL/USA ,10Sinai Chicago Health System, Chicago/IL/USA ,11Wake Forest Baptist Health, Winston-Salem/NC/USA ,12Genentech, A Member of the Roche Group, South San Francisco/CA/USA ,13Association of Cancer Care Centers, Rockville/MD/USA

Introduction: Patients' awareness of timing and purpose of biomarker testing is critical for their engagement in care but is challenging to achieve (Martin 2022). The 4R Oncology model of patient self-management and timely care delivery has shown improvements in patient knowledge of care timing/sequence (Trosman 2021, Liu 2023) but has not been studied in NSCLC specific to biomarker testing. 4R is Right Info/Care/Patient/Time. A central 4R tool is Care Sequence, a patient-facing care plan describing the course and timing/sequence of care. We implemented 4R in NSCLC at 8 centers (4-community, 3-academic, 1-VA) in 2022-2023 and assessed its impact on patients' awareness of biomarker testing timing and purpose.

Methods: We refined Care Sequences to emphasize biomarker timing versus treatment decisions, and to recommend patient actions while waiting for results, including obtaining supportive, social and health maintenance care. The intervention (4R) patient cohort received Care Sequences at care planning appointments, accompanied by patient-provider discussion. We compared survey results from the 4R cohort with historical control cohort of patients who received care pre-4R. See Table for metrics.

Results: Survey response rates: 4R cohort 67% (61/91), control cohort 66% (112/170). Respondents in 4R cohort/control cohort respectively were: 62%/46% black, 64%/48% high school educated or less, 64%/55%with annual income <$30,000, 54%/58% NSCLC Stage IV. Implementing 4R resulted in significant improvement in all 11 metrics between control and 4R cohorts (Table). In addition to improving patient awareness of biomarker test timing, the use of 4R was associated with higher rate of patients willing to wait for test results before treatment and patients understanding how they can be active with there are while waiting.

Conclusions: Utilizing 4R Oncology significantly improved patients' understanding of biomarker test timing versus treatment decisions and increased patients' willingness to wait for results before starting treatment. 4R broad national rollout is underway.

P2.16B.01 Attributes that Impact Patient and Physician Preferences for Maintenance Treatment in Advanced/metastatic NSCLC

U. Tapan1, M.V. Shah2, K.F. Bell2, Y. Wang3, Y. Meng4, H. Yang3, M. Ye3, A. Liao5

1Section of Hematology & Medical Oncology, Boston University Chobanian & Avedisian School of Medicine, and Boston Medical Center, Boston/MA/USA ,2GSK, Collegeville/PA/USA ,3Analysis Group, Boston/MA/USA ,4Analysis Group, London/GB ,5GSK, Zug/CH

Introduction: Patients with advanced/metastatic non-small cell lung cancer (a/mNSCLC) and treating physicians may have different perspectives on maintenance therapy. It is important to identify what treatment attributes are important for both patients and physicians as they may significantly affect treatment selection. This study investigated treatment attribute preferences of patients and physicians in the maintenance therapy setting after first-line (1L) treatment for a/mNSCLC.

Methods: This survey-based study, conducted alongside a discrete choice experiment, included patients and physicians in the US and UK. Eligible patients (aged ≥18 y) had an a/mNSCLC diagnosis and had completed 1L treatment. Physicians were licensed oncologists with ≥5 years' experience in a/mNSCLC treatment and had treated ≥20 such patients in the past year. Data were collected using choice cards, designed to capture treatment attribute preferences, including efficacy (overall survival [OS] and progression-free survival [PFS]), chance of new brain metastasis, and adverse events. Attributes related to quality of life were not specifically included because of their high correlations with the selected efficacy and safety attributes.

Results: Among 82 patients (34 UK, 48 US), the 3 most important treatment attributes were chance of new brain metastasis, OS, and risk of severe neutropenia (Table). The least important treatment attributes for patients were risks of severe nausea and severe vomiting. Among 101 physicians (51 UK, 50 US), the 3 most important treatment attributes were OS, chance of developing new brain metastasis, and PFS (Table). Risks of experiencing severe nausea or vomiting were the least important attributes to physicians.

Conclusions: In this real-world study, concordance was seen between patients with a/mNSCLC and treating physicians on the importance of certain treatment attributes. OS and the chance of developing new brain metastasis were among the top 2 most important treatment attributes for physicians and for patients with a/mNSCLC; however, OS and PFS were rated at a greater relative importance, and chance of new brain metastasis was rated at a lesser relative importance, for physicians than patients. These attributes will be important to consider when selecting maintenance therapy treatment following 1L therapy.

P2.16C.01 Awareness, Stigma, and Fatalism Towards Cancer Clinical Trials Among Black Individuals Diagnosed with Lung Cancer

A. Ciupek1, S. Stallings2, N. Amanna2, E. Howell3, R.E. Gaskin4, J.E. Murrel4, A. Allgood4, M. Aldrich2, N.A. Karim5,6, C.M. Lovly2, S.J. Niranjan4

1GO2 for Lung Cancer, Washington/DC/USA ,2Vanderbilt University Medical Center, Nashville/TN/USA ,3Tuskegee University, Tuskegee/AL/USA ,4University of Alabama at Birmingham, Birmingham/AL/USA ,5INOVA Schar Cancer Institute, Fairfax/VA/USA ,6University of Virginia, Charlottesville/VA/USA

Introduction: Only about 8% of people with cancer in the USA participate in clinical trials. Participation is even lower among racial and ethnic minority groups, including Black persons diagnosed with cancer who comprise about 6% of trial participants. The STRIDES (Studying

Trial Determinants of Success) study utilized patient-reported data to examine barriers and facilitators to trial participation among Black individuals diagnosed with lung cancer.

Methods: Individuals over the age of 18, previously diagnosed with lung cancer, and who identified as "all or part Black, African American, or African" were invited to respond to a survey on experiences and preferences around lung cancer clinical trials. Participants were required to have received lung cancer care within 5 years of study enrollment at one of three institutions in the Southeastern USA: University of Alabama at Birmingham, Vanderbilt University Medical Center, or INOVA Schar Cancer Institute. Surveys included demographic items and validated scales assessing experiences of stigma and cancer fatalism as well as trial knowledge. Recruitment methods were decided locally based on best practices at each participating site. Survey data, collected at each institution, were pooled, cleaned, and evaluated using descriptive statistics and bivariate analyses.

Results: 61 people with lung cancer responded to the survey (average age: 65 years; 58% female). Among respondents who were willing to provide a response (N=57), 68% reported a household income under $50,000 US dollars in the past 12 months and all currently had health insurance. The Cancer Fatalism survey (derived from Powe) and Lung Cancer Stigma Inventory were administered, and responses indicated low levels. For instance, when asked "if someone has cancer, it is already too late to get treated", 91.8% disagreed and when asked "It has been hard to tell people that I have lung cancer", 70.4% disagreed. Most participants (55%) reported that no one had discussed clinical trials with them. Among respondents who reported having trial discussions, the majority occurred at the time of diagnosis (59%), most commonly with their primary oncologist (50%). These discussions were rated on average as helpful and understandable (average 4.18 and 4.31 respectively on a 5-point Likert scale). The preferred format of clinical trials education varied among STRIDES participants, but the most frequently preferred source of clinical trials information (reported by 44% of respondents) was the primary oncologist.

Conclusions: Over half (55%) of STRIDES participants reported having had no conversations about clinical trials with a member of their clinical care team. Other studies have indicated marginalized populations are interested in trial enrollment if offered. Considering this and that we observed a large population not having trial discussions in STRIDES, increasing the frequency and modality of trial conversations could be key to increasing enrollment of underrepresented Black individuals in clinical trials. The preferred source of trial information in STRIDES was the primary oncologist, highlighting implications for practice patterns in trial enrollment and underscoring the physicians' role in addressing trial participation gaps. This data provides important information for cancer centers developing strategies to increase clinical trials diversity.

P2.16C.02 Development of a Framework to Address Lung Cancer Health Disparities: One Organization's Experience

N.M. Phipps, M. Rigney, S. Monestime

GO2 for Lung Cancer, SAN CARLOS/CA/USA

Introduction: Lung cancer remains the leading cause of cancer deaths in the United States and the developed world. Great advances, including screening implementation and innovative treatments, are being developed at a rapid rate. However, lack of access and social/structural challenges continue to have a negative impact on marginalized communities, which may be at greater risk for lung cancer and have less access to new treatment advancements. While a fair amount has been written on inequities in lung cancer care in the United States, our goal was to create a centralized repository of lung cancer disparities data, and then to use this data to create a strategic framework to target those most in need for our outreach efforts.

Methods: First, a literature review was conducted using five databases with the following inclusion criteria: (I) peer-reviewed academic journals published in English between the years 2000 and 2022; (II) research that focused on disparities across the lung cancer continuum; and (III) research articles addressing social and structural barriers to lung cancer health care access. A total of 95 articles and 24 reports were used for this narrative review. The review analyzed 10 populations: Black/African American; American Indian/Alaska Native; Hispanic/Latinx; Asian American/Pacific Islander; low income; rural; LGBTQIA+; women; active duty military and Veterans; and those at risk and diagnosed with small cell lung cancer. Those results were published in 2023. To develop the framework, a 15-week process was used to identify priority populations. First, internal interviews and an external landscape analysis were conducted. Next, findings were presented, and staff were engaged in visioning exercises to map the organizations' health equity aspirations and identify opportunities. An initial framework and strategy options were drafted and continually refined through additional interviews and focus groups. The final framework was then presented to all staff for finalization.

