Methods: Utilizing the TriNetX platform, we accessed de-identified electronic health records from 105.9 million patients, identifying 93,836 transgender individuals, including 39,573 trans men and 54,263 trans women. These cohorts were subdivided based on GAHT status, and the age-stratified lung cancer incidence was compared to the age-adjusted incidence of lung cancer among cisgender cohorts constructed from the same database.

Results: We observed significantly elevated lung cancer incidence among transgender men not undergoing testosterone therapy (TMNI) compared to cisgender females in specific age groups: 15-39 (SIR 4.96, 95% CI 2.42-9.10), 65-74 (SIR 2.43, 95% CI 1.13-4.62), and 75+ (SIR 3.96, 95% CI 1.01-10.78). No significant differences were observed for transgender men receiving testosterone therapy (TMHT) or transgender women, regardless of hormone treatment status (TWHT, TWNI).

Conclusions: These results highlight the importance of targeted interventions and supportive health practices to address cancer disparities among transgender populations. Further research is needed to understand the mechanisms underlying these observations and inform effective prevention strategies. This study contributes to advancing inclusive, gender-affirming healthcare practices and addressing health disparities within the transgender community.

P3.01D.04 Disparities in Lung Cancer Risk Assessment for People Living with HIV

S. Hardcastle[1], A.B. Paulson[2], P. Woodhouse[2], S. Valenti[2], S. Joyner[2], S.A. Deppen[3], K.L. Sandler[2], [1]Vanderbilt University School of Medicine, Nashville/TN/USA ,[2]Vanderbilt University Medical Center, Nashville/TN/USA ,[3]Vanderbilt University Medical Center, Tennessee Valley Healthcare System Veterans Affairs, Nashville/TN/USA

Introduction: People living with HIV (PLWHIV) are experiencing an increased incidence in non-AIDS-defining malignancies. Lung cancer is one of the most common cancers diagnosed in this population and the number one cause of cancer mortality. Lung screening reduces mortality from lung cancer. Screening may be even more beneficial in PLWHIV, as this population has been shown to have a higher incidence of lung cancer with shortened survival following diagnosis. To evaluate these disparities, we compared personalized PLCOm2012 lung cancer risk scores and incidence of lung cancer diagnosis in screening participants with and without HIV.

Methods: Retrospective chart review was performed on 4,233 patients enrolled in a lung cancer screening program at a single academic institution from November 2017 to November 2023. All enrolled patients met the current United States Preventive Services Task Force lung screening guidelines. PLCOm2012 risk prediction model was used to assign personalized 6-year lung cancer risk scores to patients based on demographic data from baseline lung screening. PLWHIV were identified through ICD-10 diagnostic codes and chart-review. Statistical difference in median PLCO score by HIV status was estimated by Wilcoxon rank-sum test. Logistic regression was performed to estimate lung cancer risk among HIV-positive patients after controlling for baseline risk as determined by PLCO score. All analyses were performed with Stata v18.

Results: PLWHIV (n = 269, Table 1) had a higher prevalence of lung cancer (3.35%) compared to those without HIV (2.57%, n = 3,964). However, the median PLCO score in PLWHIV was 2.2 compared to 2.7 in those without HIV (p-value 0.0001). The likelihood for receiving a lung cancer diagnosis was about 50% greater (OR=1.5; 95% CI 0.77-3.12; p=0.22) among the HIV-positive population compared to the HIV-negative cohort after controlling for baseline PLCO score in the lung screening program.

Conclusions: A statistically significant difference in baseline lung cancer risk as determined by PLCO was observed with the HIV-negative group having higher baseline score but lower prevalence of lung cancer compared to PLWHIV. This suggests that HIV status may be an independent risk factor for lung cancer in this population. This finding, while not statistically significant, should be investigated in larger cohorts of PLWHIV, given our strong, single-site observations. These data suggest that lung cancer screening guidelines may not be adequately including higher risk individuals living with HIV.

P3.01D.05 Gender Differences in Lung Cancer Incidence Among Patients Who Never Smoked Cigarettes: A Systematic Literature Review

D. Molena[1], C. Aggarwal[2], N. Florez[3], S. Peters[4], J. Brahmer[5], E. Shum[6], R. Salomonsen[7], J. Chaieb[7], M. Chau[7], R. Shenolikar[7], L. Luciani-Silverman[7], D. Guy[8], L. Woldmann[8], A-A. Ciritel[8], H. Wakelee[9], [1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]University of Pennsylvania Medical Center - Abramson Cancer Center at Perelman Center for Advanced Medicine, Philadelphia/PA/USA ,[3]Dana-Farber Cancer Institute, Boston/MA/USA ,[4]CHUV, Lausanne University, Lausanne/CH ,[5]Johns Hopkins Medicine, Baltimore/MD/USA ,[6]NYU Langone, New York/NY/USA ,[7]AstraZeneca, Gaithersburg/MD/USA ,[8]Amaris Consulting, Barcelona/ES ,[9]Stanford University School of Medicine, Stanford/CA/USA

Introduction: Lung cancer is a leading cause of mortality worldwide. While cigarette smoking is a main driver of lung cancer, a subset of cases also occurs in patients that have never smoked, particularly in women. Understanding the gender-based nuances of lung cancer incidence among patients who do not smoke, alongside other demographic characteristics, is essential for refining screening strategies and improving outcomes for all individuals at risk, irrespective of smoking history.

Methods: A systematic literature review was conducted to synthesize published literature on the gender-based differences in lung cancer incidence rates among patients who do not smoke cigarettes, considering additional factors such as race, ethnicity, age, and histology subtypes. Embase, MEDLINE, MEDLINE In-Process, and Cochrane databases were searched. Relevant conference proceedings and additional literature from experts were also considered. English language studies published between January 2004 and February 2024 that reported global, regional, or national lung cancer incidence rates for men and women were included.

Results: We found 879 studies, 609 remained after de-duplication. Of these, 550 were ineligible based on titles/abstracts. From the 59 remaining articles, eight studies will be evaluated.

Conclusions: We plan to present the incidence rates among women who never smoked compared to men, particularly in younger age groups, and indicate potential areas of differences.

Keywords: gender differences, lung cancer incidence, never-smokers

P3.01E.01 Real-World Analysis of GLP-1 Receptor Agonists and Lung Cancer Risk in Treatment-Naïve Type 2 Diabetes: Potential Impact of Obesity and Gender

J. Song[1], A.E. Cali Daylan[2], K-Y. Chi[1], Y. Chang[3], R.S. Memon[1], J. Lee[1], J. Ahn[4], C-H. Chiang[5], H. Cheng[2], [1]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx/NY/USA ,[2]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx/NY/USA ,[3]National Cheng Kung University College of Medicine, Tainan/TW ,[4]Eastern Virginia Medical School, Norfolk/VA/USA ,[5]Mount Auburn Hospital, Havard Medical School, Cambridge/MA/USA

Introduction: Type 2 diabetes (T2DM) affects over 30 million people in the United States, with approximately 15% of lung cancer patients also affected by this condition. Glucagon-like peptide-1 receptor agonists (GLP1a) have become popular in T2DM treatment and are proposed to have anti-inflammatory and immunomodulatory functions in addition to weight loss and glucose control. Initial studies of GLP1a raised concerns for increased risk of malignancies, especially pancreatic cancer. However, recent studies have proposed the contrary for colorectal cancer based on real-world data, hypothesizing that the weight-reducing effect of GLP1a may be the mechanism behind this observation. In this study, we aim to explore the association of GLP1a and the risk of developing lung cancer - which has been suggested to be inversely related to obesity.

Methods: We utilized TriNetX Global Collaborative Network, a deidentified real-world electronic health record database containing 122.6 million patient records. We included patients over the age of 18 diagnosed with T2DM who started their first diabetic medication (drug-naïve) between 2010 and 2019. Patients previously diagnosed with pulmonary nodules or lung cancer prior to initiating their initial diabetic medication were excluded. We conducted 1:1 propensity score matching to control for potential risk factors and confounders. Subsequently, survival analyses were performed among GLP1a users and comparison cohorts within the total and subgroups, calculating the incidence and hazard ratio (HR) of newly developed lung cancer.

Results: During a 15-year follow-up of 734,835 drug-naïve T2DM patients, GLP1a was associated with a decreased risk of lung cancer when compared to insulin (HR:0.681, 95% CI:0.520-0.891), metformin (HR:0.719, 95% CI:0.562-0.919), DPP4 inhibitor (HR:0.777, 95% CI:0.650-0.928), and thiazolidinediones (HR:0.777, 95% CI:0.646-0.935), and the trend was similar among the obese and non-obese population. GLP1a's protective association appeared to be more pronounced in males, especially compared to insulin (HR:0.480, 95% CI:0.304-0.758) and metformin (HR:0.617, 95% CI:0.422-0.904).

Conclusions: GLP1a use was associated with decreased lung cancer risk among drug-naïve T2DM patients. This effect was primarily driven by the male cohort, where patients on GLP1a had a 52% decrease in the risk of lung cancer development compared to insulin. In contrast to the previous study of colorectal cancer, lung cancer risk reduction was similar among the obese/overweight and non-obese/overweight populations. These findings are significant, especially considering initial concerns about increased cancer risk associated with these commonly used antidiabetic agents. Further investigations into GLP1a's preventive role in lung cancer development and underlying mechanisms are warranted.

P3.01E.02 Association Between Composite Dietary Antioxidant Index and Lung Cancer Risk in Former Smokers: A Large Prospective Cohort Study in UK Biobank

Y. Feng, B. Cheng, X. Fu, P. Chen, W. Liang, the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Lung cancer is the leading cause of cancer death worldwide. There is limited epidemiological evidence regarding the association between Composite Dietary Antioxidant Index (CDAI) and lung cancer risk. Therefore, this study was to investigate the relationship between CDAI and lung cancer.

Methods: This prospective cohort study used data from the UK Biobank cohort study on adults aged 40 to 69 years who were recruited at 22 assessment centers throughout the UK Biobank between March 13, 2006, and October 1, 2010, with follow-up through June 1, 2022. The CDAI was calculated based on the standardized intake levels of six dietary antioxidants, including manganese, selenium, zinc, and vitamins A, C, and E. The lung cancer cases were confirmed via the International Classification of Diseases-10th (ICD-10) code “C34”. Cox proportional hazards regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for the association of CDAI with lung cancer risk. Subgroup analyses were conducted to investigate the association stratified by age, sex, ethnicity, Townsend Deprivation Index, education level, Body Mass Index (BMI), weekly physical activity, smoking status, alcohol intake frequency, and family history of lung cancer. Furthermore, additive interaction was used to assess whether CDAI modifies the risk of lung cancer among smokers. Besides, the robustness of the results was assessed by multiple sensitivity analyses.

Results: A total of 201,316 participants from the UK Biobank were included in the study. During a median follow-up of 11.8 years, 1229 incident lung cancer cases were documented. The analysis showed a trend for a higher quartile of CDAI associated with a lower lung cancer risk after adjusting for covariates (HRQ4vs.Q1, 0.69; 95% CI, 0.56-0.85; Ptrend < 0.001). Similar findings were also observed in non-small cell lung cancer (HRQ4vs.Q1, 0.72; 95% CI, 0.58-0.89; Ptrend= 0.003) and small cell lung cancer (HRQ4vs.Q1, 0.38; 95% CI, 0.17-0.85; Ptrend= 0.019). In subgroup analyses, the association between CDAI and the risk of lung cancer was more significant in participants with higher education (HR, 0.94; 95% CI, 0.9-0.98; P= 0.004), BMI <25 kg/m2 (HR, 0.95; 95% CI, 0.91-0.99; P= 0.007), former smoking (HR, 0.95; 95% CI, 0.92-0.98; P= 0.002), and without a family history of lung cancer (HR, 0.97; 95% CI, 0.94-0.99; P= 0.006). Additionally, a negative interaction was observed between CDAI and smoking status, indicating that HRs (95% CIs) of lung cancer for former smokers in the lowest and highest quartile of CDAI were 4.28 (3.16-5.79) and 0.66 (0.43-1), respectively, compared to non-smokers with the lowest CDAI quartile. In the sensitivity analysis, there was no significant difference in the HR for lung cancer after excluding participants with incomplete covariate data (HRQ4vs.Q1, 0.74; 95% CI, 0.59-0.93; Ptrend = 0.005), and the association remained consistent within the subset after removing outliers of CDAI (HRQ4vs.Q1, 0.68; 95% CI, 0.56-0.84; Ptrend < 0.001).

Conclusions: Dietary antioxidants may reduce the risk of lung cancer, especially among former smokers.

P3.01F.01 Evaluating the Relationship Between Veteran Toxic Exposure Status and Lung Cancer Prevalence

P. Meyers, A. Perkins, B. Patel, R. Winter, S. Davis, E. Grogan, S. Deppen, Vanderbilt University Medical Center, Nashville/TN/USA

Introduction: Veterans face a greater risk for lung cancer. Military service-related exposures may increase the likelihood for developing lung cancer. Screening guidelines rely on tobacco use history and age, but inadequately capture the breadth of risk factors prevalent among veterans. We linked the Veterans Affairs (VINCI) and the Department of Defense service (DaVINCI) electronic health records to obtain tobacco use and military exposures. This study assesses the association between lung cancer and veteran-specific toxic exposures.

Methods: We combined individual tobacco use strata ("Ever," "Never," or "Unknown") with self-reported toxic exposure survey data among all veterans receiving care between 1/1/2022 and 12/31/2023. Toxic exposures surveyed were Agent Orange, Airborne Hazard/Burn Pit, Camp Lejune, Radiation, Gulf War, and Other. We excluded veterans who declined toxic exposure screening. Patients were stratified by toxic exposure status, tobacco use status, and age. We investigated the association between service branch and exposure. Finally, we performed logistic regression modeling to adjust for age, tobacco use status, and exposure status.

Results: 7,031,577 veterans completed toxic exposure screening. 2,132,015 (29.8%) screened positive for toxic exposure. Unadjusted prevalence of lung cancer was 1.6% in the overall cohort, 1.7% among veterans with any toxic exposure, and 1.5% with no exposure. The unadjusted lung cancer prevalence ranged from 3.6% (Agent Orange) to 0.9% (Gulf War) with marked differences in median age (Table 1). Among all services and exposures, Marine Veterans had the highest prevalence (3.8%) from Agent Orange and Coast Guard with Gulf War exposures had the lowest (0.3%, Table 2).

Conclusions: Lung cancer among veterans with any tobacco use and age greater than 50 varied widely by service branch and toxic exposure status. Many were more than PLCO 1.6% cutoff. Our investigation highlights the critical role of toxic exposure consideration in risk assessment and the critical need for veteran specific guidelines.

P3.01F.02 Retrospective Characterization of Patients with Primary Lung Cancer Related to World Trade Center Disaster Exposure

J.N. Lo Cascio[1], N. Mourikis[1], C.J. Okpara[1], R. Belenkaya[2], M. Wilkenfeld[1], M. Rybstein[1], [1]New York University Grossman Long Island School of Medicine, Mineola/NY/USA ,[2]New York University, New York/NY/USA

Introduction: Over twenty years after the World Trade Center (WTC) disaster, exposed responders and citizens continue to be diagnosed with cancers due to the toxicity of the dust, fires, and clean-up. The two decades since then have revealed common "9/11 Cancers", with lung cancer being the third most common. Here, we analyze a cohort of 250 patients treated at NYU Langone Health between 2011 and 2023 with a diagnosis of primary lung cancer who had exposure to the WTC disaster. We aim to assess how this exposure incident impacts features of patients' pulmonary tumors and resultant disease course, in order to expand providers' knowledge as these cancers continue to be diagnosed.

Methods: This is a retrospective chart review of primary lung cancer patients treated at NYULH Perlmutter Cancer Center (PCC), diagnosed between January 1, 2006 and December 31, 2023, with documented WTC exposure. Data points include age, sex, race, diagnosis date, smoking status, stage at diagnosis, disease course, next generation sequencing, and date of death (if applicable). Study dataset was curated by PCC Data Hub then manually annotated when data were inaccessible.Summary statistics were computed for demographics and clinical characteristics. Statistical tests, including the Kruskal-Wallis Rank Sum, Fisher's Exact, and Chi-Squared tests, and clustering analyses were performed as appropriate. All time-to-event outcome variables ('time to response to first-line therapy,' 'progression-free survival,' and 'overall survival') were analyzed using the Kaplan-Meier (KM) product limit method and Cox proportional hazard (CPH) regression models.

Results: Initial data curation identified 250 lung cancer patients with documented WTC toxicity exposure. Our analysis found that more than half of the study population were diagnosed with Stage I (50%) or Stage II (7.2%) disease, followed by Stage III (14%) and IV (21%), and 8.4% unknown. 160 patients were former smokers and 14 were current smokers. Of the 174 patients with smoking history, 52 had under 20 pack year histories. 67 patients in the cohort (27%) had no smoking history at all. Interestingly, the non-smoking patients as a group had the highest proportion of Stage IV disease at diagnosis, when compared to groups with smoking history.

Conclusions: In this population, there was a higher rate of diagnosis at lower stage (I-II) compared to lung cancer patients in the United States, which are commonly diagnosed at Stages III-IV. The national recommendation for annual lung cancer screening is for patients with 20 pack year histories, and a majority of the patients included here would not have qualified for screening. Thus, their earlier diagnosis could be linked to known exposure and screening through the September 11th Victims Compensation Fund (VCF). Current WTC-related lung cancer research is limited to incidence and demographics without description of detailed clinical factors. Our work highlights that screening these patients can increase the rate of earlier lung cancer diagnosis, and hopefully improve prognosis. Future studies with this population can allow us to better understand whether lung cancer in this group differs from that of patients with other exposure histories.

MONDAY, SEPTEMBER 9, 2024 - 12:00 - 14:00

P3.02F.01 CD47 Promotes Migration and Metastasis in Non-Small Cell Lung Cancer

A.P. Lau, R. Hoshi, Z. Rousseau, Y.F. Wu, H. Ni, K. Thu, St. Michael's Hospital, Toronto/ON/CA

Introduction: CD47 is a cell surface protein frequently overexpressed in non-small cell lung cancer (NSCLC). Although it has multiple biological functions, most CD47 studies in cancer have focused on its role in promoting tumor immune evasion. This inspired the development of CD47-targeted immunotherapy which is currently being evaluated in clinical trials. High CD47 expression is associated with poor survival, advanced tumor stage, and metastasis in NSCLC patients, and inhibition of CD47 impairs lung tumor growth and progression, highlighting its therapeutic potential. Yet, little is known about the involvement of CD47 in regulating NSCLC metastasis. We hypothesize that CD47 promotes metastasis by positively regulating signal transduction pathways required for cell migration and invasion. In this study, we examined the effect of CD47 loss-of-function (LOF) on lung cancer migration and metastasis and relevant signaling pathways in NSCLC models.

Methods: CRISPR/Cas9 was used to induce CD47 LOF by deleting its transmembrane and extracellular domains (ΔCD47) in the mouse NSCLC models, Lewis Lung Carcinoma (LLC) and CMT167 (CMT), as well as the human NSCLC line, H1299. ΔCD47 was confirmed in these lines using Sanger sequencing of genomic DNA, and immunofluorescence and flow cytometry to assess expression of CD47 on the cell surface. The functional effects of ΔCD47 on cell proliferation and migration were assessed using growth competition and scratch assays, respectively. Metastasis to the lungs in syngeneic mice was quantified using bioluminescence imaging (BLI) after tail-vein injections of wildtype (WT) or ΔCD47 LLC cells expressing Luciferase. Proteins related to migration and metastasis were measured in isogenic cells using immunoblotting.

Results: We observed no difference in the proliferation of LLC, CMT or H1299 cells with WT or ΔCD47 in competitive growth assays performed in vitro. However, we found that ΔCD47 significantly impaired migration of CMT and H1299 cells in vitro. We could not measure migration with scratch assays in the LLC model due to its loose adherence, but ΔCD47 significantly impaired metastasis of LLC cells to the lungs of mice after tail-vein injection. Concordantly, mice injected with ΔCD47 LLC cells exhibited significantly longer metastasis-free survival than mice injected with WT control cells. Our initial assessment of signaling proteins involved in migration/metastasis pathways suggests that E-cadherin expression is increased and phospho-AKT, phospho-FAK, and vimentin expression are reduced in ΔCD47 cells, consistent with the migration defect we observed in cells with CD47 LOF.

Conclusions: Our findings indicate that CD47 promotes migration and metastasis of NSCLC cells both in vitro and in vivo. This suggests that CD47-targeted therapy could effectively inhibit NSCLC tumors by antagonizing metastatic spread in addition to tumor immune evasion. At the molecular level, our results suggest that migration and metastasis are regulated, at least in part, by a CD47-FAK-AKT signaling axis. Future experiments will continue to unravel the metastasis signaling cascade governed by CD47 in NSCLC.

Keywords: CD47, metastasis, signaling

P3.02F.02 Long Non-Coding RNA STEAP2-AS1 Promotes Non-Small-Cell Lung Cancer Cells Progression by Interacting with ARNTL2 To Upregulate DARS2

H. Zhang[1], M. Li[2], X. Leng[1], Y. Han[1], [1]Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu/CN ,[2]Zhongshan Hospital, Fudan University, Shanghai, China; Cancer Center, Zhongshan Hospital, Fudan University, Shanghai/CN

Introduction: Circadian rhythm plays an important role in tumors. Though ARNTL2 serves as one of the core genes of circadian rhythm, there are few studies on its regulation and mechanism of lung cancer. We sought in this study to firstly define the expression, prognostic effects, and potential regulatory roles of ARNTL2 in non-small-cell lung cancer (NSCLC). We subsequently clarified the key regulatory role of the "non-coding RNA-ARNTL2-target gene" regulatory axis in the tumorigenesis and development of NSCLC through a series of cytological and animal assays.

Methods: First, the expression and prognostic significance of ARNTL2 in NSCLC were identified by data from The Cancer Genome Atlas (TCGA) and the single-cell RNA sequencing of our department. Subsequently, long non-coding RNA (lncRNA) regulatory mechanisms and target genes of ARNTL2 were fully explored by Immunoprecipitation sequencing of RNA (RIP-Seq) and transcriptome sequencing of RNA (RNA-Seq) in A549 and H1299 cells, respectively. Further, we take full advantage of molecular techniques such as bioinformatics analysis, Chromatin Immunoprecipitation (ChIP), Western blot, Immunofluorescence and Fluorescence in situ hybridization; cytological and animal experimental to fully explore the regulatory effects and mechanisms of "LncRNA-ARNTL2-target gene" regulatory axis in the proliferation, migration, and invasion of NSCLC.

Results: We found that the expression of ARNTL2 was upregulated in NSCLC and significantly associated with worse prognosis. Through bioinformatics analysis, cytology, and animal experiments, we discovered the effect of ARNTL2 in cell proliferation, migration, and invasion of NSCLC. In addition, we found that LncRNA STEAP2-AS1 was an important non-encoding RNA interacting with ARNTL2 in A549 and H1299 cells by RIP-Seq. And STEAP2-AS1 had the role of transferring the transcription factor ARNTL2 through the cytoplasm to the nucleus. We also identified DARS2 as a direct transcriptional target of ARNTL2 and verified its binding site through Luciferase reporter and ChIP assays. In addition, we found LncRNA STEAP2-AS1/ARNTL2/DARS2 axis promotes proliferation, migration and invasion, and was significantly associated with a poor prognosis in NSCLC patients.

Conclusions: The present study elucidates for the first time in NSCLC cells that ARNTL2 undergoes "Cytoplasmic-Nuclear translocation" through the LncRNA STEAP2-AS1-dependent guidance effect and binds to the promoter region of the target gene DARS2 to promote the expression. LncRNA STEAP2-AS1/ARNTL2/DARS2 axis plays an important role in promoting cell proliferation, migration, and invasion of NSCLC. Our findings will shed light, to some extent, on the key roles and regulatory mechanisms of the circadian element ARNTL2 in the development and progression of NSCLC.

P3.02F.04 Investigating the Role of Lactate Import and Metabolism in Non-Small Cell Lung Cancer

R. Cameron, N. Hammond, M. Kaur, M. Alsamraae, C. Bestvina, M. Garassino, B. Faubert, University of Chicago, Chicago/IL/USA

Introduction: Metabolic reprogramming is a hallmark of cancer, but our knowledge of nutrient preferences in cancer cells has been limited to non-physiological cell culture systems. In preclinical animal models and patients with patients with non-small cell lung cancer (NSCLC), we demonstrated that lactate, commonly thought of a waste product of cancer cells, is instead an important nutrient. Furthermore, increased lactate uptake via monocarboxylate transporter 1 (MCT1) is associated with worse disease-free and overall survival. How lactate import reprograms metabolism and how this supports aggressive lung cancers remains unclear.

Methods: In vitro studies utilized H1299 cells cultured in standard (RPMI) or physiological (HPLM) nutrient conditions. Cells were treated with the MCT1 inhibitor AZD3965 (100 uM) for 24h prior to the addition of physiological concentrations of glucose or lactate. Either glucose or lactate was uniformly labeled with the stable isotope 13C to investigate the metabolism of each nutrient. Metabolites were extracted after 24 h and were measured using GC-MS. Mouse xenografts were generated using NSCLC cell lines injected subcutaneously and were infused with 13C labeled metabolites prior to euthanasia.

Results: Adding lactate to RPMI results in decreased glucose incorporation into the TCA as demonstrated by increased m+0 citrate labeling. Lactate was taken up and incorporated into the TCA cycle, as demonstrated by m+2 citrate labeling. This incorporation was decreased by treatment with the MCT1 inhibitor AZD3965. While lactate was the preferred carbon source to generate alanine, the inhibition of MCT1 induced metabolic rewiring, as cancer cells compensated by re-directing glucose to generate alanine. Importantly, culturing cells with the physiological HPLM condition displayed greater alterations in metabolism, including diminished glucose utilization for generating lactate and citrate when compared to RPMI conditions. In cell culture, physiological media conditions (including adding lactate as a nutrient source) better recapitulated the metabolic reprogramming of lung tumors in vivo.

Conclusions: Lactate is an important nutrient in NSCLC. Addition of lactate to cell culture media allows for the import and metabolism of lactate, and results in the metabolic rewiring of other nutrients such as glucose. By further mimicking physiological nutrient conditions, such as the use of HPLM, we are better able to model the metabolism of tumors in vivo. Further optimization of culture conditions can provide a foundation to understand the role of MCT1 inhibition as a therapeutic target for NSCLC.

P3.02F.05 A Genetic Engineering Approach to Interrogate Myosin 10 As a Driver of Non-Small Cell Lung Cancer Metastasis

R. Goffe[1], A. Marcus[2], [1]Emory University School of Medicine, Atlanta/GA/USA ,[2]Emory University, Atlanta/GA/USA

Introduction: A major contributor of lung cancer mortality is associated with late cancer stage at diagnosis, with 5-year survival rates for persons with regional and distant metastasis at 29.7 and 4.7% compared to localized (non-metastatic) lung cancer at 56.3%. While minimizing lung cancer metastasis can improve overall survival, few models exist where subpopulations with stable high and low metastatic potential can be easily and reliably isolated. Previous work characterized two stable subpopulations, termed Leaders and Followers, from the H1299 Non-Small Cell Lung Cancer model. H1299 Leaders and Followers have different transcriptional profiles, biomarkers, genomic methylation patterns, metabolic states, and morphologies. Of note, H1299 Leaders express high levels of Myosin 10 (MYO10) and drive collective invasion and metastasis.

Methods: To determine how MYO10 contributes to Leader cell biology and lung cancer metastasis, we utilized CRISPR-Cas9 to generate edited pools of H1299 cells targeting MYO10. Fluorescence-activated cell sorting using a Leader-Follower biomarker, IL13R–2, was used to generate single cell derived candidate clones. Candidate clones were screened using western blot for Leader and Follower cell biomarkers (JAG1, MYO10, HTATIP2 and IL13R2) followed by Sanger sequencing of candidate clones was also conducted to confirm target gene status (Figure 1A-B).

Results: Three (3) MYO10-/- and two (2) wildtype MYO10+/+ single-cell derived clones were generated (Figure 1C). Data show that loss of MYO10 in Leader cells significantly reduces proliferation and alters the transcriptional profile of Leader cells but is not essential for survival.

Conclusions: While loss of MYO10 abrogates proliferation there is much left to be interrogated regarding how MYO10 contribute to metastasis. Clones generated in this model will be used to assess how loss of MYO10 in Leader cells influences the survival and patterns of metastasis in our in vivo model. This work is the foundation of future studies which aim to enhance our understanding not only of MYO10-dependent mechanisms that drive the Leader metastatic phenotype but also how MYO10 influences Leader cell interactions with endothelial cells as a part of the metastatic cascade.

Keywords: metastasis, lung cancer, myosin 10

P3.02F.06 Multi-Omics Reveals Effects of Gut Microbiome on Tumor Immune and Metabolism in Mouse Lewis Lung Carcinoma Model

Z. Hu, R. Shi, F. Mao, Z. Zhang, Y. Wang, B. Li, H. Zhang, Y. Li, H. Liu, J. Chen, Tianjin Medical University General Hospital, Tianjin/CN

Introduction: The gut microbiota represents the predominant symbiotic microbial community in mammalian organisms, lung cancer has long been a challenging human disease. Investigating the role of the gut microbiota in the occurrence and progression of lung cancer holds value. Our objective was to investigate the impact of gut microbiota on lung cancer progression and the effects on tumor metabolism and immune through multi-omics methods between germ-free(GF) and specific pathogen-free(SPF) mouse models.

Methods: Subcutaneous tumor was established using Lewis lung carcinoma cells(LLC) in 10 GF mice and 12 SPF mice. The distribution of intestinal and tumor microbiota as well as tumor metabolites was examined using simplified metagenomics(2bRAD-M) and metabolomics(GC/LC-MS) in random selected 6 GF and 6 SPF mice. Single-cell-RNA sequencing was performed in random selected 2 GF and 2 SPF mice.

Results: Tumor growth in SPF mice was significantly faster than in GF mice. Metagenomic analysis showed a significant difference of beta-diversity in gut microbiota between SPF and GF mice while no significant difference in tumor microbiota. Chao1 was used to quantify the alpha-diversity of microbiotas. The alpha-diversity of gut microbiota in SPF mice was significantly higher than that in GF mice while no significant difference in tumor microbiota. Pearson analysis showed a positive correlation between gut flora Chao1 value and tumor volume. Single-cell-RNA sequencing indicated the functions of vasculogenesis and morphogenesis in tumor cells of SPF mice were upregulated, as well as the number and function of neutrophils and fibroblasts related to tumor progression were increased. In GF mice, the number of CD8 cells for anti-tumor immunity was upregulated and the tumor killing function was upregulated while the number of macrophages was increased and the tendency of differentiation towards M1 macrophages was increased. Metabolomics showed glycolysis and amino acids metabolism was downregulated in SPF tumors. Combining the gut microbiota KO(KEGG Orthology) enrichment and single-cell subclustering analysis, the function of glycolysis and amino acids metabolism in gut microbiota of SPF mice was lower while no significant difference in that of tumor microbiota.

Conclusions: Gut microbiota promotes tumor development and the malignancy, upregulates the number and function of cancer-related Neutrophils and Fibroblasts while downregulates that of tumor-killing CD8 T cells and M1-type Macrophages. The relative abundance and diversity of gut flora is positively correlated with tumor progression, but not the tumor flora. The gut flora correlates with the regulation of glycolysis and amino acids metabolism in tumor, but not the tumor flora.

P3.02G.01 Therapeutic Targeting of Lung Cancer-Associated Fibroblasts Mitigates Mediastinal Lymphatic Dissemination in Non-Small Cell Lung Cancer

J.C. HO, C. Chen, The University of Hong Kong, Hong Kong SAR/HK

Introduction: Cancer-associated fibroblasts (CAFs) represent a pivotal component in tumor microenvironment. Yet, the biological function of lung CAFs in the context of mediastinal lymph node metastasis in non-small cell lung cancer (NSCLC) remains unknown. Our study endeavors to address this critical knowledge gap and explore potential therapeutics employing a novel CAFs-rich orthotopic xenograft model.

Methods: Lung CAFs were generated through the co-culturing of normal human lung fibroblasts (MRC-5) with non-small cell lung cancer (NSCLC) cell lines (H358 and HCC827). To establish orthotopic xenograft models, NSCLC cells were percutaneously injected into the left lung of mice, with or without the presence of lung CAFs. The efficacy of CAF inhibitors, namely ABT-199 and NNMTi (Nicotinamide N-Methyltransferase inhibitor), was assessed to determine their ability to inhibit lymphangiogenesis and prevent mediastinal lymph node metastasis. Tumor growth was monitored sequentially using micro-computed tomography (CT), and the response was evaluated according to RECIST v1.1 criteria. Confirmation of mediastinal lymph node metastasis was achieved through H&E staining and immunohistochemistry.

Results: The activation of lung CAFs was successfully achieved through direct co-culture. The co-inoculation of cancer cells alongside lung CAFs resulted in tumors characterized by heightened peritumoral lymphangiogenesis and a higher frequency of mediastinal lymph node metastasis compared to tumors derived from cancer cells only. In contrast, the administration of ABT-199 led to a significant reduction in lung CAFs, effectively suppressing tumor growth (mean ± SEM: 7.17 ± 0.33 vs 5.89 ± 0.28, $p<0.01$), lymphangiogenesis (mean ± SEM: 1.40 ± 0.24 vs 0.31 ±0.07, $p<0.01$), collagen deposition (mean ± SEM: 16.75 ± 0.74 vs 5.05 ± 0.78, $p<0.0001$), and mediastinal lymph node metastasis (mean ±SEM: 6.82 ± 0.55 vs 2.83 ± 0.21, $p<0.001$) in the H358-CAFs-rich NSCLC orthotopic xenograft model. Our findings unequivocally demonstrate that NNMTi administration significantly curtails tumor burden (mean ± SEM: 62.51 ± 5.68 vs 48.46 ± 1.36, $p<0.05$), proliferation (mean ± SEM: 20.86 ± 1.24 vs 15.35 ± 1.32, $p<0.05$), lymphangiogenesis (mean ± SEM: 2.00 ± 0.27 vs 0.34 ± 0.06, $p<0.0001$), and collagen deposition (mean ± SEM: 19.46 ± 1.31 vs 2.23 ± 0.49, $p<0.0001$) in the HCC827-CAFs-rich NSCLC orthotopic xenograft model.

Conclusions: Lung CAFs promote tumor-associated lymphangiogenesis and mediastinal lymph node metastases in NSCLC orthotopic xenograft model. The strategy of targeting lung CAFs holds promise in limiting cancer cells spread via lymphatics, particularly in CAFs-rich NSCLC scenarios.

P3.02G.02 Integrin-Linked Kinase Facilitates Drug Tolerant Persister Cell Survival and EMT in Response to EGFR Targeted Therapy

R. Shi[1], D. Farnsworth[1], T. Atwal[1], J. Chow[1], R. Sheena[1], C-M. Lee[1], Y. Inoue[1], S. Awrey[1], P. McDonald[1], R. Somwar[2], M. Ladanyi[2], S. Dedhar[1], K. Bennewith[1], W. Lockwood[1], [1]British Columbia Cancer Research Institute, Vancouver/BC/CA ,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Lung cancer is the leading cause of cancer-related deaths worldwide. The 3rd-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), osimertinib (Osi), has extensively improved patients outcomes. However, patients inevitably develop resistance against. Epithelial-mesenchymal transition (EMT) is an established non-genetic resistance mechanism that also associated with increased metastatic potential of tumours. In the progression towards EMT-mediated resistance exists a key transitory cell state of drug-tolerant-persistence (DTP), in which increased phenotypic plasticity permits cell survival during drug treatment. Integrin-linked kinase (ILK), an important regulator of integrin signaling, has been implicated in the pathogenesis of other cancers through the promotion of EMT. Additionally, a recent study in lung adenocarcinoma (LUAD) patients treated with EGFR-TKIs found that high ILK expression was correlated with worse prognosis. Therefore, we hypothesized that ILK may be important for DTP cell survival and EMT-mediated Osi resistance in EGFR mutant LUAD.

Methods: ILK expression and gene set enrichment analysis (GSEA) was performed on both internal and external LUAD patient databases. Conditional genetic and pharmacological manipulation of ILK were used to regulate ILK function both in vitro and in vivo. Cell viability and clonogenic assays were used to evaluate Osi sensitivity and DTP cell survival. Osi-resistant (OsiR) cells were made by dose-escalation. RNAseq and western blots were performed to assess expression levels and MSK-IMPACT to define genetic alterations. Confocal microscopy was used to evaluate YAP activity.

Results: High ILK expression was found to be significantly correlated with an EMT expression signature in patients. Genetic suppression of ILK in HCC4006 cells, an EGFR mutant LUAD line with high basal ILK expression, limited EMT progression and reduced the viability of DTP cells by impairing SRC mediated YAP activation both in vitro and in mouse models, ultimately improving Osi response. Conversely, EGFR mutant lung cancer cells with low ILK levels that were engineered to overexpress ILK lead to increased DTP cell survival after EGFR TKI treatment. Importantly, these ILK high DTP cells were able to persist long enough to acquire additional mutations that maintained their mesenchymal features and their insensitivity to Osi independent of ILK. Lastly, we show that pharmacological inhibition of ILK suppressed EMT and improved Osi response in LUAD cells, providing evidence that combination therapy of targeting ILK and EGFR is a feasible strategy in combating tumour persistence and resistance driven by EMT.

Conclusions: Our results show that ILK is important in promoting EMT and DTP survival in EGFR-driven LUAD. Targeting ILK may be a viable strategy to manage minimal residual disease and EGFR TKI resistance in lung cancer.

P3.02G.03 High-Dose Ascorbic Acid Sensitizes Immunotherapy in LKB1-Deficient Lung Cancer by Promoting Tumor Cell Pyroptosis

X. Cai, X. Guo, X. Sun, D. Han, Z. Dong, X. Bai, D. Wu, Nanfang Hospital, Southern Medical University, Guangzhou/CN

Introduction: Loss-of-function mutation of STK11/LKB1 leads to the primary resistance to immune checkpoint blockade (ICB). High-dose ascorbic acid (AA) could induce cell redox imbalance and selectively kill tumor cells with specific mutation. Whether high-dose AA could selectively kill redox-imbalanced LKB1-deficient lung cancer cell and synergize ICB remain unknown.

Methods: LKB1-deficient human lung cancer cell lines and LLC1-sgLkb1 murine lung cancer models were established and utilized to explore the effect of high-dose AA on LKB1-deficient lung cancer. Transcriptomic and transmission electron microscope were performed to distinguish the precise mechanism, validated by the inhibitors of the candidate targets and inner blockade of the key molecule. Single-cell transcriptomic atlas and multiplex immunohistochemical were mapped to decipher the immune microenvironment fueled by high-dose AA and ICB.

Results: Treating with high-dose AA, intracellular ROS level of LKB1-deficient cell were significantly accumulated and LKB1-deficient lung cancer took up significantly more AA by upregulating GLUT1. Performing integrative analysis of cellular morphology and transcriptomic data, we identified high-dose AA selectively induced LKB1-deficient lung cancer cells pyroptosis via activating the cleavage of GSMDE depending on H2O2/ROS-Caspase-3-GSDME signaling pathway. Furthermore, high-dose AA potentiated ICB efficacy in LKB1-deficient orthotopically tumor models and cytokine array analysis elucidated that high-dose AA mediated pyroptosis provoked the release of immune active chemokines and substances to ignite tumor immune microenvironment (TIME). Leveraging single cell RNA sequencing data and multiplex immunohistochemical, high-dose AA enhanced the infiltration of TCF1+ CD8+ T cells and reduced the infiltration of SPP1+ macrophages in TIME. Inner blockade of GSDME reversed the inflamed TIME and the synergistic effect of high-dose AA.

Conclusions: LKB1-deficient lung cancer is susceptible to pyroptosis induced by high-dose AA. High-dose AA might be a promising translational therapeutic strategy to potentiate ICB efficacy in LKB1-deficient lung cancer pending further clinical validation.

P3.02G.04 JP11646-mediated PIM2 Inhibition Has Potent Antitumor Effects in Small Cell Lung Cancer and Large Cell Neuroendocrine Carcinoma of the Lung

K. Minton, P.D. Pham, M. Opyrchal, K.P. Lee, M.D. Shields, Indiana University School of Medicine, Indianapolis/IN/USA

Introduction: Small cell lung cancer (SCLC) is an aggressive neuroendocrine (NE) lung carcinoma characterized by acquired chemoresistance at relapse. SCLC tumor plasticity and chemoresistance is driven, at least in part, by the downstream effects of MYC amplification or overexpression, namely the activation of Notch and subsequent induction of NE dedifferentiation. Despite increased molecular characterization of SCLC, few effective options at relapse are available, highlighting the urgency for novel therapeutic approaches, namely those that target MYC-dependent pathways. C-MYC is stabilized by the proviral integration site for Moloney murine leukemia virus 2 (PIM2) kinase through phosphorylation. Recently, a novel pan-PIM non-ATP competitive inhibitor JP11646 has shown promising antitumor activity in various cancers; however, JP11646 has not yet been studied in SCLC. Here, we report the antitumor efficacy of JP11646 in MYC-amplified SCLC and large cell neuroendocrine carcinomas of the lung (LCNEC).

Methods: Cell culture/reagents: Human SCLC lines (H209, SHP-77, H1417, H187, H2171, H69, H524) and LCNEC line H1155 were obtained from ATCC, cultured in RPMI-1640 with 10% fetal bovine serum, and incubated at 37°C in 5% CO2. JP11646 (10 mM stock, Jasco Pharmaceuticals) was gifted by Dr. Kelvin Lee. Drug sensitivity assay in vitro: A total of 1,000 cells/well were seeded in a 384-well plate and incubated overnight at 37°C. Serial dilutions of JP11646 (1 nM - 10 μM) were added in triplicate with 2-3 biological replicates and incubated for 72 h at 37°C. Viability was measured with Promega CellTiter-Glo™ Luminescent Assay Kit. Effects of JP11646: Cells were plated at 2 x 106 per 100 cm2 dish on Day 0. JP11646 (or H2O) was added at a concentration of 500 nM for 24 hours. Cells were harvested for WB analysis. Western blot analysis: Cell lysates were generated utilizing RIPA lysis buffer with protease and phosphatase cocktail inhibitors, quantified utilizing Bradford reagent, and stabilized with SDS at 95°C. Samples were loaded on a 10% precast gel, transferred with Transblot Turbo, blocked with EveryBlot Blocking Buffer (EBB) for 5 minutes, primary 1:1000 in EBB for 30 minutes, followed by serial washes, secondary 1:5000 in EBB for 30 minutes, followed by serial washes, and exposed with ECL reagent. Films were analyzed by BioRad Image Lab and BioRender.com. Antibodies utilized: PIM2 (D1D2, CST), C-MYC (D84C12, CST), N-MYC (D4B2Y, CST), and vinculin (E1E9V, CST).

Results: PIM2 protein is expressed in SCLC and LCNEC. Across the panel of SCLC and LCNEC, the mean IC50 for JP11646 was 87 nM. MYC paralog-amplified cell lines' IC50 ranged from 7 nM to 117 nM, with C-MYC amplified H524 harboring exquisite sensitivity. With JP11646 treatment, we find that PIM2 protein expression decreases. Furthermore, MYC paralog (C-MYC, N-MYC) protein expression decreases within 24 hours of JP11646 treatment across the panel.

Conclusions: PIM2 is expressed in neuroendocrine carcinomas and serves as a potential therapeutic target for relapsed disease. Treatment with a PIM2 inhibitor effectively inhibits cell viability in SCLC and LCNEC. JP11646 leads to reductions in MYC paralogs. Validation with xenograft models and exploration of the downstream effectors of MYC with JP11646 are planned.

P3.03H.01 Tumour Educated Platelets Display a Distinct RNA Content Profile Across Metastatic Patterns in NSCLC.

J. Flynn[1,2], M.G. Best[3], S.G.J.G. In 't Veld[3], S. Finn[1,4], O. Sheils[1,4], A-M. Baird[1,2], [1]Trinity Translational Medicine Institute, Trinity College Dublin, Dublin/IE ,[2]Trinity St. James's Cancer Institute (TSJCI), St. James's Hospital, D[08] RX[0]X, Dublin/IE ,[3]Department of Neurosurgery, Brain Tumor Centre Amsterdam, Cancer Center Amsterdam, Amsterdam UMC, VU University Medical Center, Amsterdam/NL ,[4]Department of Histopathology and Morbid Anatomy, Trinity Translational Medicine Institute, Trinity College Dublin, D[08] W[9]RT, Dublin/IE

Introduction: The pro-metastatic nature of non-small cell lung cancer (NSCLC) is a significant contributing factor to poor overall survival. Platelets are known to play a role in the metastatic cascade through their interaction with tumour cells. During these interactions, platelets can sample tumour macromolecules, thus changing their functionality and gene signature, resulting in tumour educated platelets (TEPs). This study examined the expression signature of TEPs in stage IV disease in the context of metastatic site patterns.

Methods: The GSE183635 dataset, which contains stage IV NSCLC TEP (n=399) and asymptomatic controls platelet (n=390) expression data, was downloaded from the Gene Expression Omnibus. Differentially expressed genes (DEGs) were identified using EdgeR from TEPs and platelets from stage IV NSCLC samples and asymptomatic controls. Further expression analysis was performed by comparing TEPs from samples with different metastatic profiles. These DEGs were used to perform gene set enrichment analysis (GSEA) to further elucidate the potential functional impact of these TEPs within the metastatic cascade.

Results: The initial analysis of stage IV NSCLC highlighted 28 significantly upregulated genes compared to asymptomatic controls. Enrichment of pathways including hydrogen peroxide metabolic processes suggests that tumours may prime platelets for aggregation upon stimulation with other tumour agonists. Other enriched processes included metabolism, gas transport and immune processes. In the cohort of brain metastases (n=56), 15 upregulated genes were identified and included CD163 (logFC = 2.13, FDR<0.05), IGHA1 (logFC = 1.85, FDR<0.01), and KSR1 (logFC = 1.9, FDR<0.001), the latter of which has been linked to epithelial-mesenchymal transition (EMT). Conversely, two genes were downregulated, CST7 (logFC = -1.83, FDR<0.001) and GLYATL2 (logFC = -1.76, FDR<0.05). TEPs from those with bone metastases (n=55) demonstrated upregulation of 34 genes including CA1 (logFC = 1.63), SNX24 (logFC = 1.04) and IFITM3 (logFC = 0.97), of which both SNX24 and IFITM3 have been implicated in tumour progression and cancer metastasis. 370 genes were downregulated in the bone metastases group. Interestingly, these downregulated genes are involved in cytoplasmic translation, ribosomal biogenesis, and immune response pathways. The gene CST7 (logFC = 1.9, FDR<0.001) was the only differentially expressed gene and was upregulated in the liver metastasis group (n=26). CST7 is a known immune regulator and prognosis marker in pancreatic ductal adenocarcinoma. ECE1 (logFC = 1.33, FDR<0.05) was upregulated in the adrenal metastases group (n=12). ECE1 is an unfavourable prognostic marker in NSCLC. Of note, the upregulated genes are unique to each group, thus highlighting distinct TEP signatures across metastatic profiles.

Conclusions: TEPs from people with NSCLC can be used to investigate potential contributing mechanisms to the metastatic process, including platelet metabolism pathways. This study highlights distinct TEP signatures across different metastatic patterns. Further investigation may elucidate how these metastatic site-specific alterations impact and guide the spread of NSCLC and identify potential anti-metastatic targets.

P3.03H.02 PMS2 Amplification Contributes Brain Metastasis from Lung Cancer

J. Chen, C. Su, Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Lung adenocarcinoma metastasizing to the brain results in a notable increase in patient mortality. The high incidence and its impact on survival presents a critical unmet need to develop an improved understanding of its mechanisms.

Methods: To identify genes that drive brain metastasis of tumor cells, we collected cerebrospinal fluid samples and paired plasma samples from 114 lung adenocarcinoma patients with brain metastasis and performed 168 panel-targeted gene sequencing. We examined the biological behavior of PMS2-amplified lung cancer cell lines through wound healing assays and migration assays. In vivo imaging techniques are used to detect fluorescent signals that colonize the mouse brain. RNA sequencing was used to compare differentially expressed genes between PMS2 amplification and wild-type lung cancer cell lines.

Results: We discovered that PMS2 amplification was a plausible candidate driver of brain metastasis. Via in vivo and in vitro assays, we validated that PMS2 amplificated PC-9 and LLC lung cancer cells had strong migration and invasion capacity. The functional pathway of PMS2 amplification of lung cancer cells is mainly enriched in thiamine, butanoate, glutathione metabolism.

Conclusions: Tumor cells elevated expression of PMS2 possess the capacity to augment the metastatic potential of lung cancer and establish colonies within the brain through metabolism pathways.

P3.03H.03 Feasibility of Metastatic Lymph Node-informed ctDNA Analysis in Surgically Resected NSCLC Patients

S. Ohara[1], K. Suda[1], E. Kalashnikova[2], A. Hamada[1], M. Chiba[1], M. Shimoji[1], T. Takemoto[1], S. Sudhaman[2], S. K. Cheung[2], M. Krainock[2], J. Feeney[2], H. Sethi[2], M.C. Liu[2], J. Soh[3], Y. Tsutani[1], T. Mitsudomi[4], [1]Kindai University, Osaka-Sayama/JP ,[2]Natera, Inc., Austin/TX/USA ,[3]Osaka Metropolitan University, Osaka/JP ,[4]Izumi City General Hospital, Izumi/JP

Introduction: Circulating tumor DNA (ctDNA) analysis is useful to detect molecular residual disease (MRD) after pulmonary resection in patients with early-stage non-small cell lung cancer (NSCLC). A tumor-informed approach for ctDNA testing typically tracks single nucleotide variants (SNVs) identified from DNA sequencing of the primary tumor. In this study, we explored the mutational landscapes of primary tumor tissue and metastatic lymph nodes (mLN) and explored the feasibility of mLN-informed ctDNA testing in patients with locally advanced NSCLC undergoing resection.

Methods: Plasma samples from 46 with clinical stage IIA-IIIA NSCLC (TNM 8th edition) were collected between January 2018 and June 2020, at Kindai University Hospital before surgery, after surgery (landmark), and then every 6 months until 2 years thereafter. Of these 46 patients, 18 patients with both primary tissue and resected mLN available were included in this study. SNVs were selected from whole exome sequencing of the primary tumor and mLN along with matched normal DNA obtained from blood. Parallel ctDNA analyses were performed using the personalized, tumor-informed 16-plex mPCR-NGS assays (SignateraTM, Natera, Inc.) developed from the primary tumor and mLN.

Results: Among the total of 64 longitudinal plasma samples analyzed, 61 (95%) had concordant sample call results between the primary tumor-informed vs. mLN-informed assays. The remaining three plasma samples had low level positive results by one of the assays only. Moreover, on comparing the total shared variants identified in the WES data from both primary and LN tissue, an average of ~30% overlap, ranging up to 93%, was observed.

Conclusions: We observed a high concordance rate between primary tumor-informed vs. mLN-informed ctDNA analysis in early-stage NSCLC patients before and/or after surgery. These data support the use of alternative tissue sources for designing personalized tumor tissue-informed ctDNA assays.

P3.03H.04 Molecular and Clonal Evolution of Primary Lesions vs Brain Metastasis and Progressive Disease of EGFR Mutated Patients

A. Ruiz-Patiño[1], O. Arrieta[2], L. Rojas[1], J. Zuluaga[1], C. Martin[3], L. Corrales[4], L. Viola[1], J. Rodriguez[5], H. Carranza[5], C. Vargas[5], J. Otero[5], A.F. Cardona[1], [1]Luis Carlos Sarmiento Angulo Cancer Treatment and Research Center – CTIC, Bogota/CO ,[2]Instituto Nacional de Cancerología (INCan), Mexico City/MX ,[3]Instituto Fleming, Buenos Aires/AR ,[4]Centro de Investigación y Manejo del Cáncer – CIMCA, San José/CR ,[5]Foundation for clinical and applied cancer research - FICMAC, Bogota/CO

Introduction: Clonality is an intrinsic phenomenon of disease evolution, with certain clones conferring increased aggressiveness and apparent tropism toward certain metastatic sites. In this analysis, we sought to evaluate the different divergent and unique mutational patterns present in brain metastases

Methods: A retrospective cohort study encompassing patients diagnosed with EGFR-mutated lung adenocarcinoma either presenting with brain metastases upon diagnosis or experiencing progression to this site. All patients underwent three NGS-based genomic profiling assessments. The initial two analyses involved tissue samples from the primary and predominant brain lesions, while the third utilized either liquid biopsy or tissue from an extracranial lesion at disease progression. Treatment for all patients consisted of Osimertinib and stereotactic radiosurgery following RANO-BM evaluation of brain lesions.

Results: The analysis comprised a total of 30 Hispanic patients. Of these, 22 patients (73%) were female, with a median age of 55 years. Nearly all patients, except one (97%), had a history of smoking, while the remaining individual was a lifelong non-smoker. Central nervous system (CNS) involvement was noted in 27 patients (90%) at diagnosis, with three experiencing subsequent compromise during disease progression. The median number of brain lesions was 2 (range: 1-3).Regarding molecular characteristics, 14 patients (46%) exhibited exon 19 deletions, while the remainder had an L858R mutation. The most frequently mutated gene in the primary lesions was TP53, accounting for 15 cases (50%), followed by RBM10 in 7 patients (23%), with three instances of co-occurrence with TP53, as well as STK11 (n=2, 6%), GNAS (n=4, 13%), and RB1 (n=1, 3%). The mean tumor mutational burden (TMB) in the primary lesion was 3.2 mut/Mb, compared to 8.5 mut/Mb in the brain metastasis. Notably, all patients exhibited increased TMB between the primary and CNS lesions. Additionally, EGFR mutations were lost in 9 patients (30%), with an almost equal distribution among Exon 19 and L858R mutations. Regarding co-mutations in brain metastases, alterations in PIK3CA/PTEN/AKT were present in 11 cases (36%). Other observed mutations included BRAF V600E (n=1, 3%), non-V600 BRAF mutations (n=3, 10%), and RB1 (n=4, 13%). Interestingly, amplifications across various genes were observed in 19 patients (63%). Upon systemic disease progression, MET amplification was detected in 5 cases (15%), while small cell transformation occurred in 2 (7%). PIK3CA mutations, initially identified solely in brain metastases, re-emerged in systemic disease in 4 cases (13%), along with a V600E mutation in one patient (3%).

Conclusions: The molecular features observed in brain metastases exhibit distinctions from both primary tumors. Results indicate that specific brain metastasis clones can also result in systemic progressions.

P3.03H.05 AKAP12 Deficiency Leads to Blood-Brain Barrier Disruption and Serves as a Crucial Diagnostic Marker for Brain Metastasis in Lung Adenocarcinoma

X. Tian[1], H. Dong[2], X. Liu[3], L. Hu[3], Y. Shen[3], [1]Nanjing University, Nanjing/CN ,[2]Xuzhou Central Hospital, Xuzhou/CN ,[3]Nanjing Jinling Hospital, Nanjing/CN

Introduction: The occurrence of brain metastasis in patients with lung adenocarcinoma is linked to poor prognoses, with approximately 50% of patients experiencing this form of metastasis. Despite this, there is a lack of well-established biomarkers for predicting the likelihood of brain metastasis in lung adenocarcinoma.

Methods: We started by analyzing single-cell RNA sequencing data from GSE69405 to identify DEGs and highly variable genes in primary lung cancer cells compared to metastatic cells. We then used mIHC and HALO software to analyze TMAs of lung adenocarcinoma brain metastases. Spatial transcriptomics of zebrafish at different developmental stages were examined using Crispant technology to suppress the AKAP12b gene. PCR analysis was used to study genes related to the blood-brain barrier. Proteomics identified protein expression differences in extracellular vesicles from lung adenocarcinoma patients and healthy individuals.

Results: The study determined AKAP12 to be a critical gene in differentiating primary tumor cells from metastatic cells in lung adenocarcinoma. Utilizing multiplex immunohistochemistry (mIHC) analyses, a connection was established between the lack of AKAP12 and the impairment of the blood-brain barrier (BBB) in individuals with brain metastases originating from lung adenocarcinoma. Spatial transcriptomic analysis revealed increased expression of the AKAP12b gene in specific brain regions of a zebrafish model, leading to significant brain hemorrhage upon knockdown of AKAP12b. Furthermore, our results indicated a notable reduction in AKAP12 expression in extracellular vesicles (EVs) isolated from the plasma of patients with lung adenocarcinoma compared to those from healthy individuals, suggesting its potential as a diagnostic biomarker.

Conclusions: Our findings elucidate that the deficiency of AKAP12 is intricately linked to the destruction of the blood-brain barrier (BBB) during the brain metastasis of lung adenocarcinoma. Moreover, the presence of AKAP12 within extracellular vesicles (EVs) in plasma emerges as a critical diagnostic biomarker for patients afflicted with this condition.

P3.03I.01 Targeting RLIP76 with a Novel Small Molecule for Lung Cancer Therapy

S.R. Ghafouri, R. Horn, A. Kamat, J. Sekhon, D. Pawar, S. Shahrokh, L. Tijani, M. Melkus, S. Singh, Texas Tech University Health Science Center, Lubbock/TX/USA

Introduction: KRAS and TP53 (p53), the most common mutations in non-small-cell lung cancer (NSCLC), are associated with poor prognosis and poor treatment responses. The tumor suppressor functions of p53 are evident by the near universal predisposition to cancer in mice and humans with hereditary alterations of p53 function. RLIP76 (RALBP1 or RAL-Binding Protein 1) is an ATP-dependent transporter in the mercapturic acid pathway that catalyzes the efflux of cellular toxins and serves as a regulator of p53, Ras, PI3K/AKT, and TGF-ß signaling through direct interaction of RLIP76 to p53 instead. We discovered from crosses of RLIP76 knockout mice with p53 knockout mice that hereditary RLIP76 deficiency exerts a strong dominant negative effect on the cancer susceptibility of p53-/- mice. There are currently no RLIP76-targeted therapeutics.The newly discovered small molecule TTU-1 provides a unique opportunity and starting point from which to generate first-in-class therapeutics with an entirely novel mechanism of action.

Methods: Based on a partial crystal structure of RLIP76 and contact residue maps generated from 3-dimensional NMR, a in-silico search using the Vina docking algorithm, and an induced fit docking (IFD) method that allows side-chain flexibility for model refinement (MCule Inc.), we identified novel small molecule TTU-1. We performed growth inhibition of lung cancer cell lines by TTU-1 in vitro and in vivo mouse models. We examined TTU-1's effect on HDAC, DMNT, and caspase-3 activity, and performed qRT-PCR analyses of signaling protein transcripts in A549-luc xenograft tumor tissues from control and TTU-1 treated mice.

Results: Using virtual high throughput screening, we discovered a non-toxic lead compound, TTU-1, with broad-spectrum sub-micromolar potency against multiple lung cancer (LC) cell lines. A plot of docking scores vs. LD50 revealed a reasonably good linear fit. These compounds could serve to develop a structure-activity relationship (SAR). TTU-1 competitively binds RLIP76 as demonstrated in binding studies, and inhibits RLIP76 transport activity. TTU-1 also exhibits activation of caspase-3 and inhibition of DNMT and HDAC activity; these mechanisms of anticancer activity are different from how doxorubicin kills cancer cells. Transcript analysis indicated that several cancer hallmark pathways were suppressed following TTU-1 treatment.

Conclusions: RLIP76 knockdown modulates gene expression between p53 wild-type vs. null NSCLC (non-isogenic) cell lines, potentially through CpG island methylation changes, and the novel compound TTU-1 shows good activity and specificity as a RLIP76 inhibitor. TTU-1 itself will serve as an excellent tool for the mechanistic studies proposed and as a first proof-of-principle that targeting RLIP76. TTU-1 can exert the antineoplastic and cancer preventative effects.

P3.03I.02 Co-Inhibition of MEK/RTK Pathways Induces High Therapeutic Efficacy in Pan-KRAS-Mutant Non-Small Cell Lung Cancer

J. Lu[1], M. Hu[1], Y. Zhao[2], H. Zhong[1], H. Ji[2], B. Han[1], [1]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[2]Chinese Academy of Sciences, Shanghai/CN

Introduction: Oncogenic KRAS mutations frequently detected in non-small cell lung cancer (NSCLC). It still remains as a big challenge to target all the KRAS mutants. MEK inhibitors have been considered as candidates to address the KRAS-mutant NSCLC; however, the easily adaptive resistance to MEK inhibitor precluded the further application.

Methods: To assess the effectiveness of anlotinib in combination with trametinib for KRAS-mutant NSCLC, a panel of KRAS-mutant NSCLC cell lines was employed for functional analysis. These cell lines included H23 (G12C), H358 (G12C), SW1573 (G12C), Calu1 (G12C), SK-LU-1 (G12D), SW900 (G12V), A549 (G12S), and H460 (Q61H). Molecular mechanism analyses were conducted not only on these cell lines but also on the cell-derived xenografts. Transcriptome and proteome analyses were conducted to elucidate the underlying targets. Western blotting, RT-qPCR, H&E staining, immunofluorescent staining, and other techniques were employed to validate alterations in signaling pathways. Five advanced NSCLC patients, each harboring distinct KRAS mutations (KRASG12D, KRASG12F, KRASG12C, KRASQ61H, and KRASG12V), were enrolled to evaluate therapeutic efficacy. Companion plasma ctDNA mutation profiling and protein profiling were utilized to analyze potential associations with drug response.

Results: Here, we found that MEK inhibitor-trametinib treatment results in the feedback activation of multiple receptor tyrosine kinases (RTKs) in NSCLC, and combined with a pan-RTK inhibitor-anlotinib treatments effectively inhibited KRAS-mutant lung cancer progression. Furthermore, our data suggested that the co-inhibition of MEK/RTKs pathways resulted in synergistic anti-tumor efficacy in pan-KRAS-mutant NSCLC, potentially mediated through the MEK/RTKs-IGFBP2-RTKs signal loop. Importantly, we observed the effective demonstration of the combination strategy involving MEK inhibitor-trametinib and RTK inhibitor-anlotinib in 5 advanced NSCLC patients harboring different KRAS mutations including KRASG12D, KRASG12F, KRASG12C, KRASQ61H, and KRASG12V, respectively. Companion plasma ctDNA mutation profiling suggested that the combination strategy is effective for pan-KRAS mutations, regardless of whether KRAS co-mutates with other driver genes. Additionally, plasma protein profiling analysis indicated upregulation of multiple protein levels in blood, such as PLP2 and GINS1, potentially associated with drug response.

Conclusions: Collectively, this study provides a potential combinational therapeutic strategy for pan-KRAS-mutant NSCLC through co-targeting MEK and RTKs.

P3.03I.03 AptBCis1 - A Novel DNA Therapeutics for Lung Cancer Leptomeningeal Carcinomatosis

E.P-Y. Lin[1], B-T. Huang[1], P-C. Yang[2], [1]Taipei Medical University, Taipei/TW ,[2]National Taiwan University, Taipei/TW

Introduction: Therapy for lung cancer leptomeningeal carcinomatosis (LM) remains challenging partly due to the biological nature of blood-brain-barrier (BBB). Cisplatin serves as the backbone for systemic chemotherapy in lung cancer, but it has limited effects on LM diseases and it is notorious for neurotoxicity. Aptamers are small synthetic oligonucleotides considered as antibody surrogates for targeted delivery. Here we report an aptamer-cisplatin conjugate, AptBCis1. The AptBCis1 is a BBB-penetrating and cancer-targeting novel DNA aptamer therapeutics.

Methods: The aptamer was identified via in vivo SELEX using a lung cancer LM orthotopic mouse model. The aptamer was then conjugated with cisplatin to form AptBCis1. The tumor suppressive effects were investigated using mouse models. The AptBCis1 was administered through the tail vein and the tumor burden was monitored via In Vivo Imaging System. The plasma and the CSF cisplatin concentrations were measured via Inductively Coupled Plasma Mass Spectrometry.

Results: AptBCis1 1 mg/kg (equivalent to cisplatin 0.35 mg/kg) showed superior tumor suppressive effects than cisplatin 2 mg/kg in lung cancer LM orthotopic mouse models. The aptamer sequence was identified both in the plasma and cerebrospinal fluid (CSF). The CSF platinum concentration in the AptBCis1 1 mg/kg treatment group was 5% of that in the cisplatin 2 mg/kg treatment group. The AptBCis1 at an equivalent cisplatin dose of 0.7 mg/kg showed identical tumor suppressive effects to cisplatin 2 mg/kg in lung cancer subcutaneous xenograft mouse models. Aptoprecipitation and Mass Spectrometry studies revealed three interacting proteins that might contribute to the promising tumor suppressive effects of the AptBCis1.

Conclusions: The AptBCis1 showed promising anti-tumor effects at lower cisplatin concentrations both in lung cancer LM orthotopic and subcutaneous xenograft mouse models. The data suggested the translational potential of AptBCis1 as novel therapeutics in cancer.

P3.03I.04 Annamycin: Opening New Doors for Organotropic Targeting of Primary and Metastatic Lung Cancer

R. Zielinski[1], K. Grela[1], S. Peng[1], R. Cardenas-Zuniga[1], S. Skora[1], I. Fokt[1], W. Dempke[2], W. Priebe[3], [1]UT MDAnderson Cancer Center, Houston/TX/USA ,[2]Moleculin Biotech, houston/TX/USA ,[3]The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: Lung cancer and distant metastasis to lung is a major cause for cancer related deaths- worldwide. Targeting topoisomerase II-alpha (Top2a) is an effective therapy for a wide range of human malignancies. However, primary lung cancer or lung metastatic cancers are less responsive to Top2a targeting agents, including doxorubicin (DOX). Even sarcomas that are usually highly sensitive to DOX are not responsive after metastasis to lungs. Annamycin (ANN) is a novel potent Top2a poison that displays activity against multidrug resistant cancers and lack of cardiotoxicity. It is currently clinically evaluated (NCT03388749; NCT05319587; NCT04887298) as a liposome formulated drug (L-ANN). ANN and L-ANN display unique organotropism and dramatically increased lung uptake compared to DOX. We hypothesize that suboptimal tissue-organ distribution is a significant factor limiting DOX efficacy in lung localized cancers. The objective of this study was to correlate PK and tissue-organ distribution of ANN and DOX with preclinical efficacy in orthotopic models of lung cancer and lung-metastasis of breast, sarcoma, and colon cancer.

Methods: Pharmacokinetics and tissue-organ distribution of ANN, L-ANN, and DOX was performed in rats and mice using LC/MS. In vivo preclinical efficacy was assessed in orthotopic NSCLC models (H1299 and LLC) and lung metastasis models 4T1-Luc (triple negative breast cancer), MCA205 (fibrosarcoma), K7M3 (fibrosarcoma), and CT26-luc (colorectal cancer). Survival was a primary output of the studies. Tumor burden was also confirmed by ex vivo analysis.

Results: Pharmacokinetics and tissue organ-distribution demonstrated superior penetration and accumulation of ANN administered as free drug or L-ANN when compared to DOX. In mice, calculated AUC levels were 6.7 to 7.5-fold higher for L-ANN and ANN than for DOX. In a lung metastasis MCA205 model (Fig. 1), no survival benefits were observed in DOX treated mice but ANN elicited a significant increase in survival and inhibition of metastatic nodule growth. Similar activity was observed in orthotopic NSCLC (H1299 and LLC) and experimental metastatic models (K7M3, 4T1, CT26).

Conclusions: Our data clearly support the notion that low concentrations of DOX in lung correlates with low efficacy, while a significantly higher uptake of ANN in lung tissue positively correlates with robust in vivo activity in lung localized cancers. These results are opening doors for clinical testing of a new class of Top2a targeting drugs with high lung uptake for treatment of cancer patients with primary lung and lung metastatic cancers

Keywords: Annamycin, lung metastatsis, cardiotoxicity

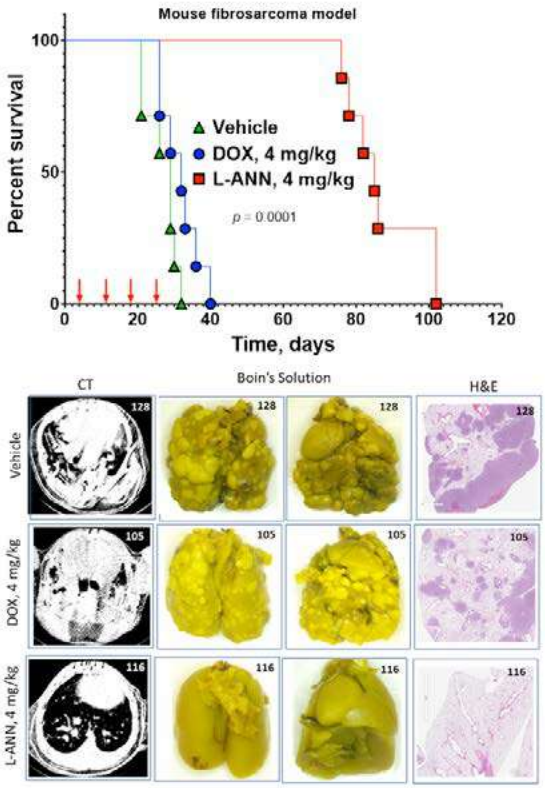

Figure 1. *In vivo* activity of L-ANN and DOX in mice MCA205 lung metastasis model.

P3.03I.05 DSTYK Inhibition as a Novel Strategy for Taxane-Based Chemotherapy Sensitation in Early and Advanced Lung Cancer

M. Echepare[1], B. Picabea[1], A. Arricibita[1], A. Teijeira[1], A. Pasquier[1], C. Zandueta[1], E. Santamaría[2], J. Fernández-Irigoyen[2], O. Romero[3], M. Sánchez-Céspedes[3], F. Lecanda[1], J. Hernández[4], E. Felip[4], A. Cruz[5], M. Provencio[5], L.M. Montuenga[1], K. Valencia[1], [1]Center of Applied Medical Research. University of Navarra, Pamplona/ES ,[2]Navarrabiomed, Pamplona/ES ,[3]Josep Carreras Leukaemia Research Institute, Barcelona/ES ,[4]Hospital Universitari Vall d'Hebron & Vall d'Hebron Institute of Oncology (VHIO), Barcelona/ES ,[5]Hospital Universitario Puerta de Hierro, Madrid/ES

Introduction: One of the main problems of lung cancer treatments is resistance, which is acquired to every therapy over time, including chemotherapy. Chemotherapy continues to be the standard treatment for patients non-eligible for targeted or immune-based therapies. We previously found that DSTYK, a poorly explored dual serine/threonine and tyrosine kinase frequently amplified in cancer, identifies lung cancer patients with bad response to immune checkpoint inhibitors and whose inhibition experimentally sensitizes to immunotherapy. At the molecular level, DSTYK has been observed to be a central regulator of autophagy and oxidative stress response, being these molecular pathways also described to be involved in chemotherapy resistance. Besides, DSTYK KO cells are severely damaged under stressful conditions, being more prone to apoptosis.

Methods: In silico analysis to study the differential sensitivity to Paclitaxel, Carboplatin, Pemetrexed and Cisplatin drugs were performed using pan-cancer human cancer cell line DSTYK CN data downloaded from Depmap portal (https://depmap.org/portal/depmap/). Two cohorts of lung cancer patients were used. An adjuvant cohort composed of Advanced IV stage lung adenocarcinoma patients treated with Carboplatin+Paclitaxel or Carboplatin+Pemetrexed in first line from VHIO; A neoadjuvant cohort including resectable stage IIIA or IIIB NSCLC tumor samples of patients from NADIM I and NADIM II clinical trials perioperative treated with nivolumab plus chemotherapy (Carboplatin+Paclitaxel). DSTYK CN was assessed by FISH and qRT-PCR. Proteomics and bioinformatic analyses were performed to study differentially expressed protein signatures. Functional in vitro experiments (adhesion, migration, invasion) in both murine and human systems, and in vivo lung orthotopic, intracardiac and intratibial xenograft and syngeneic models complete the study.

Results: Here we report that DSTYK depletion overcomes resistance to chemotherapy. We show that DSTYK inhibition specifically sensitizes lung cancer cells to taxane-based chemotherapy, particularly in combination with Carboplatin. Consistently, clinical data of early (neoadjuvant) and advanced (adjuvant) treated lung cancer patients shows a correlation between DSTYK amplification and taxane resistance. Mechanistically, DSTYK inhibition remodels the cytoskeleton, reducing cellular tumorigenic hallmarks and impairing homing and metastasis establishment in vivo. DSTYK downregulation sensitizes both primary and metastatic lung tumors to Carboplatin+ Paclitaxel+ anti-PD1 treatment in mouse models leading to the cure of 100% of the mice.