Results: The top priority groups were identified as those at risk and living with lung cancer who are Black/ African American, those living in rural areas, and those of lower socioeconomic status. Secondary priority populations of importance include Veterans, Hispanic/Latinos, and women. Each department with GO2 for Lung Cancer was then assisted in identifying up to three strategies for 2024 to begin to address health disparities.

Conclusions: Future studies are needed to further develop meaningful solutions to disparities in health outcomes and access for those who are at risk, diagnosed with, or surviving lung cancer from marginalized populations.

Keywords: lung cancer, health disparities, marginalized populations

P2.16D PATIENT ADVOCACY - LUNG CANCER EDUCATION, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.16D.01 Changes in Students' Perceptions of Cancer Through Cancer Education and Lectures by External Instructors with Cancer Experience

K. Hasegawa1,2, N. Saito1, R. HASHIMOTO3, K. Katayama4

1NPO–Lung Cancer Patient Network ONE STEP, YOKOHAMA/JP ,2General Incorporated Association Kanagawa Prefecture Cancer Patient Organizations, Kanagawa/JP ,3General Incorporated Association Kanagawa Prefecture Cancer Patient Organizations, Yokohama/JP ,4National University Corporation Gunma University, Maebashi/JP

Introduction: The fourth phase of the Basic Plan for Cancer Control also emphasizes the importance of cancer education and the dissemination of knowledge about cancer. The purpose of this study is to investigate how students' perceptions of cancer change through lectures by external instructors with cancer experience and to verify the effectiveness of cancer education conducted by those who have experienced cancer.

Methods: The Kanagawa Prefecture Cancer Patient Organizations conducted pre- and post-cancer education surveys from 2020 to 2022 under the framework of the Kanagawa Voluntary Activity Promotion Fund 21 Project. The survey targeted 29 schools (14 high schools, 11 middle schools, and 4 by academic year), with a total of 1485 students participating in the pre-survey and 1375 students in the post-survey. The main focus of the analysis was on the changes in students' perceptions of cancer. The data from the pre- and post-surveys were compared to quantitatively analyze the changes in cancer perceptions. Specifically, the differences in the statistical proportions before and after for each item were analyzed.

Results: Perception of being bedridden or in the hospital: "Yes" responses significantly decreased from 50.1% before to 31.6% after. (p = 0.0251) Thinking that nothing special changes just because it's cancer: "Yes" responses significantly increased from 22.2% before to 45.1% after. (p = 0.0297) Feeling pity: "Yes" responses decreased from 46.5% before to 29.7% after, showing a significant trend. (p = 0.0545) Associating cancer with excessive smoking or drinking: "Yes" responses decreased from 26.6% before to 21.3% after, showing a significant trend. (p = 0.0911) Thinking the person looks pale and thin: "Yes" responses decreased from 27.5% before to 15.2% after. (p = 0.184) Thinking the person is always depressed: "Yes" responses increased slightly from 10.7% before to 11.5% after. (p = 0.314) Believing that the person can work: "Yes" responses increased from 6.8% before to 25.5% after. (p = 0.319) Thinking the person can enjoy life: "Yes" responses increased from 4.7% before to 29.7% after. (p = 0.433)

Conclusions: Changes were observed in students' perceptions of cancer, particularly in the beliefs that people with cancer are bedridden or in the hospital and that having cancer does not significantly change things. It is believed that the presence of external instructors with cancer experience delivering the lectures had an impact. Although there was no significant difference regarding the belief that cancer is caused by excessive smoking or drinking, a significant trend was observed. This suggests a reduction in the prejudice that cancer patients acquire the disease due to poor lifestyle habits.

Keywords: Stigma, Cancer Education

P2.16E PATIENT ADVOCACY - NEEDS OF PATIENTS AND CAREGIVERS, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.16E.01 Lung Cancer Patients' Support Preferences: Insights from a Global Patient Experience Survey

K. Clayton1, M. Daniels2, J. Fox3, B. Gaspar4, M. Hennink5, J. Mayans4, A. McNamara6, L. Pretorius2, M. Rigney7, M. Dohr8

1Lung Cancer Nursing UK, London/GB ,2Campaigning for Cancer, Randburg/ZA ,3Roy Castle Lung Cancer Foundation, Liverpool/GB ,4Asociación Española de Afectados de Cáncer de Pulmón, Valencia/ES ,5Longkanker Nederland, Utrecht/NL ,6Irish Cancer Society, Dublin/GB ,7GO2 Foundation for Lung Cancer, Washington, D.C./DC/USA ,8Incisive Health, London/GB

Introduction: The Global Lung Cancer Coalition (GLCC), a partnership of 43 patient organisations across 30 nations, reaffirms in its charter the right of all lung cancer patients to be treated with dignity and respect and to have informed self-determination. Understanding lung cancer patients' experience and what support they need to help them cope with their condition is an important aspect of the GLCC's work. This survey therefore sought to better understand the support preferences of lung cancer patients around the world.

Methods: In the GLCC's fifth annual survey, the coalition commissioned Censuswide to conduct a global survey of lung cancer patients. The survey is currently in the field across 18 countries (Australia, Argentina, Bulgaria, Canada, Denmark, Greece, Ireland, Israel, Italy, Japan, Mexico, Portugal, Netherlands, South Africa, Spain, Taiwan, UK, USA). As part of this survey, the GLCC included questions about where respondents currently seek help in coping with their condition and where they would like to receive help.

Results: 67% (602/905) of respondents reported receiving support from healthcare professionals to cope with their disease, followed by 62% (559/905) of respondents who reported receiving support from family and friends. Other prominent modes of support include in-person support groups (29%), online support groups (25%), social media communities (21%) and counselling/therapy (19%).

When asked what support they would like to receive to help them cope with their disease, answers were broadly aligned with what support is already being accessed. Although there was a greater desire for counselling or therapy (23% v 19%), as well as a desire for greater

support from spiritual or religious communities (11% v 7%) and work colleagues (7% v 4%).

Conclusions: By identifying where patients seek help and their preferences for receiving support, from family and friends to online communities and professional services, patient organisations and providers can tailor their assistance, support services, and interventions to better meet patients' needs, thus upholding their integrity and dignity.

P2.16E PATIENT ADVOCACY - NEEDS OF PATIENTS AND CAREGIVERS, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.16E.02 Emotional Support Resource Access and Utilization Among People with Lung Cancer

H. Law1, K. Chansky2

1GO2 for Lung Cancer, Washington/DC/USA ,2Chansky Consulting LLC, Mercer Island/WA/USA

Introduction: A systematic review conducted by Rajapakse in 2021 found that up to 80% of people with lung cancer experience psychological distress, including depression, which is three times higher than other types of cancer. Despite this, mental health services are generally underutilized. Given these challenges, we examined patterns of underutilization using data from a real-world patient-reported data registry.

Methods: The Lung Cancer Registry (lungcancerregistry.org) from GO2 for Lung Cancer is an online collection of surveys for people with lung cancer to provide treatment information and disease status updates. From the annual questionnaire data collected from 2019-2023, we included US-based participants who had indicated any level of depression (at least "a little bit" depressed) when responding to "Did you feel depressed?" on the EORTC Core Quality of Life questionnaire, and then evaluated whether they had utilized emotional support resources (i.e. support group and/or counseling). In the subset of participants who reported any level of depression, our objective was to describe the demographics and disease-related characteristics of the group who reported utilizing emotional support resources, as compared to those who did not. To determine access to emotional support resources, we looked at travel time to clinic and the participant's distance from the nearest NCI-Designated Cancer Center. Associations between categorical groupings were evaluated for statistical significance using chi-square tests of association or Fishers exact test as appropriate. Distributions of continuous variables (domain scores, age, and time from diagnosis) were compared using a Wilcoxon rank-sum test.

Results: Of the 82 participants who indicated at least "a little bit" depression and may have particularly benefited from support resources of counseling or support groups, only 36 (43.9%) reported receiving such support. Furthermore, a greater percentage of participants who reported travel time to clinic of less than one hour did access a resource, as compared to those who reported longer travel times (54% versus 32%), although the association was not significant (p=0.12). The distance between the participant's residence and the nearest NCI-Designated Cancer Center was significantly lower in those who utilized resources (mean of 30 miles versus 54 miles, p=0.007). Other characteristics (demographics, stage of disease, physical function, and global health) were essentially the same across the two groups.

Conclusions: In this study, we sought to determine whether people with lung cancer who experience depression have access to and receive the emotional support resources they need. While we found a correlation between distance to NCI-Designated Cancer Center and receipt of emotional support resources, we did not collect information on whether the support groups and counseling sessions were conducted in-person or virtual. Further analysis with larger sample sizes is needed to determine the barriers to receiving emotional support among those who report depression. Regardless, these findings suggest that collaboration between health care teams and advocacy or cancer organizations is warranted in increasing access to emotional support programs for people with lung cancer.

P2.16F.01 Patient-Led Oncogene-Driven Lung Cancer Translational Research to Expedite Therapeutic Development

M.A. Muskavitch1, R.B. Hall2, J. Lowy3, E. Gefroh4, E.S. Venanzi5, J. Noonan3, K. Li6, K.W. Culver7

1ALK Positive Inc, MILLIS/MA/USA ,2ALK Positive Inc, Annville/PA/USA ,3Regeneron, Tarrytown/NY/USA ,4Just-Evotec Biologics, Seattle/WA/USA ,5ALK Positive Inc, West Newton/MA/USA ,6EirClin Co, Lexington/MA/USA ,7ALK Positive Inc, King of Prussia/PA/USA

Introduction: Oncogene-driven lung cancers (LCs) arise in people from all walks of life. Therefore, it is no surprise that ALK Positive Inc. (API), a nonprofit patient advocacy organization, has formed Medical Committees comprised of patients and caregivers with experience in medicine, research, pharma, biotech, business, and finance. The API Medical Committees are dedicated to advancing new therapies for ALK+ cancers that will convert these lethal cancers into chronic and curable diseases. The primary goal of these patient-driven analyses of ALK+ tumor gene expression is to nominate candidate targets for new therapies and biomarkers of tumor treatment response.