Conclusions: Our data indicates that DSTYK amplification may be a predictor of resistance to taxane-based treatments and could be an actionable target for lung cancer patients in early or/and advanced stages.

P3.03I.06 Neoadjuvant Gefitinib in EGFR Mutated NSCLC (a Phase 2 Window-Of-Opportunity Study): Deep Genomic and Transcriptomic Analysis

A.C. Tan[1], J-C. Yeo[2], M. Pang[2], J.J.S. Alvarez[2], A.Y. Guo[2], R. Hoo[1], A. Takano[3], B-H. Ong[4], J. Yeong[3], Z. Wu[2], J. Yuan[2], S. S[2], N.L. Sim[2], K.P. Chua[2], W.L. Tam[2], L. Wang[1], D.P.X. Lau[1], S.P.L. Saw[1], A. Jain[1], G.G.Y. Lai[1], W.L. Tan[1], M-K. Ang[1], Q.S. Ng[1], R. Kanesvaran[1], W.T. Lim[1], A.J. Skanderup[2], D.S.W. Tan[1], [1]National Cancer Centre Singapore, Singapore/SG ,[2]Genome Institute of Singapore, Singapore/SG ,[3]Singapore General Hospital, Singapore/SG ,[4]National Heart Centre Singapore, Singapore/SG

Introduction: EGFR TKI therapy is well established as first-line therapy in advanced EGFR mutated NSCLC. Despite high response rates, the determinants of therapeutic response remain poorly understood. We conducted a phase 2 window-of-opportunity study to uncover the dynamics and mechanisms of anti-tumour response through comprehensive in-depth tissue sequencing of resected tumours. The clinical outcomes from this study have been presented previously (JTO 2019, 14;10:S609-610; NCT02804776). Here, we present the deep multi-region genomic and transcriptomic translational analyses from the study.

Methods: Patients (pts; n=13) with stage IA-IIIA EGFR mutated NSCLC received minimum 4-weeks of gefitinib 250 mg orally prior to surgery. Translational studies included multi-region whole exome sequencing (WES; n=44 sectors) and both bulk and spatial RNA sequencing (RNA-seq; n=39 sectors) in resected tumours, and compared with a matched treatment naive cohort (n=21 pts; n=66 sectors).

Results: The objective response rate (ORR) was 62% and disease control rate (DCR) was 100% to neoadjuvant gefitinib. All pts underwent surgical resection, with pathological downstaging in 6 (46%) pts, and major pathological response (MPR) in 1 (8%) pt. Deep genomic (including multi-region) and transcriptomic (including spatial) sequencing revealed early indicators of response and adaptation in both the tumour and microenvironment. On multi-region WES, neoadjuvant gefitinib tumours had no appreciable development of EGFR T790M gatekeeper or other genomic features of reported EGFR TKI resistance; apart from an increase in ERBB2 gene amplification (although this was of low magnitude and ERBB2 was not over-expressed). TMB was also not significantly different between neoadjuvant gefitinib versus treatment naive tumours, suggesting known resistance mechanisms may not commonly be present de novo or during the early phases of EGFR TKI therapy. However, early tumour genomic adaptation were observed, with neoadjuvant gefitinib treated tumours having lower tumour purities, lower clonal diversity and lower levels of EGFR amplification. On RNA-seq in neoadjuvant gefitinib tumours, upregulation of immune regulatory/inflammatory response genes (such as the T-cell inflamed gene expression profile [GEP] score), upregulation of immune tolerance checkpoint genes and metabolic switching from glycolysis to oxidative phosphorylation was observed. Using both immunofluorescence and whole transcriptome digital spatial profiling, this metabolic switch was seen to be occurring predominantly in cancer cells rather than immune or stromal cells. This suggests a dynamic metabolic state within the tumour microenvironment, with diverse metabolic reactions serving as key potential drivers of the initial tumour response to neoadjuvant gefitinib. This observed shift also underscores the adaptability of tumour cells, and a potential role for additional metabolic interventions.

Conclusions: After neoadjuvant gefitinib, deep genomic and transcriptomic sequencing, including multi-region and spatial analysis, provided unique insight into early adaptive response in both the tumour and local microenvironment. This phase 2 window-of-opportunity study uncovered the potential for rational combination approaches to improve therapeutic efficacy in EGFR mutated NSCLC.

P3.03I.07 Comprehensive Pan-Cancer Analysis of Oncogenic MET Rearrangements with a Focus on Targetability in NSCLC

Somwar[2], [1]Northwell Health - Lenox Hill Hospital, New York/NY/USA ,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[3]Brigham and Women's Hospital, Harvard Medical School, Boston/MA/USA ,[4]Oregon Health Sciences University, Portland/OR/USA ,[5]The University of British Columbia, Vancouver/BC/CA ,[6]Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[7]Fudan University Shanghai Cancer Center, Shanghai/CN ,[8]Mazumdar Shaw Center for Translational Research, Bangalore/IN ,[9]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Rearrangements of receptor tyrosine kinases play a pivotal role in driving oncogenesis in NSCLC. While activating rearrangements involving ALK, ROS1, RET, and NTRK1/2/3 are FDA-recognized biomarkers of response to tyrosine kinase inhibitors (TKI), the lack of FDA-approved therapies for MET rearrangements remains a challenge. Here, we provide a pan-cancer analysis of oncogenic MET rearrangements, focusing on its targetability in NSCLC.

Methods: We conducted an in-depth manual curation of structural genomic variants involving MET from a large institutional NGS cohort. Demographic variables, histopathology, genomic alterations, and treatments were annotated. Cases were classified according to the presence of co-occurring MET/RTK/RAS/RAF drivers into: 1) Group A: MET amplification-negative and RTK/RAS/RAF-negative, representing putative de novo drivers, 2) Group B: MET amplification-positive, representing amplified rearrangements or rearrangements arising as a result of amplification of wild-type MET, and 3) Group C: MET amplification-negative and RTK/RAS/RAF-positive, representing rearrangements putatively acquired during or after completion of targeted therapies. Oncogenicity and response to type I/II MET-TKIs were profiled in vitro and in patients.

Results: Fifty-six MET rearrangements from 91,119 patients (0.06%), involving MET exon 15 (52%) and 30 different partners, were recurrently detected in lung (30%), brain (20%), and other tumor types. A comparison of 45 cases where NGS was performed using both DNA and RNA sequencing revealed that 38% (17/45) of cases were DNA-negative but RNA-positive for MET fusion. Thirty partners were recurrent while others were present in single cases only. Fusion partner distribution was heterogeneous, with exclusive detection of HLADRB1 and CD47 in LUAD. We identified 17 cases (0.17%) of NSCLC harboring a MET rearrangement. Group A events were more frequent in lung cancer (n=13/38, 34%) than in other locations. MET-rearranged NSCLC patients were more frequently female never-smokers (8/13, 62%) and slightly younger (median age: 63). Nearly all cases (12/13, 92%) were LUAD or harbored an adenocarcinoma component, mostly TTF1-positive (11/12, 92%), non-mucinous (8/12, 67%), and lacking STK11/KEAP1 mutations. Acquired MET rearrangements (Group C) were also recurrently found in NSCLC coincidental with resistance to osimertinib (n=1), capmatinib (n=1), and crizotinib (n=1). Growth of Ba/F3 cells transformed with ZKSCAN1::MET was inhibited upon treatment with type 1 (crizotinib, capmatinib, savolitinb) and type 2 (cabozantinb) MET-TKI. We examined the clinical activity of MET-TKIs in a cohort of 11 cases from Group A, including 6 NSCLC (5 LUAD and 1 LUPC). Exceptional clinical responses were observed in patients with LUAD driven by HLADRB1::MET or CD47::MET.

Conclusions: MET rearrangements are widely distributed pan-cancer drivers with prevalence in NSCLC. We observed distinct paradigms of fusion pathogenesis defined by partner homodimerization and genomic contexts with substantial differences in in vitro sensitivity to, and clinical responses to, MET-TKIs. We also describe a cohort of patients with acquired MET fusions as a resistance mechanism to different targeted therapies. Our findings provide further support for clinical trial evaluation of MET inhibitors in MET fusion driven cancers, particularly NSCLC.

P3.03I.08 Efficacy of Novel Third-Generation Tyrosine Kinase Inhibitors for Uncommon EGFR Mutations- Anin Vitrostudy

H. Oiki, K. Suda, A. Hamada, K. Obata, K. Sakai, T. Fujino, S. Fukuda, S. Ohara, M. Ito, J. Soh, K. Nishio, T. Mitsudomi, Y. Tsutani, Kindai University Faculty of Medicine, Osakasayama-shi, Osaka-fu/JP

Introduction: Clinical guidelines recommend afatinib or osimertinib for patients with non-small cell lung cancer (NSCLC) harboring uncommon EGFR mutations, albeit with limited efficacy. Here, we evaluated novel third-generation tyrosine kinase inhibitors (3G-TKIs) including almonertinib(=aumolertinib, lazertinib, alfultinib(=furmonertinib), rezivertinib, and befotertinib) in addition to osimertinib using Ba/F3 models transduced with five uncommon EGFR mutation (Del18, E709K, G719A, S768I, L861Q). Additionally, we explored secondary resistant mutations to afatinib or osimertinib.

Methods: Ba/F3 cells transduced with uncommon EGFR mutation were previously established. The efficacy of each drug was evaluated using an in vitro growth inhibitory assay after 72 h of drug exposure. Efficacy of each drug was assessed using the sensitivity index (SI), defined as the IC50 value multiplied by 100 and divided by the clinically achievable drug concentration (Ctrough) reported in the literature. We employed the N-ethyl-N-nitrosourea (ENU) mutagenesis technique to obtain resistant cells against afatinib or osimertinib. The presence of secondary mutations of the EGFR (exons 18-21) were analyzed using direct sequencing.

Results: SIs of afatinib were ≤ 5 for all uncommon EGFR mutations tested. Although 3G-TKIs were all active for L861Q with SI≤5, they were generally ineffective, especially for S768I and E709K. However, befotertinib was active for all mutations except S768I (Table 1). In the analysis of secondary resistant mutations against osimertinib, we identified a novel secondary T725M mutation in Ba/F3 cells with G719A mutation, which remained sensitive to afatinib and lazertinib. Conversely, the T790M secondary mutation emerged after afatinib treatment in Ba/F3 cells with G719A or S768I mutations, and these resistant cells were sensitive to lazertinib. Resistant cells with secondary V769L/M mutations were refractory to all EGFR-TKIs tested.

Conclusions: Afatinib exhibits broad activity against all uncommon EGFR mutations tested, while 3G-TKIs did not display generation-specific activity but rather drug-specific activity, despite befotertinib, alfultinib, and almonertinib sharing very similar structures with osimertinib. The T790M secondary mutation that emerged after afatinib treatment remain sensitive to lazertinib.We conclude that afatinib is the best drug for uncommon EGFR mutations among currently available EGFR-TKIs.

Keywords: Uncommon EGFR, EGFR mutation, novel third-generation tyrosine kinase inhibitors

P3.03I.09 Augmenting Post-Surgical Tumor Immune Response and Recurrence Prevention via Nanoparticle-Assisted Targeted Drug Delivery

H. Zhou[1], H. Qiu[1], B. Xu[2], S. Liu[1], H. Wang[1], H. Hou[3], S. Li[1], W. Zhan[1], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]School of Biomedical Sciences and Engineering, South China University of Technology, Guangzhou/CN ,[3]School of Medicine, South China University of Technology, Guangzhou/CN

Introduction: Lung cancer patients often face post-surgery recurrence due to changes in the tumor immune microenvironment. The development of Nanoparticle-aided Targeted Drug Delivery Systems (NDDS) offers a refined approach for delivering small molecule inhibitors, enhancing therapeutic outcomes and minimizing side effects. The mechanism of ferroptosis and its associated immunogenic cell death (ICD) effect can potentially amplify the efficacy of immunotherapy through the synergistic activation of the stimulator of interferon genes (STING) pathway. This signifies a significant step towards personalized and precise treatment.

Methods: FP/Vad@CC-aT2, a biomimetic nanoparticle system containing FePt and Vadimezan, was prepared via extrusion and conjugated with anti-Trem2 antibodies. In a mouse model, subcutaneous tumors were grown and partially resected to simulate a positive margin and establish a recurrence model. Post-treatment analyses of tumor tissues, including flow cytometry and immunohistochemistry, provided insights into immune cell composition, molecular expression, and treatment efficacy.

Results: We established a mouse model for postoperative tumor recurrence. Our treatment protocol, which was evaluated by monitoring tumor volume and body weight, showed no significant weight changes, indicating its relative safety. Notably, the FP/Vad@CC-aT2 group exhibited significant tumor inhibition compared to other groups (Fig. 1B, D). Immunohistochemical analysis showed increased expression of CRT and HMGB1, proteins associated with immunogenic cell death (ICD), in tumor cells treated with FP@CC-aT2 (Fig. 2), suggesting ICD induction. Analysis of the tumor microenvironment using flow cytometry and immunostaining revealed that the treatment resulted in increased infiltration of M1-type macrophages and CD8+ T cells. Conversely, the presence of Treg was significantly reduced.

Conclusions: The study developed FP/Vad@CC-aT2, a targeted delivery system with good biocompatibility and significant antitumor effects. It was found to promote immune remodeling, induce immunogenic cell death, and alter immune cell composition in post-surgical relapse mouse models, suggesting its potential in preventing postoperative relapse and providing a basis for clinical applications.

P3.03I.10 RRAS and RRAS2 Mutations Are Oncogenic Drivers in Lung Cancer and are Sensitive to the Pan-RAS Inhibitor RMC-6236

A.J. Pfeil[1,2], T. Zhang[1,3], C.A. Febres-Aldana[1], R. Cheng[1,4], M.S. Mattar[1], K. Arbour[1], M. Ladanyi[1], S-R. Yang[1], R. Somwar[1], [1]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[2]University of North Carolina School of Medicine, Chapel Hill/NC/USA ,[3]New York Medical College, Valhalla/NY/USA ,[4]Renaissance School of Medicine at Stony Brook University, Stony Brook/NY/USA

Introduction: RRAS and RRAS2 encode a subfamily of Ras-like small GTPases that share considerable structural similarity with the well-known family of RAS oncogenes, including KRAS, HRAS, and NRAS. RRAS/RRAS2 are thought to play a role in signal transduction pathways that control cellular proliferation and survival. Whether RAS-like homologous mutations in RRAS/RRAS2 are oncogenic and actionable drivers in lung cancer remains unexplored.

Methods: An institutional cohort of 6,470 lung adenocarcinoma (LUAD) cases profiled by comprehensive targeted DNA sequencing (MSK-IMPACT) between 2016-2024 was evaluated for RRAS/RRAS2 mutations. Missense mutations in RRAS/RRAS2 homologous to RAS family hotspot mutations were modeled by viral transduction of cDNA constructs into murine IL3-dependent Ba/F3 cells, NIH-3T3 fibroblasts, and immortalized human bronchiolar epithelial cells (HBEC). The oncogenic potential of RRAS/RRAS2 mutations was evaluated via an IL3-withdrawal assay and tumor growth in immunocompromised mice (NSG strain). Cell viability was assessed following 96-hour treatment with targeted PI3K/AKT or MAPK signaling inhibitors, including the novel pan-RAS inhibitor RMC-6236, which is currently being evaluated in clinical trials (NCT05379985). Western blotting was used to analyze protein expression and activation state.

Results: RRASQ87L or RRAS2Q72L mutations, homologous to codon 61 substitutions in KRAS/NRAS/HRAS, were found in ~0.5% of LUAD cases (35/6,470), with all but two lacking other RTK-MAPK oncogenic drivers. Notably, RRASG38X and RRAS2G23X mutations, which are homologous to KRAS/NRAS codon 12 substitutions, were extremely rare (n=1 and n=2, respectively). Ba/F3 cells expressing either RRASQ87L or RRAS2Q72L became IL3-independent and formed xenograft tumors in mice in contrast to their wild-type counterparts, suggesting oncogenic transformation by these two mutant proteins. Expression of RRASQ87L or RRAS2Q72L in HBEC cells resulted in strong PI3K-mTOR pathway activation. Enhanced ERK phosphorylation was only observed in HBEC-RRASQ87L cells. Both cell lines exhibited strong induction of negative regulators of the MAPK pathway (SPRY2, SPRY4, SPRED1), suggesting that RRASQ87L/RRAS2Q72L oncogenicity required attenuation of ERK signaling output in the setting of upregulated PI3K-mTOR signaling. ERK1/2 (ulixertinib and SCH772984), MEK1/2 (binimetinib), and PI3K (pictilisib) inhibitors inhibited growth of RRASQ87L or RRAS2Q72L cells more potently than cells expressing wildtype proteins. Importantly, the novel pan-RAS inhibitor RMC-6236 blocked phosphorylation of ERK and S6, inhibited growth of RRASQ87L and RRAS2Q72L cell lines, and induced apoptosis. ERK, MEK and PI3K inhibitors did not stimulate apoptosis at equimolar concentrations. Ongoing studies are evaluating RMC-6236 efficacy in vivo.

Conclusions: RRASQ87L and RRAS2Q72L are actionable oncogenic drivers that display mutual exclusivity with other RTK-MAPK alterations. Oncogenic RRAS/RRAS2 mutations were detected in LUAD at a rate similar to some other well-characterized lung cancer drivers, such as HRAS/NRAS hotspot mutations or NRG1 fusions. Our study supports the inclusion of RRAS/RRAS2 into routine molecular diagnostic protocols for precision oncology and clinical development of pan-RAS inhibitors, such as RMC-6236, for patients with these driver mutations in order to fully realize the potential benefit of RAS-targeted therapies.

P3.03I.11 The ATXN3-USP25-TRMT1 Axis Regulates tRNAm2,2G Modification and Promotes Osimertinib Resistance in Lung Cancer

T. Chu[1], J. Li[1], K. Huang[1], S. Pan[1], H. Lu[1], J. Qian[1], Y. Wu[2], [1]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN ,[2]Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Osimertinib is an oral third-generation EGFR-TKI, which is recommended as the first-line treatment for patients with advanced non-small cell lung cancer with EGFR activation mutation. However, patients receiving osimertinib inevitably experience acquired drug resistance. Deubiquitinases (DUBs) play a crucial role in the occurrence and development of tumors. But, there is limited research on the relationship between drug resistance and DUBs of osimertinib.

Methods: In this study, we constructed cell lines resistant to osimertinib, screened the high expression of DUBs in drug-resistant cells, and found that ATXN3 was highly expressed in drug-resistant cells and promoted osimertinib resistance. CO-IP and IP-MS screening revealed the interaction of ATXN3 with USP25, and USP25 with TRMT1. Ubiquitination assay and the CHX assay demonstrated that ATXN3 stabilizes USP25 by deubiquitination, and that USP25 in turn can regulate TRMT1 at the protein level. The tRNA mass spectrometry results revealed that TRMT1 can regulate tRNAm2,2G modification levels. Detection of ROS and osimertinib-resistant phenotypes revealed that TRMT1 promotes osimertinib resistance by downregulating intracellular ROS levels.

Results: It was found that ATXN3 promoted tumor cells resistance to osimertinib by stabilizing USP25. Further research found that USP25 interacts with TRMT1 and can regulate the expression of TRMT1 at the protein level. Mechanism studies have shown that TRMT1 regulating tRNAm2,2G modification can selectively enhance the translation efficiency of oxidoreductase and promote osimertinib resistance by reducing the level of intracellular ROS. In vitro and in vivo experiments showed that targeted USP25/TRMT1 could overcome the drug resistance of osimertinib. Clinical specimens confirmed that the expression of TRMT1 and USP25 in tumor tissues was up-regulated after osimertinib resistance, and the expression level of TRMT1 and USP25 was negatively correlated with PFS before treatment.

Conclusions: In summary, we found that: 1) ATXN3-USP25-TRMT1 axis regulates tRNAm2,2G modification by affecting the translation efficiency and activity of oxidoreductase, regulating ROS levels in tumor cells and promoting osimertinib resistance; 2) Targeting USP25 / TRMT1 can increase the sensitivity of drug-resistant cells to osimertinib and inhibit tumor growth. This study discovered a new mechanism of osimertinib resistance and provided a new treatment direction to overcome osimertinib resistance.

P3.03I.12 Modulation of EMT Increases the Activity of Lurbinectedin in Small Cell Lung Cancer

A. Iñañez[1], R. del Rey-Vergara[1], F. Quimis[1], L. Masfarré[2], N. Navarro-Gorro[2], Á. Taus[2], A. Rovira[1,2,3], E. Arriola[1,2,3], [1]Hospital del Mar Research Institute, Barcelona/ES ,[2]Hospital del Mar, Barcelona/ES ,[3]Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Madrid/ES

Introduction: Small cell lung cancer (SCLC) comprises 15% of lung cancer cases with a poor prognosis despite recent advancements. While standard chemotherapy initially yields high response rates, chemorefractory relapse limits patient survival partly due to epithelial-mesenchymal transition (EMT) mediated by the hepatocyte growth factor (HGF)/MET pathway. Inhibiting MET receptor has potential in reversing EMT and restoring chemotherapy sensitivity. Lurbinectedin, an alkylating agent that binds to GC-rich gene promoter regions, has shown promising results in SCLC treatment and is currently used in the second-line setting. However, it only benefits a subset of patients. We hypothesize that EMT modulation through MET inhibition can revert resistance and improve lurbinectedin efficacy in SCLC.

Methods: Eleven human SCLC cell lines were characterised for SCLC subtypes, EMT state (E-cadherin, vimentin and fibronectin expression), MET and phospho-MET expression (by RT-qPCR and WB). Their sensitivity to cisplatin and etoposide (chemotherapeutic drugs), as well as lurbinectedin alone and combination with capmatinib (MET inhibitor), was tested using the Cell Titer-Glo® Luminiscent Cell Viability Assay (Promega).

Results: The cell lines H196 and H841 were classified as SCLC-I subtype, due to the lack of expression of ASCL1, NEUROD1 and POU2F3. They were the top MET expressors in basal conditions among the cell line panel and displayed a mesenchymal phenotype. Upon HGF exposure, p-MET was induced in both these cells and the rest of the MET expressor cells within the panel, suggesting functional pathway activity. Conversely, HGF exposure failed to induce MET or p-MET expression in cells lacking basal MET expression. Treatment with lurbinectedin revealed that H69M, a mesenchymal cell line derived from the parental epithelial H69 by our group, exhibited significantly greater resistance than its counterpart (74±10 % vs 50±5 % of cell viability, n=3 replicates, p<0.0001). H196 and H841 cells also exhibited resistance to lurbinectedin. In H841 cells, combined lurbinectedin and capmatinib treatment significantly reduced cell viability compared to lurbinectedin alone (70±5 % vs 49±8 % of cell viability, n=2, p=0.0003). However, this effect was not observed in H196 cells.HGF exposure affected cell viability in H69 and H196 but not in H841, making them less sensitive to lurbinectedin treatment (12±6 % vs 23±12 % n=3, p=0.04 for H69, 44±16 % vs 61±16 % n=3, p=0.04 for H196). HGF had no impact on the sensitivity of lurbinectedin in the non-expressor MET H82 model. Treatment with capmatinib reversed HGF-induced lurbinectedin in H69 and H196, resulting in a slight, albeit not significant, enhancement of cell death (72±12 % vs 63±7 % n=2, p>0.05 for H69, 58±9 % vs 46±6 % n=2, p>0.05 for H196).

Conclusions: The MET/HGF pathway is functional in MET-expressing cells, as evidenced by MET phosphorylation upon HGF exposure. Cells with a mesenchymal phenotype displayed increased resistance to lurbinectedin. HGF exposure reduced lurbinectedin sensitivity in certain cell lines, but capmatinib treatment reversed this, enhancing the effect of lurbinectedin. This highlights the potential synergy of combining lurbinectedin with MET/HGF pathway targeting. However, heterogeneous responses to HGF suggests the need for further studies to identify response biomarkers for this combination therapy.

P3.03I.13 High EGFR Expression Confers Acquired Resistance to Adagrasib - In Vitro Study Using KRASg12C Mutated Lung Cancer Cells

A. Hamada[1], K. Suda[1], K. Obata[1], H. Sato[2], H. Oiki[1], S. Fukuda[1], S. Ohara[1], M. Ito[1], J. Soh[1], Y. Tsutani[1], T. Mitsudomi[1], [1]Kindai University Faculty of Medicine, Osaka-Sayama/JP ,[2]Yamagata University Well-being Institute, Yamagata/JP

Introduction: KRASG12C inhibitors such as adagrasib can produce substantial regression of tumors in patients with non-small cell lung cancer (NSCLC) harboring KRASG12C mutation. However, the acquisition of resistance is almost inevitable, and the underlying molecular mechanisms are not fully understood. In this study, we established adagrasib-resistant cells via chronic exposure to the drug and explored the underlying molecular mechanism.

Methods: First, we confirmed that the H2122 lung cancer cell line with KRASG12C was sensitive to adagrasib (IC50 = 123 nM). Adagrasib-resistant H2122 (H2122AR) was then established by chronic exposure to increasing concentrations of adagrasib. The mechanism for the resistance was explored using direct sequencing of the KRAS gene, phospho-RTK (receptor tyrosine kinase) array, quantitative real-time PCR, and RNA sequencing.

Results: We successfully established H2122AR by the exposure to increasing concentrations of adagrasib to a final concentration of 10 μM for up to 6 months. H2122AR was > 25 times resistant compared with its parent with IC50of 3.2μM. We did not detect any KRAS secondary mutation. However, the phospho-RTK array experiment revealed high phosphorylation of EGFR in H2122AR but not in H2122, in the presence of 10 μM of adagrasib. Although there was no copy number gain of the EGFR in H2122AR cells (1.2-fold), EGFR mRNA expression was increased by 2.1-fold compared with parental H2122 cells. This was also confirmed by the Western blot. Furthermore, this resistance was overcome by a combination treatment of 50 nM afatinib with adagrasib in H2122AR cells (IC50 = 60 nM).

Conclusions: High EGFR expression, without evidence of EGFR gene amplification, led to the development of acquired resistance to adagrasib. Dual blockade of EGFR and KRASG12C could be a potential treatment option for KRASG12C - inhibitor resistant cells if the resistant cells have high EGFR protein expression.

P3.03I.14 Osalmid Inhibits the Progression of Lung Adenocarcinoma and Sensitizes It to EGFR-TKIs: A Preclinical and Translational Study

L-L. Wu[1], W-M. Jiang[1], R-R. Wang[2], D. Xie[2], [1]Zhejiang Cancer Hospital, Hangzhou/CN ,[2]Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Therapeutic resistance to current treatment strategies indicates the need for more effective agents to treat lung adenocarcinoma. Despite evidence indicating the potential efficacy of the novel RRM2 inhibitor osalmid as an anticancer agent, its exact mechanism remains unknown. We sought to explore the antitumor effects and possible underlying mechanisms of osalmid and investigated potential combinatorial approaches with third-generation EGFR tyrosine kinase inhibitors (EGFR-TKIs) for the treatment of lung adenocarcinoma patients with EGFR mutations.

Methods: Patient data were used to analyze survival based on RRM2 expression. Cell viability assays, half-maximal inhibitory concentration (IC50) determination, colony formation assays, and cell-derived xenograft (CDX) models were used to explore the antitumor effects of osalmid, AST2818, and AZD9291as single-agents and in combination. Ferroptosis-related data obtained via CRISPR screens and western blotting were used to explore the relationships between RRM2 and ferroptosis suppressor genes (GPX4 and SLC7A11). Immunohistochemical analysis of 4-hydroxynonenal (4-HNE) was conducted to evaluate lipid peroxidation in tumor tissues after treatment with osalmid.

Results: Lung adenocarcinoma patients with high RRM2 expression had poorer survival than patients with low RRM2 expression ($p<0.001$). RRM2 knockdown or osalmid treatment decreased the proliferation and colony formation of lung adenocarcinoma cell lines. When AST2818 and osalmid were combined, the IC50 value of AST2818 was decreased. The expression of RRM2 gradually increased with the increase of AST2818 treatment time, implying that RRM2 is regulated by EGFR and could be a drug-resistant target of AST2818. In addition, the tumor suppression rate in the drug combination group was larger than that in the single-drug group (89% vs. 70%, $p<0.001$). Western blotting revealed that the expression of GPX4 and SLC7A11 was lower in the shRRM2 cell line than in the shNC cell line. In addition, the abundance of 4-HNE increased as the concentration of osalmid increased.

Conclusions: Osalmid may inhibit the progression of lung adenocarcinoma and sensitize it to EGFR-TKIs by inhibiting RRM2 activity to increase ferroptosis. Besides, RRM2 could be a drug-resistant target of AST2818. Our study has translational value supporting the clinical use of osalmid as an anti-lung adenocarcinoma agent either alone or in combination with third-generation TKIs, for lung adenocarcinoma patients with EGFR mutations.

P3.03I.15 The Mechanisms and Impact of EGFR TKIs in Modulating Blood Immune Cells in Patients with Oncogene-Driven NSCLC

T. Li[1], W. Ma[1], S. Chen[2], D. Montoya[3], V.M. Viswanath[1], I.C. Zhao[1], A.P. Steele[1], [1]University of California Davis Comprehensive Cancer Center, Sacramento/CA/USA ,[2]University of California Davis, Davis/CA/USA ,[3]University of California Davis, Sacramento/CA/USA

Introduction: In a previous study, we demonstrated that EGFR tyrosine kinase inhibitors (TKIs) influence blood immune cell counts in patients with oncogene-driven, metastatic non-small cell lung cancer (mNSCLC). This study aims to elucidate the underlying mechanisms and validate these blood biomarkers for assessing and monitoring clinical responses at different treatment timepoints in mNSCLC patients.

Methods: To uncover the mechanisms of TKIs on immune cells, we conducted in vitro simulations using peripheral mononuclear blood cells (PMBCs) with and without osimertinib for 72 hours, followed by RNA sequencing. Bulk RNA sequencing was also performed on PBMCs isolated from patients with EGFR-mutant lung adenocarcinoma (LUAD) before and after osimertinib treatment. Additionally, we identified 139 mNSCLC patients treated with TKIs from pharmacy databases at our institute, with 114 patients having complete blood counts at four timepoints: before treatment (T0), 2-6 weeks post-treatment (T1), approximately 3 months with the first radiographic evaluation (T2), and at censor or progression (T3). Data for each blood biomarker were summarized, and progression-free survival (PFS) and overall survival (OS) were determined using Kaplan-Meier estimates. Univariable and multivariable survival analyses were performed using Cox proportional hazards models, and post-treatment changes in blood cell counts were estimated using linear mixed-effects models.

Results: In PBMCs from patients with EGFR mutant LUAD, we observed a decrease in both CD4+ and CD8+ T subsets. RNAseq differential analysis showed that osimertinib significantly inhibited lymphocyte and T cell proliferation pathways, reduced cytokine production and receptor tyrosine kinase activity, and increased apoptotic signaling, protein ubiquination, and chromosomal organization pathways. Among the 114 TKI-treated patients, there were transient but statistically significant declines in absolute lymphocyte counts (ALCs) at T1, followed by significant increases at T2 and T3 in patients with good clinical responses, and decreases at T2 and T3 in patients with poor clinical responses (P <0.001). High leukocyte counts at T0 and T3, as measured by absolute neutrophil counts (ANCs) ≥4.6 x103 cells/μL, derived neutrophil-to-lymphocyte ratio (dNLR) ≥2.4, or NLR ≥4, were associated with poor prognosis. ALCs ≥1400 cells/μL at T2 and ≥800 cells/μL at T3 were associated with good PFS in univariable and multivariable analyses, respectively. Among 29 patients who received immune checkpoint inhibitors (ICIs) after TKIs, only 3 (10.3%) were good responders. Median PFS was 8.1 ±3.4 months with TKIs and 5.3 ±1.9 months with ICIs. Despite similar patterns of dynamic ALC changes, ALCs were lower in ICI-treated patients than in TKI-treated patients (P=0.025).

Conclusions: TKIs modulate blood immune cells in a manner similar to ICIs. Our in vitro analysis suggests that osimertinib may have a direct anti-proliferative and pro-apoptotic effect on lymphocytes. ALCs and neutrophils serve as independent blood biomarkers for monitoring responses to TKI and ICI treatments in patients with oncogene-driven mNSCLC, warranting prospective validation.

P3.03I.16 Treatment Outcomes in Patients who Received Bevacizumab Therapy for Radiation Induced Brain Necrosis

J.A. Merchant[1], K. Dumais[2], A. Khan[2], K. Brice[2], M. Muminovic[2], L.E. Raez[2], [1]Memorial Cancer Institute, Pembroke Pines/FL/USA ,[2]Memorial Cancer Institute/Florida Atlantic University (FAU), Pembroke Pines/FL/USA

Introduction: Brain metastases is the most frequently diagnosed type of brain tumor and has a higher propensity in breast and lung cancer. The use of radiation therapy for brain tumors and metastatic brain lesions is associated with radiation induced brain necrosis (RBN). There is currently no standard of care for managing RBN. Patients with RBN present with an array of neurological symptoms in addition to clinical findings. Coupled with capillary leakage and hypoxia, an increase in vascular endothelial growth factor (VEGF) is a notable characteristic of endothelial damage propagated by radiation. Bevacizumab, an anti-VEGF antibody that works by blocking VEGF from reaching its target on the endothelium, represents an attractive therapeutic modality for treating patients with RBN. This study aims to assess the safety and efficacy of bevacizumab in the treatment of RBN. The objective of the study is to evaluate the clinical benefit and safety of bevacizumab for the treatment of RBN

Methods: A retrospective chart review was performed at Memorial Cancer Institute of patients ≥ 18 years who had RBN and received treatment with bevacizumab between January 1, 2015 and January 31, 2024. Data points included: age, sex, ethnicity, race, bevacizumab dose and dosing frequency, number of treatment cycles, number of treatment events, treatment related adverse events (TRAE), and clinical benefit. The primary endpoint was to determine if patients who received bevacizumab for RBN had a clinical benefit. Clinical benefit was defined as improvements or resolution of RBN associated neurological symptoms and supporting MRI findings. The secondary outcomes were to assess the safety of bevacizumab for the treatment of RBN in adults, evaluate whether clinical benefit varied based on bevacizumab dosing strategy, and determine if there are differences in outcomes with bevacizumab and biosimilar product, bevacizumab-awwb.

Results: The study included 26 patients (37 independent treatment events [treatment incidents ranging from months to years after prior clinical benefit]) who received bevacizumab for RBN. Non-small cell lung cancer (NSCLC) and breast cancer were the most common primary pathologies, documented in 19 (73%) and 4 (15%) of the patients respectively. Most patients,15 (58%) of the 26 patients were women and the median age was 66 years. The most common dosing strategy was 10 mg/kg administered biweekly, which was utilized in 25 (68%) of the 37 treatment events. The median number of treatment cycles was 4. Clinical benefit was attained in 34 (91.89%) of the 37 treatment events. Treatment outcomes were similar for bevacizumab and its biosimilar. Bevacizumab treatment was generally well-tolerated, with hypertension (43%), mild fatigue (19%), mild occasional nosebleeds (16%) and serum creatinine elevations (11%) being the most frequent TRAE of the 37 treatment events. There was no bevacizumab-related adverse event reported in 8 (22%) of the 37 treatment events. One patient had grade 4 hypertension leading to treatment discontinuation.

Conclusions: Patients with RBN treated with bevacizumab derive meaningful clinical benefits. Bevacizumab possessed a manageable safety profile and was well-tolerated. Additionally, our study demonstrated that clinical benefits were similar across dosing strategies including dosage, frequency, and biological product.

P3.03I.17 Exploring Autophagy Flux-Related Molecules to Overcome in Acquired Resistance to EGFR TKIs in NSCLC Patients Harboring EGFR Mutations

J-H. Kang[1], J-O. Kim[2], M-R. Lee[2], M-Y. Kim[2], S. Kim[3], H.K. Kim[4], K. Lee[5], S.R. Baek[5], J.I. Kim[5], D. Jeon[6], Y.S. Lee[1], [1]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/KR ,[2]Cancer Research Institute, College of Medicine, The Catholic University of Korea, Seoul/KR ,[3]Bucheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Bucheon/KR ,[4]Chuncheon Sacred Heart Hospital, Gangwon-do, Chuncheon-si,/KR ,[5]Daewon pharmaceutical, Seoul/KR ,[6]L-Base Company, Seoul/KR

Introduction: To date, mechanisms of EGFR TKI resistance in EGFR mutant non-small cell lung cancer (mEGFR NSCLC) include the EGFR T790M mutation, activation of the bypass pathway, and cellular phenotypic changes etc. Recently, it has been recognized that latent intracellular autophagy is another cause of the acquired drug resistance to targeted therapies in a variety of cancers, including melanoma, pancreatic cancer, and breast cancer. We aimed to identify autophagy flux-related signaling molecules that may be closely associated with acquired resistance in mEGFR NSCLC. .

Methods: We established H1975OR (166-fold) and PC9ER (3,650-fold) resistant cell lines by long-term exposure of H1975 (L858R/T790M), PC9 (Del19), and H838 (L858) cells to osimertinib and erlotinib, respectively. We also explored genes that drive autophagy flux activity using transmission electron microscopy (TEM), cytotoxicity, mRNA seq and qRT-PCR, western blot, and siRNA knockdown assays. Using immunohistochemical staining, we investigated protein expression of autophagy flux molecules (p-AMPK, p-Beclin1, ULK1, GABARAPL1) in the paired FFPE tissues before and after EGFR TKI treatment in the patients with advanced/metastatic mEGFR NSCLC.

Results: We found that autophagosomes were widely distributed in H1975OR with TEM. No significant changes were observed in the protein expression of c-Met and IGF1R. p-Beclin1, LC3, P62, and ATG5 were all increased in the resistant cell lines, while p-AMPK was decreased. In H1975OR cells, mRNA expressions of BECLIN1, PINK1, GABARAPL1, NBR1, and ULK1 were much higher compared to those of parental H1975 cells (11.5, 11.0, 46.4, 18.4, and 54.2 times, respectively). The differences of GABARAPL1 and ULK1 mRNA expression were significantly higher among them. Knockdown of GABARAPL1 and ULK1 genes by siRNA treatment showed a decrease in cell proliferation as well as their protein expressions. ULK1 siRNA treatment significantly decreased IGF1R, p-AMPK, and p-Beclin1, while no changes of c-Met, LC3B, and ATG5 were observed. The results of GABARAPL1 siRNA treatment were similar to ULK1, except the decrease of LC3B and P62. In H1975OR cells treated with each of ULK1 and GABARAPL1 siRNA, osimertinib treatment did not significantly change the cell viability compared to H1975 parental cells, but hydroxychloroquine (HCQ), an autophagy inhibitor, markedly decreased cell viability. In addition, p-Beclin1 protein expression was significantly increased in the tumor tissues of treatment failure status, when compared to pre-treatment status (13.0±10.9 vs. 59±7.2, P<0.018).

Conclusions: Taken together, our results suggest that ULK1 and GABARAPL1, two genes involved in osimertinib-induced autophagy, are closely related to the acquired drug resistance. Now, we are underway additional RNA profiling and functional studies to examine a possibility as potential targets for overcoming EGFR TKI resistance.

P3.03I.18 Optimizing Delivery of Anti-Cancer Therapeutics in Lung Adenocarcinoma Using Ultrasound-Induced Cavitation of Microbubbles

R. Hoshi[1], K. Joshi[1], R. Sanwal[1], M. Lodyga[2], E. Hysi[1], A. Lau[1], Y.F. Wu[2], W. Lee[1], K. Thu[1], [1]University of Toronto, Toronto/ON/CA ,[2]St. Michael's Hospital, Toronto/ON/CA

Introduction: Methods that preferentially deliver anti-cancer drugs to tumor tissues are needed to enhance their efficacy which is often limited by dose-restricting toxicities. An innovative strategy that could circumvent this challenge involves using ultrasound and microbubbles (USMB). USMB can focus drugs administered intravenously along with microbubbles (MB) to tissues where ultrasound (US) is applied. Tumor-directed US causes MB circulating in the tumor vasculature to oscillate and/or burst, enhancing membrane permeability and drug uptake in cancer cells, thereby reducing systemic toxicity. While studies have demonstrated the feasibility of this approach in various pathologies including cancer, parameters for robust drug delivery and tumor regression in lung cancer (LC) remain to be established. Here, we aimed to develop a USMB-based approach for preferential delivery of molecular cargo and anti-cancer drugs to lung tumors in mice.

Methods: The LC cell lines, CMT167 and H1299, were used to optimize USMB parameters for in vitro delivery of molecular cargo including siRNA and chemotherapy. The in vitro USMB platform consisted of a 3D-printed water bath designed to fit a clinical US transducer at its base, and cells in suspension were mounted onto a 3D-printed coverslip holder positioned above the transducer at a fixed distance to ensure insonation at maximum intensity. Cells in suspension were exposed to an US beam in the presence of MB with Cy3-tagged non-targeting siRNA (Cy3-siRNA) or the intrinsically fluorescent chemotherapy drug, doxorubicin, and USMB-mediated uptake was evaluated using flow cytometry. The induction of apoptosis by USMB-mediated doxorubicin administration was also evaluated in H1299 cells using AnnexinV/DAPI staining. In vivo USMB parameters were investigated using orthotopic CMT167-Luc+ lung tumors grown in mice and delivery of rhodamine-labeled dextran as proof of concept. MB with dextran were given intravenously and US was applied to the chest. Dextran uptake in tumor tissues was then confirmed using flow cytometry on dissociated tumors.

Results: USMB facilitated siRNA uptake with efficiencies comparable to lipofection in LC cells in vitro. USMB also enhanced doxorubicin uptake in vitro, which was associated with an increase in apoptosis in H1299 cells compared to control cells treated with doxorubicin alone or doxorubicin with MB only. In vivo, flow cytometry on CMT167 lung tumors dissociated after USMB delivery of dextran indicated that dextran uptake was greater in lung tumor tissues treated with USMB (56%) compared to control tumors treated with dextran and MB alone (42%).

Conclusions: USMB enhanced in vitro uptake of siRNA and doxorubicin, which was associated with enhanced cytotoxicity. USMB also increased in vivo uptake of fluorescently-tagged dextran. These results highlight the potential of USMB for delivering various types of molecules to treat LC. Future experiments will include those to refine in vivo parameters for focusing delivery of molecular cargo to orthotopic lung tumors in mice and confirming the tissue specificity of USMB-mediated delivery. Subsequently, we will evaluate the anti-tumor efficacy and toxicity of LC therapeutics like doxorubicin delivered using USMB in comparison to conventional administration by intravenous injection.

P3.03I.19 The International Pregnancy and Lung Cancer Registry at Dana-Farber Cancer Institute

N. Florez[1], M. Horiguchi[2], O. Abioye[2], R. Kaufman[2], D. Haradon[2], S. Walton[2], R. Lederman[2], A. Morabito[2], A. Hebert[2], R. Camidge[3], L. Kiel[2], [1]Dana-Farber Cancer Institute/Harvard Medical School, Boston/MA/USA ,[2]Dana-Farber Cancer Institute, Boston/MA/USA ,[3]University of Colorado School of Medicine, University of Colorado School of Medicine/CO/USA

Introduction: For the first time in history, young women are getting lung cancer (LC) more than young men. As women increasingly postpone childbearing, we expect a growing number of women to be diagnosed with LC while pregnant or become pregnant during LC treatments. Launched in December 2023, the IRB-approved Pregnancy and Lung Cancer (PLC) Registry is the first international registry recording cases of pregnancy and lung cancer.

Methods: Clinicians and patients worldwide were invited via email or social media outreach to enter cases of pregnant patients with LC or patients diagnosed with LC <1 year post-delivery; a query was also developed to enter retrospective cases from DFCI. Descriptive statistics summarized characteristics from patients' baseline (immediate post-delivery) form.

Results: Between December 2023 and March 2024, a baseline form was completed for 22 women, 17 of whom are alive. Cases were entered from institutions in the United States (20) and Brazil (2). At the time of pregnancy and LC, most women were 31-34 years old. Nearly all (18) were diagnosed with Stage IV LC, mainly adenocarcinoma (20), and had an actionable biomarker (20). Three patients were diagnosed in first trimester, six in second, two in third, and three post-partum. Radiation was the most comment treatment during first trimester (3; range: 9-50 Gy), whereas targeted therapy was most common during second trimester (5; range: 3-5+ cycles), followed by chemotherapy (3; 1-3 cycles); in third trimester, four women received targeted therapy (5+ cycles) and three received chemotherapy (1-3 cycles). Treatment was deferred in the first, second, and third trimesters for three, one, and two women, respectively. Five patients reported accelerating their delivery to receive treatment sooner. Three patients terminated their pregnancy. Common radiographic imaging performed during pregnancy included CT scans (12) and MRIs (12). Most women experienced a partial treatment response during pregnancy and had a PFS for 1st line treatment of 6-9 months. Pregnancy complications included oligohydramnios/polyhydramnios (2), gestational hypertension or diabetes (2), stillbirth (1), and intrauterine growth restriction (1). Delivery complications included pre-eclampsia/eclampsia (4), bleeding (3), emergency caesarian section (2), umbilical cord avulsion (1), and fetal malpresentation due to spinal metastases (1). Maternal complications due to treatment during pregnancy included neutropenia (1) and thrombocytopenia (1); fetal complications included low birth weight (2) and icterus (1). Early infant gestational age (≤ 35 weeks) was reported for seven patients and a low APGAR score (<7) was reported for three (of nine) women. Five infants required the NICU post-birth and one required an operation; reported birth defects included respiratory (1) and GI (1) defects.

Conclusions: Among 22 cases, we observed a lack of uniformity in treatments utilized, treatment deferrals, and imaging modalities, demonstrating the lack of consensus in the treatment of pregnant women with LC. The Registry will continue to report data as more cases become available, including follow-up of maternal and fetal outcomes at 6 and 12-months post-delivery. We aim to ultimately create empirical guidelines and provide clinicians with an understanding regarding optimal therapies, potential adverse outcomes, and unique LC characteristics in this population.

P3.03J.01 Genomic and Spatial Characterization of Neoadjuvant Efficacy Differences in Non-Small Cell Lung Cancer

Y. He[1], W. Wang[1], Q. Liu[1], Z. Li[2], F. Yang[1], J. Wang[1], K. Chen[1], [1]Department of Thoracic Surgery, Peking University People's Hospital; Peking University People's Hospital Thoracic Oncology Institute, Beijing/CN ,[2]Peking University Health Science Center, Beijing/CN

Introduction: Among a large cohort aimed at characterizing the features of early-stage NSCLC in the east Asian non-smoking dominant population, patients who had undergone neoadjuvant therapy were specifically chosen for separate analysis. Multiple sampling regions were selected within the tumor area. The elucidation of spatio-temporal heterogeneity, immune microenvironment composition, and genomic characterization holds promise for explaining the underlying mechanisms governing differential treatment efficacy (Figure 1.A).

Methods: This prospective cohort comprising 36 patients with 112 region WES data and paired 34 patients with 91 region RNA-Seq data. According to the results of unsupervised NMF rank survey, the RNA data were dichotomized, and the region level was divided into A1 and A2 clusters. We employed Ward's method, XCell, ssGSEA, random forest, and other analytical approaches to comprehensively investigate immunophenotypes and ascertain immune infiltration situation. The tumor, junction, and normal tissues were collected from neoadjuvant patients for the characterization of spatio-temporal heterogeneity in tumors using single-cell spatial transcriptome technology.

Results: Patients undergoing neoadjuvant chemotherapy exhibit a favorable response predominantly enriched in the A1 subtype. Conversely, patients displaying a suboptimal response to neoadjuvant treatment are more likely to exhibit enrichment in the A2 subtype (P<0.05). The findings of immunophenotyping were also in line with these results. Used nine immune cell infiltration assays and found that the consistent cell subsets affecting the efficacy of neoadjuvant immunotherapy were B cells, macrophages and T cells, which were all highly abundant in tumor tissues with good response. We will also focus on macrophages, with the increase of macrophages in tumor tissue is associated with good efficacy, while the increase of macrophages in normal tissue is associated with poor efficacy (Figure 1.B). By employing single-cell spatial transcriptome technology with enhanced resolution and more comprehensive positional information, we conducted further analysis exhibiting distinct therapeutic effects to corroborate the findings of the supplementary genomic analysis (Figure 1.C). The SCNA-ITH, FLOH, wGII, and TNB exhibited significantly higher levels in patients with poor response (P<0.05), indicating a potential association between genomic copy number alterations and genomic instability in the context of poor response. Patients with poor neoadjuvant response displayed a higher prevalence of overall gene mutations, and the top differentially expressed genes will be listed (Figure 1.D).

Conclusions: This study presents a comprehensive analysis of the spatio-temporal heterogeneity among neoadjuvant patients with varying treatment efficacy, providing an in-depth characterization of the tumor immune microenvironment at a higher resolution.

P3.03J.02 Identification of CD200 as Potential Endothelia Target to Relieve the Immune Suppression in Precursor Lung Adenocarcinoma

C. Zhang, Y-s. Liu, L-s. Peng, H-z. Hong, W-z. Zhong, Guangdong Lung Cancer Institute, Guangzhou/CN

Introduction: Heterogeneity of endothelial cell phenotype in precursor lung adenocarcinoma and matched normal lung tissues remained poorly inventoried at the single-cell level. Understanding how these pivotal components involved in development of precursor lung adenocarcinoma could shed light on cancer initiation.

Methods: 31 patients with adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and invasive adenocarcinoma (IAC) as well as match paired normal tissues were obtained for single-cell RNA sequencing. 10,668 high quality cells clustered as endothelia cells were analyzed. Multiple immunohistochemistry of CD3, CD8, CD31, CD34 and CD200 through continuous slides were performed. In-vivo experiments involving drug test were pending.

Results: 6 endothelia major phenotypes were identified including aerocytes, general capillary, lymphatics, arteries, immature and venous subtypes. Whether it stratified by histology subtypes or not, only immature (***) and venous (***) endothelia subtypes were significantly higher in tumor compared to matched normal lung tissues. A subtype of venous endothelia cell (VEC) was identified and defined as systemic-venous (SVs) which was highly enriched in tumor rather than normal tissue (***). SVs exhibited remarkably high expression of CD200, CD34 and MYC. Profiling of immune checkpoints confirmed high expression of CD200, VSIR and LGALS9 without CD276 and PD1/PD-L1 high expression. Function enrichment analysis also indicated SVs enriched MYC pathway and oxidative phosphorylation without inflammatory response and IFNy response compared to normal venous endothelia cells. By integrating CD31 and CD34 staining, we verified that these micro-vessels existed in precursor lung adenocarcinoma with significantly increased number in relatively late stage. Continuous staining of CD31, CD200, CD3 and CD8 further revealed highly enriched CD3+CD8+lymphocytes within CD31+CD200+endothelia hotspot area while limited CD3+CD8+lymphocytes within tumor. Cell-chat analysis also indicated highly interaction between VEC and macrophages. Specifically, a strong interaction of CD200-CD200R1 signaling between M2 macrophages and VEC was observed in tumor instead of normal lung tissues. Besides, M2 macrophages as well as tumor cells exhibited strong pro-angiogenesis through VEGFA-VEGFR1 signaling with VEC. Pseudotime analysis identified two major subsets involving immune regulation (CXCL10, ACKR1, CCL14) and stress (HSPB1, MEOX1, MYC) in SVs while immature endothelia subtype exhibited progenitor (VEGFC, PECAM1, CD93) and vascularization subtypes(VEGFR2, THY1, MMP2).

Conclusions: Distinct endothelia ecosystem has long been developed in precursor lung adenocarcinoma compared to normal lung tissue. CD200, specifically expressed in SVs, could highjack tumor infiltrating lymphocytes and interact with M2 macrophages which might be served as a potential treatment target.

P3.03J.03 Genetic Signature Derived from Single-Cell Defined Microenvironment Remodeling Correlate with Efficacy of Neoadjuvant Immunotherapy in LUSC

C. Wu[1], Y. Huang[1], L. Hou[1], S. Li[1], T. Hu[2], T. Sun[2], J. Wang[2], X. Li[2], C. Zhu[2], [1]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN ,[2]Amoy Diagnostics Co., Ltd., Xiamen/CN

Introduction: Neoadjuvant therapy (NAT) of chemo-immunotherapy improved prognosis of LUSC patients. Treatment induced remodeling of tumor microenvironment may contribute to the therapeutic efficacy, but still largely unknown. This study aimed to disclose the dynamics of TME remodeling. And a TME remodeling genetic signature on pre-treatment sample was developed to predict response to chemo-immunotherapy.

Methods: Paired samples were collected pre- and post-NAI from 40 LUSC patients from 2019 to 2021. RNA was extracted and subjected to RNA-seq. scRNA-seq defined signatures of over 70 immune cell subtypes were curated from recent publications. ssGSEA was used to evaluate these signatures in each sample. Weighted gene co-expression network analysis (WGCNA) to identify hub genes associated TME remodeling by NAI (Fig.a).

Results: Out of 40 patients 30 achieved a major pathological response (MPR) (75%), with 9 cases (22.5%) achieving a complete pathological response (pCR). A significant increase in immune cell infiltration in patients with MPR following NAI.A significant “cold” to “hot” transition in the TME pre- and post- NAI was observed. Of note, activated CD8+ T cells (p<0.005), effector memory CD4+ T cells (p<0.005), and NK cells (p<0.005) (Fig.b), significantly increased post-treatment, a trend not observed in non-MPR patients. While Patients with ‘cold’ TME after NAI had a significantly lower proportion benefit from NAI (MPR, cold vs. hot, 25% vs. 96.4%, p<0.005) (Fig.c-d). Signature of seven genes (ASS1, HOXC13, KLK1, NEFL, FOXL2, TNNT1, and LMX1B), derived by WGCNA, represented ‘cold’ TME transition. Especially, it displayed negative correlation with infiltration of pro-inflammatory cells, like GZMK+ CD8+ effector memory T cell, GZMK+ CD4+ effector memory T cell (P<0.005) (Fig.e). Further, it also correlated with non-MPR (OR: 4.87, 95%CI: 1.61-14.73, P=0.005) and was validated to associate with dismal efficacy to immunotherapy in OAK cohort (HR=1.336, p=0.042).

Conclusions: “Hot”- “Cold” transition of TME was introduced by NAI, which may determine patients’ response and benefit in LUSC. A seven-gene signature, representing “cold” TME transition, may indicate poor therapeutic efficacy of NAI.

P3.03J.04 Single-Cell Landscape of Senescent Cells in the Lung Cancer Microenvironment Unveils Pivotal Roles of Senescent Cancer Cells

J. Huang[1], J. Shen[1], J. Liang[1], Y. Qiu[1], H. Jiang[2], S. Ma[1], X. Chen[1], [1]Hangzhou Cancer Hospital, Hangzhou/CN ,[2]Affiliated Hangzhou First People's Hospital, Westlake University School of Medicine, Hangzhou/CN

Introduction: Aging is intricately linked to carcinogenesis, and cellular senescence, a known driver of aging, has been increasingly recognized as playing a critical role in immune editing. Evidence suggests that senescent macrophages and T cells can accelerate cancer growth and progression. However, the landscape of senescence in both normal and cancer cells, as well as the biological functions of senescent cancer cells within the tumor microenvironment, remain elusive.

Methods: Single-nucleus RNA sequencing was performed on surgically resected tissues from two normal lungs and three lung cancers across three patients. The InferCNV algorithm was employed to score each cell for the extent of copy number variation (CNV) signal. Malignant cells were identified using K-means clustering, with normal T cells and fibroblasts as references. Non-malignant cell clusters were labeled based on known canonical markers. The SenMayo gene set was utilized to calculate the senescence-associated secretory phenotype (SASP) score for each cell. The top 10% of malignant or non-malignant cells with the highest scores were recognized as senescent cells, respectively.

Results: Compared to normal lung tissues, lung cancer tissues exhibited increased infiltration of macrophages and plasma cells but reduced endothelial cell (EC) presence. In normal tissues, capillary or lymphatic ECs were the predominant subtypes, while tumor ECs maintained a consistent primary subtype across different tumors. Matrix fibroblasts were the major population in normal tissues, whereas myofibroblasts were predominant in tumors. Senescent scores based on SenMayo consistently correlated with CellAge and GeneAge, two independent senescence signatures, validating the identified senescent cells. Compared to non-senescent malignant cells, senescent malignant cells displayed higher expression of PLAUR, IL32, MMP1, AREG, ATF3, GEM, BMP2, TNFAIP2, and MMP7. Gene set enrichment analysis revealed that senescent cancer cells exhibited enrichment in cytokine-cytokine receptor interaction, IL-17 signaling pathway, TNF signaling pathway, and antigen processing and presentation. In non-malignant cells, 20-30% of arterial ECs, monocyte-derived macrophages, and inflammatory fibroblasts were senescent, with similar distribution in normal and tumor tissues. Cell-cell communication analysis demonstrated that senescent malignant cells played crucial roles in the tumor microenvironment, with enhanced communication from these cells to all other cell types.

Conclusions: Collectively, our study provides, for the first time, a comprehensive landscape of senescent cells, including both normal and cancer cells, within the tumor microenvironment of lung cancer patients at single-cell resolution, reinforcing the pivotal role of senescent cancer cells in lung cancer.

P3.03J.05 Enhancement of Chemotherapy and Immunotherapy in LUSC Animal Models Through Tumor Microenvironment Remodeling by Losartan

H. Zhou[1], Z. Lin[1], H. Li[1], M. Lanuti[2], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Massachusetts General Hospital, Boston/MA/USA

Introduction: Emerging research indicates the potential of Angiotensin Receptor Blockers (ARBs), particularly Losartan, in combating specific solid tumors. Our prior investigations, involving an analysis of the TCGA database, have established a correlation between AGTR1 expression and both Epithelial-Mesenchymal Transition (EMT) and immune-related pathways in Lung Squamous Cell Carcinoma (LUSC) patients. Preliminary in vitro studies with diverse LUSC cell lines have further revealed that a low dosage of Losartan can reduce LUSC migratory capabilities and amplify the cytotoxic effects of Cisplatin. Western blot analyses suggest Losartan's potential in suppressing EMT in tumor cells. To delve deeper into Losartan's therapeutic implications for LUSC, we have undertaken a series of animal experiments and subsequent mechanistic explorations.

Methods: For the evaluation of ARBs' anti-tumor efficacy, we established zebrafish models of LUSC and administered losartan treatment. Subsequently, we developed two distinct in vivo murine models of LUSC, which were treated with either losartan alone or in combination with chemotherapy, and chemoimmunotherapy. The underlying mechanism was investigated using Flow Cytometry and Western Blot to assess EMT and immune-related markers.

Results: Firstly, in the zebrafish tumor model experiments, we found that losartan treatment could reduce intra-tumor angiogenesis and inhibit tumor cell escape. Subsequently, in vivo drug experiments conducted in BALB/c nude mice revealed that combination therapy with losartan and cisplatin was more effective in inhibiting lung squamous cell carcinoma growth compared to cisplatin alone (P=0.0097). Finally, in vivo drug experiments in DBA/2 mice showed that combination therapy with losartan, cisplatin, and PD-1 antibody was more effective in suppressing lung squamous cell carcinoma growth compared to cisplatin combined with PD-1 antibody (P=0.0328). Flow cytometry analysis of tumor tissues and lymph nodes obtained from animal experiments revealed that losartan could ameliorate T cell exhaustion and upregulated CD8+ T cell in lymph nodes after chemoimmunotherapy (P<0.0001).

Conclusions: Our findings indicate that Losartan can bolster the effects of chemotherapy and chemoimmunotherapy in LUSC treatment. This study offers initial insights into the potential mechanisms of ARB in LUSC therapy, thereby endorsing its potential as a key component in a comprehensive therapeutic strategy for LUSC.

Keywords: Losartan, LUSC, Chemoimmunotherapy

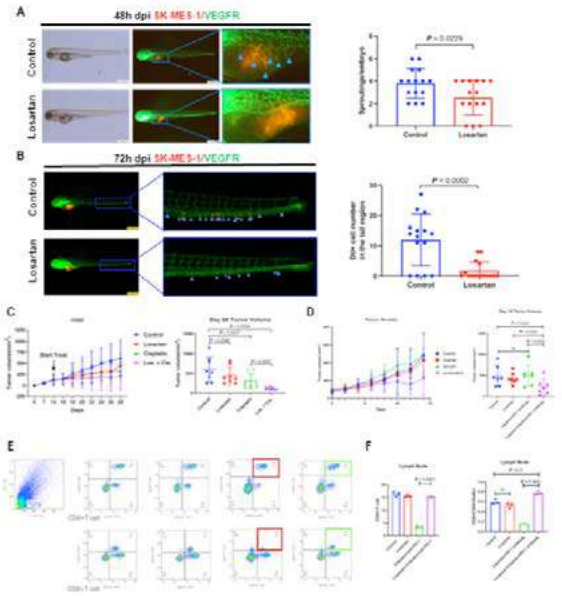

Figure: A. Impact of Losartan Treatment on Intestinal Angiogenesis in Zebrafish Embryo Tumor Model. Control (top) versus Losartan-treated (bottom) groups. T-test of intestinal vessel sprouting number shown on the right (n=15, P=0.0229). B. Impact of Losartan Treatment on Tail Vein Metastasis in Zebrafish Embryo Yolk Sac Injection Tumor Model. Control (top) versus Losartan-treated (bottom) groups. Statistical analysis of metastatic cell count in the tail region shown on the right (n=15, P=0.0002). C. Tumor Growth Curve and Tumor Volume Comparison on Day 28 of Losartan Combined with Cisplatin Therapy in Subcutaneous HS20 Mouse Tumor Model. The four groups include Control, Losartan, Cisplatin, and Losartan + Cisplatin. On Day 28, the tumor volume of the Losartan + Cisplatin group is significantly smaller compared to the Cisplatin group (t-test, n=8, P = 0.0097). D. Tumor Growth Curve and Inter-group Tumor Volume Comparison on Day 15 of Losartan Combined with Cisplatin and PD-1 Therapy in Subcutaneous KLN205 Mouse Tumor Model. The four groups include Control, Losartan, Cisplatin + PD-1, and Losartan + Cisplatin + PD-1. On Day 15, the tumor volume of the Losartan + Cisplatin + PD-1 group is significantly smaller compared to the Cisplatin + PD-1 group (t-test, n=7, P = 0.0328).E. P3.03J.06 The Co-Location of APOE+ Macrophages and MMP7+ Tumor Cells Contributed to Worse Immunotherapy Response in NSCLC

G. Fan[1], T. Xie[2], L. Dai[2], Y. Shi[2], [1]Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN ,[2]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN

Introduction: Intra-tumor immune infiltration is a crucial determinant affecting immunotherapy response in non-small cell lung cancer (NSCLC). However, its phenotype and related spatial structure have remained elusive.

Methods: To address these limitations, we undertook a comprehensive study comprising spatial transcriptomics (ST) data (28,712 spots from six samples).

Results: We identified two distinct intra-tumor infiltration patterns: immune exclusion (characterized by macrophages) and immune activation (characterized by plasma cells). The immune exclusion and immune activation signatures showed adverse and favorable roles in NSCLC patients' survival, respectively. Notably, APOE+ tumor-associated macrophages (TAMs) were recognized as the main cell type in immune exclusion samples, with increased epithelial-mesenchymal transition and decreased immune activities. The co-location of APOE+ TAMs and MMP7 +tumor cells was observed in both ST and bulk transcriptomics data, validated by multiplex immunofluorescence performed on twenty NSCLC samples. The co-location area exhibited the upregulation of proliferation-related pathways and hypoxia activities. This co-localization inhibited T cell infiltration and the formation of tertiary lymphoid structures. Both APOE+ TAMs and MMP7+ tumor cells were associated with worse survival. In an immunotherapy cohort from the ORIENT-3 clinical trial, NSCLC patients who responded unfavorably exhibited higher infiltration of APOE+ TAMs and MMP7+ tumor cells. Within the co-location area, the MK, SEMA3 and MIF signaling pathway was most active in cell-cell communication.

Conclusions: This study identified immune exclusion and activation patterns in NSCLC and the co-location of APOE+ TAMs and MMP7+ tumor cells as contributors to immune resistance.

P3.06D.01 Quantitative and Dynamic ctDNA as a Biomarker of Response and Survival in Treatment-Naive Patients with Advanced Lung Squamous Cancer

F. Zhou[1], J. Zhang[2], F. Li[2], C. Zhou[1], [1]Shanghai East Hospital, Tongji University School of Medicine, Shanghai/CN ,[2]Genecast Biotechnology Co., Ltd, Wuxi [214104], China/CN

Introduction: Radiological imaging technologies have long been used to assess therapeutic response and track post-treatment outcomes in cancer patients. However, these imaging-based approaches have limitations, including inconsistency in image interpretation and technical limitations in visualizing malignancies in specific locations. Recently, circulating tumor DNA (ctDNA) has emerged as a viable tool for monitoring cancer treatment response. In this proof-of-concept study, we proposed MinerVa-Delta as a novel approach to accurately identify advanced lung squamous cell carcinoma (LUSC) patients who can benefit from first-line PD-1 blockade plus chemotherapy or chemotherapy.

Methods: This post-hoc analyses were performed in two independently conducted trials: Camel-Seq (NCT03668496) (Cohort A) and LIPUSU (NCT02996214) (Cohort B). Plasma samples were collected at two time points: pre-treatment baseline and post-treatment after 6 weeks or two cycles of treatments. MinerVa-Delta, a novel ctDNA dynamics quantification method, based on the differentially weighted sum of the ratio changes of variant allele frequencies of variants before and after treatment were developed. Variants de-novo called by a 769-gene based NGS panel in pre-treatment, serving as a basis for personalized variant tracking in post-treatment plasma. The established MinerVa-Delta model based on plasma-informed strategy was discovered from the Cohort A (discovery cohort) and was independently validated in cohort B (validation cohort).

Results: Using the MinerVa-Delta cutoff of 30%, patients with advanced LUSC receiving PD-1 blockade plus chemotherapy or chemotherapy alone were distinguishingly divided into “molecular responders” and “non-responders” groups. Patients in the molecular response group (MinerVa-Delta < 30%) exhibited significantly better PFS (HR 0.19 , 95% CI 0.13-0.28, p < 0.001) and OS (HR 0.24, 95% CI 0.16-0.35, p < 0.001) compared with those in the molecular non-response group (MinerVa-Delta ≥ 30%) (Fig 1). The results were further validated in the multivariate analysis model and in the validation cohort. More importantly, the MinerVa-Delta-defined molecular response but radiological stable disease (SD) group exhibited a significantly better PFS in comparison to molecular non-response and radiological SD group in both cohort A (HR = 0.28, p < 0.001) and cohort B (HR = 0.16, p = 0.007).

Conclusions: In summary, the current MinerVa-Delta tool provides useful insights into monitoring cancer treatment response. MinerVa-Delta effectively classified treatment-naïve LUSC patients into molecular responders and non-responders groups. More importantly, MinerVa-Delta is able to accurately identify SD patients, a heterogeneous patient population in clinic, who can benefit from the initial treatment. This makes it a valuable supplement to the current image-based RECIST classification system.

P3.06D.02 Dynamic ctDNA-mrd Indicates Pathological Benefits of Additional Neoadjuvant Chemoimmunotherapy Courses for Locally Advanced NSCLC

D. Lin, X. Wang, J. Fan, Shanghai General Hospital, Shanghai/CN

Introduction: Neoadjuvant chemoimmunotherapy (NCI) targeting the PD-1 pathway has proven effective for non-small-cell lung cancer (NSCLC). However, few studies have focused on the optimal cycles of NCI. This study introduced minimal residual disease (MRD) based on circulating tumor DNA (ctDNA), and investigated the association between ctDNA-MRD and NCI cycles and pathological response.

Methods: This study was based on a phase III trial (NCT05157776). The patients with IIIA NSCLC without driver genes were given two cycles of NCI (initial two-cycle NCI), after which they were 1:1 randomly assigned to the two-cycle NCI groups (no additional NCI) or four-cycle NCI group (with another two cycles of NCI). Peripheral blood was collected before each cycle and surgery for ctDNA-MRD detection via ultradeep-targeted next-generation sequencing.

Results: This study involved 13 patients. Six were in the four-cycle NCI group, and seven in the two-cycle group. At the start, ctDNA-MRD was detected in 10 patients (77%) (Figure.1). The pathologically complete response (pCR) rate was higher in the four-cycle group (3/6, 50%) than in the two-cycle group (1/7, 14.2%). Remarkably, the subgroup that achieved ctDNA-MRD elimination after two cycles and resisted elimination after additional two cycles had the highest pCR rate (3/4, 75.0%). The subgroup that did not achieve ctDNA-MRD elimination after two cycles and resisted existence after additional two cycles had the lowest pCR rate (0/2, 0%). Generally, in the four-cycle group, a strong correlation between ctDNA-MRD and radiological assessment was observed (5/6, 83.3%) (Figure.2).

Conclusions: According to the study, patients with locally advanced NSCLC who achieve ctDNA-MRD elimination after two-cycle NCI are more likely to benefit from additional two-cycle NCI, manifesting higher pCR rates.

P3.06D.03 Prognostic and Predictive ctDNA Signature for Patients on Targeted Therapy for Metastatic NSCLC: A Pathway-based Approach

Z. Raza, J. Zhang, X. Le, J.V. Heymach, H.T. Tran, S. Heeke, J. Bronk, M.S. Ning, S. Gandhi, A. Chen, J.W. Welsh, Q-N. Nguyen, M.S. O'Reilly, J.Y. Chang, Z. Liao, S.H. Lin, D.C. Qian, The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: Patients with metastatic non-small cell lung cancer (mNSCLC) harboring the same actionable genomic alterations (GAs) often display varying responses to targeted therapy. Co-occurring GAs related to growth signaling cascades, p53 co-interactions in DNA binding, and immunologic activation have been implicated. Given the vast combinatorics of GAs, we sought to develop a unifying biologic pathway-based risk score leveraging ctDNA.

Methods: From a previously reported multi-institutional cohort study of ctDNA-sequenced mNSCLC (NCT01775072), we identified genes with GAs (including non-synonymous mutations, structural variations, copy number alterations) for every patient. GAs were constructed into a ctDNA Risk Score (CRS) to reflect potential molecular pathway disturbances that lead to targeted therapy resistance: among affected genes that also belong to Gene Ontology terms for cell surface receptor signaling (GO:0007166), nucleotide binding (GO:0000166), or immune system response (GO:0006955), 2 points were accrued for every gene with a non-actionable GA and 1 point for every other gene.

Results: Between 2016 and 2020, 1127 patients enrolled in this study of whom 418 (65% female) received targeted therapy for mNSCLC (Table). On average, each unit increment of CRS was associated with shorter OS (HR 1.07, 95% CI 1.02-1.13, P=0.003). The rise in OS hazard ratio was most pronounced for CRS hikes from 0 to 1 and 2 to 3. These survival differences remained independently significant following multivariable adjustment for age, sex, ethnicity/race, smoking status, histology, presence of actionable GAs, history of prior treatment, and enrollment site (Figure). For patients without any actionable GAs, CRS was not predictive of OS (P>0.05).

Conclusions: The genomic landscape that accompanies actionable GAs in mNSCLC is crucial for outcomes inference and personalized surveillance. By leveraging ctDNA and known biologic pathway information, we developed a CRS that is both prognostic and predictive of treatment response on targeted therapy. Additional prospective external validation is warranted.

P3.06D.04 Role of ctDNA Variant Allele Frequency in Predicting Response to Immune Checkpoint Inhibitors in Non-Small Cell Lung Cancer

R. Paredes de la Fuente, A. Peleg, S. Litchman, J. Gomez, D. Doroshow, F. Hirsch, R. Veluswamy, T. Marron, C. Smith, N. Rohs, C. Rolfo, Ichan School of Medicine at Mount Sinai, New York/NY/USA

Introduction: The landscape of lung cancer therapy has been transformed with the advent of immune checkpoint inhibitors (ICIs). Biomarkers such as PD-L1 expression and tumor mutational burden (TMB) have been traditionally utilized to predict responses to these therapies, particularly with respect to non-small cell lung cancer (NSCLC). Recent insights suggest that the variant allele frequency (VAF) of individual mutations could serve as a predictor for the efficacy of immunotherapies in NSCLC. This study investigates the potential of using total VAF from somatic mutations in Circulating Tumor DNA (ctDNA) as a biomarker for predicting responses to ICIs in patients with NSCLC.

Methods: We conducted a retrospective analysis at a single center from January 2018 to March 2024, focusing on patients who underwent liquid biopsies. Participants included those with confirmed NSCLC at any disease stage, ascertained via tissue biopsy. Data collected included demographic information, histological subtype, PD-L1 % expression from initial tissue samples, and first-line treatments, including the use of ICIs. ctDNA was analyzed using Guardant360 reports, excluding genetic variants with a VAF greater than 40% to filter out germline mutations. The total VAF for each patient was calculated by summing the VAFs of all somatic mutations identified. Patients were then categorized into high (≥1%) and low (<1%) VAF groups. Logistic regression was used to explore the relationship between total VAF and PD-L1 % expression, while survival outcomes were analyzed using Kaplan-Meier curves and Cox proportional hazards models, adjusting for relevant clinical variables.