Methods: We have utilized publicly available single cell RNA (scRNA) sequence data to analyze expression of over 18,000 protein-coding genes among 61 cell types defined within a human lung cell atlas from Sikkema et al 2023. Raw data were from Kim et al 2020, Laughney et

al 2020, Maynard et al 2020, Bischoff et al 2021 and Wu et al 2021. EirClin utilized an scRNASequest (Li et al 2023) computational workflow, including but not limited to Harmony, Azimuth, Seurat, Scanpy and Nebula, to perform data harmonization, reference-based cell type annotation and differential analysis. Single cell expression profiles were visualized with CellXGene VIP software (Li et al 2020) to create trackplots (Figure 1) in which each vertical line represents a single tumor cell.

Results: We characterized scRNA expression profiles in 64 LC patients, including ALK+, BRAF+, EGFR+, HER2+, KRAS+, MET+ and ROS1+ patients. Our analysis identified targets expressed among multiple oncogenic drivers. The figure below visualizes expression profiles for 12 representative target genes among these 64 LC patients. Understanding expression profiles among drivers can inform clinical trial design by enabling inclusion of driver subpopulations that express of a particular therapeutic target, and facilitate faster trial enrollment by including all driver subpopulations likely to benefit from a given therapeutic intervention.

Conclusions: Our goals are to enable faster, more effective clinical trials to improve treatment responses in oncogene-driven lung cancers. We are open to collaborating with other advocacy groups to expand datasets across multiple drivers. Our study demonstrates that patients and caregivers have the capacity and can acquire funding to undertake independent, patient-centric research that will advance personalized treatments and facilitate transformation of oncogene-driven cancers into chronic and curable diseases.

P2.16F.02 LIFE Project: Lung Cancer Patients' Involvement in Research Fostering Their Empowerment

B. Gaspar1, X.C. Bayona2, I. Brao3, M. Jové3, S. Lorente3, M.A. Mosteiro3, A. Navarro3, R. Palmero3, A. Sedano4, E.C. Nadal3

1Spanish Association of People Affected by Lung Cancer - AEACAP, Valencia/ES ,2Institut Català de la Salut, Barcelona/ES ,3Catalan Institute of Oncology, Barcelona/ES ,4Unio Consorci Formacio UCF, Barcelona/ES

Introduction: The LIFE project aims to strengthen patient-centered clinical research by empowering lung cancer patients through their active participation in the research process. While addressing the current gaps in patient engagement, the project's primary focus is upon designing a framework that would facilitate collaboration between patients and healthcare professionals to ensure that the clinical research conducted is both ethical, relevant, and meaningful for all stakeholders involved.

Methods: The study utilized a qualitative research method that incorporated Metaplan technique workshops with lung cancer patients and healthcare professionals from the Catalan Institute of Oncology (ICO). These workshops aimed to explore the benefits of patient involvement in research, address concerns from both patients and professionals about such involvement, and identify the necessary skills and knowledge required for patients to participate effectively.Two exploratory workshops were executed. The first included eight patients (6 women and 2 men), while the second was attended by seven health-professionals (4 medical oncologists, 1 radiation oncologist, and 2 advanced practice nurses) from the Thoracic Cancer Unit at ICO.To conclude the qualitative research project, the final exploratory phase, which involved the focus group's exploration and consensus phase, was conducted. A workshop was organized, where 7 patients and a family member, along with the seven healthcare-professionals, collaboratively reviewed the outcomes of the previous workshops.At the conclusion of the workshop, a prioritization exercise was conducted to assess various proposed areas concerning the skills and knowledge that patients need to enhance. This assessment focused on the significance of each skill/competence and its feasibility, using a simple priority matrix, which aligns with the main goal of the LIFE project. The prioritization process involved scoring each identified element on a scale from 0 to 10, based on the consensus reached between patients and professionals.

Results: The study successfully identified key areas of cooperation between patients and professionals that contribute to strengthening research. These areas include research design, informed consent, and the dissemination of results. The primary concerns raised encompassed meeting patients' expectations, ethical considerations, and practical issues. Additionally, the study highlighted the necessary skills for patients, with a focus on research literacy and effective interpersonal communication. An analysis comparing the average results from patients and professionals revealed no statistically significant differences. "Knowledge training" emerged as the top priority among the necessary skills for patients. The essential areas where training is considered necessary include knowledge of the disease and treatment options, understanding of the entire clinical research process, communication skills, and teamwork.

Conclusions: The findings of the LIFE project demonstrate the vast potential of patient involvement in lung cancer research and the mutual benefit of patient-professional cooperation in clinical trials. By including patients in the clinical research process from start to end, the project enables the development of more ethical and relevant patient-centered clinical studies. Future research should engage in addressing the presented concerns, enhancing patient literacy, and supporting patient leadership in clinical studies. The results clearly support the shift to more participative patient-oriented research methodology in lung cancer studies and, probably, in patient care practice.

Keywords: patient empowerment, lung cancer, clinical trials

P2.16F.03 Development of a Patient-Friendly Lung Cancer Lexicon

J. Feldman1, N. Daaboul2, H. Husain3, D. Montague4, T. Patil5, M. Hull6

1EGFR Resisters, Deerfield/IL/USA ,2Centre Intégré de Cancérologie de la Montérégie, Hôpital Charles LeMoyne, Longueuil/QC/CA ,3UCSD Moores Cancer Center, La Jolla/CA/USA ,4ALK+ Patient Group, Surrey/GB ,5University of Colorado Cancer Center, Aurora/CO/USA ,6Janssen Research & Development, Raritan/NJ/USA

Introduction: The IASLC Language Guide was published in 2021, promoting the adoption of preferred language and phrasing in oral and written communication that is person centered, eliminates blame, ends stigma, and is equitable. Although recent trends in the scientific literature point to increasing use of patient-centric titles, some language used in scientific publications, including those meant for lay audiences, continues to be overwhelming and overly technical for patients and caregivers; commonly used terms are sometimes not inclusive or empathetic to the patient's lived experience. This project aimed to expand on the IASLC guide by developing a patient-friendly lexicon for lung cancer communications and is intended for adoption within a major pharmaceutical company.

Methods: Development of this lexicon involved a multistep process. The unmet need was examined through social media analysis of lung cancer conversations and literature analysis of terms currently used in lung cancer plain language summaries. Additional insights into existing language barriers and complex concepts in the lung cancer space were elucidated via an advisory board and multiple stakeholder interviews of experts, including lung cancer healthcare providers, patients, and patient advocates. A set of commonly used complex or noninclusive scientific terms was discussed, and alternative simplified and/or more inclusive terms or phrases were suggested. Further validation and refinement of the patient-friendly lexicon was conducted with a team of pharmaceutical company lung cancer researchers and a lung cancer patient/advocate.

Results: Social media listening analysis revealed that online communities discussing lung cancer often could not interpret or understand medical terminology used in clinical trial summaries, healthcare provider conversations, and online resources from medical associations or pharmaceutical companies. Results of the literature analysis showed that lung cancer plain language summaries do not utilize consistent or standardized language when describing concepts involving disease state, treatment descriptions (eg, how targeted treatments work), and treatment outcomes. Insights gathered from lung cancer experts found that many common terms used to describe treatment outcomes were not patient-centric (eg, describing a safety profile as "tolerable" when not reported as such by patients) and/or challenging for patients to understand and/or for providers to explain (eg, "median"). Alternative patient-friendly terms or explanations were proposed and pressure tested to be empathetic, clear, and easily understood. The final set of validated patient-friendly lexicon terms was divided into three categories: safety, efficacy, and other. In addition, use cases were assigned such that the lexicon terms could be appropriately used in either low complexity cases (eg, plain language summaries), high complexity cases (eg, professional congress abstracts), or both. For example, the term "side effect" was included in the lexicon as a simpler alternative to "adverse event" but may only be appropriate in low complexity cases. The entire lexicon will be shared in the presentation.

Conclusions: Some commonly used terms in lung cancer research can be simplified to be more patient-centric, empathetic, and inclusive. The patient-friendly lung cancer lexicon was developed with the hope that widespread adoption in medical communications could help advances in lung cancer research be more easily understood among patients and caregivers.

Keywords: patient-centric, lexicon

P2.16G PATIENT ADVOCACY - SCREENING, SUNDAY, SEPTEMBER 8, 2024 - 18:15 - 19:45

P2.16G.01 Annual Lung Cancer Screening Day in the United States- Year Two

D. Dyer1, T. Gowen2, E. Kazerooni3, C. Brathwaite4, L. Rosenthal5, H. Burson5, K. Burn5, B. Carlisle2

1National Jewish Health, Denver/CO/USA ,2American College of Radiology, Reston/VA/USA ,3University of Michigan Medical Group, Ann Arbor/MI/USA ,4Radiology Health Equity Coaltion, Reston/VA/USA ,5American Cancer Society, National Lung Cancer RoundTable, Atlanta/GA/USA

Introduction: The American Cancer Society National Lung Cancer Roundtable, American College of Radiology, and Radiology Health Equity Coalition, partnered again for the second annual National Lung Cancer Screening Day on Saturday, November 11, 2023, as an important part of Lung Cancer Awareness Month. In acknowledgment of National LCS Day falling on Veterans Day, the ACS NLCRT, ACR, and RHEC partnered with the Veterans Health Administration on this campaign to salute our Veterans by increasing outreach and awareness to our veteran population, in turn saving more lives. The LCS day campaign asks facilities to open their doors on the second Saturday in November to offer lung cancer CT screening. Opening on a Saturday increases access to lung cancer screening particularly for individuals who may not be able to take time off work Monday through Friday. National LCS Day serves as a catalyst for lung cancer screening, increasing the profile of this life saving test among health care providers and in the community, with the goal of increasing community and patient education and increasing lung screening as a year-round priority.