Results: Our cohort included 463 patients. PD-L1 % expression and VAF were reported in 350 (76.5%) and 306 (67.6%) of the cases, respectively. Regression analysis revealed a significant negative correlation between total VAF levels and PD-L1 % expression (p=0.02). No significant demographic differences were observed between the high and low VAF groups. Survival analysis was focused on patients receiving ICIs (n= 135, 29.6%). Of those, patients with high VAF (n= 73, 53.2%) had a mean VAF of 16.8%, while low VAF patients (n=31, 22.6%) had a mean VAF of 0.54%. It was found that patients with high VAF had significantly shorter overall survival compared to those with low VAF (6.16 months vs. 13.83 months, p=0.03). Furthermore, high VAF was associated with more than twice the risk of mortality (HR: 2.554, 95% CI: 1.206 to 5.408, p=0.02), according to the Cox model adjusted for smoking history, brain metastasis, histology, and ECOG performance status.

Conclusions: Our study found that higher levels of VAF in ctDNA are associated with lower levels of PD-L1 expression in tissue biopsies from patients with NSCLC. Moreover, a high VAF was correlated with a marked decrease in overall survival among patients treated with ICIs, across all stages of the disease. As liquid biopsy becomes more integrated into clinical practice, its potential for providing prognostic insights and enabling a more tailored therapeutic approach may become increasingly evident. Our findings highlight the potential role of total VAF in ctDNA as a predictive biomarker for ICI therapy outcomes in patients with NSCLC.

P3.06D.05 Stratifying Risk in Oligoprogressive EGFR-Mutated Non-Small Cell Lung Cancer: The Role of ctDNA

O. Arrieta[1], A. Guijosa[1], D. Heredia[1], D. Dávila-Dupont[1], E. Rios-Garcia[1], [1]National Cancer Institute Mexico (INCan), Mexico City/MX

Introduction: EGFR-TKIs have markedly enhanced outcomes for non-small cell lung cancer (NSCLC) patients, but resistance development is virtually inevitable. In the context of oligoprogressive disease (OPD), local treatments can target resistant clones while EGFR-TKIs maintain systemic control, potentially extending the duration of therapy. However, a major challenge is distinguishing patients with true OPD from those with undetected micrometastatic spread using conventional imaging techniques. This distinction is crucial for identifying patients who are likely to benefit from the combined approach of local treatment and continued EGFR-TKI therapy. The present study aims to evaluate the prognostic impact of circulating tumor DNA (ctDNA) in this context.

Methods: We conducted a retrospective study (2013-2024) on advanced EGFR-NSCLC patients with OPD during first-line TKI therapy, treated with local therapy and continued TKI. Serum liquid biopsies for ctDNA EGFR mutations were performed at oligoprogression. We assessed the effect of ctDNA status on liquid biopsies and relevant clinical variables on progression-free survival-2 (PFS2), defined as the time from oligoprogression to the second disease progression or death. The effect of ctDNA on post-progression survival (PPS) was also assessed. Univariate analyses were conducted using Kaplan-Meier analysis, and multivariate analyses were performed with Cox-proportional hazard models.

Results: Among 84 patients, 70 (83%) underwent liquid biopsies at oligoprogression, with 56% testing positive for ctDNA. A positive ctDNA liquid biopsy was associated with worse PFS2 (4.99 vs. 11.73 months, p<0.001) and PPS (15.47 vs. 32.43 months; p=0.004). Stratified analysis showed that for patients with CNS oligoprogression (n=17), PFS2 did not differ based on ctDNA liquid biopsy status (4.47 vs. 4.73 months, p=0.75), while for patients with non-CNS oligoprogression (n=53), a significant difference in PFS2 was observed (5.13 vs. 13.70 months, p<0.001). In univariate analysis, shorter PFS1, CNS oligoprogression, poor performance status at oligoprogression, high carcinoembryonic antigen levels at oligoprogression, and non-SBRT radiotherapy were associated with worse PFS2. However, multivariate analysis identified positive ctDNA liquid biopsy status as the only independent factor associated with PFS2 (HR 3.57; 95% CI 1.68-7.59, p=0.001).

Conclusions: Detectable ctDNA is a significant prognostic marker in extracranial EGFR-oligoprogressive NSCLC, suggesting its potential in identifying patients who may benefit from continued TKI and local therapies. Further prospective studies are warranted to confirm these findings and explore alternative treatment strategies for OPD.

P3.06D.06 Incremental Value of Liquid Biopsy in the Initial Evaluation of Non-Small Cell Lung Cancer Patients Undergoing Tissue Based Molecular Testing

B.A. Bleiberg, D.G. Scholes, D.A. Dravid, L.L. Sun, A.P. Singh, R.B. Cohen, C.J. Langer, M.E. Marmarelis, C. Aggarwal, Perelman School of Medicine at the University of Pennsylvania, Philadelphia/PA/USA

Introduction: Actionable genetic alterations (AGAs) are identified in 45% of patients with non-squamous metastatic non-small cell lung cancer (mNSCLC). Guidelines support the use of concurrent tissue (T) and plasma (P) -based next-generation sequencing (NGS) at initial diagnosis. This approach is associated with an improved sensitivity in detecting AGAs compared to either molecular profiling approach alone. However, the incremental value of P NGS in patients who have tissue analyzed for NGS testing has not been determined.

Methods: Patients in a single hospital system with newly diagnosed mNSCLC who underwent concurrent T+P NGS upon initial diagnosis were included in an IRB approved protocol. Patients with discordant results in AGAs between T+P NGS were reviewed. Patients with mutations detected in P alone were categorized into three groups with respect to T status; i.) true tissue negative (relevant tissue panels were completed, but the gene was missed by T testing), ii.) inadequate panel (limited T NGS panel ordered) and iii.) incomplete test (≥1 components of the T NGS panel not completed due to insufficient tissue).

Results: Of 552 patients evaluated between 01/01/19 and 03/31/22, 416 (75.4%) had orders placed for concurrent T+P NGS; 58 (13.9%) had inadequate tissue for T NGS and were excluded. The remaining 358 (86.1%) patients underwent T+P NGS, with 173 (48.3%) AGAs detected. 113 (65.3%) alterations were concordant in T+P NGS, 42 (24.3%) were identified in T NGS alone, and 18 (10.4%) were observed in P alone. Amongst patients with AGAs in P NGS only, most were female 61% (11/18), current or former smokers 66% (12/18), and ECOG PS <2 75% (14/18). P alone NGS alterations were identified across all actionable markers. 28% (5/18) of the cases were true tissue negative, 22% (4/18) had an inadequate T NGS panel, and 50% (9/18) had an incomplete test performed. 44% (8/18) of patients with alterations detected in P NGS alone received first-line targeted therapy.

Conclusions: Concurrent T+P NGS is included in current guidelines for molecular testing in advanced NSCLC and has been shown to improve overall detection rates of AGAs. We demonstrated that even amongst patients who undergo concurrent T testing, P NGS can improve AGA detection rates, compensating in part for inadequate or suboptimal tissue assays and thereby enhancing the comprehensiveness of molecular profiling. Our study demonstrates the benefit of P NGS for all patients with non-squamous mNSCLC, reinforcing the importance of concurrent T+P NGS testing at initial diagnosis.

P3.06D.07 Liquid Biopsy: Exploration of its Added Value in a Daily Practice

M. Weiner[1], M. Borgeaud[1], C. De Vito[1], A. Addeo[1], [1]Hôpitaux Universitaires de Genève, Geneva/CH

Introduction: Non-small-cell lung cancer (NSCLC) is frequently driven by genetic mutations identified through next-generation sequencing (NGS) performed on tissue biopsies. Technological advancements enabled performing NGS on plasma circulating tumor DNA (ctDNA), offering viable alternative when tissue sampling is challenging and potentially reducing turnaround time (doi: 10.3390/cancers12041009; doi: 10.1158/1078-0432.CCR-19-0624).

We explored concordance between blood ctDNA NGS results and tissue NGS. We compared their respective turnaround times, evaluating efficiency and reliability of blood based NGS in the management of NSCLC.

Methods: Patients were recruited prospectively at the oncology service of the Geneva University Hospitals. All included patients had histological confirmation of metastatic NSCLC. NGS (hybrid capture custom panel) on tissue sample and liquid biopsy (FoundationOne®, LBx) were performed. Comparison and concordance between the two tests and their turnaround time were evaluated.

Results: We analyzed data from 37 patients, of which 26 were eligible. Tissue sample was not obtained in 3 patients. Liquid biopsy was not performed in one. Another patient was diagnosed with small cell lung cancer. The 6 other non-eligible patients only had limited molecular analysis performed on tissue sample (no NGS).

Mean concordance between tissue sample and LBx was 51% (range: 0-100%). LBx enabled changing treatment in 2 patients. The first was treated with BRAF-MEK inhibitors after finding BRAF V600E mutation in plasma only. No clinical response was observed, raising the question of whether this might have been just a subclonal mutation. The second had an exon 20 EGFR point mutation detected in the tissue, while LBx revealed concomitant L858R and exon 20 EGFR point mutations, enabling osimertinib treatment. One patient's tissue biopsy revealed an ALK translocation that was missed by LBx.

Turnaround time was quicker for tissue biopsy in 54% of cases, but median days was 13 for both (range LBx 10-26 and tissue 4-24).

62 likely pathogenic or pathogenic variants were identified in the tissue, and 76 in the LBx (excluding clonal hematopoiesis of indeterminate potential). 7 out of 10 driver mutations were identified in both samples.

Liquid biopsy was inconclusive in 3 patients.

Conclusions: LBx identified two driver mutations missed on tissue biopsy, enabling these patients to receive tyrosine kinase inhibitors as part of their treatment. One of them did not show any clinical benefit from BRAF-MEK inhibitors, suggesting a possible subclonal mutation. LBx failed to detect an ALK translocation, revealed only by tissue analysis. Turnaround time was similar between the two tests (median 13 days, range 4-26).

P3.06D.08 ctDNA-NGS Assay (Liquid Biopsy) for Non-Small Cell Lung Cancer: Utility of Plasma Cell-Free DNA and Tissue NGS in Detecting Genetic Mutations

A. Papadakis[1], G. Kasymjanova[2], A. Spatz[1], V. Cohen[2], C. Pepe[2], L. Sakr[2], R. Merza[1], J. Agulnik[2], [1]Lady Davis Institute for Medical Research, Montréal/QC/CA ,[2]Jewish General Hospital, Montréal/QC/CA

Introduction: Liquid biopsy, specifically analyzing plasma cell-free nucleic acids, has emerged as a promising approach for NSCLC diagnosis and monitoring, particularly in advanced stages. This method enhances cancer diagnostics by enabling the assessment of tumor genetics and actionable biomarkers through a minimally invasive procedure that involves collecting peripheral blood for circulating tumor DNA (ctDNA) analysis. This is complementary to traditional tissue biopsies by allowing a comprehensive evaluation of tumor genetics, providing valuable insights into the molecular profile of NSCLC tumors enabling precision medicine with targeted therapies.

Methods: This is a prospective cohort study focused on the collection of ctDNA from patients suspected to have advanced NSCLC based on radiologic imaging. The blood samples were collected prior to any tissue obtaining procedure, ensuring a comprehensive analysis. The ctDNA was analyzed using the Oncomine Pan-Cancer Cell-Free Assay. The study was conducted at the Peter Brojde Lung Cancer Centre and received support from the McGill Rossy Cancer Network

Results: 73 ctDNA were obtained, with 61 analyzed. 51 cases were NSCLC, 4 SCLC, 1 mesothelioma and 5 hematologic malignancies. Mutation were found in 32/51 NSCLC, with 17/32 being targetable. EGFR (47%) and KRAS p.G12C (35%) were the most frequently observed, accounting for a significant portion of the targeted mutations identified. Other rare and non-targetable mutations are presented in the table. The study identified TP53 mutation in all 4 SCLC , indicating the potential utility of liquid biopsy across different lung cancer subtypes. This finding underscores the value of liquid biopsy in capturing genetic information from various tumor types, guiding treatment decisions across the lung cancer spectrum. The concordance between the ctDNA-NGS assay and standard of care (SOC) methods for detecting actionable mutations showed relatively high agreement rates for EGFR and KRAS G12C, 80% and 85% respectively. Discordances attributed to heterogeneity that is not captured in tissue, as well as low ctDNA shedding. The study also revealed 9 inconclusive results due to low amounts of ctDNA.

Conclusions: ctDNA represents a valuable tool in NSCLC management. Its potential benefits include early detection, personalized treatment strategies based on tumor genetics, and minimally invasive sample collection, which reduces patient discomfort and risk compared to traditional tissue biopsies. Ongoing improvements in technology and methodology, may help address challenges related to sensitivity detection limitations. By being complementary or when tissue is not available, liquid biopsy has great potential in lung cancer management, ultimately improving patient outcomes and treatment efficacy.

P3.06D.09 Reciprocal DNA Fusions and their Association with DNA Damage Response Genes in Patients with NSCLC Through cfDNA NGS

L.C. Roisman[1], R. Gillis[1], S. Jain[2], A. Anoze[1], W. Kian[3], D. Levitas[3], R. Grinber[1], T. Ben Shitrit[4], L. Soussan-Gutman[4], S. Olsen[2], N. Peled[1], [1]Helmsley Cancer Center, Shaare Zedek Medical Center, Jerusalem/IL ,[2]Guardant Health, Fusionopolis Link/SG ,[3]Assuta Ashdod Medical Center, Ashdod/IL ,[4]Rhenium Oncotest Ltd., Modi'in-Maccabim-Re'ut/IL

Introduction: Patients (pts) with non-small cell lung cancer (NSCLC) harboring activating gene rearrangements of ALK, ROS1, or RET derive clinical benefit from targeted tyrosine kinase inhibitors (TKIs). Assessment of gene rearrangements can be conducted by many methods, including next-generation sequencing (NGS) of tumor tissue or cell-free DNA (cfDNA). The most common driver rearrangement in NSCLC is EML4-ALK. However, reciprocal fusions, such as ALK-EML4, also occur and may be detected by NGS. We explored the genomic profiles of lung tumours that shed activating and/or reciprocal gene rearrangements into plasma and the prevalence of co-mutations in genes associated with DNA damage repair (DDR).

Methods: NSCLC pts with a cfDNA NGS report (Guardant360) from October 2016 to September 2022 indicating the presence of a gene rearrangement (involving ALK, RET, or ROS1) were categorized by the type of rearrangement detected: activating, reciprocal, or both. The presence of co-mutations in genes associated with DDR (TP53, BRCA1, BRCA2, ATM, ARID1A and MLH1) was assessed within each category.

Results: We analyzed a cohort of 2,385 patients with advanced-stage NSCLC, as described in Table 1. Among the entire patient population, 72% exhibited solely activating rearrangements, while 6% displayed exclusively reciprocal rearrangements, and 23% had both types concurrently. ALK rearrangements were identified in 63.4% of the patient subset, with 75.5% exclusively displaying activating rearrangements, 5.4% showing solely reciprocal rearrangements, and 19.1% presenting both. RET rearrangements were observed in 25.3% of patients, among whom 61.9% had activating rearrangements only, 4.3% exhibited solely reciprocal rearrangements, and 33.8% displayed both types. ROS1 rearrangement occurred in 11.3% of cases, with 71.8% exhibiting activating rearrangements exclusively, 9.3% showing only reciprocal rearrangements, and 18.9% displaying both activating and reciprocal rearrangements concurrently. In the analysis of co-mutations involving rearrangement subtypes and genes associated with DDR, we have observed that co-mutations in ALK rearrangements occurred at consistent frequencies regardless of the rearrangement subtype. Conversely, when considering RET or ROS1 rearrangements, variations are apparent in co-mutations involving TP53, ATM, and ARID1A between reciprocal-only and activating (with or without reciprocal) rearrangements.

Conclusions: In advanced NSCLC patients with gene rearrangements identified through cfDNA NGS, 6% exhibited only the reciprocal fusion. Notably, individuals with exclusive reciprocal rearrangements of RET or ROS1 might be less prone to co-mutations in TP53, ATM, and ARID1A, than are those with detectable activating rearrangements. This emphasizes the significance of evaluating co-mutations in DNA repair genes alongside fusions to refine treatment approaches.

P3.06D.10 Concordance of Liquid Biopsy and Tissue Biopsy for the Detection of EGFR Mutation in Stage III NSCLC in the United States

U. Malapelle[1], F. Nasirova[2], A. Wang[3], M. Cooper[4], R. Salomonsen[5], E. Baser[6], E-A. Raiber-Moreau[2], C. Ortiz-Villalón[7], Y. Chuang[8], Y.J. Kim[9], [1]Department of Public Health, University of Naples Federico II, Naples/IT ,[2]Global Medical Affairs, AstraZeneca, Cambridge/GB ,[3]Global Oncology Data and Analytics, AstraZeneca, Gaithersburg/MD/USA ,[4]Oncology Biometrics, AstraZeneca, Macclesfield/GB ,[5]Oncology Outcomes Research, AstraZeneca, Gaithersburg/MD/USA ,[6]US Medical Affairs, AstraZeneca, Gaithersburg/MD/USA ,[7]Global Medical Affairs, AstraZeneca, Stockholm/SE ,[8]Global Medical Affairs, AstraZeneca, Gaithersburg/MD/USA ,[9]Oncology Outcomes Research, AstraZeneca, Mississauga/ON/CA

Introduction: Molecular profiling is empirical in NSCLC to guide appropriate treatment selection. Although tissue sampling remains the gold standard approach for detection of oncogenic driver mutations, there are innate limitations associated with tissue biopsy (TBx). Liquid biopsy (LBx) could offer a practical alternative for investigation of tumor-derived somatic mutations. Clinical application of LBx is established for metastatic NSCLC with guidelines recommending combination of tissue and plasma testing concurrently or in sequence. Nonetheless, the clinical utility of LBx in stage III NSCLC remains unclear. We present the findings on the concordance rate between LBx and TBx and the effectiveness of LBx to detect EGFR mutations in stage III NSCLC.

Methods: This retrospective study of Flatiron EDM database included adult patients (aged ≥18 years) diagnosed with stage III NSCLC between January 2017 and August 2023 with receipt of both LBx and TBx for detection of EGFR mutations in the United States. Patients must have received LBx and TBx between stage III diagnosis date and date of metastasis (if patient metastasized) with no missing EGFR test results to be eligible for inclusion. Descriptive statistics were used to summarize the study outcomes including concordance rate and performance of LBx against TBx.

Results: A total of 425 patients were included in the study. Median age was 67 years; 51% were males, 83% were current/former smokers, 69% had adenocarcinoma, and 43% had stage IIIA, while 41% and 9% had stage IIIB and IIIC NSCLC, respectively. Tumor PD-L1 expression was negative (<1%), low (1-49%), high (≥50%), and unknown in 37%, 33%, 20%, and 11% of patients, respectively. A total of 494 LBx and 499 TBx tests were performed. LBx was performed using next generation sequencing (NGS) method (74%), real-time polymerase chain reaction (RT-PCR) method (23%), and other methods (3%). TBx testing was performed using NGS (67%), RT-PCR (5%), and other methods (29%). Concordance rate between LBx and TBx was 93.0% (95% confidence interval [CI]: 90.6-94.9). The sensitivity and specificity of LBx were 45.3% (95% CI: 31.6-59.6) and 97.7% (95% CI: 96.1-98.8), respectively. PPV and NPV of LBx were 66.7% (95% CI: 49.0-81.4) and 94.7% (95% CI: 92.5-96.4), respectively. In the analysis limited to LBx NGS versus TBx NGS, the concordance rate was 94.1%. Furthermore, NGS performed in patients diagnosed between 2020 and 2023 had numerically higher concordance rates (95.7%) relative to NGS performed in patients diagnosed between 2017 and 2019 (90.6%). In other subgroups, numerically higher concordance rates were observed in patients with unresectable stage III NSCLC (98.1%) versus patients not classified as having unresectable stage III NSCLC (91.0%); stage III B/C (95.7%) versus stage IIIA (90.2%); PD-L1 high (98.2%) versus PD-L1 negative (90.7%) and PD-L1 low (95.8%); and LBx performed prior to initiation of chemotherapy (97.3%) versus after initiation of chemotherapy (95.3%).

Conclusions: Our findings suggest LBx could be an additional tool for detection of EGFR mutations in stage III NSCLC. However, negative LBx results should be considered inconclusive due to lower sensitivity. Further work to confirm specificity in EGFRm patients is warranted.

P3.06D.11 Faster Treatment Decision-Making Using Liquid Biopsies NGS in Non-Small Cell Lung Cancer

C.B. Huynh[1], K. Brice[2], J. Tsai[3], K. Dumais[2], S. Almuinas[4], C.E. Carracedo[1], S.E. Musleh[4], N.E. Theik[4], P.E. Izquierdo[1], A.E. Alvarez[4], L. Drusbosky[3], L.E. Raez [2], [1]Memorial Cancer Institute, Pembroke Pines/FL/USA ,[2]Memorial Cancer Institute/Florida Atlantic University (FAU), Pembroke Pines/FL/USA ,[3]Guardant Health, Redwood City/CA/USA ,[4]Memorial Healthcare System, Pembroke Pines/FL/USA

Introduction: Recent advancements in identifying key molecular markers have revolutionized non-small cell lung cancer (NSCLC) treatment with therapies boosting survival rates for patients with targetable mutations. The introduction of Next Generation Sequencing (NGS) into clinical practice has provided methods to examine the genetic profile of the tumor and identify possible targets for treatment. Traditionally, tissue biopsies have been the benchmark for tumor profiling despite being invasive; yet, plasma-based "liquid biopsies" have emerged as a faster and less invasive means to evaluate circulating tumor DNA. This technology has challenged prior paradigms and optimized treatment decisions with demonstrated improvements in patient outcomes, particularly as part of a comprehensive testing paradigm with tissue biopsy. This study evaluated a real-world, community cohort of NSCLC patients tested with both tissue and liquid biopsies done at the same time to examine testing features related to treatment decision-making, initiation, and outcomes.

Methods: This was a retrospective review of adults with advanced NSCLC treated at Memorial Cancer Institute with both a tissue and liquid NGS ordered between July 1, 2015 to December 31, 2022. We analyzed demographics, clinical features, and qualities of each biopsy, including biopsy turnaround time (TAT), time to treatment decision (TtT), frequencies of on-label alteration detection, and outcomes (progression free survival (PFS) and overall survival (OS). TAT and TtT were analyzed with unpaired t-tests. Descriptive statistics for outcomes were conducted via a Log Rank (Mantel-Cox) test. The choice of NGS used for treatment decision was conducted based on available sample report, i.e., sample failed due to 'quality not sufficient' (QNS)), presence of on-label alterations, and TAT.

Results: The study cohort (N=331 NSCLC patients) predominantly consisted of white (79.5%), non-Hispanic (65.65), women (53.8%) with a median diagnosis age of 65 who were largely former smokers (65.3%) and diagnosed with adenocarcinoma (89.7%). Liquid biopsy NGS demonstrated a significant 12-day advantage in TAT vs. tissue biopsy with a median of 8 versus 20 days ($p<0.0001$). On-label alterations were detected in both biopsies with concordance >96% across genes. Liquid biopsy NGS also demonstrated a significantly faster TtT than tissue biopsy in patients with any treatment (24 vs. 34 days $p=0.0003$) and specifically with targeted therapy (18 vs. 36 days $p= 0.0007$). Of note, 13.6% of tissue samples were not reported due to QNS, while all liquid biopsy samples reported. In this cohort, 80.5% of samples used a liquid biopsy NGS for treatment decision. In comparing outcomes, there were no statistical differences in PFS or OS depending on type of biopsy NGS used for treatment decision ($p\geq0.67$).

Conclusions: This study demonstrates the utility of NGS liquid biopsy to support comprehensive genomic profiling in a community based, real-world cohort. Liquid biopsy demonstrated faster TAT, TtT, and sample success as compared to tissue biopsy, while demonstrating high concordance and similar outcomes (OS and PFS). This data supports liquid biopsy alongside tissue biopsy to streamline diagnostic processes and enhance the practice of precision medicine in patients with advanced NSCLC.

P3.06D.12 Racial Differences in ALK Gene Alterations Detected by Tissue and Liquid Biopsy Across Patients with Lung Cancer.

B. Potugari[1], F. Abu Rous[1], R. Gutta[1], E. Teslow[2], C. Chao[2], E. Jaeger[2], S. Gadgeel[1], [1]Henry Ford Health System, Detroit/MI/USA ,[2]Tempus Labs, Inc., Chicago/IL/USA

Introduction: Racial and ethnic differences in incidence are well-reported in lung cancer associated with Tobacco smoking. ALK gene alterations as driver genetic alterations occur in 2-4% of lung cancer patients. Racial differences in ALK gene-altered lung cancer are not well defined. The objective of this study was to assess the frequency and type of ALK alterations observed in lung cancers across races.

Methods: Patients with a primary lung cancer diagnosis (histology and stage agnostic) that underwent testing with the Tempus xT/xR (tissue) or xF (liquid biopsy) assays (n=27,991) and had a confirmed pathogenic ALK gene alteration (SNVs, CNAs, or fusions) were retrospectively identified within the Tempus database (n=377). Race was determined based on abstracted clinical records, and patients were stratified as either white, Black or African American (BAA), Asian Pacific Islander (API), unknown or other. Somatic pathogenic co-mutations were compared across races using Chi-squared/Fisher's Exact tests with FDR correction.

Results: Among tissue-tested lung cancer patients (n=17,482), ALK alterations occurred in 1.4% (n=135) white, 1% (n=13) BAA, 3.4% (n=15) API, 3.1% (n=16) other, and 2% (n=108) unknown, which differed across race (p<0.001). The most common ALK alterations were fusions, as detected by DNA or RNA-seq, which also differed across race (p<0.001), with the lowest frequency in BAA patients (0.9%, n=12). EML4-ALK fusions were most common, occurring in 86% (n=116) of white patients with an ALK alteration, 62% (n=8) BAA, 87% (n=13) API, 100% (n=16) other, and 93% (n=100) unknown race (p=0.013). Atypical gene fusion partners ACYP2, RMND5A, BABAM2, MYT1L, and TPR were observed only in BAA, and SOS1, KLC, NPM1, PRKAR1A were observed only in white patients. Interestingly, a subset of patients with ALK fusions also harbored ALK amplifications (n=28), SNVs (n=11), or both (n=2). Similar results were observed in the smaller cohort of patients harboring ALK gene alterations as detected by liquid biopsy (n=90). There were no significant differences in co-mutated genes across races in ALK-altered tumors, including TP53, CDKN2A, or SETD, as detected by liquid or tissue testing.

Conclusions: In this large cohort of lung cancer patients, ALK fusions were more commonly observed in API and "other" groups compared to white or BAA patients, with the lowest frequency in BAA. Some atypical fusion partners were observed in white and BAA that were not observed in other races. These data emphasize the importance of testing lung cancer patients with assays that allow for unbiased fusion detection and identification of novel fusion partners across racially diverse populations to better understand racial and ethnic differences in ALK-rearranged lung cancers.

P3.06D.13 Patterns of Tissue NGS Alterations are Associated with ctDNA Shedding in Non Small Cell Lung Cancer Tumors Harboring EGFR Mutations

A. Di Lello[1], V. Torri[2], V. Behera[1], S. Wu[1], J.B. Hines[1], C.M. Bestvina[1], R. Thawani[1], J.M. Dolezal[1], J. Chin[1], A. Pezeshk[1], A. Esposito[1], M. Sacco[1], A.N. Husain[1], J. Segal[1], P. Wang[1], E. Vokes[1], M.C. Garassino[1], R.B. Cameron[1], [1]University of Chicago, Chicago/IL/USA ,[2]"Mario Negri" Institute for Pharmacological Research- IRCCS, Milan/IT

Introduction: The presence ctDNA at baseline in Non Small Cell Lung Cancer (NSCLC) tumors harboring EGFR mutations is a negative prognostic factor. While it is already known that ctDNA is associated with disease burden, low Performance Status and brain metastasis, it is still unknown if it is associated with particular molecular alterations in the tumor.

Methods: We reviewed all patients with NSCLC and EGFR exon 19 or 21 mutations treated at University of Chicago from 2011 to 2022 for whom Next-Generation Sequencing (NGS) both on tissue and liquid biopsy was available. NGS on tissue samples was performed using Oncoplus, an in-house panel targeting 168 genes, while liquid biopsy was performed with Guardant360 assay. ctDNA shedders were defined as having an identical EGFR mutation identified both on tissue biopsy and liquid biopsy sequencing. Differences among predefined groups of mutations on tissue and shedding were evaluated with $\chi 2$ test for heterogeneity and test for trend when appropriate and by means of multivariate logistical model.

Results: We analyzed 84 patients with EGFR exon 19 or 21 mutations treated with EGFR tyrosine kinase inhibitors (TKI). Results are described in Table1. Median age at diagnosis was 66 and 64 years for ctDNA shedders and non-shedders respectively. Females were 86% (n= 18) in the non-shedders' cohort and 70% (n= 44) in the shedders'- of the latter, two of them did not have available genomic data beyond EGFR mutations. 51 (61%) patients had metastatic disease at diagnosis, of which 42 (82%) were shedders.The multivariate analysis controlled for stage (early vs. metastatic) showed an association between ctDNA shedding and specific groups of co-mutations (p value for heterogeneity= 0.048) and with the increasing number of additional gene mutations (p value for trend = 0.056).

Conclusions: These are the first data showing that ctDNA at baseline is associated with a specific pattern of mutations found on tissue NGS. This suggests that ctDNA shedding might be associated with some underlying tumor biology, reflective of a more aggressive phenotype. Given the small sample size, validation using a larger cohort should be performed.

Keywords: Non Small Cell Lung Cancer, ctDNA, EGFR

	Shedders (n=63)	Non-Shedders (n=21)	R/R
Combination of significant mutations

P3.06D.14 Liquid Biopsy-Based Single T-Cell Dynamic Polyfunctionality Profiling as a NSCLC Immunotherapy Biomarker

Z-F. Lim[1], X. Wu[1], L. Zhu[1], H. Albandar[2], M. Hafez[2], C. Zhao[1], M. Almubarak[2], M. Smolkin[2], H. Zheng[1], S. Wen[2], P.C. Ma[1], [1]Penn State Cancer Institute, Hershey/PA/USA ,[2]WVU Cancer Institute, Morgantown/WV/USA

Introduction: Predictive biomarkers for immune checkpoint inhibitors (ICI), such as PD-L1 expression tumor proportional score (TPS), remain limited in clinical applications in NSCLC immunotherapy. Improved novel ICI predictive biomarkers are urgently needed. Currently available NSCLC ICI predictive biomarkers require invasive tumor biopsy procedures to obtain the tissues for testing and are practically challenging to follow longitudinally on ICI treatment course. Importantly, the clinical utility of tissue-based PD-L1 tumor proportion score also becomes diluted when the ICI is combined with cytotoxic chemotherapies.

Methods: We evaluated a novel live single-cell functional liquid biopsy cytokine profiling platform to track ICI treatment response and clinical outcomes. Peripheral blood mononuclear cell samples of healthy donors and NSCLC patients undergoing ICI-based therapies were collected longitudinally pre-/post-treatment under IRB-approved protocols. Samples were enriched for CD4+ and CD8+ T-lymphocytes and analyzed on the IsoLight platform. The single T-cells were captured in microchambers on IsoCode chips for proteomic immune cytokines profiling (Fig.). Functional polyfunctionality data from 55,775 single cells were analyzed using the IsoSpeak software, 2D- and 3D-tSNE analyses, kappa coefficient, and Kaplan-Meier survival plots.

Results: Pre-treatment baseline polyfunctionality profiles could not differentiate NSCLC patients from healthy subjects. Neither baseline overall polyfunctionality (PolyFx) nor polyfunctionality strength index (PSI) of NSCLC patients differentiated ICI responders from non-responders. Conversely, we found a statistically significant difference between responders and non-responders in CD8+ T-cells' changes in overall polyfunctionality (ΔPolyFx) and polyfunctional strength index (ΔPSI) in our dynamic pre-/post-treatment single cell measurements. In the 3D-tSNE analysis, there were subpopulations of post-treatment CD8+ T-cells in ICI responders that displayed distinct immune cytokine profiles from those of the pre-treatment cells. Conversely, this was not evident in the non-responders analysis. ΔPSI score in CD8+ T-cells performed better than PD-L1 TPS in ICI response correlation. Moreover, when combined with PD-L1 TPS, ΔPSI score strongly correlated with early ICI treatment response with a robust kappa coefficient of 1.0 (p=0.003), which was statistically established to indicate a perfect agreement between the prediction and actual response status. Interestingly, high CD4+ T-cells ΔPSI was found to correlate with a strong trend of improved progression-free survival (3.9-fold) and overall survival (3-fold) in ICI-treated NSCLC patients.

Conclusions: In conclusion, our study nominates single peripheral T-cell polyfunctionality dynamics analysis to be a promising liquid biopsy profiling platform to determine ICI predictive biomarker in NSCLC. It warrants further studies in larger prospective clinical cohorts to broaden available tools to further optimize lung cancer immunotherapy clinical adoption.

P3.06E.01 Evaluation of the Immune Landscape of Patients with Adenosquamous NSCLC (LUAS)

M. Lee[1], T. Adeyelu[2], S. Wang[1], A. Elliott[2], A. Vanderwalde[2], L. Villaruz[3], H. Khan[4], B. Herzberg[5], S.Y. Kim[6], P. Ma[7], S. Liu[8], B. Halmos[1], H. Cheng[1], [1]Montefiore Einstein Comprehensive Cancer Center (MECCC), The Bronx/NY/USA ,[2]Caris Life Sciences, Phoenix/AZ/USA ,[3]UPMC Hillman Cancer Center, Pittsburgh/PA/USA ,[4]Brown University Legorreta Cancer Center, Providence/RI/USA ,[55]. Columbia University Herbert Irving Comprehensive Cancer Center (HICCC), New York City/NY/USA ,[6]Yale Cancer Center, New Haven/CT/USA ,[7]Penn State Cancer Institute, Hersey/PA/USA ,[8]Georgetown Lombardi Comprehensive Cancer Center, Washington D.C./DC/USA

Introduction: Adenosquamous lung cancer (LUAS) is a rare subset of non-small cell lung cancer (NSCLC) characterized by at least 10% of both adenocarcinoma (AC) and squamous (SCC) components, comprising up to 4% of NSCLC cases. Given limited investigations into LUAS's genomic and immune characteristics, this study aimed to delineate molecular and immune variances between LUAS, AC, and SCC, as well as between primary and metastatic sites of LUAS, while examining associated clinical outcomes. Such insights may help to address the significant clinical challenges in LUAS management.

Methods: NSCLC samples (n=35404) underwent DNA (592 genes or whole exome)/RNA (whole transcriptome) sequencing at Caris Life Sciences. Cell infiltration in the tumor microenvironment was estimated by quanTIseq. Primary and metastatic samples included lung and extra-pulmonary biopsies, respectively. Real-world overall survival (rwOS) was obtained from insurance claims data, calculated from either time of biopsy, or start of immunotherapy to last contact. Mann-Whitney U and X2/Fisher-Exact tests were applied, with p-values adjusted ($p < .05$).

Results: Among NSCLC samples, 72.5% (n=25665) AC, 26.5% (n=9365) SCC, 1.0% (n=374) were LUAS. Of the LUAS, 74.9% were from primary and 25.1% from metastatic sites. PD-L1 expression (TPS >1%) was significantly higher in LUAS compared to AC and SCC but there was no significant difference between LUAS primary and metastatic sites. PD-L1 high (TPS >50%) was significantly more in LUAS compared to SCC but not LUAD. Analysis of the tumor microenvironment showed significantly higher cell fractions of neutrophils, NK cells, T cells CD8 and Dendritic cells in LUAS compared to either AC or SCC, particularly prominent in primary LUAS sites compared to LUAS metastatic sites. There was also significantly higher expression of immune-related genes in LUAS compared to either AC or SCC, but no difference in LUAS primary vs metastatic sites (Table 1).

No significant difference in rwOS from start of immunotherapy between LUAS and AC ($p = 0.928$) or SCC ($p = 0.928$). However, prolonged rwOS was noted in LUAS compared to SCC (HR = 0.79 CI 0.70 - 0.89, $p < 0.001$) from time of biopsy to last contact.