Methods: Marketing for National Lung Cancer Screening Day began in July, a shift from the previous year when it started in September. Facilities sign up on a website (https://nlcrt.org/lung-cancer-screening-day) which provided access to complementary marketing and instructional materials with patient- friendly videos to facilitate opening their doors to patients on Saturday, November 11, 2023. Resources included promotional flyers for patients in English and Spanish, a logistics guide for opening a screening center on a Saturday, a patient-centered marketing email template, a sample press release for facilities to engage their local news platforms, and an order form for white ribbon lapel pins. A post-survey was sent to participating facilities to collect information on patients screened and perceptions of event success.

Results: There was a significant steady increase in registered facilities in 2023 compared to 2022, with 759 facilities in 47 states and Puerto Rico in 2023 as illustrated in Figure 1, compared to 328 facilities in 2022 Among the 2023 facilities, 74% were new to LCS Day and 26% had participated in the inaugural 2022 LCS day. Facilities that were already open on Saturday made up 41% of the facilities of which 31% opened specifically for LCS Day, and 28% were advocacy organizations

Conclusions: The second National Lung Cancer Screening Day was successfully held at facilities in 97% of states across the U.S., an increase from 75% from the prior year, increasing patients screened and awareness about LCS in their communities. The participation of both screening facilities and LCS advocacy organizations demonstrates commitment to use NLCSD as a way to educate patients and communities to reduce lung cancer deaths through this life saving screening exam.

P2.16G.02 “It’s Like A Donut!”- Veteran Perspectives of Lung Cancer Screening with Low Dose CT

C.A. Castagna-McLeod1, H. Brooks1, K. Bonnet1, D. Schlundt2, S. York1,3, F. Hendler4, S. Byerly1, C. Audet1,2, D. Moghanaki5,6, R. Dittus1,3, C. Roumie1,3, J. Lewis1,3, L. Spalluto1,3

1Vanderbilt University Medical Center, Nashville/TN/USA ,2Vanderbilt University, Nashville/TN/USA ,3VA Tennessee Valley Healthcare System, Nashville/TN/USA ,4VA Louisville Healthcare System, Louisville/KY/USA ,5University of California, Los Angeles, Los Angeles/CA/USA ,6VA Greater Los Angeles Healthcare System, Los Angeles/CA/USA

Introduction: Screening with low dose computed tomography (LDCT) reduces mortality from lung cancer. However, LDCT utilization is low in clinical practice, including in the United States Veterans Health Administration. We explored Veteran experiences with lung cancer screening and perceived barriers to receiving LDCT screenings and opportunities for improving lung cancer screening at Veterans Affairs Medical Centers (VAMCs).

Methods: We conducted a cross-sectional, qualitative study of Veterans at a single VAMC between January 1, 2021 and August 6, 2021. Our research team led semi-structured telephone interviews with Veterans after they were referred to the VAMC’s Lung Cancer Screening Program, including those who agreed or declined to enroll. We utilized the Socioecological Model as a framework for data analysis. This model includes four domains: Organizational, Interpersonal, Individual and Societal. The qualitative data were analyzed using an iterative inductive-deductive approach to identify themes and relationships between themes.

Results: A total of 34 interviews (20 with Veterans who enrolled in the lung screening program and 14 with Veterans who did not enroll) were conducted and included in the final analytic sample. The strongest factor associated with Veterans’ decision to pursue lung cancer screening was their level of personal education and awareness about this early detection test (individual, interpersonal and organizational domains of socioecological model). Veterans indicated a lack of understanding of the steps involved in LDCT screening would make them less likely to enroll. Veterans reported not understanding that lung cancer screening is an imaging-based study. Another common theme included rural factors include location and societal norms (societal domain) and access to care (organizational domain) as barriers influencing the decision to undergo LDCT. Organizational suggestions for improvement included developing accessible Veteran-centric educational materials on what a CT scanner looks like and sounds like, and the duration of LDCT examination (less than 1 minute). Regarding the LDCT scan, one participant stated “it’s like a donut!”, indicating that if others understood the simplicity of the exam, they too may be more likely to participate. Societal suggestions from Veterans for improvement included implementing mobile screening units, broadening education and awareness, and improving the overall personal screening experience.

Conclusions: Veterans interviewed relayed a lack of clarity on the process and duration of lung cancer screening, negatively influencing decisions to pursue lung cancer screening. Interview participants offered a variety of solutions that were specifically tailored to address educational barriers and increase LDCT screening in the Veteran population, including the use of mobile screening units and improved, Veteran-centric education. Future studies are warranted to test the effectiveness and acceptability of these recommended strategies aiming to increase LDCT utilization in the Veterans Health Administration.

P2.17A.01 Treatment Outcomes after Access to Broad Molecular Tests, Targeted Agents and Immunotherapy in NSCLC Patients from Brazil

F.L.V. Visani1, C. Mathias1, R.D. Paes2, T. Montella3, N. Afonso3, I. Negreiros4, L. Moreira5, G. Veloso6, M.X. Reis3, I. Barcelos7, B. Ferrari6, C.G. Ferreira3, P. De Marchi3, R. Dienstmann2

1Oncoclinicas Brazil, Salvador/BR ,2Oncoclinicas Brazil, São Paulo/BR ,3Oncoclinicas Brazil, Rio de Janeiro/BR ,4Oncoclinicas Brazil, Brasília/BR ,5Escola Bahiana de Medicina, Salvador/BR ,6Oncoclinicas Brazil, Belo Horizonte/BR ,7Oncoclinicas Brazil, Vitória/BR

Introduction: Tailored management of metastatic NSCLC demands access to broad NGS panels and PDL1 expression in a timely manner

for first-line treatment selection. In Brazil, patient support programs sponsored by pharma give access to molecular diagnostic assays since 2017, with broad NGS covered since 2020. We aimed to evaluate the real-world Overall Survival (rwOS) after first-line palliative treatment modality with tyrosine kinase inhibitors (TKIs), and immunotherapy (IO).

Methods: Between jan/2017 and sep/2023, data from all patients diagnosed with metastatic NSCLC were retrieved from the Oncoclínicas datalake (largest Brazilian private oncology institution). Epidemiological characteristics, treatment details, and survival outcomes were extracted from structured fields of EHRs combined with elements from unstructured sources using technology-based abstraction techniques and human curation. Biomarker data was available for a subset of patients tested at internal Oncoclínicas Precision Medicine lab. rwOS was calculated from start of first treatment regimen until death or last follow-up with Kaplan Meier method. Study was approved by Reseach Ethics Committee (CAAE 75373323.5.0000.0047).

Results: Median age was 71 years (range 22-101), 51% were male, and 67% were from southeast region of the country. In 782 cases with comprehensive molecular data, the most common alterations were KRAS mut (28.4%, KRASG12C in 9.7%), followed by EGFR mut (23.6%, exon 20 ins in 2.9%), ALK fusions (6.4%), MET exon 14 skipping (4.4%), ERBB2 mut (3.4%), ROS1 fusions (3.1%), and BRAFV600E mut (1.9%). Overall, high PD-L1 expression (>=50%) was found in 12.3% of the samples. Over the seven years period, we observed a major decrease in the use of chemotherapy (CT) alone (from 76% in 2017 to 29% in 2023) accompanied by an increase in the use of combination of IO + CT (from 2% in 2018 to 43% in 2023). Meanwhile, TKI (EGFR, ALK and ROS1) and IO single-agent increased gradually over time. With median follow-up of 12 months, rwOS was 26.5 months (CI95% 20.3-46.7) for patients who had TKI in first-line, 15.7 months (CI95% 13-17.8) for patients with IO and 15.5 months (CI95% 12.17-19.3) for patients with IO + CT.

Conclusions: Targeted therapies have been associated with better outcomes in our real-world cohort of patients. Access to comprehensive molecular profiling has expanded the application of precision medicine to greater proportion of patients in recent years.

Keywords: non-small cell lung cancer, access, next-generation sequencing

P2.17A.02 Cost-Efficiency Modeling of Conversion to Biosimilar Bevacizumab-bvzr in Metastatic Non-Small Cell Lung Cancer in Medicare

J.A. Roth1, D. Kratochvil2, S. Dorman1, J.M. Kelton1, M. Bernauer2

1Pfizer, New York/NY/USA ,2OPEN Health, Bethesda/MD/USA

Introduction: Biosimilars to originator bevacizumab (Avastin®), such as bevacizumab-bvzr (Zirabev®), can deliver substantial savings and/or expanded access to biologic therapy for patients with metastatic non-squamous non-small cell lung cancer (mNSCLC). The objective of this study is to explore the cost-efficiency and budget-neutral expanded access of bevacizumab-bvzr in mNSCLC in Medicare.