Conclusions: This study provides unique insights into LUAS. Although our results revealed multiple significantly higher immune environment factors in LUAS, still there were no significant OS differences when treated with immunotherapy. This suggests that additional factors beyond the immune environment may also influence immunotherapy responses in LUAS, highlighting the need for further investigation.

P3.06E.02 Serum NY-ESO-1 And XAGE1 Antibodies Are Diagnostic and Cancer-Specific Immunomonitoring Markers in NSCLC

M. Oka[1], K. Kurose[2], Y. Nojima[2], S. Saisho[2], K. Shimizu[2], M. Nakata[2], T. Oga[2], [1]Kawasaki Medical School, Kurashiki/JP ,[2]Kawasaki Medical Scool, Kurashiki/JP

Introduction: NY-ESO-1 and XAGE1 cancer/testis antigens are exclusively expressed in cancer and germ cells only. These antigens are highly immunogenic and elicit spontaneous humoral and cellular immune responses in NSCLC patients. Notably, NY-ESO-1 is broadly expressed in various cancers, but XAGE1 expression is comparatively specific in lung adenocarcinoma. Thus, antibodies (Abs) against these antigens are cancer-specific immune response biomarkers. We previously reported that serum NY-ESO-1/XAGE1 Abs were detected in approximately 25% of advanced NSCLC and potentially predicted clinical response to immune checkpoint inhibitor (ICI) regardless of tumor PD-L1 status. Although ICI therapy has been a standard care of NSCLC, immune responses against cancer antigens remain unexplored in the treatment of NSCLC. Here, cancer-specific immunomonitoring using NY-ESO-1/XAGE1 Abs was performed in various NSCLC treatments.

Methods: This retrospective biomarker study included 543 patients with NSCLC and 36 with non-malignant pulmonary diseases at Kawasaki Medical School Hospital, between 2015 and 2023. This NSCLC cohort was composed with 331 (61%) adenocarcinoma, 151 (28%) squamous cell carcinoma, and 61 (11%) others. The patients' sera were obtained at diagnosis, and serum NY-ESO-1 and XAGE1 Abs were quantitatively measured by ELISA. The cutoff value of the positive Abs was defined as ≥ 100 titer. For immunomonitoring, the Abs in 83 NSCLC patients were serially measured after the treatments including 20 surgery, 20 chemotherapy, 17 targeted therapy, and 25 ICI therapy.

Results: NY-ESO-1/XAGE1 Abs were never detected in non-malignant patients. In NSCLC, the positive rate of the Abs was 19% (105/543) overall, and it was 13% (73/543) in XAGE1 Ab, 6% (32) in NY-ESO-1 Ab, and 0.1% (4) in both Abs. According to disease stage (8th ed), the Ab-positive rate was 5% (8/150) in stage I, 16% (10/63) in stage II, 21% (26/126) in stage III, and 30% (60/199) in stage IV. The Ab-positive rate was 23% and 11%, in adenocarcinoma and squamous cell carcinoma, respectively, and especially it was the highest 33% in advanced adenocarcinoma of stage IIIB and stage IV. In systemic therapy, the Ab dynamics showed three patterns according to clinical responses (CR, PR, SD, PD); the Ab levels were gradually decreased or became negative in CR/PR, not changed in SD, and increased in PD. However, the Abs even in CR never disappeared in targeted therapy for EGFR and ALK, indicating cytostatic activity. In surgery, the Ab dynamics showed three patterns after resection; the Abs completely disappeared without recurrence and were decreased with recurrence and increased at recurrence only.

Conclusions: This study detected serum Ab against cancer-specific antigens in NSCLC patients and first monitored cancer-specific Ab response in the treatment of NSCLC. Our results indicate that NY-ESO-1/XAGE1 Abs are diagnostic markers in NSCLC, especially XAGE1 Ab in lung adenocarcinoma. NY-ESO-1/XAGE1 Ab levels were increased in association with disease progression, suggesting potential response biomarkers of immunotherapy, as we previously reported. In addition, immunomonitoring using NY-ESO-1/XAGE1 Abs are probably useful to monitor response to various treatments and predict postoperative recurrence in clinical practice. Recently, we developed a fully automated immunoassay measuring NY-ESO-1/XAGE1 Abs for clinical application.

P3.06E.03 Anlotinib Mediated Inflammation Response Through NFKB/TNFRSF11A Cascade in Lung Cancer

Y. Chen, J. Shen, Y. He, Y. Qiu, J. Huang, W. Cai, X. Chen, Hangzhou Cancer Hospital, Hangzhou/CN

Introduction: Anlotinib is a highly promising anti-tumor drug in advanced non-small cell lung cancer (NSCLC). Previous studies have shown that Anlotinib plays a significant role in anti-angiogenesis and proliferation inhibition in the treatment of advanced NSCLC. These anti-tumor effects may be attributed to the selective inhibition of tyrosine kinase receptors by Anlotinib, including VEGFR (2/3), PDGFR (α/β), FGFR (1-4), and others. Recent studies have also revealed some potential biomarkers associated with anti-angiogenesis used for stratifying Anlotinib. However, due to the complex structure of angiogenesis signal transduction and the direct anti-tumor effects of Anlotinib being discovered, further exploration is needed to predict potential biomarkers of NSCLC patients responsive to Anlotinib.

Methods: Establish a patient-derived xenograft (PDX) model of NSCLC and treat it with Anlotinib. Transcriptome analysis to study the changes in gene expression profiles and molecular pathway activation levels underlying the anticancer effects of Anlotinib. In vitro cell experiments confirm the anti-cancer effects of Anlotinib are related to NFκB activation and cytokines IL1B and TNFRSF11A. Collect patient serum, ELISA experiments confirm the relevance of IL1B and TNFRSF11A to the anticancer effects of Anlotinib.

Results: After 14 days of Anlotinib gavage treatment in PDX mice, there were 621 differentially expressed genes and 2168 different transcripts between the Anlotinib group and the control group tissues. Functional analysis using GO and KEGG on differentially expressed genes revealed differences in 1616 pathways. Among them, changes in the NFκB pathway affected by Anlotinib were particularly prominent, with significantly reduced expression of NFκB-related cytokines IL1B and TNFRSF11A. Furthermore, Kaplan-Meier survival analysis on TCGA cohort showed that NSCLC patients with higher mRNA levels of NFKB pathway-related genes (including IL1B and TNFRSF11A) had a poorer prognosis. Subsequently, in vitro cell experiments verified that Anlotinib can downregulate NFκB expression and downregulate the expression of immune-related cytokines IL1B and TNFRSF11A in the NFκB pathway. In vivo experiments confirmed a significant decrease in the expression of IL1B and TNFRSF11A in patient serum after Anlotinib treatment.

Conclusions: The expression levels of immune-related genes IL1B and TNFRSF11A in the NFKB pathway have potential clinical applications and can be used to predict the response to Anlotinib.

P3.06E.04 Genetic and Immunological Backgrounds in Advanced NSCLC Patients Treated with Immunotherapy - NGS and Flow Cytometry Analysis

N. Krzyzanowska[1], M. Nicoś[1], K. Wojas-Krawczyk[1], P. Krawczyk[1], I. Chmielewska[1], T. Jankowski[1], T. Kucharczyk[1], M. Wójcik-Superczyńska[1], A. Sroka-Bartnicka[1], T. Stokowy[2], J. Milanowski[1], [1]Medical University of Lublin, Lublin/PL ,[2]University of Bergen, Bergen/NO

Introduction: The treatment of non-small-cell lung cancer (NSCLC) patients at advanced stages of the disease relies on immunotherapy. Programmed death ligand 1 (PD-L1) expression on tumor cells and tumor mutational burden (TMB) are used to predict the response to immune checkpoint inhibitors treatment and qualify patients to the therapy, but in some cases those biomarkers are not efficient enough. Discovering new predictive markers would therefore allow clinicians to modify therapy course for the patient's benefit. We performed a preliminary analysis aimed at describing genetic and immunological background of immunotherapy course and discovering factors possibly related to clinical benefit or lack of response.

Methods: We applied next generation sequencing (NGS) of tumor tissue and flow cytometry analysis of peripheral blood lymphocytes' subpopulations. Both materials were obtained from 20 patients with advanced NSCLC just before treatment. Nine patients received pembrolizumab in monotherapy and 11 people received pembrolizumab combined with chemotherapy (carboplatin and pemetrexed). Then, bioinformatic and statistical analysis were performed.

Results: Based on progression-free survival (PFS) time, the study group was divided into short (n=11) and long (n=9) responders (PFS ≤6 months or >6 months, respectively). In short responders, the most frequently altered genes were NOTCH4 (55%), H3-3A (45%) and KDR (36%), while in long responders KDR and TP35 genes were the most commonly mutated in 44% and 33% samples, respectively. Then, 22% of long responders had KRAS, NOTCH4, PDGFR, JAK2 and PMS2 gene mutations, and none had H3-3A gene mutations. Moreover, the co-occurrence between KRAS/STK11 genes occurred in short responders, while PMS2/NOTCH4 and PDGFRA/JAK2 overlaps were significantly often observed in long responders. Flow cytometry analysis results revealed a higher baseline CD4+/GATA3+ cells percentage and higher baseline T regulatory cells (CD4+/CTLA-4+/FoxP3+) percentage in long responders. High CD62L expression on CD8+ cells and high CD4+/GATA3+ cells percentage turned out to be favorable in terms of PFS in Kaplan-Meier analysis. Considering the whole analysis, the following molecules appear relevant: CD62L, GATA3, CTLA-4, TIM-3, LAG-3, CXCR3, PD-1, and EOMES.

Conclusions: Even though the complexity of molecular and immunological landscape in cancer disease is not entirely understood, our work indicates that NGS and flow cytometry analysis of tumor tissue in NSCLC may constitute a useful tool providing an overview of the background affecting the response to immunotherapy. In our study, some of the alterations and immunological features detected appear to be favorable, whereas other seem to be disadvantageous and this is not always in consistency with literature data. Therefore, there is much more research to be conducted in this matter in order to understand the anti-cancer response and discover new predictive factors. We continue our research to elucidate the interplay between genetic and immunological processes in lung cancer.

P3.06E.05 The Inflammation Induced by Neoadjuvant Immunotherapy Facilitated Favorable Clinical Outcomes

M. Xie[1], X. Lin[2], Y. Jing[3], X. Xue[2], [1]the Chinese PLA General Hospital, Beijing/CN ,[2]Beijing Shijitan Hospital, Capital Medical University, Beijing/CN ,[3]Center for Intelligent Medicine, Greater Bay Area Institute of Precision Medicine (Guangzhou), School of Life Sciences, Fudan University, Guangzhou/CN

Introduction: After neoadjuvant therapy for non-small cell lung cancer (NSCLC), resected tumors exhibit varying degrees of inflammation formation. Usually, the inflammatory reactive changes in non-neoplastic lung must be separated when defining the tumor bed. However, the relationship between inflammation around the tumor bed and treatment response and prognosis in NSCLC with neoadjuvant therapy is yet to be elucidated.

Methods: We retrospectively collected hematoxylin and eosin-stained slides from patients with NSCLC (stage IA-IIIB) from two cohorts based on neoadjuvant immunochemotherapy(N=68) and neoadjuvant chemotherapy(N=41). Inflammation surrounding the tumor bed in different treatment groups was assessed and its' relationship with treatment response and prognosis was also analyzed.

Results: Peritumoral inflammation were identified in 79.4% of the patients with neoadjuvant immunochemotherapy and 42.5% of the patients with neoadjuvant chemotherapy, respectively. A higher proportion of peritumoral inflammation was found in neoadjuvant immunochemotherapy group (p<0.001). Inflammation surrounding the tumor bed was significantly correlated with pathological response in patients with neoadjuvant immunochemotherapy, while there was no significant correlation between peritumoral inflammation and pathological response in neoadjuvant chemotherapy group. Kaplan-Meier analyses revealed that the presence of inflammation around tumor bed was significantly associated with improved recurrence-free survival (RFS, p=0.042) and overall survival (OS, p=0.019) for patients with neoadjuvant immunochemotherapy. However, the presence of inflammation around tumor bed was not significant correlated with neither recurrence-free survival (RFS, p=0.83) nor overall survival (OS, p=0.63) for patients with neoadjuvant chemotherapy.

Conclusions: This study for the first time elucidates the correlation between inflammation surrounding tumor bed and treatment response and prognosis for NSCLC patients with neoadjuvant therapy. The findings reveal that peritumoral inflammation was more frequently induced by immunotherapy. Notably, the inflammation surrounding the tumor bed was correlated with favorable treatment response and prognosis in patients who received neoadjuvant immunochemotherapy. Improving the clinical outcomes through the induction of increased inflammation represents a significant benefit of neoadjuvant immunotherapy.

P3.06E.06 Angiogenesis and Immune-Related Biomarkers in Advanced Non-Small Cell Lung Cancer Treated with Immune Checkpoint Inhibitors

D. Grapsa[1], A. Papadopoulou[2], E. Kokkotou[1], S. Gaitanakis[1], I. Gkiozos[1], A. Charpidou[1], K. Syrigos[1], [1]Medical School, National & Kapodistrian University of Athens, Athens/GR ,[2]Medical School, National and Kapodistrian University of Athens, Athens/GR

Introduction: Previous data have shown that immune cells may interact with angiogenesis-related factors in the tumor microenvironment, regulating the development and progression of cancer, and that angiogenesis and immune checkpoint-related biomarkers may be useful as predictors of prognosis and treatment response in immunotherapy-treated solid tumors. We herein aimed to investigate the prognostic and predictive value of baseline and post-treatment levels of serum VEGF-A, VEGF-B and soluble programmed cell death-1 (sPD-1) and programmed cell death-ligand 1 (sPD-L1) in patients with advanced non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICIs).

Methods: 55 patients with advanced NSCLC eligible to receive immunotherapy (as monotherapy or in combination with chemotherapy) were prospectively enrolled. A group of sex- and age-matched healthy controls (n=16) was also recruited, for determination of the optimal cut-off value of the examined biomarkers. Serum VEGF-A, VEGF-B, sPD-1 and sPD-L1 levels were measured in peripheral blood samples using ELISA, both at baseline and at the time of treatment response evaluation, and were correlated with prognosis (PFS, OS), treatment response and the remaining clinicopathological features of patients.

Results: Mean age of patients was 66.5 years (SD=8.0 years); 65,5% of patients received chemotherapy and pembrolizumab combination while the remaining patients received pembrolizumab monotherapy. VEGF-B and sPD-1 levels were significantly decreased and increased, respectively, after treatment (p=0,028 and p<0,001, respectively). VEGF-A and sPD-L1 levels were also decreased and increased, respectively, albeit without reaching statistical significance. Univariate Cox regression analysis showed that increased pre-treatment values of sPD-1 (HR=10.96; p=0.037) and sPD-L1 (HR=1.68; p=0.040) and increased post-treatment levels of VEGF-B (HR=2.99; p=0.049) were all significantly associated with reduced OS. VEGF-B and sPD-L1 retained their prognostic significance in multivariate analysis (HR=3.37; p=0.032 and HR=2.10; p=0.014, respectively).

Conclusions: sPD-L1 and VEGF-B may represent independent biomarkers of prognosis in advanced-stage NSCLC patients treated with ICIs.

P3.06F.01 Proteomic Profiling Reveals Distinct Biological Characteristics of EGFR L858R Mutation and a Prognostic Model in Lung Adenocarcinoma

J. Huang[1], Y. Xu[2], Q. Zhang[3], Y. Qiu[1], X. Chen[1], [1]Hangzhou Cancer Hospital, Hangzhou/CN ,[2]Zhejiang Chinese Medical University, Hangzhou/CN ,[3]liyang people's hospital, Liyang/CN

Introduction: EGFR (epidermal growth factor receptor) gene mutations are among the key molecular drivers of lung adenocarcinoma. The L858R subtype, in particular, is often associated with more aggressive biological behavior and poorer prognosis compared to the 19DEL subtype and wild-type (WT), but its underlying mechanisms remain elusive.

Methods: To investigate the biological differences between EGFR mutation subtypes and their impact on patient prognosis, we established isogenic NCI-H520 cell line models harboring EGFR WT, 19DEL, or L858R mutations through stable lentiviral transfection. Comparative proteomic profiling using liquid chromatography-mass spectrometry (LC-MS) was performed to reveal proteome variations between the L858R mutation and other subtypes. Subsequent bioinformatic analyses were conducted to construct potential prognostic models for predicting recurrence in EGFR-mutated lung adenocarcinoma patients.

Results: Proteomic data revealed 11 proteins with significantly higher expression levels in L858R compared to 19DEL and WT, including TERF2IP, CDCA5, MRPL1, ACOT13, AKTIP, ROMO1, NFKBIL1, AKR1C3, NDUFAF4, GUSB, and PPME1. Conversely, 9 proteins, namely MTFP1, ENTPD8, PTRH2, KTN1, KANK2, PRIM1, PNPLA4, FBXO18, and ISY1, exhibited lower expression in L858R. Gene set enrichment analysis indicated common enriched pathways between 19DEL and L858R, such as ribosome and antigen processing and presentation, while L858R uniquely enriched metabolism-related pathways like lysine degradation and oxidative phosphorylation. Integrative analysis of our proteomic data and a clinical RNA-array dataset identified 28 differentially expressed genes (DEGs) between EGFR-mutated and WT samples. Lasso-Cox regression analysis yielded a 4-gene prognostic model effectively predicting disease-free survival (DFS) in EGFR-mutated lung adenocarcinoma patients. Higher expressions of BAG4 (HR(95%CI): 2.764 (1.215 - 6.288), P= 0.015), PLGRKT (HR(95%CI): 2.589 (1.383 - 4.846), P= 0.003), and PRIM1 (HR(95%CI): 2.960 (1.526 - 5.740), P= 0.001) correlated with worse DFS, while higher MOCS2 expression associated with improved DFS (HR(95%CI): 0.398 (0.168 - 0.945), P= 0.037). Multivariate analysis confirmed PRIM1 as an independent prognostic factor for DFS in EGFR-mutated lung adenocarcinoma (HR(95%CI): 2.225 (1.029 - 4.811) , P= 0.042).

Conclusions: In summary, this study uncovered proteomic variations and biological behavior differences among classical EGFR mutations in lung adenocarcinoma cell line models, highlighting distinct characteristics of the L858R mutation. The constructed risk model effectively predicted DFS in EGFR-mutated patients, with PRIM1 identified as a potential prognostic biomarker warranting further investigation.

P3.06F.02 Role of GOLT1B and PTGES3 In Suppressing Lung Adenocarcinoma Progression

J. Ye[1], Y. Wei[2], M. Gong[3], J. Hu[1], [1]The First Affiliated Hospital of Zhejiang University, Hangzhou/CN ,[2]The Second Affiliated Hospital of Nanchang University, Nanchang/CN ,[3]West China- Washington Mitochondria and Metabolism Research Center, West China Hospital, Chengdu/CN

Introduction: The current clinical diagnosis of cancer metastasis relies mainly on pathology and genetic tests, due to the lack of practical diagnostic biomarkers, early clinical diagnosis and treatment are hindered, which consequently leads to poor prognosis. Herein we applied proteomics and non-targeted metabolomics to identify biomarkers associated with lung adenocarcinoma progression.

Methods: In this study, analysis of cancer tissues and adjacent tissues was conducted based on proteomics and untargeted metabolomics. Patients were categorized into two groups based on long-term follow-up data: those with metastasis and those without. Pearson correlation analysis was used to calculate the correlation between clinical outcomes of metastasis and differentially expressed proteins (DEPs) and metabolites (DEMs). Cytoscape was utilized to construct a network diagram of DEPs/DEMs related to metastasis, and the cytoHubba plugin was used to select the top 2 central genes, GOLT1B and PTGES3. The inhibitory effect of overexpressed GOLT1B and PTGES3 on tumors was determined through in vitro and in vivo experiments. Furthermore, the correlation between GOLT1B and PTGES3 and the degradation of HIF1-α was explored and validated based on transcriptome sequencing.

Results: Based on proteomic and metabolomic analyses of 40 patients, 99 differentially expressed proteins and 58 metabolites related to postoperative metastasis of lung adenocarcinoma were identified. The core genes GOLT1B and PTGES3, along with 27 metabolites, were considered highly associated with lung adenocarcinoma metastasis. Preliminary results from in vitro and in vivo experiments demonstrated the inhibitory effect of GOLT1B and PTGES3 overexpression on the malignant behavior of lung adenocarcinoma. Furthermore, preliminary validation indicated that GOLT1B and PTGES3 promote the degradation of HIF1-α.

Conclusions: Our findings suggest that the alterations in GOLT1B and PTGES3, along with 27 related metabolites, may be highly associated with the metastasis of lung adenocarcinoma. Preliminary results from in vitro and in vivo experiments indicate that the overexpression of GOLT1B and PTGES3 exerts an inhibitory effect on the malignant progression of lung adenocarcinoma by promoting the degradation of HIF1-α.

P3.06F.03 Unbiased Proteomics and Multi-Omics Discovery of a Peripheral Blood-Based Classifier for Early Lung Cancer Detection

B. Koh[1], M. Liu[1], L. Yarmus[2], J. Choi[1], E. Khaledian[1], P. Ranjan[1], G. Shu[1], D. Vitko[1], R.J.X. Zawada[1], J.Y. Zeng[1], J. Yee[1], B. Wilcox[1], C. Belthangady[1], P. Ma[1], [1]PrognomiQ, Inc., San Mateo/CA/USA ,[2]Johns Hopkins University, Baltimore/MD/USA

Introduction: Blood-based approaches to detect early-stage cancer provide an opportunity to improve survival rates for lung cancer. Multiple approaches for blood-based cancer detection using molecular analytes derived from individual 'omics (cell-free DNA, RNA transcripts, proteins, metabolites) have been developed and tested, generally showing significantly lower sensitivity for early- versus late-stage cancer. We hypothesized that using a multi-omic approach, including broad and untargeted coverage of proteins using the Proteograph™ Product Suite (Seer Inc., Redwood City, CA), could potentially improve detection of early-stage lung cancer.

Methods: This report describes an observational case-control study of 2513 subjects enrolled from 77 unique clinical sites in the US. 2094 subjects were clinically eligible, including 816 with histopathologically confirmed lung cancers and 1278 non-cancer controls.

Study subjects were assigned into either a training or hold out set such that clinical sites were separated between these two sets. Sample processing was done in a blinded fashion for all subjects.

K2 EDTA plasma samples were processed with the Proteograph in conjunction with liquid chromatography-mass spectrometry following the manufacturer's protocol. 1623 subjects (1225 in training and 398 in validation) were profiled across all molecular assays and passed QC checks. Metabolomics and RNA sequence data were also collected.

A regularized, tree-based gradient boosted model (XGBoost) was fitted to the training data using hyperparameters optimized across 10 repeats of 10-fold cross validation. The trained classifier was used for inference on the hold out set.

Results: Multi-omics profiling detected 113,671 peptides corresponding to 8385 protein groups, 219,729 RNA transcripts, 71,756 RNA introns, and 1801 metabolites across all subject samples.

The machine learning-based multi-omics classifier for lung cancer detection was comprised of 682 of these analytes and demonstrated 89%, 80%, 88%, 100% and 98% sensitivity for all-stage, stage I, stage II, stage III, and stage IV lung cancer, respectively, at 89% specificity in the hold out set.

Conclusions: The application of a multi-omics platform for discovery of blood-based disease biomarkers, including proteins and complementary molecular analytes, enables the detection of early-stage lung cancer with the potential for downstaging at initial diagnosis and the improvement of clinical outcomes.

Keywords: lung cancer, biomarkers, multi-omics

P3.06F.04 Multi-Omics Analysis of SMARCA4-Deficient Tumors

Y. Dong, M. Li, Y. Zhang, W. Li, J. Wang, Z. Wang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: SMARCA4 (BRG1) encodes an ATPase subunit of the evolutionary conserved SWI/SNF chromatin remodeling complex. SMARCA4-deficient thoracic-origin tumors exhibit high malignancy and currently lack effective treatment options, whereas most patients are diagnosed at an advanced stage, and miss the chance of surgery. A comprehensive understanding of the landscape of SMARCA4-deficient tumors is needed.

Methods: Pan-cancer surgical samples suspected BRG1 loss from the National Cancer Center collected retrospectively between 2019 and 2023 were subjected to BRG1 IHC staining, whole-exomes sequencing (WES), and RNA-sequencing. The BRG1 protein deficient status, categorized as total-deficient (TD) or partial-deficient (PD), was twice-confirmed independently. Additionally, samples from lung cancer were acquired as control group for comparative analysis.

Results: A total of 66 patients were included in this study, with tumors originating primarily from various sites: lung (43), kidney (6), stomach (5), uterus (3), ovary (2), liver (2), colon (2), cervix (1), thyroid (1), and salivary (1). Among TD (n=38) and PD (n=11) groups, 39 out of 49 (79.6%) patients were heavy smokers, with TTN (68%), TP53 (57%), and SMARCA4 (41%) being the top three frequently mutated genes. Notably, no SMARCA4 mutations were detected in the control group (n=17), and SMARCA4 mutations were significantly more frequent in TD group than PD group (18/38, 47.4% vs. 2/11, 18.2%, P<0.05). SMARCA4 loss of heterogeneity (LOH) was only observed in TD group, while copy number amplification/deletion was observed in all three groups. Class I SMARCA4 mutations were exclusively present in the deficient groups, particularly more frequent in TD group than PD group (15/38, 39.5% vs. 2/11, 18.2%, P<0.05). Moreover, tumor mutational burden (TMB) was significantly higher in the deficient groups compared to the control group (P<0.05), with no significant variation observed between TD and PD groups. PD-L1 IHC staining did not show differences among the three groups. Regarding DNA damage response (DDR) pathways, mutations were significantly more common in all pathways, as well as the MMR, NER, and BER pathways in the deficient group compared to the control group (P<0.05). Conversely, mutations in the NHEJ and TLS pathways of PD group were significantly more common than those in TD group (P<0.05). Notably, for other subunits of SWI/SNF, the expressions of SMARCC1, ARIDA1, PHF10, GLTSCR1L, SS18L1, ACTL6A, and PBRM1 in PD group were significantly higher than those in TD group (P<0.05), suggesting a possible functional compensatory effect. The expression of SMARCA4 or SMARCA2, another ATPase subunit of SWI/SNF, was significantly higher in the deficient group than in the control group (P<0.05), with no significant difference observed between PD and TD groups. Further analysis revealed a positive correlation between SMARCA4 expression and SMARCA2 expression regardless of BRG1 status. Additionally, the expression of SOX-2, a biomarker distinguishing SMARCA4-deficient undifferentiated tumors from SMARCA4-deficient non-small cell lung cancer, was highest in TD group compared to PD and the control groups.

Conclusions: Discrepancies between SMARCA4 mutation and BRG1 status persist, calling a further exploration in mechanisms. Additionally, tumors exhibiting varying degrees of BRG1 integrity demonstrate distinct characteristics and potentially divergent biological behaviors. Further studies are underway.

P3.06F.05 Spatial Profiling of the Tumor Microenvironment of SMARCA4-Mutant NSCLCs Using Whole-Slide Multiplex Fluorescence Imaging

A. Gagné[1], J-R. Lin[2], S. Santagata[3], S.R. Talemi[2], M. Mino-Kenudson[4], M. Trovero[5], M. Paschini[5], L.V. Sequist[4], J. Luo[6], A.J. Iafrate[4], C. Kim[5], D.A. Barbie[6], L.M. Sholl[7], I. Dagogo-Jack[4], P.K. Sorger[2], [1]Dana Farber Cancer Institute/Harvard Medical School, Boston/MA/USA ,[2]Harvard Medical School, Boston/MA/USA ,[3]Brigham and Women's Hospital/Harvard Medical School, Boston/MA/USA ,[4]Massachusetts General Hospital, Boston/MA/USA ,[5]Boston Children's Hospital, Boston/MA/USA ,[6]Dana Farber Cancer Institute, Boston/MA/USA ,[7]Brigham and Women's Hospital, Boston/MA/USA

Introduction: SMARCA4 alterations are found in ~10% of non-small cell lung carcinomas (NSCLC), predominantly in adenocarcinomas among patients with a smoking history. Patients with these tumors may derive limited benefit from immune checkpoint inhibitor (ICI) therapy. The etiology of ICI primary resistance remains uncertain, as these tumors demonstrate high tumor mutational burden (TMB) and an inconsistent association with PD-L1 tumor proportion score (TPS) across studies. Frequent co-occurring mutations (e.g. STK11 mutations), may contribute to ICI resistance. To explore our hypothesis that lack of sensitivity to ICI in SMARCA4-deficient NSCLCs may be attributable to impaired immune infiltration, we investigated the tumor immune microenvironment of these tumors in relation to STK11 co-mutation status.

Methods: We conducted a retrospective study of patients diagnosed with NSCLC who underwent a lung surgical resection or a large surgical biopsy. Patients were selected based on SMARCA4 and STK11 alteration status detected using a 447-gene next generation sequencing panel (OncoPanel). Patients with SMARCA4/STK11 wild-type NSCLC served as a control group. Clinical and pathological data was collected from medical records, and additional molecular alterations were retrieved from OncoPanel reports. Immunohistochemistry (IHC) for SMARCA4/BRG1 and STK11/LKB1 was used to confirm loss of protein expression and to assess SMARCA2/BRM and PD-L1 expression. High-plex fluorescent spatial profiling using cyclic immunofluorescence (CyCIF) was performed to analyze the tumor immune composition with a 60-plex panel covering tumor, lineage, and immune, and checkpoint markers.

Results: We included 40 samples from 38 patients: 24 SMARCA4/STK11 mutant, 10 SMARCA4 mutant/STK11 wild-type, and 6 SMARCA4/STK11 wild-type (controls). Among the patients, 63% were female (mean age: 63.2 years; range 34-80 years). Adenocarcinoma was diagnosed in 90% of cases, and 72.5% of samples were from primary lung tumors. The cohort included seven patients with SMARCA4 missense mutations, and 25 with truncating mutations, including 10 nonsense mutations, 6 frameshift, and 6 splice site alterations. SMARCA4 loss of heterozygosity occurred in 9 (36.0%) patients with truncating mutations and in 6 (85.7%) with missense mutations. Complete or partial loss of SMARCA2/BRM was seen in 6 (17.6%) SMARCA4-mutant tumors and all had a loss of SMARCA4/BRG1 expression. TMB was higher in SMARCA4-mutant NSCLCs (SMARCA4/STK11 mutant: 13.2, SMARCA4 mutant/STK11 wild-type: 12.4, control: 4.6), with no significant difference in PD-L1 TPS between groups. Initial findings from CyCIF profiling indicate that SMARCA4-mutant NSCLCs exhibit significantly increased infiltration of myeloid cells (CD14 p=0.003) and macrophages (CD163 p=0.002).

Conclusions: SMARCA4-deficient NSCLCs has a distinct tumor immune microenvironment characterized by increased myeloid cell and macrophage infiltration, potentially contributing to resistance to immune checkpoint inhibitors. Additional work is underway to profile and spatially analyze the tumor immune microenvironment and to characterize its relation to STK11 co-mutation status.

P3.06F.06 Spatial Transcriptomic Profiling Reveals Molecular Patterns Associated with Poor Prognosis in ALK-Rearranged NSCLC Patients

W. Khatoon, A. Nambirajan, P.S. Malik, S. Vasant, K. yadav, A. Katiyar, D. Jain, All India Institute of Medical Sciences, New Delhi/IN

Introduction: ALK-rearranged NSCLC patients typically exhibit a median overall survival of 4-5 years. The pateint's response to treatment is influenced by factors including baseline and on-treatment genetic alteration, comorbidities, and the patient's age. Given the varying risks of poor prognosis among patients, early identification of high-risk profiles becomes imperative. Recently the interaction of tumors and their microenvironment has gained importance as determinants of treatment response in cancer. Therefore, this study employs Spatial transcriptomics (ST)-based molecular analysis of tumor and tumor microenvironment to characterize the risk landscape in ALK-rearranged NSCLC patients.

Methods: Retrospectively, 16 ALK-rearranged NSCLC FFPE tumor blocks (2016-2022) with clinical details and 3 control FFPE blocks (Normal: Brain, Lung, Lymph Node: LN) were collected. A tumor microarray consisting of 20 cores from 19 blocks were subjected to ST (NanoString GeoMx DSP). Immunohistochemical markers including PanCytokeratin for tumor, SYTO 13 for nuclei, and CD45 for immune cells were used to select 20 Regions of Interest (ROI) and 36 Areas of Illumination (AOI). RNA sequencing data was analyzed using various bioinfomatics tools

Results: Out of 16 ALK-rearranged NSCLC cases, six cases were in the High-risk patient/poor treatment responder (PTR) category, who succumbed to their disease in less than 1.5 years of the diagnosis (2 Brain metastasis and 4 LN metastasis) and the 10 cases were in Treatment Responder (TR) category, who survived for more than 1.5 years. ST data showed distinct immunological features linked with PTR and TR. TR stromal segment of LN metastasis shows enriched B cell markers in comparison to PTR, and the stroma of brain metastasis PTR showed enriched Effector cell and Tumor-Associated macrophage Markers in comparison to TR. The Differential gene expression analysis (DGEA) in the tumor segment of LN metastasis of TR and PTR showed 30 differentially expressed genes (DEG), the top upregulated genes (TUGs) in PTR were related to surfactant, epithelial barrier, and immune response. The top-downregulated genes (TDGs) in TR were related to immune response and angiogenesis. Similarly, the DGEA of stromal lymph node metastasis of TR and PTR showed 29 DEG, the TUGs in PTR were related to tumor proliferation, whereas the TDGs in TR were related to inflammation and angiogenesis.

Conclusions: This study reveals distinct gene expression patterns in tumor and stroma segments for immune response, angiogenesis, and tumor proliferation TR and PTR. This signifies its application in the early detection of PTR-related gene expression patterns, enabling tailored clinical management.

P3.06F.07 Effect of Neoadjuvant Chemotherapy on the Spatial Landscape of Regulatory T Cells in Non-Small Cell Lung Cancer Patients

S. Cai[1], G. Yang[1], X. Sun[1], L. Xing[2], [1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, Shandong, China, Jinan/CN ,[2]Shandong Cancer Hospital and Institute, Jinan/CN

Introduction: It is crucial to decipher the modulation of regulatory T cells (Tregs) in tumor microenvironment (TME) induced by chemotherapy, which may contribute to improving the efficacy of neoadjuvant chemoimmunotherapy in resectable non-small lung cancer (NSCLC).

Methods: We retrospectively collected specimens from patients with II-III NSCLC, constituting two cohorts: a neoadjuvant chemotherapy (NAC) cohort (N =141) with biopsy (N = 58) and postoperative specimens (N = 141), and a surgery-only cohort (N =122) as the control group. Then, the cell density (Dens), infiltration score (InS), and Treg-cell proximity score (TrPS) were conducted using multiplex fluorescence staining (Foxp3, CD4, CD8, CK, CD31, αSMA). Subsequently, the association of Tregs with cancer microvessels (CMVs) and cancer-associated fibroblasts (CAFs) was analyzed.

Results: Patients with NAC treatment have a higher density of Tregs in both paired (P < 0.001) and unpaired analysis (P = 0.022). Additionally, patients with NAC treatment showed higher infiltration score (paired, P < 0.001; unpaired, P = 0.014) and more CD8+T cells around Tregs (paired/unpaired, both P < 0.001). Multivariate analysis identified that the Dens(Tregs), InS(Tregs) and TrPS(CD8) were significantly associated with better chemotherapy response [OR= 8.54, 95%CI (1.69, 43.14), P = 0.009; OR= 7.14, 95%CI (1.70, 30.08), P = 0.024; OR= 5.50, 95%CI (1.09, 27.75), P = 0.039, respectively] and positive recurrence-free survival [HR = 3.23, 95%CI (1.47, 7.10), P = 0.004; HR = 2.70; 95%CI (1.27, 5.72); P = 0.010; HR = 2.55, 95%CI (1.21, 5.39), P = 0.014, respectively]. Moreover, TrPS(CD8) and TrPS(CD4) were negatively correlated with the CMVs and CAFs.

Conclusions: These discoveries have deepened our comprehension of the immune-modulating impact of chemotherapy and underscored that the modified spatial landscape of Tregs after chemotherapy should be taken into account for personalized immunotherapy, aiming to ultimately improve clinical outcomes in patients with NSCLC.

Introduction: Human leukocyte antigen (HLA) class I molecules present antigenic peptides to T-lymphocytes, favoring specific responses. Loss of HLA expression and loss of heterozygosity (LOH) are common events in cancer development that could be implicated in antigen diversity presentation and primary resistance to immunotherapy. Here, we studied the relationship of HLA-I tumor status at diagnosis, with tumor microenvironment and clinical outcomes of NSCLC patients treated with perioperative nivolumab plus chemotherapy (ChIO) from NADIM clinical trial (NCT03081689).

Methods: Diagnostic tissue from 24 patients were analyzed. Baseline HLA tumor status (HLA-deficient or -proficient) was determined by DNA LOH (ImmunoArray-24.v2) combined with immunohistochemistry for protein levels. PD-L1 and TMB were measured in pretreatment FFPE tissue samples. Immune cell populations were determined in baseline and surgery samples by multiplex immunofluorescence. Spatial transcriptomics was performed in posttreatment HLA-deficient tumors using Visium Spatial FFPE Gene Expression and Space Ranger pipeline 2.1.1 with Loupe Browser 7.0.1 analysis (10X Genomics).

Results: Baseline LOH and/or decreased HLA protein levels occurred in 41.7% of tumors and were categorized as HLA-deficient status. HLA-deficient tumors showed a desert-like tumor microenvironment at baseline, with lower PD-L1 levels and immune cell infiltrate, supporting the key role of HLA status in tumor development and immune microenvironment coevolution. Despite their "cold" microenvironment, perioperative ChIO induced similar Complete pathological response (CPR) rates in both HLA-deficient and proficient tumors (50% and 60% respectively, p=0.670). Similarly, ChIO induced high 3-year PFS and OS rates in both HLA-deficient (PFS 70% [95%CI 32.9-89.2] and OS 70% [95%CI 32.9-89.2]) and HLA-proficient (PFS 71.4% [95%CI 40.6-88.2] and OS 92.9% [95%CI 59.1-99.0]) (PFS p=0.909, OS p=0.137). In fact, the study of the post-treatment tumor bed microenvironment of an CPR HLA-deficient tumor showed a strong immune response, supporting observed long-term benefit of ChIO in some patients with HLA-deficient tumors. Focusing on reactive stroma, CPR HLA-deficient tumor had B-cell aggregates (MS4A1/CD19) forming tertiary lymphoid structures (TLS, MS4A1/CD19/CXCL13/CR2), while these were absent in non-CPR HLA-deficient tumor. Additionally, CD4+ T-cells were present in both CPR and Non-CPR HLA-deficient tumors, but CD4+ T-cells/HLA-II colocalization occurred mainly inside TLS of CPR tumor (CD4/CIITA/CD80). Similarly, CD8+ T cells were identified in both HLA-deficient tumors, but activation was only detected in CPR HLA-deficient tumor (CD8A/GZMB/KLRK1).

Conclusions: Our findings highlight the activity of perioperative ChIO in NSCLC HLA-deficient tumors, and the potential role of TLS, as well as the coordinated action of helper and cytotoxic T-cells, in tumor resolution.

P3.08E.02 An Artificial Intelligence Driven Approach to Predict Pathological Response to Neoadjuvant Chemoimmunotherapy for Non-Small Cell Lung Cancer

Y. Xia[1], J. Zhao[1], J. Zhou[1], X. Yan[2], X. Yang[3], J. Shou[4], Y. Lu[5], F. Yang[2], Y. Zhang[6], W. Li[1], [1]Second Affiliated Hospital of Zhejiang University School of Medicine, Hanghou/CN ,[2]Peking University People's Hospital, Beijing/CN ,[3]Peking University Cancer Hospital and Institute, Beijing/CN ,[4]Sir Run Run Shaw Hospital, Hangzhou/CN ,[5]Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou/CN ,[6]Hunan Cancer Hospital, Changsha/CN

Introduction: Neoadjuvant chemoimmunotherapy has been evident to play critical roles in perioperative Non-small Cell Lung Cancer (NSCLC). Increased neoadjuvant cycles have been found to be associated with improved pathological response, albeit at the potential of higher adverse effects. To date, it is unlikely to make precise pathological evaluation at the preoperative setting. The aim of our study is to develop an artificial intelligence driven radiomics approach to estimate the pathological response before surgery, optimizing the individualized neoadjuvant strategies.

Methods: 314 patients with II to IIIB NSCLC who received neoadjuvant therapy of anti-programmed death-1(PD-1) combined with chemotherapy in five medical centers in China from May 2019 to August 2023 were retrospectively included. We constructed a training set (n=202), an internal validation set (n=51) and an external validation set (n=61). Radiomic features were extracted from regions of interest delineated on pre- and post-neoadjuvant therapy chest CT imaging. The change in radiomics features, termed as delta features was calculated. The Mann-Whitney U test was employed to eliminate redundant features. Major pathological response (MPR) and non-MPR statuses served as outcome labels. Feature selection within the training set was performed using LASSO regression through a process of 10-fold cross-validation. The predictive model was developed employing eXtreme Gradient Boosting (XGBoost), with the AUC being computed to assess model performance. All statistical analyses were executed using Python (Version 3.11).

Results: Among 314 patients (mean [SD] age,63.2[8.7] years) included, squamous cell carcinoma (209, 66.6%) and stage III disease (212, 67.5%) were predominantly presented. MPR was achieved in 198 patients (63.1%). Over a median follow-up time of 17.0 months, the HR of event-free survival (EFS) between patients achieving MPR and non-MPR was 0.36 (95%CI: 0.20, 0.65, P < 0.01). 4 pre-treatment features, 30 post-treatment features and 11 delta features were selected by LASSO regression. By utilizing these features, we developed pre-treatment, post-treatment, and delta radiomics prediction models based on XGboost algorithm. Of note, compared with pre-treatment and post-treatment model, the delta model demonstrated superior performance in predicting MPR achievement (AUC for internal validation and external validation, respectively: delta model 0.86 and 0.87; pre-treatment model 0.70 and 0.58; post-treatment model 0.83 and 0.65). Moreover, there was significant difference in EFS between MPR and non-MPR predicted by the delta model across training plus internal validation set, as well as external validation set, yielding an HR of 0.31 (95% CI: 0.15, 0.62, P < 0.01) and 0.30 (95% CI: 0.10, 0.94, P = 0.03), respectively.

Conclusions: The establishment of an artificial intelligence based radiomics approach can precisely predict the pathological response to neoadjuvant chemoimmunotherapy, facilitating the identification of the optimal timing for surgery.

P3.08E.03 Dynamics of Peripheral Blood Inflammatory Index Predict Response of Neoadjuvant Immunotherapy in Non-Small Cell Lung Cancer

W. Zhai, F. Duan, H. Long, J. Wang, Sun Yat-sen University Cancer Center, Guangzhou/CN

Introduction: Static tumor features before treatment were insufficient to select responding tumors under the selective pressure of immunotherapy. Herein, we investigated the value of longitudinal dynamics of peripheral blood inflammatory indexes (dPBI) in predicting major pathological response (MPR) in non-small cell lung cancer (NSCLC).

Methods: 147 NSCLC patients underwent neoadjuvant immunochemotherapy were reviewed as training cohort and 26 NSCLC patients from a phase II trial were validation cohort. dPBIs were calculated as posttreatment values of PBI minus their baseline values. Least absolute shrinkage and selection operator algorithm was utilized to screened out predictors for MPR and integrated a MPR score. We constructed a model incorporating this MPR score and clinical predictors for predicting MPR and evaluated its predictive capacity via the area under the curve (AUC) of the receiver operating characteristic and calibration curves. Furthermore, we sought to interpret this MPR score in the context of micro-RNA transcriptomic analysis in plasma exosomes for 12 paired samples (baseline and posttreatment) obtained from training cohort.

Results: Longitudinal dynamics of monocyte-lymphocyte ratio, platelet-to-lymphocyte ratio, platelet-to-albumin ratio, and prognostic nutritional index were screened out as significant indicators for MPR and integrated a MPR score, an independent predictor of MPR. Then, a predictive model incorporating MPR score, histology and differentiated degree, discriminated MPR and non-MPR patients well in both training and validation cohorts with an AUC of 0.803 and 0.817, respectively. Furthermore, micro-RNA transcriptomic analysis revealed the association between our MPR score and immune regulation pathways. And significantly better event-free survival was seen in subpopulations with high MPR score.

Conclusions: dPBI reflected responses to neoadjuvant immunochemotherapy for NSCLC. The MPR score, a non-invasive biomarker integrating four dPBIs, captured the miRNA transcriptomic pattern and distinguished MPR from non-MPR for neoadjuvant immunochemotherapy, which could support the clinical decisions on the utilize of ICIs-based treatments in NSCLC patients.

Keywords: non-small cell lung cancer, neoadjuvant immunotherapy, dynamics

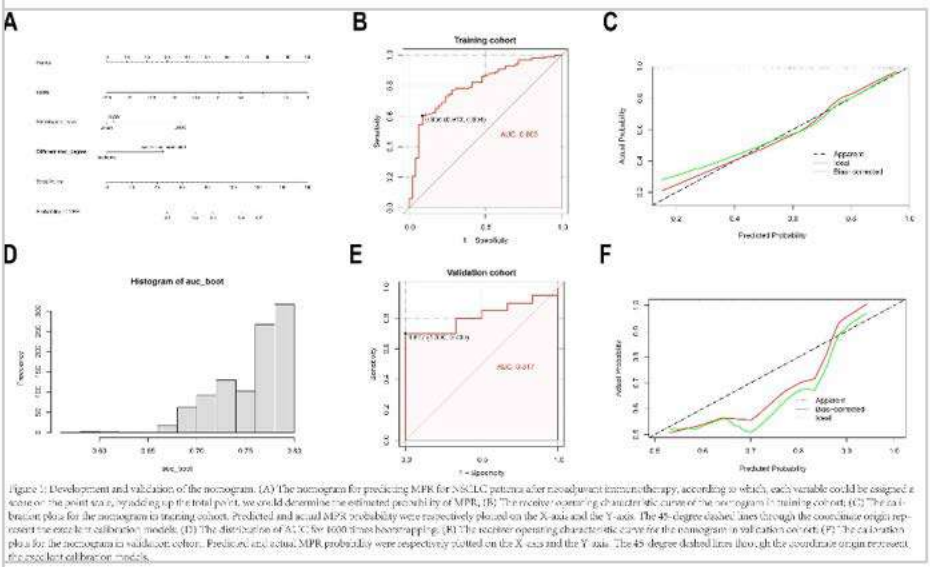

Figure 1: Development and validation of the nomogram. (A) The nomogram for predicting MPR for NSCLC patients after neoadjuvant immunotherapy, according to which, each variable could be assigned a score on the point scale, by adding up the total points, we could determine the estimated probability of MPR; (B) The receiver operating characteristic curve of the nomogram in training cohort; (C) The calibration plots for the nomogram in training cohort. Predicted and actual MPR probability were respectively plotted on the X-axis and the Y-axis. The 45-degree dashed lines through the coordinate origin represent the excellent calibration models; (D) The distribution of AUC for 1000 times bootstrapping; (E) The receiver operating characteristic curve for the nomogram in validation cohort; (F) The calibration plots for the nomogram in validation cohort. Predicted and actual MPR probability were respectively plotted on the X-axis and the Y-axis. The 45-degree dashed lines through the coordinate origin represent the excellent calibration models.

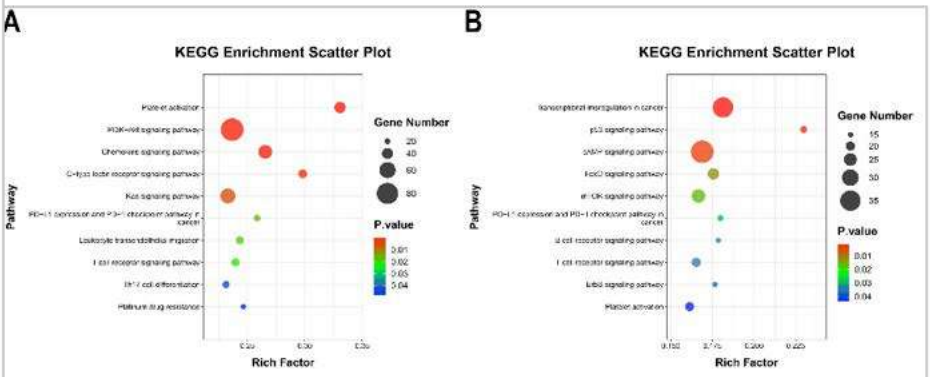

Figure 2: The scatter plot of KEGG enrichment analysis. (A) The pathways involved in immune regulation and signal transduction of 3 miRNAs which positively correlated with MPR signature; (B) The pathways of involved in immune regulation and signal transduction 2 miRNAs which negatively correlated with MPR signature.

P3.08E.04 TCR Metrics as Predictive Biomarkers of Response and Survival after Perioperative Chemoimmunotherapy. NADIM & NADIM II Trials

Hospital Universitario Quiron Dexeus, Grupo QuironSalud,, Barcelona/ES

Introduction: T-cell Receptor (TCR) repertoire metrics have shown potential as efficacy biomarkers for immunotherapy treated patients. In NADIM trial (NCT03081689), higher TCR repertoire clonality in tumors at baseline, were associated to hot microenvironment, improved rates of complete pathological responses (CPR), and survival after perioperative nivolumab plus chemotherapy (ChIO) in locally-advanced NSCLC. In this study, we aimed to confirm our previous results increasing the patient cohort and follow-up, including patients from NADIM and NADIM II (NCT03838159) trials.

Methods: TCR data from FFPE tissue samples obtained before and after neoadjuvant treatment was available from 71 patients (NADIM-ChIO, n=42; NADIM-II-ChIO, n=19; NADIM-II-Ch, n=10). TCR repertoire was determined using the NGS Oncomine TCR Beta-SR assay. The association of different TCR metrics (Convergence, Evenness and TOP1% clonal space (CS) with pathological response and survival, were performed by U-Mann Whitney test and Kaplan-Meier with log-rank analysis, respectively. ROC curves and best likelihood ratio were used to determine cut-off points in survival analyses. Analyses were performed on the pooled ChIO-treated patients (NADIM+NADIM-II-ChIO), and individually in NADIM-ChIO, NADIM-II-ChIO, and NADIM-II-Ch arms.

Results: The median follow-up time was 27 and 60 months for NADIM II and NADIM trials, respectively. Regarding pathological responses in NADIM+NADIM-II-ChIO, metrics derived from baseline TCR repertoire analysis presented a relevant ROC curve for predicting CPR (Convergence AUC=0.79, p=0.0078; Evenness AUC=0.86, p=0.0011; TOP1% CS AUC= 0.95, p<0.0001) compared with PD-L1 or TMB (PD-L1 AUC=0.71, p=0.0037; TMB AUC=0.61, p=0.226). CPR tumors showed increased levels of baseline TCR convergence (p=0.008), TOP1% CS (p=0.000005), PD-L1 (p=0.0024) and reduced Evenness (p=0.001). Concerning survival, baseline TCR metrics were associated to PFS and OS. Thus, patients harboring tumors with higher TCR evenness, or lower TOP1%CS or convergence, showed higher risk of disease progression (Hazard Ratio (HR)=4.38, p=0.0096; HR=5.37, p=0.0017; HR=3.72, p=0.019; respectively), or death (HR=3.08, p=0.093; HR=4.96, p=0.0077; HR=4.06, p=0.023; respectively). Patients with negative PD-L1 tumors or TMB-low (<3.8 mut/Mb) showed a trend for increased risk of disease progression or death (PD-L1 PFS HR=2.32, p=0.054; PD-L1 OS HR=1.83, p=0.284; TMB PFS HR=3.62, p=0.069; TMB OS HR=5.84, p=0.043. Similar results for biomarkers were observed in NADIM and NADIM II ChIO cohorts analyzed separately, and were not predictive of patients' outcomes when analyzed in posttreatment samples or in chemotherapy treated patients.

Conclusions: Baseline TCR metrics, particularly convergence, evenness, and TOP1% CS, demonstrate robust predictive value for CPR and survival in locally-advanced NSCLC patients undergoing perioperative nivolumab plus chemotherapy, warranting further investigation in larger cohorts.

P3.08F.01 Interim Analysis of a Phase 2 Prospective Trial of Induction Lorlatinib in Locally Advanced ALK-Positive NSCLC (LORIN)

W-Z. Zhong[1], C. Zhang[1], Y. Yang[1], J. Yang[1], Q. Zhou[1], Q. Zhong[2], W. Liang[3], Z. Chen[1], Y. Wu[1], [1]Guangdong Provincial People's Hospital, Guangzhou/CN ,[2]Guangzhou medical University, Guangzhou/CN ,[3]the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Induction ALK-TKIs in locally advanced NSCLC remained an emerging area for further exploration. Although lorlatinib has exhibited superb clinical benefit in advanced NSCLC, no corresponding date regarding locally advanced disease was reported. Herein, we report an interim analysis of a phase 2 prospective trial (NCT05740943).

Methods: This is an open-label, phase 2 prospective trial with Simon two-stage design. 13 patients with confirmed stage III through PET scan as well as brain MRI and ALK fusion were estimated to enroll for stage I cohort. Patients would be provided with 3 cycles (90 days) induction lorlatinib and evaluated by multidisplenary team to determine the subsequent local treatment. The primary endpoint was pathological complete response (pCR). At least 3 patients achieved pCR could allow for initiation of stage II cohort. Longitudinal tumor-naive MRD and large panel NGS were performed.

Results: By March 1, 2024, 13 patients were consecutively enrolled and 11 patients had completed induction treatment and surgery. 2 patients refused surgery and local radiotherapy due to patient's willingness and sever toxicity, respectively. 4, 8 and 1 patients diagnosed as stage IIIA, IIIB and IIIC disease, respectively. PD-L1 positive was found in 69.2% patients and 30.8% had PD-L1 high expression. The overall response rate was 76.9% and disease control rate was 100%. The most common treatment-related adverse events included hypercholesterolemia, hypertriglyceridemia and weight gain. For patients who underwent surgery, one patient received 4 cycles induction treatment while others completed 3 cycles treatment. In terms of the baseline evaluation, 7 patients (53.8%) had unresectable disease due to N3 metastasis and the surgical conversion rate was 85.7% with pathologically confirmed N3 negative after induction treatment. pCR and MPR for ITT and PP cohort was 23.1% vs. 27.3% and 76.9% vs. 90.9%, respectively. LN-pathologically downstaging rate was 63.6%. All patients had undergone minimally invasive lobectomy except for one patient had conversion to open thoracotomy. 3 patients had mild surgical difficulties while others (72.7%) had moderate to severe surgical difficulties regarding fibrosis and adhesion. Baseline PD-L1 expression did not impact treatment efficacy and all patients with MRD positive (46.2%) at baseline had ctDNA clearance after induction treatment.

Conclusions: Induction lorlatinib was clinically feasible and tolerable in stage III ALK-mutant NSCLC regardless of PD-L1 expression, leading to high surgical conversion. Short-term lorlatinib could efficiently eliminate ctDNA though sensitivity for fusion detection warranted further improvement.

Introduction: The current standard therapy for patients with unresectable stage III non- small cell lung cancer (NSCLC) is concurrent or sequential chemoradiotherapy followed by immune-maintenance therapy (Pacific). However, the recent studies have shown that EGFRm+ stage III unresectable NSCLC who received epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) after chemoradiotherapy had longer survival. Our study aims to firstly evaluate the efficacy and safety of aumolertinib induction therapy in EGFRm+ patients with unresectable stage III NSCLC and dynamic minimal residual disease (MRD) guided maintenance therapy with aumolertinib after local therapy (surgery or chemoradiotherapy) evaluated by multidisciplinary team (MDT) (NCT04841811/CTONG2101).

Methods: This is an open-label, multi-center, randomized, phase III study. Patients have histopathology or cytology confirmed Stage III non-squamous NSCLC and investigator confirmed unresectable. The performance status (Eastern Cooperative Oncology Group) is 0 or 1. This trial is prepared to enroll 192 patients (Figure 1). Eligible patients receive aumolertinib 110 mg QD for 8 weeks, followed by local treatment (surgical or chemoradiotherapy) which is evaluated by MDT assessment. Patients are randomized (1:2) to group A or B. Stratification factors include EGFR exon 19 deletion or 21L858R mutation, shedding or non-shedding ctDNA at baseline, surgery or chemoradiotherapy under MDT. Patients in group A receive aumolertinib 110 mg QD. Patients in group B receive aumolertinib 110 mg QD guided by dynamic MRD monitoring: aumolertinib treatment or drug holiday (only observation) in the first cycle is determined by the d7 and d14 MRD status after local therapy; after that, when ctDNA positive (MRD+), patients receive aumolertinib 110 mg QD until ctDNA turns to negative (MRD-); at this time, patients stop aumolertinib until ctDNA turns to positive and restart aumolertinib. Imaging evaluation and ctDNA testing will be conducted every 12 weeks. The treatment paradigm of group A and B will be continued until disease progression or fulfillment of discontinuation criteria. Primary endpoints are objective response rate after 8 weeks of aumolertinib induction therapy and 24-month event-free survival (EFS) rate assessed by independent review committee between group A and B. Secondary endpoints are comparison of 24-month EFS rate among three cohorts (patients with longitudinal negative MRD in group B vs patients with any positive MRD in group B vs group A), overall survival, EFS, major pathological response rate in patients undergoing surgery, safety and quality of life. The trial initiated on June, 2022. Now is ongoing.

P3.08F.03 NRG LU008: Phase III Randomized Trial of Primary Tumor SBRT Followed by Concurrent Mediastinal Chemoradiation for LA-NSCLC

J. Heinzerling[1], C. Hu[2], C.B. Simone II[3], K.F. Mileham[4], K.A. Higgins[5], L. Lin[6], M.E. Abazeed[7], N. Ohri[8], J.D. Bradley[9], [1]Atrium Health Levine Cancer/Wake Forest School of Medicine, Charlotte/NC/USA ,[2]NRG Oncology, Philadelphia/PA/USA ,[3]New York Proton Center and Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[4]Levine Cancer Atrium Health/Wake Forest School of Medicine, Charlotte/NC/USA ,[5]City of Hope, Atlanta/GA/USA ,[6]Emory University/Winship Cancer Institute, Atlanta/GA/USA ,[7]Northwestern University, Chicago/IL/USA ,[8]Montefiore Medical Center, Bronx/NY/USA ,[9]University of Pennsylvania/Abramson Cancer Center, Philadelphia/PA/USA

Introduction: Outcomes remain poor for unresectable LA-NSCLC treated with concurrent chemoradiation followed by immunotherapy. The primary tumor is the most common site of non-metastatic failure, and local failure (LF) directly correlates with overall survival (OS). While local control (LC) and OS have improved by increasing the biological effective dose with SBRT in early-stage NSCLC, SBRT use in LA-NSCLC has largely been limited to primary tumor boost after chemoradiation, which has high morbidity. A recent phase II trial of SBRT to the primary tumor and chemoradiation to involved lymph nodes demonstrated lower rates of pulmonary and cardiac toxicities relative to historical controls, while improving LC, progression-free survival (PFS), and OS. We hypothesize that replacing conventionally fractionated radiotherapy with SBRT to the primary tumor followed by concurrent chemoradiation to the mediastinum will be associated with lower rates of toxicity and improved QOL, while also improving LC, PFS, and OS.

Methods: LU008 is a phase III randomized trial in stage II-III NSCLC conducted by NRG Oncology (NCT05624996). Patients are randomized to chemoradiation to all disease (60/2 Gy) (control arm) or SBRT to the primary (BED ≥100 Gy in 3-5 fractions) followed by chemoradiation to nodal disease (60/2 Gy) (experimental arm). Standard concurrent chemotherapy regimens are allowed in both arms. Maintenance therapy is pragmatic, with most patients expected to receive durvalumab for up to 12 months. Inclusion criteria include node-positive stage II-III NSCLC, medically inoperable or refuse surgery, identified primary tumor ≤7 cm, ECOG performance status (PS) 0-2, and ≤4 cycles of systemic therapy prior to registration. Key exclusion includes central primary tumor location that is <2cm from involved nodal disease. The primary objective is to compare OS and PFS. Secondary objectives are response rate, LC, patterns of failure, pulmonary function changes, QOL, and toxicity. Exploratory objectives include biospecimen analyses, regional lung ventilation, and proton vs. photon differences. Real-time pre-treatment reviews are conducted

Results: LU008 was activated nationally on 5/10/23. As of 4/3/24, 40 patients have been accrued, and 280 sites have the trial open to accrual. Final target accrual is 474 subjects, with an expected 9.5 accruals per month after an initial 6-month ramp up.

Conclusions: LU008 is poised to change the standard of care in inoperable LA-NSCLC by improving LC, PFS, and OS. It is the most pragmatic thoracic NCI National Clinical Trial Network (NCTN) trial, with no lab/PFT cutoffs, no CT chest/MRI brain/lab time windows, and allowing patients with actionable mutations and ECOG PS 2. LU008 is the only phase III NCTN trial accruing for inoperable LA-NSCLC, and robust accrual is expected.

P3.08F.04 Developing Circulating and Imaging Biomarkers Towards Personalised Radiotherapy in Lung Cancer: An Update on the VIGILANCE Study

A. Horne[1], H. Crawford[2], C. Dempsey[1], C. Faivre-Finn[1], [1]University of Manchester, Manchester/GB ,[2]The Christie NHS Foundation Trust, Manchester/GB

Introduction: Multi-modality radiotherapy-based treatments are available to treat patients with stage III non-small cell lung cancer and are associated with improved clinical outcomes. However, not all patients benefit from these complex treatments and there is a paucity of biomarkers supporting treatment decisions tailored to the individual patient.

The VIGILANCE study's primary aim is to build a prognostic model using longitudinal novel health technology data collected before, during and for 1 year after completion of radiotherapy in patients with stage III non-small cell lung cancer. This includes blood samples for methylated circulating tumour DNA analysis, electronic patient reported outcome measures (ePROMs) and radiomic analysis of standard of care imaging.

The study is sponsored by the University of Manchester and funded by CRUK, a Rosetree Grant and AstraZeneca.

Methods: The VIGILANCE study opened to recruitment on 24th March 2023 for 18 months. Up to 80 patients will be enrolled. Key eligibility: Inoperable stage III NSCLC planned to be treated with either radical radiotherapy, sequential chemoradiotherapy and concurrent chemoradiotherapy +/- consolidation immunotherapy. Participants will have additional blood samples and ePROMs performed and their standard of care imaging will be acquired as per schema (see Image 1 below).

As of 06/04/2024, 35 patients have been registered: 21 patients were treated with concurrent chemoradiotherapy, 5 patients with sequential chemoradiotherapy, 5 patients with radiotherapy alone, 1 patient died of a pneumonia prior to starting treatment, 1 patient progressed and was no longer ineligible and 2 patients withdrew their consent.

The study continues to recruit and further information is available: https://clinicaltrials.gov/study/NCT06086574

P3.08F.05 Four-Cycle Compared with Two-Cycle Neoadjuvant Chemoimmunotherapy Achieved a Higher Rate of pCR: Preliminary Results of a Phase III Trial

D. Lin, X. Wang, X. Li, J. Fan, Shanghai General Hospital, Shanghai/CN

Introduction: Neoadjuvant chemoimmunotherapy (NCI) targeting the PD-1/PD-L1 pathway is effective for non-small-cell lung cancer (NSCLC). However, few studies have focused on the optimal cycles of NCI. We have launched a prospective, multicenter, phase III randomized controlled clinical study to evaluate the safety and efficacy of two-cycle versus four-cycle neoadjuvant PD-1 antibody plus chemotherapy followed by surgery in resectable stage IIIA non-small cell lung cancer (NCT05157776).

Methods: The patients with IIIA NSCLC without driver genes were given two cycles of NCI (initial two-cycle NCI), after which they were 1:1 randomly assigned to the two-cycle NCI groups (no additional NCI) or four-cycle NCI group (with another two cycles of NCI) (Figure.1). The primary endpoint is pathological complete regression (pCR) rate.

Results: Of the 26 patients that had completed neoadjuvant NCI, surgical resection and pathological re-evaluation, the pCR rate was 23.1% (3/13) in the two-cycle group, and it was 53.8% (7/13) in the four-cycle group. These were mostly consistent with the pre-estimated rates. The incidences of immunotherapy-related accidental events (AEs) were comparable between the groups. And no new AE was observed.

Conclusions: Compared with two-cycle NCI, four-cycle NCI achieved a higher rate of pCR, with comparable incidences of immunotherapy-related AEs. More data is needed to further validate it.

P3.08F.06 PLATINUM Trial: Preliminary Analysis of Lazertinib Therapy in Locally Advanced, Unresectable, EGFR Mutation(+) NSCLC Following CCRT

S.Y. Lee[1], J. Choi[1], T.W. Jang[2], S.H. Lee[3], D.W. Park[4], S.I. Choi[5], S.H. Yoon[6], J.H. Lim[7], J.E. Lee[8], S.Y. Lee[9], S.H. Park[10], I-J. Oh[11], E.Y. Kim[12], J.C. Lee[13], [1]Korea University Guro Hospital, Seoul/KR ,[2]Kosin University Gospel Hospital, Busan/KR ,[3]Kyung Hee University Hospital, Seoul/KR ,[4]HanYang University Hospital, Seoul/KR ,[5]Korea University Anam Hospital, Seoul/KR ,[6]Pusan National University Yangsan Hospital, Busan/KR ,[7]Inha University Hospital, Incheon/KR ,[8]Chungnam National University, Daejeon/KR ,[9]Kyungpook National University Chilgok Hospital, Daegue/KR ,[10]Keimyung University Dongsan Hospital, Daegu/KR ,[11]Chonnam National University Medical School and Hwasun Hospital, Hwasun/KR ,[12]Yonsei University Severance Hospital, Seoul/KR ,[13]Ulsan University Asan Medical Center, Seoul/KR

Introduction: The PACIFIC trial has demonstrated sustained overall survival (OS) benefit with durvalumab as consolidation therapy after concurrent chemoradiation therapy (CCRT). In a subgroup analysis, the effect was not proven in EGFR mutation positive patients. Lazertinib is 3rd generation EGFR TKI as osimertinib and shows good anti-cancer effect in EGFR sensitive mutations in LASER 301 trial. PALTINUM trial is an ongoing, phase II trial, evaluating the efficacy and safety of lazertinib as consolidative treatment after CCRT in patients who had EGFR mutation positive NSCLC (E19del/L858R, Stage III). We present data from the preliminary efficacy and safety data.

Methods: Eligible patients (≥18 years) with inoperable stage III EGFR mutation positive NSCLC (AJCC 8th edition), who have not progressed following CCRT, received lazertinib as consolidation therapy. Primary endpoint is PFS and 2ndary endpoints are OS, the objective response rate, the duration of response, the time to death or distant metastasis, and safety.

Results: Twenty-five patients enrolled in this analysis. At the 29 Feb 2024 database lock (median follow-up, 12.7 mo), the median age was 67 years, 56% were females, 56% were never smokers. The objective response rate and disease control rate were 72%, 100%, respectively. Among never or former smokers, 50% demonstrated a partial response to lazertinib, indicating significant tumor regression. Conversely, all current smokers exhibited only stable disease, with no cases of partial response observed. Median PFS was not reached. The most common treatment-related Grade 3 adverse events (AEs) were dermatitis (8%), paraesthesia (4%), asthenia (4%) and pulmonary embolism (4%). Treatment-related AEs leading to discontinuation occurred in 16% of patients. Grade 2 radiation pneumonitis developed in three patients (12%), but no lazertinib-related pneumonitis was observed (table).

Conclusions: In this preliminary analysis from PLATINUM trial, consolidative lazertinib demonstrated clinically meaningful efficacy and no new safety signal was detected at interim analysis.$$graphic_{D3846C3D-AA63-41BE-8D4B-0BA4522B9029}$$

P3.08F.07 Efficacy and Safety of Envafolimab Plus Platinum-based Chemotherapy as Neoadjuvant Therapy in Resectable Stage II-IIIB NSCLC

H. Zhang, G. Zhao, J. Gu, D. Ge, Zhongshan Hospital, Fudan University, Shanghai/CN

Introduction: Multiple clinical trials have reported the striking benefit for PD-1/PD-L1 monoclonal antibody combined with chemotherapy neoadjuvant therapy for non-small cell lung cancer (NSCLC), while the efficacy of subcutaneous injection of anti-PD-L1 Envafolimab combined with chemotherapy neoadjuvant therapy for NSCLC patients has not been demonstrated yet. Envafolimab is a novel recombinant protein of a humanized camel-derived single-domain anti-PD-L1 antibody fused with a human IgG1 Fc fragment designed for subcutaneous injection, making it easy to administer and improving patient compliance. This study aims to investigate the efficacy and safety of Envafolimab plus platinum-based chemotherapy as neoadjuvant therapy in resectable stage II-IIIB NSCLC.

Methods: In this prospective, open-label, single-arm study aims to enroll histologically confirmed, potentially resectable stage II-IIIB NSCLC patients. Eligible patients will receive concurrent 300 mg Envafolimab and chemotherapy (cisplatin 50~100mg/m2 or carboplatin AUC = 4~6 plus pemetrexed 500mg/m2 or docetaxel 60-75mg/m2) on day 1 for three 21-day cycles. Radical surgery was scheduled within 4-6 weeks after the last dose of neoadjuvant therapy, followed by optional adjuvant therapy. Follow up will last for three years unless the subject withdraws. The primary endpoint was pathological complete response (pCR) rate. The secondary endpoints included event-free survival (EFS), major pathologic response (MPR) rate, R0 resection rate, safety and quality of life.

Results: Thirteen patients were enrolled. The pCR rate was 30.7%, and the MPR rate was 53.8%. R0 resection rate reached 92.3%. Two patients (15.4%) had at least one grade 3 or 4 related treatment-emergent adverse event. No grade 5 treatment-emergent adverse events related to Envafolimab were reported.

P3.08F.08 NEOLA: Phase II Study of Osimertinib Treatment Before and after Chemoradiotherapy in Unresectable Stage III EGFRm NSCLC

H. Wakelee[1], E. Arriola[2], M. Chen[3], N. Peled[4], M.H. Kwint[5], R. Taylor[6], T. van der Gronde[7], F. Nasirova[8], J.V. Aredo[1], [1]Department of Medicine, Division of Oncology, Stanford University School of Medicine and Stanford Cancer Institute, Stanford/CA/USA ,[2]Department of Medical Oncology, Hospital del Mar-CIBERONC, Barcelona/ES ,[3]Department of Radiotherapy, Sun Yat-Sen University Cancer Center, Guangzhou/CN ,[4]Helmsely Cancer Center, Shaare Zedek Medical Center, Jerusalem/IL ,[5]Medical Affairs, AstraZeneca, The Hague/NL ,[6]Biometrics, Late-stage Development, Oncology R&D, AstraZeneca, Macclesfield/GB ,[7]Late-stage Development, Oncology R&D, AstraZeneca, New York/NY/USA ,[8]Global Medical Affairs, AstraZeneca, Cambridge/GB

Introduction: Epidermal growth factor receptor (EGFR) mutations are detected in up to one third of patients with unresectable stage III NSCLC. Osimertinib - a third-generation, central nervous system-active EGFR-tyrosine kinase inhibitor (TKI) - is recommended in advanced and early-stage surgically-resectable EGFR mutation-positive (EGFRm) NSCLC. The Phase III LAURA study (NCT03521154) is evaluating osimertinib efficacy and safety in patients with unresectable stage III EGFRm NSCLC after definitive CRT. A number of small studies have shown EGFR-TKIs may be effective as induction treatment prior to CRT in unresectable stage III EGFRm NSCLC; however, further investigation is required. NEOLA (NCT06194448) is a global Phase II, open-label, single-arm study assessing the efficacy and safety of induction osimertinib followed by chemoradiotherapy (CRT) and osimertinib maintenance in patients with unresectable stage III EGFRm NSCLC.

Methods: Approximately 70 patients ≥18 years of age with unresectable stage III (International Association for the Study of Lung Cancer Staging v8) EGFRm (exon 19 deletion or exon 21 L858R mutation) NSCLC, who are eligible for curative-intent CRT, will be enrolled in the NEOLA study. Patients will receive osimertinib (80 mg once daily [QD]) as induction treatment for 8 weeks (±1 week). After a minimum 5-day washout, patients will receive sequential/concurrent platinum-based CRT. Within 6 weeks post-CRT, patients without progressive disease (PD) will receive osimertinib (80 mg QD) until PD (per Response Evaluation Criteria in Solid Tumors v1.1) or another discontinuation criterion. The primary endpoint is 12-month progression-free survival rate. The secondary endpoints are: objective response rate and disease control rate at the end of the induction phase; overall survival; eventfree survival; and safety, including the incidence and characterization of interstitial lung disease, pneumonitis, and radiation pneumonitis. The exploratory endpoints include description of target volumes, radiological exposure, and dosimetric variables. Recruitment for NEOLA will begin in early 2024.