Methods: We developed a Medicare payer perspective simulation model of patients treated for mNSCLC to estimate cost-savings from converting bevacizumab (originator) to bevacizumab-bvzr. The target patient population receiving annual first line systemic therapy for non-squamous mNSCLC treatment in Medicare (n=26,370) was calculated using Medicare enrollment data, SEER incidence rates for distant adenocarcinoma & large cell carcinoma among those age ≥65, and an assumption that 11% of new diagnoses receive bevacizumab-based treatment based on recent evidence from Voruganti et al. (2023). We modeled combination therapy with paclitaxel + carboplatin—a common U.S. clinical guideline-recommended regimen in non-squamous mNSCLC. Costs were derived from 2024 Average Sales Price (ASP). Results include per-patient per-month (PPPM) cost savings (vs. originator), total monthly savings in the cohort, and number needed to convert (NNC) to biosimilar to fund treatment of an additional 100 patients.

Results: PPPM savings from conversion to bevacizumab-bvzr were $8,410. In 50% (n=1,947) and 100% (n=3,894) conversion scenarios mean PPPM savings were $4,205 and $8,410, and full cohort monthly savings were $16,374,114 and $32,748,228 respectively. These savings represent 35% and 70% reductions in cost vs. originator-based treatment, respectively, and exceed savings from conversion to alternative biosimilars bevacizumab-adcd, -awwb, or -maly (See Table). At 100% conversion, monthly savings from biosimilar conversion could fund up to 8,460 additional patient-months of treatment with bevacizumab-bvzr + paclitaxel + carboplatin. The NNC was 43 to treat an additional 100 patients with bevacizumab-bvzr + paclitaxel + carboplatin and ranged from 55 to 4,422 with alternative biosimilars (See Table).

Conclusions: In the first cost-efficiency and expanded access study of biosimilar bevacizumab in mNSCLC, we find that bevacizumab-bvzr + paclitaxel + carboplatin can result in substantial cost savings relative to originator-based first line treatment of patients with non-squamous mNSCLC in Medicare. These cost savings could be reinvested to treat a substantial number of additional patients with mNSCLC, or fund other costs of care in Medicare, on a budget-neutral basis.

P2.17A.03 Preoperative Anxiety in Patients Undergoing Video-Assisted Thoracoscopic Surgery: Predictive Factors and Specific Concerns and Fears

Y. Huang, C. Lin, Z. Wu, M. Chen, W. Li, B. Zheng, C. Chen

Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: Preoperative anxiety is a common reaction of patients admitted for surgery, which constitutes a bad emotional experience for surgical patients. The prevalence and influencing factors of preoperative anxiety in patients undergoing video-assisted thoracoscopic surgery remain unclear. The study aims to explore the independent predictive factors for preoperative anxiety in patients undergoing video-assisted thoracoscopic surgery and to analyze the specific concerns and fears faced by patients.

Methods: Study participants included patients scheduled for video-assisted thoracoscopic surgery intervention who underwent preoperative anxiety assessments using interview-based questionnaires. Demographic, clinical, and surgical variables were collected. The interview questionnaire included the anxiety component of the Hospital Anxiety and Depression Scale. The prevalence and intensity of anxiety were primarily analyzed descriptively. Univariate and multivariate logistic regression analyses were conducted to identify independent risk factors and to establish a risk scoring model.

Results: A total of 540 patients (57% female) were enrolled. According to the Hospital Anxiety and Depression Scale score composition, 22.4% exhibited preoperative anxiety (score ≥ 8 points). The prediction model had good discrimination, with an area under the receiver operator characteristic curve (AUC) of 0.760 (95% CI = 0.711-0.809) . The predictive variables included in the final clinical model were an age of <60 years (OR = 3.257; 95% CI = 1.791-5.924), body mass index of <25 kg/m2 (OR = 2.266; 95% CI = 1.302-3.946), lung nodule diameter of >1 cm (OR =3.071; 95% CI = 1.826-5.164), lung nodule observation time of >1 month (OR = 2.644; 95% CI = 1.511-4.627), preoperative comorbidities (OR = 2.356; 95% CI = 1.451-3.827), and marital status (divorced vs. married) (OR = 4.842; 95% CI = 2.333-10.049). The primary concerns and fears reported by patients undergoing minimally invasive thoracoscopic surgery encompassed long-term prognosis, postoperative complications, and postoperative discomfort. Surgical patients exhibit varying degrees of concerns and fears, with notable differences observed among individuals based on their levels of anxiety, gender, and age.

Conclusions: Preoperative anxiety remains common in patients planning to undergo video-assisted thoracoscopic surgery. The nomogram demonstrated good predictive performance for preoperative anxiety in patients undergoing video-assisted thoracoscopic surgery. Using this nomogram can help to identify patients with preoperative anxiety, enabling the provision of more personalized support to these individuals to help them cope with their preoperative anxiety.

P2.17A.04 Cost Effectiveness of a System-Level Precision Medicine Intervention for Stage IV Non-Small Cell Lung Cancer Patients

J. Rose1, V. Gosula1, S. Cho1, N. Sadri2, J. Yoest2, A. Donner2, D.S. Bruno2

1Case Western Reserve University School of Medicine, Cleveland/OH/USA ,2University Hospitals Seidman Cancer Center/Case Comprehensive Cancer Center, Cleveland/OH/USA

Introduction: We modeled four scenarios for implementation of a system-level precision medicine intervention to increase the effective use of next generation sequencing (NGS) in newly diagnosed stage IV non-small cell lung cancer (NSCLC) patients.

Methods: The intervention modeled was based on the PREcision meDICine Thoracic (PREDICT) service in place at our institution, consisting of system-wide reflex testing of newly diagnosed stage IV NSCLC patients by an in-house solid tumor focused assay (hybrid DNA/RNA NGS panel) and PD-L1 testing; a PREDICT navigator; a molecular tumor board (MTB); and an integrated information portal for real-time updates on sample processing, results, and MTB recommendations. Using a decision tree model, we examined four implementation scenarios: 1) send-out sequencing and PD-L1 testing for all newly diagnosed Stage IV NSCLC patients, 2) PREDICT for all newly diagnosed patients, 3) send-out NGS for patients with non-squamous disease (plus PD-L1 regardless of histology), and 4) PREDICT for those with non-squamous disease (those with squamous histology receive only PD-L1 testing). Based on the literature, we assumed 79.9% of patients undergoing send-out NGS would receive usable results; from experience, we assumed 97% of patients in the PREDICT groups would receive usable results. Epidemiologic parameters describing the distribution of stage IV NSCLC by histology, specific actionable genomic alterations, and PD-L1 expression were derived from the literature, as were estimates for survival, cost, and health-state utilities under indicated scenarios of first-, second-, and third-line treatment with targeted therapies, checkpoint inhibitors, and chemotherapy. We examined costs (in 2023 US dollars) from the health system perspective. For purposes of spreading fixed costs, we assumed 500 stage IV NSCLC lung cancer patients per year at a hypothetical institution. Costs and QALY's were discounted at a standard 3%.

Results: Table 1 lists the predicted costs and QALYs gained per patient for each scenario as well as the proportions of patients receiving targeted therapy and chemotherapy as part of first-line treatment. Scenarios 1 and 2 were each more costly and less effective than alternatives and were thus eliminated from the cost-effectiveness analysis. The incremental cost-effectiveness ratio (ICER) for moving from the less costly but less effective strategy 3 to strategy 4 was $242,139 per QALY gained.

Conclusions: Implementing a comprehensive precision medicine intervention centered around in-house NGS for non-squamous stage IV NSCLC patients spared a high proportion of patients chemotherapy in first-line treatment but cost $242,139 per QALY gained compared to a more conventional strategy.

P2.17A.05 Racial and Gender Disparities in Immune-Related Adverse Effects: A Nationwide Inpatient Sample Database Analysis

K. Uttam Chandani1, S.P. Agrawal2, Y. Patel2, M. Raval1, H. Khan3

1New York Medical College/Landmark Medical Center, Woonsocket/RI/USA ,2Smt. NHL Municipal Medical College, Ahmedabad/IN ,3Brown University Warren Alpert School of Medicine/Lifespan Cancer Institute, Providence/RI/USA

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of several solid tumors and has led to an improvement in 5-year-survival of these patients. However, they cause various immune-related adverse events (irAEs). Across clinical trials, incidence of irAEs varies between different cancer subtypes, treatment combinations and study settings. There is a lack of validated predictive biomarkers for irAEs. This study aims to evaluate an association between the occurrence of irAEs and patient demographics, in particular race and gender of the patient.

Methods: We analyzed data from the National Inpatient Sample (NIS) database of 2016-2020, of the Agency of Healthcare Research and Quality (AHRQ) focusing on all cancer patients hospitalized between 2016-2020. Using ICD-10 codes, database was queried for patients who had received immune checkpoint inhibitors and developed irAEs. Characteristics including demographics, comorbidities; and AEs were studied using chi-square for categorical or ANOVA for continuous data (statistical significance p-value < 0.05) and results were stratified

based on patient's races and gender.

Results: A total of 25,814 patients receiving immune checkpoint inhibitors were identified of which 58.58% (15,124) were male and 41.41% (10,690) female. The ethnic background information was available for 24,775 patients; of which 63.9% (15835) were White, 7.12% (1765) African American, 12.43% (3080) Hispanic, 4.37% (1085) Asian/Pacific Islander, 0.42% (105) Native American, and 11.72% (2905) belonged to other races. Majority (42.4%) of the African American patients belonged to the lowest income quartile while majority (59.4%) of Asian/Pacific Islander patients belonged to the highest income quartile. The proportion of patients with commercial/private health insurance was higher in the White (51.7%), African American (37.4%), Asian/Pacific Islander (47%) and Native American (42.9%) subgroups. In contrast, 39.1% of the Hispanic patients had Medicaid. irAEs were most prevalent in Asian/Pacific Islander patients (12%) followed by African American patients (11.9%), and White patients (11%). The adjusted odds ratio (aOR) of irAEs was lower in Hispanic patients as compared to White patients (aOR 0.61, 95% CI 0.44-0.84, p 0.003). Females had higher aOR of irAEs (1.27, 95% CI 1.06-1.53, p 0.009) as compared to males.

Conclusions: This study underscores the demographic influence on irAEs among patients receiving immune checkpoint inhibitors; including race and ethnicity, given the lower odds in Hispanic and Asian/Pacific Islander subgroups as compared to White patients. Moreover, females had higher incidence and odds of irAEs as compared to males. Understanding these disparities is critical to facilitate equitable healthcare for all cancer patients.

P2.17A.06 Impact of COVID-19 Diagnosis and Treatment for Lung Cancer in the US National Cancer Database (NCDB) from 2014 To 2021

I. Emmerick1, A. Crawford1, M. Epstein1, A. Markel1, L. Suh1, C. Gray2, M. Maxfield1, C. Berg1, K. Uy1, F. Lou1

1UMass Chan Medical School, Worcester/MA/USA ,2UMass Memorial Health Care, Worcester/MA/USA

Introduction: The COVID-19 pandemic impacted healthcare services, including cancer diagnostics and management. This study analyzes the effects of COVID-19 on staging at diagnosis, first treatment performed, and mean time to treatment initiation (TTI) for non-small cell lung cancer (NSCLC).

Methods: Retrospective cohort analysis of all individuals registered with NSCLC in the US National Cancer Data Base (NCDB) from 2014 to 2021. Individuals with missing data for TTI or clinical stage were excluded. ANOVA, Chi-square, and t-tests were used to compare the pre-COVID (2014-2019) to-COVID (2020-2021) periods.

Results: 767,101 individuals were included, with an average age of 69 years, 49% female, 85% white, 3.2% of Hispanic origin, 73% with Medicare/Medicaid, and 47% with diagnosis and treatment at the same facility. The percent of cancers diagnosed at early-stage (stages 0-2) was 44% in the pre-COVID and 46% in the COVID period ($p<0.01$). Minor differences in the Initial treatment were observed. (Table.1). The TTI was 5.5 days higher in the COVID period (45.8 days) than during pre-COVID (40.3 days) ($p<0.01$) (Table.1) (Figure.1). Community cancer programs had a higher pre-COVID TTI (41.8 days) than other programs and experienced a greater TTI increase during COVID (7 days), while other programs experienced a 5-day increase. New England facilities experienced a higher increase in TTI (7 days) than other regions. Individuals diagnosed with early-stage disease had an increase of 8 days in TTI in the COVID period ($p<0.01$). Black and Hispanic individuals experienced higher TTI, respectively, 49.7 and 46.4 days in the COVID period, when compared to white (45.4 days).

Conclusions: Time to Treatment Initiation for NSCLC increased after COVID-19. Further studies are needed to determine the consequences of delay in lung cancer care due to the pandemic on the levels of survival and effects on health care systems, and whether this persisted in more recent years.

P2.17A.07 Impact of Preoperative Anxiety on Postoperative Outcomes in Patients Undergoing Minimally Invasive Thoracoscopic Surgery

Y. Huang, Z. Wu, C. Lin, M. Chen, W. Li, B. Zheng, C. Chen

Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: Preoperative anxiety is a common preoperative psychological state in patients with cancer and associated with worsening perioperative outcomes. However, high-quality prospective research studies on preoperative anxiety in patients undergoing lung surgery are scarce. We conducted this study to observe the incidence of preoperative anxiety and its effect on short-term postoperative outcomes,

including postoperative complications and non-complicated adverse events (e.g., sleep, pain, nausea, and vomiting).

Methods: We prospectively used the Hospitalization Anxiety Scale to measure preoperative anxiety in patients undergoing thoracic surgery. Patients were grouped according to the Hospitalization Anxiety Scale scores as follows: no anxiety (score < 8) and anxiety (score ≥ 8). The association of preoperative anxiety with postoperative complications and non-complicated adverse events was determined by univariate regression and polynomial regression analyses.

Results: A total of 121 patients (22.4%) presented with preoperative anxiety. The mean length of hospitalization was longer in the anxiety group than in the non-anxiety group (4.33 vs. 3.85 days, respectively). However, the rates of postoperative complications were comparable between the two groups. Regarding perioperative sleep quality, the Athens Insomnia Scale scores at baseline were comparable between the two groups. Nonetheless, the mean score was higher in the anxiety group than in the non-anxiety group; the difference was statistically significant on postoperative days 1 and 3. The anxiety group had a significantly higher rate of severe and mild pain on postoperative days 2 and 3, respectively, compared with the non-anxiety group. The incidence of postoperative nausea and vomiting on postoperative day 1 was significantly higher in the anxiety group than in the non-anxiety group.

Conclusions: Preoperative anxiety may not increase the rates of postoperative complications in patients undergoing lung surgery. However, it may be associated with postoperative sleep disturbances, pain, nausea, and vomiting, as well as prolong the length of postoperative hospitalization. Typically, even high levels of preoperative anxiety do not meet the clinical diagnosis of generalized anxiety disorder. Importantly, preoperative anxiety is modifiable. Identification of patients developing preoperative anxiety provides an opportunity to increase psychological comfort and, thus, improve postoperative outcomes. Hence, preoperative anxiety should be closely monitored and treated accordingly.

P2.17A.08 Trends in Pulmonary Embolism Outcomes Among Lung Cancer Patients: A Nationwide Analysis Across a Decade

D. Solipuram1, S. Solipuram2, S. Katragadda1

1Nassau University Medical Center, East Meadow/NY/USA ,2INOVA Alexandria Hospital, Alexandria/VA/USA

Introduction: Lung cancer[LC] is the second most common cancer and leading cause of cancer mortality in the United States[US]. Pulmonary embolism[PE] contributes to nearly 10% mortality in LC. Nationally representative data on the trends of PE among LC patients are lacking. Determining these trends will assist in evaluating adequacy of current guidelines and assess for scope of any improvements.

Methods: This is a longitudinal study of all LC patients admitted with PE across the US from 2012 to 2021 using National Inpatient Sample. Incidence, mortality, health care utilization, rates of surgical intervention among LC patients admitted with PE were assessed and compared with PE patients without LC. Confounders were adjusted for using multivariate regression analysis. Conditional marginal effects were used to adjust for changing demographics over years.

Results: Total hospital admissions for PE increased from 179615 to 197115 from 2012 to 2021 in the US with a decline in the LC patient admissions with PE from 3.8% to 3.4%. There was an increase in adjusted odds of mortality from 2.7 to 3.1 from 2012 to 2021 for PE patients without LC while mortality increased from 7.2 to 7.7% during the same period for PE patients with LC. Surgical interventions rates were 2% and 3.8% for PE patients with and without LC in 2012 which increased to 4.2% and 12.9% in 2021 with similar increasing trends in mechanical thrombectomy, catheter guided thrombolysis and embolectomy rates in both groups. Use of IVC filters was greater among LC patients compared to non-LC patients with a declining trend in usage across the years[17% vs 10% in 2012 & 5.8% vs 4% in 2021]. ICU admission rates were higher in LC compared to non-LC patients with PE with an increasing trend over the years[3.5% vs 2.7% in 2012 & 4% vs 3.8% in 2021] with a similar pattern in rates of respiratory failure and intubation. Mean length of hospitalization was higher among PE patients with LC compared to those without LC across years with a declining trend in number of days overall[5.7 vs 5.1 in 2012 & 5.1 vs 4.4 in 2021]. Total hospitalization charges increased from $53588 to $61441 for PE patients with LC from 2012 to 2021 while it increased from $44670 to $61503 for PE patients without LC during the same period after adjusting for inflation.

Conclusions: Though there is a declining incidence of PE in LC, mortality rates are increasing over the decade with an associated decreased usage of surgical interventions, higher morbidity and increased health care utilization compared to non-LC patients. Surgical interventions in general are reserved for high risk PE patients. Further assessment of adequacy of these policies in catering to the unique characteristics of LC patients with PE may help in reducing their morbidity and mortality. There is also a compelling need to revisit the thromboprophylaxis guidelines in this subpopulation.

Introduction: Internet-based full-course management for cancer patients is considered an effective mode for enhancing treatment outcomes. This study aims to understand and evaluate the impact of outpatient management via an internet-based physician-patient communication tool on the treatment outcomes of lung cancer patients undergoing immunotherapy.

Methods: Physicians can formulate outpatient management plans for patients on the platform(Wedoc). Patients can also engage in online communication with their attending physicians, report symptoms and corresponding test reports encountered outside the hospital, and receive timely guidance from physicians. We conducted a retrospective cohort study using data collected from this platform. Data were collected from 35 hospitals nationwide, establishing a cohort of lung cancer patients treated with PD-1/L1 inhibitors to explore the effects of this outpatient management model on the efficacy and adverse reactions of immunotherapy.

Results: A total of 1110 lung cancer patients receiving immunotherapy for at least two cycles were included. 86.3% of patients were male, with a median age of 67 years. Squamous cell carcinoma accounted for 34.1%, adenocarcinoma for 39.4%, and stage IV patients for 57.7%. Patients received a median of 8.5 cycles of immunotherapy, evaluated by physicians using RECIST 1.1 criteria. The overall response rate (ORR) was 64.7%, and disease control rate (DCR) was 93.3%. The median follow-up duration for all patients was 108 days. Patients initiated a median of 220 dialogues with physicians on the platform, with a median communication frequency of 3.8 times per week. 52.8% of patients reported adverse reactions after immunotherapy, with 35.9% experiencing grade 3 or higher adverse reactions. The most common adverse reactions were decreased appetite, rash, and fatigue. Pearson analysis showed a strong correlation between patient communication frequency and density on the platform and the occurrence of adverse reactions (correlation coefficients 0.52 and 0.46, respectively). However, these factors showed weak correlations with short-term treatment efficacy and the number of treatment cycles (correlation coefficients 0.14 and 0.1; 0.19and 0.04, respectively).

Conclusions: Internet-based outpatient management plays a positive role in promptly identifying adverse reactions following immunotherapy and providing timely interventions. In this retrospective analysis, no significant correlation was found between patient communication behavior on the platform and treatment efficacy evaluated by physicians based on RECIST criteria. Further rigorous controlled trial designs are needed for further exploration.

Introduction: New and advanced therapies have improved the 5-year survival of lung cancer patients. With increased lifespan of patients, major adverse cardiovascular and cerebrovascular events (MACCE) occur during treatment. The use of potentially cardiotoxic therapies further emphasizes the importance of pretreatment risk stratification and monitoring for MACCE.

Methods: Using ICD-10 codes, the National Inpatient Sample (NIS) database of the Agency of Healthcare Research and Quality (AHRQ), was queried from 2016 to 2020, for patients with lung cancer. MACCE including all-cause in hospital mortality (ACIHM), myocardial infarction (MI), atrial fibrillation (AF), cerebral events, and sudden cardiac death (SCD) were identified. Characteristics including demographics, comorbidities and MACCE were studied using chi-square for categorical or ANOVA for continuous data (statistical significance p-value < 0.05) and results were stratified based on patient's races. Multivariate regression models were applied to adjust for cofounders.

Results: Among 1,961,429 lung cancer hospitalizations, 32.8% (643,404) experienced MACCE. Predominantly, 77.39% (1,518,040) were White, 12.6% (247,310) African American, 4.6% (90,250) Hispanic, 2.88% (56,565) Asian/Pacific Islanders, 0.38 % (7640) Native Americans and 2.12% (41,624) other races. Dyslipidemia (41.9%) prevailed in Whites while hypertension (46.8%), renal failure (21.5%), congestive heart failure (19%) prevailed in African Americans. Diabetes (32.5%) was frequent in Hispanics, whereas obesity (8.8%) in Native American patients. ACIHM was higher in Asian/Pacific Islanders as compared to Whites, with adjusted odds ratio (aOR) of 1.22 (95% CI 1.14-1.3,

p<0.001). African Americans had lower mortality (aOR of 0.96, 95% CI 0.92-0.99, p 0.041) when compared to Whites. MI was higher in African Americans, aOR 1.1 (95% CI 1.06-1.15, p<0.001) and lower in Hispanics, aOR 0.88 (95% CI 0.80-0.98, p 0.021), and cerebral events were also higher in African Americans (aOR 1.1, 95% CI 1.06-1.15, p<0.001) and lower in Hispanics (aOR 0.91, 95% CI 0.85-0.97, p 0.008), when compared to Whites. As compared to Whites, SCD was higher in African Americans (aOR 1.67, 95% CI 1.55-1.81, p<0.001), Hispanics (aOR 1.41, 95% CI 1.24-1.60, p<0.001), Asian/Pacific Islanders (aOR 1.23, 95% CI 1.04-1.47, p 0.016), and other races (aOR 1.25, 95% CI 1.01-1.54, p 0.038).

Conclusions: This study underscored the high prevalence of MACCE across the lung cancer population with a disproportionately higher incidence in the non-White patients with lung cancer. This highlights the need for equitable healthcare access to all patients, to address underlying risk factors and comorbidities to mitigate these racial and ethnic disparities. Involvement of cardio-oncology in this high-risk population, may improve outcomes.

P2.17B.01 The Construction and Application of a Novel Precise Health Management Model for Lung Nodule Population

D. Liu, W. Li, H. Zhang, Y. Xiao, M. Gu

The Affiliated Hospital of Qingdao University, Qingdao/CN

Introduction: The early screening of lung cancer faces issues such as a high rate of false positives, overtreatment, complex patient visit processes, poor compliance, and significant psychological harm. To optimize the patient management processes, a novel precise health management model for lung nodules has been proposed.

Methods: A novel precise health management model for lung nodules was proposed. In this proposed model, a series of workflows including a new follow-up communication protocol and multidisciplinary treatment (MDT) for lung nodules has been designed. To compare

the proposed model with traditional model, consecutive participants undergoing early lung cancer screening with LDCT at our department from May 1, 2021 to December 31, 2021 were selected to be studied. Initially, patient were divided into two groups: the new model group managed by the Laoshan District and studied by using the new model, and the old model group managed by the Shinan District and traditional model will be applied to. To investigate the performance of new proposed model, different aspects, such as loss to follow-up rate, timely return visits after detection of lung nodules, the proportion of surgical patients who underwent surgery at our hospital, the proportion of benign nodules among surgical patients, the follow-up interval for low-risk lung nodule patients, the psychological health status of patients, and patient satisfaction with lung nodule management services were evaluated between the two groups.

Results: A total of 2816 individuals were included in the two groups with 1178 individuals in the new model group and 1638 individuals in the old model group. Following the detection of lung nodules, the rate of loss to follow-up was notably lower in the new model group compared to the old model group (28.5% versus 32.5%, P=0.025). Among those who completed the follow-up process, the new model group demonstrated a significantly higher rate of timely return visits (60.3% versus 53.0%, P=0.001). Additionally, a larger proportion of surgical patients in the new model group underwent surgery at our hospital (93.9% versus 82.6%, P=0.035), and among these surgical patients, the incidence of postoperative benign lesions was lowered from 13.0% to 3.0% by applying the proposed model. The follow-up interval for low-risk lung nodule patients was also much longer in the new model group (12.152±3.439 months versus 11.295±4.823 months, P=0.022). As of January 1, 2024, or the conclusion of the follow-up period, the prevalence of anxiety among patients was lower in the new model group (15.0% versus 21.1%, P<0.001), and patient satisfaction with lung nodule management services was notably higher in the new model group (83.8% versus 76.2%, P<0.001).

Conclusions: This study proposes a novel precision health management model for lung nodules and its effectiveness is demonstrated. The proposed model provides a more rational and effective management strategy for patients with lung nodules, simplifies the patient visit process, improves patient compliance, avoids overdiagnosis of lung nodules, reduces psychological harm to patients, and enhances the technical level and service quality of our medical institution.

P2.17B.02 Healthcare Providers' Perceptions of Barriers and Enablers to Adopting New Surveillance Protocols

A. Fraser, R. McNeill, J. Robinson

University of Auckland, Auckland/NZ

Introduction: Lung cancer patients with non-curative disease currently face frequent follow-up visits to the outpatient clinic associated with anxiety, time commitment, and out of pocket costs. In New Zealand (NZ) there are significant equity issues for Indigenous Māori around access to healthcare, impacting diagnosis and outcomes. Unsustainable demand for oncology services in NZ has led to calls for the introduction of a new national framework for managing people with cancer. Evidence suggests virtual follow-up can lead to higher patient satisfaction without negatively impacting on health outcomes such as survival time, as well as reducing demand on clinical space. The aim of this study was to explore healthcare providers' perception of barriers and enablers to adopting new surveillance protocols for people with non-curative lung cancers or mesothelioma.

Methods: Semi-structured interviews were conducted with a range of healthcare providers (HCPS) across NZ, including medical oncologists, primary care providers, radiation oncologists, oncology psychologists, oncology nurses and navigators, respiratory physicians, and Māori HCPs. A generally inductive thematic analysis method was used to explore the themes around barriers and enablers to using new surveillance protocols. Themes were organised using a Micro-Meso-Macro level framework to identify day-to-day attributes, institutional factors, or influences, and regulatory or economic conditions which might impact on how services are delivered.

Results: There was a general agreement from HCPs that there is a lack of evidence around current practice, and clinicians recognised the need to provide flexibility for surveillance options. Enablers for developing novel models of care identified by clinicians were equity focused with a strong emphasis on developing connections, building on trusted relationships between HCPs and patients, improving communication within and across services, and developing options for local delivery of care. New models of care could be strengthened through use of supportive care roles and better education of oncology pathways for primary care clinicians. Micro level barriers included: Costs to attend follow-up, communication, patient experience, nihilism and stigma, quality of communication, clinician engagement, anxiety, health literacy, patient choice, paternalism. Micro level enablers included: Trusted relationships, connection, and engagement with providers. Meso level barriers included: Travel and regional variation and challenges. Meso level enablers included: support roles and local delivery of care. Macro level barriers included: Capacity in clinics and radiology, diagnostics, and IT issues for both patients and providers. There were no macro level enablers identified.

Conclusions: Alternative models of care (MOC) are acceptable to HCPs, and clinician flexibility was identified as a key enabling theme. Māori HCPs identified the importance of co design in development of MOC, emphasizing a 'one size fits all' approach did not provide the flexibility individual communities needed to enable them to access care and stay connected to their HCP. Implications for future MOC development include working in co design with patients and families to develop flexible MOC.

P2.17B.03 Improving Lung Cancer Screening Utilization and Efficiency Through a Patient-Centered Pathway with Virtual Visits

S. Ghandehari, D. Gregory, M. Sobolev, M. Sweeney

Cedars Sinai Medical Center, Los Angeles/CA/USA

Introduction: Lung cancer screening (LCS) via low-dose computed tomography (LDCT) remains underutilized, with fewer than 6% of those deemed eligible for LCS getting screened in the United States. One of the many barriers to screening is the requirement of a face-to-face shared decision-making (SDM) counseling visit before ordering LDCT, imposed by third-party payers. During the COVID-19 pandemic, screening rates declined dramatically due to reduced clinic and personnel resources and concerns about potential exposures. Under the COVID-19 Public Health Emergency waiver, Medicare temporarily approved telehealth services for SDM visits. Established LCS programs (LCSP) could transition their in-person visits to telehealth. Despite the extension of the waiver, utilization of telehealth services has diminished in many areas. It is unclear if the predominant use of telehealth for LCS evaluation outside of a pandemic health emergency is practical or feasible. The purpose of this research is to evaluate the effectiveness of implementing virtual visits as part of a centralized LCSP (C-LCSP) in rapidly increasing LCS in an efficient, patient-centered pathway.

Methods: This research was performed in a large academic medical center in Los Angeles. Considering the diversity of clinic practices with a mix of faculty, staff physicians, and affiliated community private practitioners, a hybrid LCSP with a centralized navigated pathway alongside a decentralized provider-managed screening was launched in April 2022. The goal of the C-LCSP was to navigate the screening process and address some common barriers to screening, such as the time-consuming SDM counseling. To further facilitate the screening process, virtual visits were offered. We use a retrospective cohort analysis to investigate the utilization and efficiency of LCS in the two years following the launch of the C-LCSP. We report the number of LDCTs performed in the navigated and provider-managed pathways.

Results: In the three years preceding the launch of the LCSP, fewer than 100 LDCTs for LCS were performed annually. 1540 LDCTs were done between April 2022 and March 2024, representing a 670% increase compared to the prior two years. 38% of the screening studies were part of the C-LCSP, 95% of which were performed via telehealth. Our efforts steadily increased the number of screenings, with 106% more screening in the C-LCSP and 85% more screening in the provider-managed pathway from April 2023 to March 2024 compared to the previous year.

Conclusions: We report the successful implementation of a patient-centered pathway for LCS featuring virtual SDM counseling visits. We show that virtual SDM visits are feasible outside of the public health emergency of a pandemic and are associated with a rapid screening uptake. Our research is limited as it does not explore the causality for this rapid uptake. Rapid growth is noted in centralized and provider-managed pathways, likely attributable to extensive efforts to educate patients and providers within the health system. Further studies are needed to explore whether the convenience of virtual visits by a dedicated provider trained to perform SDM counseling for LCS drives rapid uptake in the C-LCSP.

P3.01D.01 Racial Disparities Among Patients Diagnosed with Lung Cancer at a Young Age

A. Manoharan, K. Edwards, N. El-Abbar, L. Ramos, N. Parikh, S. Kareff, G. Lopes, E. Rodriguez, C. Olazagasti, University of Miami, Miami/FL/USA

Introduction: Lung cancer is the leading cause of cancer mortality in the US. Survival trends vary by sex, age, race/ethnicity, and socioeconomic status. While lung cancer outcomes have improved among all groups, mortality is highest among Black males. Studies showed that Black patients have lower smoking rates than White patients. Despite this, Black patients have a worse overall survival. Furthermore, the rates of lung cancer among younger patients have been increasing, with little known about this unique population. We aimed to explore racial disparities among young patients with lung cancer.

Methods: We created a single institution study at the University of Miami. A total of 128 patients (111 White and 17 Black) under the age of 45, who were treated for lung cancer from 2013-2021 were included in the analysis. Data analysis was conducted using t-tests and chi square analysis.

Results: The median age at diagnoses was 38 and 39 years for White and Black patients (p=0.34), respectively. (Table 1) While 59.4 % of White patients smoked tobacco, only 41.1% of Black patients endorsed a history of smoking tobacco (p=0.009). The average days between a positive biopsy and surgical intervention was 102 days for White and 15 days for Black patients (p=0.72). The average number of days between a positive biopsy and chemotherapy initiation for White vs Black patients was 37 days vs 44 days, respectively (p=0.59). The most common histology for White patients was adenocarcinoma (62%), whereas Black patients had only 35% prevalence of adenocarcinoma (p=0.017). Most patients in both groups had stage IV disease at diagnosis, 61% white vs 64% Black (p=.35). Despite lack of statistical association, Whites had more than two-fold rates of actionable mutations than Black patients, 56% in White patients vs 25% in Black patients (p=0.177).

Conclusions: Our single institution analysis revealed notable trends in the clinicopathologic characteristics of young patients with lung cancer. We found that Black patients had lower rates of adenocarcinoma despite lower rates of tobacco use, which is paradoxical to prior studies which have shown that adenocarcinoma is more common in non-smokers. Notably, Black patients were found to have lower rates of actionable mutations and were more frequently diagnosed with metastatic disease than their white counterparts. Thus likely resulting in less targetable and precise treatment plans for Black patients. Ongoing large prospective studies would be of paramount important to assess and understand potential racial disparities in young patients with lung cancer.

Keywords: Racial, disparities, young patients

Characteristic	White (N=111)	Black (N=17)	p-value

P3.01D.02 Lung Cancer Incidence Trends by Histology and Sociodemographic Characteristics in the US from 2000-2019

J. Jeon[1], P. Cao[2], R. Meza[3,4], [1]University of Michigan, Ann Arbor/MI/USA ,[2]University of Texas MD Anderson Cancer Center, Houston/TX/USA ,[3]British Columbia Cancer Research Institute, Vancouver/BC/CA ,[4]University of British Columbia, Vancouver/BC/CA

Introduction: Lung cancer incidence has been decreasing in the US overall, largely due to declining smoking trends. However, adenocarcinoma incidence has been relatively stable compared to the other histological types until recently, causing its proportion among lung cancer cases to increase. Trends of histology-specific lung cancer incidence vary by sociodemographic characteristics, but the extent of this variation is unknown.

Methods: SEER 17 registry data was used to calculate annual age-adjusted lung cancer incidence over 2000-2020 by histology stratified by sex, race/ethnicity (non-Hispanic White, non-Hispanic Black, non-Hispanic American Indian/Alaska Native [NH-AI/AN], non-Hispanic Asian/Pacific Islander [NH-API], Hispanic), education (US counties grouped in quartiles of the percentage of people who are 25 or older and have at least bachelor's degree based on the American Community Survey (ACS)), poverty (US counties grouped in quartiles of the percentage of persons at above the federal poverty line based on the ACS), and region (Rural-Urban Continuum Codes were used to stratify US counties into metro counties (Urban) and non-metro counties (Rural)). Histology was categorized into four groups: adenocarcinoma, small cell carcinoma, squamous cell carcinoma, and other cell carcinoma. Age-adjusted incidence rates were computed using the 2000 US Standard Population. Incidence trends were assessed using Joinpoint regression analyses.

Results: Incidence of small cell, squamous cell, and other cell carcinoma have been decreasing since 2000 in both sexes and all racial/ethnic groups, although the decrease is either slower or statistically not different from 0 among the NH-AI/AN population. On the other hand, adenocarcinoma incidence was roughly stable for both sexes, with increases among female NH-API and Hispanic populations until 2019. Similar temporal patterns in lung cancer incidence by histology were observed in the analyses by education, poverty, and region. In general, counties with higher education levels or lower poverty rates experienced faster declines in small cell and squamous cell carcinoma in recent years. For example, the average annual percent change [AAPC] of small cell carcinoma in females from 2015 to 2019 was -0.7 (95% CI: -1.2, -0.1), -1.6 (95% CI, -2.0, -1.1), -3.2 (95% CI, -6.6, -2.2), and -3.9 (95% CI, -4.6, -3.5) for the first, second, third, and fourth education quartiles, respectively. Incidence of small cell and squamous cell carcinoma has been decreasing more rapidly in urban than rural areas in recent years. The analysis also found a clear gradient by educational attainment, poverty level, and region—with the lowest lung cancer incidence in the most educated and wealthy counties and urban areas in both sexes and all histological types, except for the adenocarcinoma among females, which showed the highest incidence rates in these subpopulations.

Conclusions: Disadvantaged groups have higher lung cancer rates and slower decreases in incidence over time, resulting in widening disparities. This highlights the need for targeted prevention strategies to accelerate lung cancer decreases in vulnerable populations. It will be important to continue monitoring lung cancer trends by histology to evaluate potential differential impacts of screening and the changing tobacco and nicotine landscape across different sociodemographic groups.

P3.01D.03 Evaluating Lung Cancer Disparities Among Transgender Populations: A Retrospective Cohort Analysis

T. Tabernacki[1,2], A. Thakur[1,2], R. Amkraut[1,2], M.A. Maravillas[2], S. Gupta[2], S. Banik[3], M. McNamara[1,4], K. Mishra[1,2,5], [1]Case Western Reserve University School of Medicine, Cleveland/OH/USA ,[2]University Hospitals, Cleveland/OH/USA ,[3]Center for Health Disparities Research & Education, Baldwin Wallace University, Berea/OH/USA ,[4]Louis Stokes VA Medical Center, Cleveland/OH/USA ,[5]MetroHealth Cleveland Medical Center, Cleveland/OH/USA

Introduction: Lung cancer remains the leading cause of cancer-related mortality in the United States, imposing a significant burden on healthcare systems and communities across all demographic groups. The epidemiology of lung cancer among transgender and gender diverse (TGD) individuals remains incompletely understood. TGD individuals face unique risk factors including a high rate of cigarette smoking and decreased access to healthcare and screening. The impact of gender-affirming hormone therapy (GAHT) on lung cancer risk also remains unclear, with conflicting results from previous studies. In this large retrospective cohort study we used a large nationwide database to investigate lung cancer incidence in transgender individuals compared to cisgender counterparts.