P3.12C.01 BRAF Mutation Diversity and Impact on Clinical Outcomes in Non-Small Cell Lung Cancer

K. Lu[1], J.P. Shen[2], F.J. Lopez-Diaz[3], A. Leal[4], B.D. Woodward[1], V. Velcheti[4], J.W. Riess[5], A.S. Mansfield[6], R. Salgia[7], H. Husain[1], [1]UC San Diego, La Jolla/CA/USA ,[2]MD Anderson Cancer Center, Houston/TX/USA ,[3]CEPIMP Genomics, Córdoba/AR ,[4]NYU Langone, New York/NY/USA ,[5]UC Davis, Sacramento/CA/USA ,[6]Mayo Clinic, Rochester/MN/USA ,[7]City of Hope, Duarte/CA/USA

Introduction: Both the combinations of dabrafenib with trametinib and more recently encorafenib with binimetinib have been FDA approved for the management of BRAF V600E-mutant advanced non-small cell lung cancer (NSCLC). However, questions remain regarding how targeted therapies and immunotherapies should be incorporated into the overall treatment regimen for this subset population. BRAF V600E mutations account for 50% of BRAF mutations in NSCLC and some, but not all, non-V600E BRAF alterations can be oncogenic. Prior investigations have classified BRAF mutations into three distinct functional classes. In this study, we analyze the therapeutic implications of class variants on targeted and immunotherapy strategies.

Methods: Here we retrospectively evaluate a multi-institutional cohort of BRAF-mutant NSCLC patients (n=97) and conduct chemical screens of class II and class III BRAF-mutant cell lines to better understand pathway dependencies for each mutational class. We utilize a clinco-genomic database (n=342) to identify co-occurring genetic alterations and tumor mutation burden (TMB) associated with each class.

Results: Class I BRAF mutations were detected in 46 of 97 patients (47%), class II mutations in 12 patients (12%), and class III in 17 patients (18%). Of the class I BRAF-mutant patients, 22 were treated with combination BRAF-MEK inhibitor therapy. We identified that class I BRAF mutation treated with BRAF-MEK inhibitors at any line had greater overall survival compared to those without targeted treatment regardless of immunotherapy treatment (median OS 40.0 vs 10.0 months, Log-rank p=0.043). From our clinico-genomic database analysis, we observed that tumors with class II BRAF variants were significantly more likely to harbor concurrent MAPK pathway alterations relative to class I and III (Chi Square p<10-4). A total of 33 RAS alterations (15 NRAS, 15 KRAS, 3 HRAS) were seen in class II and III tumors in contrast to two in class I tumors. In addition, BRAF class I mutant tumors had significantly lower median TMB (4.8 mut/Mb) compared to class II (8.65 mut/Mb, Wilcoxon p = 1.77e-9) and class III (10.8 mut/Mb, Wilcoxon p<10-10). Computational modeling demonstrated a stereochemical impediment to stable binding between vemurafenib and the class III BRAF mutations G466V, G596R, and D594H. In vitro testing identified that some class II mutant cells were pharmacologically inhibited by pan-RAF, MEK, and pan-EGFR inhibitors.

Conclusions: We conclude that BRAF variants have distinct functional and genomic signatures that have therapeutic implications. Receiving combination BRAF-MEK inhibitor therapy for class I mutations was associated with superior overall survival compared to those patients who did not receive the medicines. Class II and III tumors have higher TMB which may suggest the role of immunotherapy in this subset population. In vitro drug testing in class II and III cell lines demonstrates cell death in select lines for pan-RAF, ERK, MEK, and pan-EGFR inhibitors. Further analyses are needed to determine the clinical value of EGFR, ERK, MEK, and pan-RAF inhibition in class II and III patients.

P3.12C.02 MET Fusions in NSCLC: Prevalence, Oncogenicity, and Resistance Mechanism

S. Nakazawa, F. Pecci, D. Gazgalis, F. Gottlieb, B. Ricciuti, J. Alessi, A. Di Federico, M. Aldea, E. Garbo, M. Gandhi, A. Saini, W. Feng, F. Facchinetti, M. Makarem, D. Haradon, J. Che, M. Awad, P. Jänne, Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Molecular testing is part of the standard diagnostic algorithm of advanced non-small cell lung cancer (NSCLC). As a result, MET fusions are increasingly detected, with reports demonstrating clinical response to MET tyrosine kinase inhibitors (TKIs). We aimed to characterize MET fusions in NSCLC both as a primary oncogenic alteration and as a mechanism of acquired resistance to targeted therapy.

Methods: Clinicopathological features of NSCLC with MET fusions were queried from three datasets (cBioportal; GENIE; and Dana-Farber Cancer Institute). We describe a clinical case of advanced NSCLC harboring a MET fusion treated with a MET TKI. This index case of MET fusion was modeled in vitro for oncogenicity, resistance, and activating mechanisms. This MET fusion was also modelled as a mechanism of acquired resistance to EGFR TKI in the context of EGFR-mutant NSCLC.

Results: Among the three pooled cohorts, MET fusions were observed in 0.13% of NSCLC (43/33, 927). ST7 was the most common fusion partner gene (19%, 8/43), followed by HLA-DRB1 (14%, 6/43), and KIF5B (9%, 4/43). The median age of patients was 66 years (range: 25-89), 54% (N=23) were female; and the most common histology was adenocarcinoma (77%, 33/43), followed by squamous cell carcinoma (9%, 4/43). Co-occurring driver alterations were seen in 33% (14/43) of cases, including EGFR mutations (57%, 8/14), KRAS mutations (29%, 4/14), ALK fusion (7%, 1/14), and METex14 alteration (7%, 1/14). Co-occurring MET amplification was detected in 35% of cases. Within the DFCI cohort, a MET fusion was detected after targeted therapy in other oncogene-driven NSCLC (1 case of ALK fusion-positive NSCLC after alectinib and crizotinib treatment; and 1 case of EGFR-mutant NSCLC after osimertinib treatment), suggesting the potential implication of MET fusion in conferring resistance to targeted therapy in the setting of other oncogene-driven NSCLC. Our index case harbored a HLA-DRB1::MET fusion and showed a clinical response to a type Ib MET TKI, APL-101. Biopsy at disease progression revealed a D1228V mutation in the tyrosine kinase domain of MET. The oncogenicity of HLA-DRB1::MET was confirmed in Ba/F3 cells. The MET D1228V mutation led to resistance to type I MET TKIs (i.e. crizotinib, APL-101, capmatinib, tepotinib). Both homo- and hetero-dimerization of HLA-DRB1::MET were observed in vitro, suggesting diverse mechanisms of transactivation. Transduction of HLA-DRB1::MET in an EGFR-mutant NSCLC cell line resulted in resistance to an EGFR TKI, which was overcome by the addition of a MET TKI.

Conclusions: MET fusions are detected in 0.13% of NSCLC, and concomitantly to another driver gene alteration in one-third of cases. We present a clinical case of NSCLC harboring a MET fusion, with in vitro modeling suggesting that MET fusions can be an actionable oncogenic driver. Similar to NSCLC with MET exon 14 skipping alterations, a mutation in the kinase domain of the MET fusion could conferred resistance to a MET TKI. Additionally, MET fusions were detected at resistance after targeted therapy for other oncogene-driven NSCLC, with in vitro modeling showing that it could be overcome by combinatorial treatments with TKIs.

P3.12C.03 Efficacy and Safety of Brigimadlin, a MDM2-p53 Antagonist, in Patients with Advanced Lung Adenocarcinoma

N. Yamamoto[1], U.M. Lauer[2], T. Humphries[3], N. Natarajan[4], P. LoRusso[5], H. Prenen[6], J. Bartolomé[7], M. He[8], G. Jayadeva[8], M. Teufel[8], A. Märten[9], J. Kratz[10], [1]Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo/JP ,[2]Department of Medical Oncology & Pneumology and Tübingen Early Phase Clinical Trials Unit, University Hospital Tübingen, Tübingen/DE ,[3]Linear Clinical Research, Perth, WA/AU ,[4]Nebraska Cancer Specialists, Omaha/NE/USA ,[5]Yale University School of Medicine, Yale Cancer Center, New Haven/CT/USA ,[6]Oncology Department, University Hospital Antwerp, Edegem/BE ,[7]Medical Oncology Department, Hospital Clínico San Carlos, Madrid/ES ,[8]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield/CT/USA ,[9]Boehringer Ingelheim International GmbH, Ingelheim am Rhein/DE ,[10]Carbone Cancer Center, University of Wisconsin, Madison/WI/USA

Introduction: Mouse double minute 2 homolog (MDM2) amplification occurs in 4-6% of cases of lung adenocarcinoma (LUAD) and is associated with poor survival. There is frequent co-occurrence of MDM2 amplification with known genomic alterations: in patients with LUAD with mutated METex14, EGFR, or KRAS, MDM2 is amplified in 36%, 8%, and 5% of cases, respectively. The MDM2-p53 interaction represents a potential therapeutic target. Brigimadlin, a potent oral MDM2-p53 antagonist, has shown encouraging early efficacy in patients with MDM2-amplified solid tumors.

Methods: We present an analysis of data from patients with LUAD treated in 3 trials of brigimadlin in patients with advanced solid tumors (Phase Ia/Ib monotherapy trial, NCT03449381; Phase Ia/Ib trial of brigimadlin in combination with ezabenlimab [anti-PD-1], NCT03964233; Phase IIa/IIb monotherapy trial, NCT05512377). Across trials, eligible patients had advanced/metastatic solid tumors, MDM2 amplification (monotherapy Phase Ib and Phase IIa/IIb only), ECOG PS 0-1, ≥1 measurable target lesion (RECIST v.1.1) and adequate organ function. Prior treatment with MDM2-p53 or MDMX/MDM4-p53 antagonists was not permitted. Patients received brigimadlin 45 mg on Day 1 of 21-day cycles (once every 3 weeks [q3w]). Patients in the combination trial also received ezabenlimab 240 mg q3w.

Results: 16 patients were included in this analysis, most had received prior treatment and had documented MDM2 amplification (Table). In 7 patients treated in the Phase Ia/Ib monotherapy trial (median 3 [range 0-7] prior lines of treatment), all evaluable patients (n=4) achieved stable disease (SD; unconfirmed partial response [PR] in one patient). 6 patients were treated in the Phase Ia/Ib combination trial (median 3 [range 1-6] prior lines of treatment); of 5 evaluable patients, 1 patient achieved a PR (tumor shrinkage 56%) and 3 achieved SD. In 3 patients treated in the Phase IIa/IIb monotherapy trial, having received 2 prior lines of conventional treatment, all achieved PR (tumor shrinkage 48%, 49%, 65%). Patient progression-free survival (PFS) is summarized in the Table. Safety in this small group with LUAD was consistent with observations in the overall trial populations. In patients who received brigimadlin 45 mg q3w in the Phase Ia/Ib monotherapy (n=140)/combination trials (n=74), the most common any-grade treatment-related adverse events (TRAEs) were nausea (67.9%/70.3%) and fatigue (53.6%/39.2%), respectively. The most common grade ≥3 TRAEs were neutropenia (25.0%/24.3%) and thrombocytopenia (22.9%/21.6%, respectively).

Conclusions: Brigimadlin treatment was associated with encouraging preliminary efficacy in patients with advanced MDM2-amplified LUAD and a manageable safety profile.

P3.12C.04 Seribantumab Results in Robust and Durable Responses in NRG1 Fusion-Positive Non-Small Cell Lung Cancer: A Multi-Center Case Series

C.E. Lau[1], T. Patil[2], V. Jansen[3], D.R. Carrizosa[4], J.D. Patel[1], [1]Northwestern Memorial Hospital, Chicago/IL/USA ,[2]UCHealth Anschutz Medical Campus, Aurora/CO/USA ,[3]Elevation Oncology, Boston/MA/USA ,[4]Atrium Health Wake Forest Baptist Comprehensive Cancer Center/Levine Cancer, Winston-Salem/NC/USA

Introduction: NRG1 (neurgulin-1) gene fusions are implicated in oncogenesis in lung adenocarcinoma with an incidence of ~0.3%. More commonly seen in never-smokers with mucinous adenocarcinoma, NRG1 fusions produce chimeric proteins that promote constitutive activation of HER3 and HER4 via their heterodimerization with other ERBB kinases. NRG1 fusion-positive lung cancers are less likely to respond to standard-of-care therapies; for patients with metastatic disease enrolled in the global eNRGy1 registry, ORRs to chemotherapy (platinum doublet or taxane) and single-agent immunotherapy were <15% and 20%, respectively. Targeted agents, such as the pan-ERBB kinase inhibitor afatinib, fare slightly better, with an ORR in the eNRGy1 registry of 25%. Seribantumab, or MM-121, is a fully human monoclonal antibody targeting HER3 via blockade of heregulin-mediated signaling. Based on pre-clinical models demonstrating inhibition of NRG1-fusion mediated tumorigenesis, the phase II CRESTONE trial enrolled patients with locally advanced or metastatic solid tumors harboring NRG1 fusions, including patients with NSCLC. In data previously presented at AACR 2023, seribantumab produced a response rate of 39% in 18 NSCLC patients. Herein, we describe three NSCLC patients treated on that trial with deep and prolonged response.

Methods: The study was conducted retrospectively by reviewing medical records of patients treated with seribantumab at Northwestern Memorial Hospital, Atrium Health, and UCHealth between 1/1/2021 and 4/1/2024. All patients were enrolled on CRESTONE and completed at least one year of seribantumab as per trial protocol; responses were determined by RECIST 1.1 criteria.

Results: Patient one was a 43-year-old woman with advanced NSCLC, SLC3A2-NRG1 fusion. Following four cycles of neoadjuvant intent cisplatin/pemetrexed/durvalumab therapy, resection was aborted when pleural studding was noted intraoperatively, pathologically confirmed as adenocarcinoma. She initiated seribantumab with clinical benefit demonstrated by tumor reduction and partial response achieved at 21 months; at time of discontinuation of therapy at 35 months, response was sustained. She underwent pleurectomy and lobectomy with complete response noted in the pleura and no evidence of disease on subsequent imaging. Patient two was a 70-year-old man with bilateral metastatic NSCLC, CD74-NRG1 fusion. He was initially treated with dual immunotherapy (nivolumab/ipilimumab), then an investigational PGE2-receptor antagonist in combination with pembrolizumab. At time of progression he was initiated on seribantumab with partial response of 17 months duration. Patient three was a 59-year-old woman with bilateral metastatic recurrence of NSCLC, ITGB1-NRG1 fusion, previously treated with multiple resections, radiation, and systemic therapy including carboplatin/pemetrexed and nivolumab with progression. Seribantumab was subsequently initiated with a partial response on her first scans at 6 weeks deepening to a complete response after 6 months with a duration of response of 20 months. She continued on seribantumab through disease progression for a total of 32 months with clinical benefit.

Conclusions: NRG1 fusion-positive lung cancer remains a challenging clinical entity, with poor response to standard-of-care therapy in the advanced and metastatic setting. In patients with lung cancer positive for various NRG1-fusions with progression on prior lines of therapy, inhibition of HER3 with seribantumab has resulted in deep and prolonged responses, representing a promising treatment for this unique group of patients.

P3.12C.05 Thromboembolic Events in Patients with Oncogene-Addicted Advanced NSCLC

M. Aldea[1], E. Garbo[1], B. Ricciuti[1], M. Makaram[1], X. Wang[2], F. Pecci[1], A. Saini[1], F. Paoloni[1], T. Gorria[1], J. Connors[3], M. Awad[1], [1]Dana Farber Cancer Institute, Boston/MA/USA ,[2]Harvard University, Cambridge/MA/USA ,[3]Brigham and Women's Hospital and Harvard Medical School, Boston/MA/USA

Introduction: Thromboembolic events (TEs) in advanced non-small cell lung cancer (aNSCLC) increase morbidity, mortality, and healthcare costs with prevalence rising from 5-14% in the general NSCLC population to 30-48% in patients with oncogenic fusions. This study investigates TEs in molecular subsets of aNSCLC to identify high-risk patients.

Methods: This single-center, retrospective study includes patients with aNSCLC diagnosed after January 1, 2015, with comprehensive molecular profiling (OncoPanel, 447 genes) and ≥6 months follow-up. TEs—deep vein thrombosis, pulmonary embolism, and arterial thrombosis—were recorded throughout the cancer course or within six months before aNSCLC diagnosis. We assessed the prevalence, cumulative incidence of TEs (time 0=diagnosis of advanced disease) and median time to TE. Logistic regression evaluated factors independently predicting TE risk.

Results: Of 2,807 patients with aNSCLC, 59% were women, 43% were <65 years of age, 25% had no smoking history, and 74% had adenocarcinoma. The prevalence of venous TEs was 23%, including 44% in ROS1 (N=12/27), 40% in RET (N=12/30), 29% in MET exon 14 (N=13/45), 26% in EGFR (N=153/589), 23% in KRAS (N=127/563), 22% in BRAF (N=30/139), 20% in ALK (N=17/86), 20% in KRAS with STK11, KEAP1 or SMARCA4 (N=62/315), 17% in HER2 mutations (N=9/54) and 22% in other cases (N=208/959) (p=0.014). The prevalence of ischemic stroke was 2.2%, including 13% in RET, 3.7% in ROS1, 2.3% in ALK, 2.9% in KRAS with STK11, KEAP1 or SMARCA4, 2.3% in KRAS, 2.2% in MET exon 14, 2.2% in BRAF, 1.9% in EGFR, 1.9% in HER2, and 1.9% in other cases. The cumulative incidence of venous and arterial TEs is outlined in the Table. The median time to the first TE was 8.1 months for ROS1, 15 months for RET, 20.9 months for KRAS vs 14.1 months for KRAS with STK11, KEAP1 or SMARCA4 (p=0.0015), 21.4 months for HER2, 21.9 months for BRAF, 24.1 months for MET exon 14, 27.2 months for ALK, 27.3 months for EGFR and 16.4 months for other cases. Factors independently associated with venous TEs were ROS1 (OR = 3.09, p = 0.012) and for ischemic stroke, RET and age ≥65 (OR = 7.5, p = 0.02; OR = 1.94, p =0.024).

Conclusions: In aNSCLC, patients with RET and ROS1 fusions had the highest TE risk, with RET also predisposing to ischemic strokes. TEs occurred later with EGFR and ALK, while earlier with ROS1 or KRAS with STK11, KEAP1 or SMARCA4 co-mutations compared to those with KRAS mutations alone.

P3.12C.06 Clinical Characteristics and Outcomes in Patients with Leptomeningeal Disease (LMD) from Non-Small Cell Lung Cancer

K. Pan, L. Hong, J. Zhang, L.A. Byers, D.L. Gibbons, J.V. Heymach, T.H. Beckham, S.D. Ferguson, X. Le, UT MD Anderson Cancer Center, Houston/TX/USA

Introduction: Leptomeningeal disease (LMD) is a devastating complication occurring in 3-5% of patients with advanced-stage non-small cell lung cancer (NSCLC) that is associated with a dismal prognosis and remains a critical area of unmet need. Currently, there are very few prospective randomized clinical trials evaluating patients with LMD from NSCLC, and little is known about the impact of many novel targeted therapies, chemo/immunotherapy, intrathecal therapy, and intracranial radiation therapy on leptomeningeal survival.

Methods: We performed a single-center retrospective analysis using the Lung Cancer Moon Shot GEMINI database at the University of Texas MD Anderson Cancer Center, and identified a total of 124 individual patients in our institutional database from 2015 to 2023 with a diagnosis of NSCLC and radiographically or cytologically confirmed LMD. We collected data on their baseline demographic and clinical/ treatment history, and performed subgroup analyses to determine their association with leptomeningeal survival outcomes.

Results: Out of 124 individuals with a diagnosis of LMD from NSCLC, 53.7% of patients harbor an EGFR mutation, among which 45.5% are EGFR exon 19 deletions and 40.9%% EGFR exon 21 L858R. This is followed by 24.4% of patients without a driver mutation, 7.3% with KRAS, 5.7% with ALK, 4.1% with MET, and 1.6% each with RET, HER2, and ROS1-driven NSCLC. Most treatment-eligible patients (91.1%) were treated with a combination of systemic (71.0%), intrathecal (13.7%), and palliative CNS radiotherapy (64.5%) after establishing the diagnosis of LMD. The median overall survival from the diagnosis of LMD (LM-overall survival, LM-OS) was 4.3 months (95% CI 2.1-6.4 mo), with an overall survival (OS) of 30.5 months (95% CI 27.5- 33.6 mo) since NSCLC diagnosis. LM-OS was significantly improved among patients with better performance status (Fig 1A), alterations in EGFR and ALK (Fig 1B), as well as patients with oncogene-driven NSCLC who were treated with highly CNS-penetrant tyrosine kinase inhibitors (TKIs) (Fig 1C). CSF cytology result at diagnosis was not associated with significant differences in survival. Treatment of LMD with immunotherapy and palliative CNS radiation were not significantly associated with improved LM-OS, while treatment with intrathecal therapy trended towards improved LM-OS (Fig 1D).

Conclusions: Despite their overall poor prognosis, certain genomic features and treatment strategies of LMD in NSCLC are associated with improved survival. These factors may be considered in guiding treatment strategies and future clinical trial design for this population.

P3.12C.07 Breaking New Ground: Selecting the Best Treatment for Non-Small Cell Lung Cancer According to Mutational Status

J.H. Maselli Schoueri[1], P. Nazareth Aguiar Jr[2], S. Matsas[3], A. del Giglio[1], [1]ABC Medical School, Santo André/BR ,[2]Grupo Oncoclínicas, São Paulo/BR ,[3]Faculdade de Ciências Médicas da Santa Casa de São Paulo, São Paulo/BR

Introduction: Precision Medicine was established as a new paradigm in cancer treatment, especially for Non-Small Cell Lung Cancer (NSCLC) where actionable mutations and individual characteristics might lead to better outcomes. Therefore, the need for comparison between multiple different clinical trials - with similar aspects, but different drugs being tested - has been made paramount to offer the best treatment option for NSCLC patients. This paper aims to elucidate the best treatment regimen for NSCLC based on STK11, KEAP1 and KRAS status.

Methods: Network meta-analysis (NMA) conducted for multicenter clinical trials that tested Immune Checkpoint inhibitors (ICI) for NSCLC over the last 15 years. Two independent researchers searched for and extracted data from articles in English on PUBMED/MEDLINE using MeSH terms and keywords related to NSCLC and ICI. Eligible studies were selected based on predefined criteria - if any discrepancies were found, a third researcher would resolve. All analyses were conducted with R®. The protocol was registered on PROSPERO (CRD42024525536).

Results: Of 463 articles found, 17 met inclusion criteria and were fully read, of which the following 6 trials were included: POSEIDON, CHECK-MATE 9LA, CHECK-MATE-227, KEYNOTE-042, KEYNOTE-189 and IMPOWER-150, comprehending a pool of 5069 eligible patients. For all mutations, ICI tended towards benefit as compared to chemotherapy, except for KRASm, which also showed the greatest heterogeneity between studies (I^2 = 61%). Of all, POSEIDON showed the lowest NNT consistently amongst all mutations and across time, as well as higher LYS except for KRASwt. In NMA, no trial was superior for any mutational status.

Conclusions: In this paper, we found that ICI was better than Chemotherapy overall and each mutation might benefit from different treatment combinations due to their intrinsic behavior.

P3.12C.08 Surufatinib Plus Docetaxel in Patients with Relapsed Advanced Driver-Negative Non-Squamous NSCLC: A Phase Ib/II Study

W. Jiang, J. He, R. Ning, Y. Zhao, S. Zhou, L. Xu, H. Wang, S. Chen, H. Gan, J. Lin, Q.T. Yu, Guangxi Medical University Cancer Hospital, Nan Ning/CN

Introduction: Recurrent advanced driver-negative non-squamous non-small cell lung cancer (nsq-NSCLC) has few treatment options. Docetaxel is recommended by NCCN guidelines (Version 3.2024) as the standard second-line therapy. Surufatinib (a small-molecule inhibitor of VEGFR1-3, FGFR1 and CSF-1R) has shown a synergistic effect with cell cycle-specific chemotherapy drugs in lung cancer cell lines (A549 cells and PC9 cells) and nude mice model. Here, we evaluated the efficacy and safety of surufatinib combined with docetaxel in advanced driver-negative nsq-NSCLC patients failed with first-line therapy.

Methods: This phase Ib/II, single-arm, open-label study included stage IIIb/IV nsq-NSCLC patients who progressed after first-line platinum-based treatments, allowing prior anti-PD-1 antibody/bevacizumab therapy. Patients received surufatinib (250mg, qd, po, q3w. Adjusted by DLTs at first cycle in 50mg dose units from 200mg to 300mg) plus docetaxel (60mg/m2, iv, d1, q3w). Treatment continued until disease progression, intolerable toxicity, or death. Primary endpoint was PFS. Secondary endpoints included DCR, ORR, OS, and safety.

Results: Up to Mar 20, 2024, 19 patients were enrolled. The median age was 56 years (range: 29-67 years) with male 52.63%, TNM stage IV 89.47%, ECOG PS 1 73.68%. Metastases occurred in 31.58% (bone), 15.79% (brain), and 10.53% (adrenal gland). Adenocarcinoma was confirmed in 84.21% of patients. Of the 16 patients assessable post-baseline, the ORR was 31.25% (5/16), DCR was 100 % (16/16). Based on best of response, 81.25% (13/16) patients had stable or shrinking tumors. Additionally, patients without extrapulmonary metastases had a notably higher ORR compared to those with such metastases (57.14% vs 11.11%, Table 1). Median PFS was 5.4 months (95% CI: 3.4, NA) with longer PFS (5.8 months) in patients with bone metastases. Median OS had not reached yet. All patients experienced at least 1 treatment emergent adverse events (TEAEs). The most common TEAEs included decreased white blood cell count (47.37%, 15.79% Grade ≥3), decreased neutrophil count (42.11%, 26.32%), and increased aspartate aminotransferase (36.84%, 5.26%).

Conclusions: Surufatinib combined with docetaxel demonstrated notable survival benefits and promising anti-tumor activity with manageable toxicity in the recurrent advanced driver-negative nsq-NSCLC, particularly effective in patients without extrapulmonary metastases. Surufatinib plus docetaxel warrant further investigation in a broader NSCLC patient group.

P3.12D METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - CLINICAL TRIALS IN PROGRESS
MONDAY, SEPTEMBER 9, 2024 - 12:00 - 14:00

P3.12D.01 A Phase Ib Study of Osimertinib and Tegavivint as First-Line Therapy in Patients with Metastatic EGFR-Mutant Non-Small Cell Lung Cancer (NSCLC)

R. Memmott[1], J. Gheeya[1], L. Wei[1], M. Phelps[1], W. Yang[1], D. Stenehjem[2], S. Horrigan[3], A. Duncan[3], D. Uribe[1], G. Amato[1], G. Otterson[1], J. Kaufman[1], A. Alahmadi[1], C. Presley[1], D. Owen[1], D. Carbone[1], [1]The Ohio State University Comprehensive Cancer Center--James, Columbus/OH/USA ,[2]University of Minnesota, Minneapolis/MN/USA ,[3]Iterion Therapeutics, Houston/TX/USA

Introduction: Drugs that inhibit the tyrosine kinase activity of EGFR, TKIs, improve clinical outcomes in patients with EGFR-mutant NSCLC. However, EGFR TKIs are not curative in the metastatic setting because of a nidus of drug-tolerant cells that persist due to transcriptional reprogramming. These cells eventually acquire genetic mutations that cause resistance and progression. Our preclinical studies showed that a subset of EGFR-mutant lung cancer cells enter a persistent state in response to TKIs due to increased transcriptional activity of β-catenin. Treatment of mice bearing EGFR-mutant NSCLC xenografts with the combination of an EGFR TKI and a β-catenin inhibitor caused a greater depth and duration of response than treatment with an EGFR TKI alone. Our studies also showed that patients who have the greatest increase in serum levels of the secreted β-catenin transcriptional target PAI-1 following treatment with a TKI have significantly worse progression free survival. These results provide rationale for a clinical trial evaluating the combination of an EGFR TKI with an inhibitor of β-catenin transcriptional activity as first-line therapy in patients with metastatic EGFR-mutant NSCLC.

Methods: NCT04780568 is a single-arm phase Ib trial investigating osimertinib (EGFR TKI) in combination with tegavivint, which inhibits β-catenin transcriptional activity by disrupting the interaction of β-catenin with TBL1. Patients with metastatic classical EGFR-mutant NSCLC who have not received prior treatment with an EGFR TKI are eligible. Patients receive osimertinib 80 mg by mouth daily (FDA approved dose). Tegavivint is administered intravenously weekly using a dose escalation schedule with four dose levels. Dose escalation is determined by Bayesian optimal interval design. The combination of osimertinib and tegavivint is given for four 28-day cycles, and then patients are switched to maintenance with osimertinib alone. The primary objectives are to assess safety and tolerability and to determine the recommended phase 2 dose (RP2D) of tegavivint in combination with osimertinib. Once the dose escalation phase of this trial is complete, the dose expansion phase will include a total of 12 patients at the RP2D to further assess clinical outcomes, including response rate, progression free survival, duration of response, and overall survival. Correlative studies include PK analysis, the evaluation of pharmacodynamic markers of β-catenin pathway activity, assessment of the clearance of EGFR-mutant ctDNA, and CT tumor volumetric studies.

Results: Eleven patients have been treated on study with three patients at each of the first three dose levels and two patients at the highest dose level of tegavivint (8 mg/kg). No dose limiting toxicities (DLTs), nor drug-related serious adverse events have occurred. Accrual is ongoing.

Conclusions: This phase Ib trial studies the safety and tolerability of an EGFR TKI, osimertinib, in combination with an inhibitor of β-catenin transcriptional activity, tegavivint, as first-line therapy in patients with metastatic EGFR-mutant NSCLC. NCT04780568 is currently enrolling at The Ohio State University, James Comprehensive Cancer Center

P3.12D.02 Phase 1/2 Clinical Trial of JIN-A02, a 4th Generation EGFR-TKI in EGFR Mutated Advanced/metastatic Non-Small Cell Lung Cancer (NSCLC)

S.M. Lim[1], B.C. Cho[2], J.Y. Han[3], S.W. Kim[4], K.H. Lee[5], M. Nagasaka[6], A. Jo[7], E. Seah[7], C. Kim[7], T. Reungwetwattana[8], [1]Yonsei Cancer Center, Seoul/KR ,[2]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul/KR ,[3]Center for Lung Cancer, National Cancer Center - Graduate School of Cancer Science and Policy, Goyang/KR ,[4]Division of Medical Oncology, Asan Medical Center, University of Ulsan, Seoul/KR ,[5]Division of Medical Oncology, Chungbuk National University Hospital, Cheongju/KR ,[6]Department of Medicine, Chao Family Comprehensive Cancer Center, University of California Irvine Healthcare, California/CA/USA ,[7]J INTS BIO Inc., Seoul/KR ,[8]Division of Medical Oncology, Department of Medicine, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/TH

Introduction: Epidermal growth factor receptor (EGFR) mutations are the predominant drivers of NSCLC. While EGFR tyrosine kinase inhibitors (TKIs) are the primary treatment for EGFR-mutant NSCLC patients, resistance inevitably develops, leading to disease progression. JIN-A02, a novel 4th generation EGFR-TKI intended for oral administration, selectively and reversibly binds to EGFR mutations, including the C797S and/or T790M mutation that causes resistance to 3rd generation of EGFR-TKIs. Pre-clinical studies with EGFR C797S and/or T790M mutated cell lines and C797S+ xenograft mice model showed that JIN-A02 inhibits cell and tumor growth in a dose dependent manner and exhibits high selectivity over wild-type EGFR. Moreover, JIN-A02 has been shown to penetrate the blood-brain barrier and exhibit anti-tumor activity in an intracranial tumor model. This phase 1/2 study is designed to evaluate the safety and anti-tumor activity of JIN-A02 in EGFR-mutant NSCLC patients.

Methods: JIN-A02 is under evaluation in Phase 1/2, multicenter, an open-label trial (NCT05394831) for subjects with advanced NSCLC harboring C797S and/or T790M mutation as a monotherapy. The primary object is to assess safety, tolerability, pharmacokinetics, and anti-tumor effect for determining the recommended phase 2 dose (RP2D) of JIN-A02. Inclusion criteria are that the subject (≥ 18 years) must have advanced or metastatic NSCLC showing progressive disease post-treatment with approved standard EGFR-TKI therapies and/or platinum-based anticancer chemotherapy, with ECOG status 0 or 1. EGFR mutation status is determined using either tumor tissue and/or plasma ctDNA prior to study enrollment. The study consists of three parts: dose escalation (Part A), dose exploration (Part B), and dose expansion (Part C). Part A comprises five cohorts ranging from a starting dose of 12.5 mg to a maximum dose of 150 mg orally once daily, with three subjects per cohort, conducted over 28-day cycles to evaluate the maximum tolerated dose. Dose-limiting toxicities (DLTs) are assessed over 21 days. Part B aims to further evaluate JIN-A02 safety and to determine the RP2D using two preliminary effective dose levels from Part A. In Part C, subjects are divided into five cohorts based on the EGFR mutation status (both or single positive for C797S and T790M), and the anti-tumor activity of JIN-A02 is evaluated according to RECIST v1.1 at the RP2D.

Results: As of March 27, 2024, Part A is still in progress at Cohort 4 of 100 mg daily. A total of 10 subjects were enrolled in the earlier three cohorts (12.5 mg, 25 mg, and 50 mg), and four subjects are still on therapy at 50 mg daily. No DLT has been reported in any of these three cohorts in Part A. Objective response evaluation showed that one subject achieved partial response (PR) and two subjects with stable disease (SD). There is a trend towards deepened response with increasing dose. Administration of JIN-A02 at a dose 50 mg once daily for 15 days resulted in approximately 3.6 to 4.8 fold accumulation, with Tmax observed at 3.8 h.

Conclusions: Further dose escalation is warranted to comprehensively assess both safety and anti-tumor efficacy of JIN-A02.

P3.12D.03 A Study to Investigate Safety, PK, And Anti-Tumor Activity of TRX-221 In EGFR Mutant NSCLC: TRX-221-001 In Progress

J. Park[1], S. Lim[1], K. Chun[1], K. Lee[1], [1]Therapex, Seoul/KR

Introduction: EGFR-TKIs are established as first-line therapy in NSCLC patients with known activating mutations in EGFR. Despite several therapeutic advances, resistance to EGFR-TKIs inevitably occurs, resulting in disease progression. C797X mutations have been considered one of the most frequent EGFR resistance mechanisms occurring upon progression after exposure to 3rd generation EGFR-TKIs, with different incidence. To date, the only approved second or further line therapy for patients experiencing disease progression following the use of 3rd generation EGFR-TKIs is platinum-based chemotherapy. TRX-221 is an investigational novel 4th generation EGFR-TKI designed to selectively target EGFR sensitizing mutations (exon19del and L858R), T790M as well as C797X. Preclinically, TRX-221 has shown robust anti-tumor activity in various osimertinib-resistant patient-derived xenograft (PDX) models harboring C797S mutation. First-in-human trial of TRX-221 (TRX-221-001; NCT06186076) is planned to investigate the safety, tolerability, pharmacokinetics, and anti-tumor activity of TRX-221 in the treatment of patients with EGFR mutant NSCLC, who progressed following prior EGFR-TKIs with activity against T790M (e.g., osimertinib).

Methods: Key eligibility criteria include adults with histologically or cytologically confirmed diagnosis of relapsed or refractory, locally unresectable advanced or metastatic NSCLC harboring activating EGFR mutations, Eastern Cooperative Oncology Group (ECOG) performance status 0-1, and previous treatment with at least 1 EGFR-targeted TKI. NSCLC with mixed cell histology or a tumor with histologic transformation of small cell elements and patients having tumor with any additional known driver of alteration are excluded. Primary endpoints are maximum tolerated dose (MTD), recommended phase 2 dose (RP2D) and safety in Phase 1; overall response rate (ORR) by RECIST 1.1 in Phase 2. Key secondary endpoints include ORR, pharmacokinetics in Phase 1; duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety in Phase 2. Phase 1 dose escalation will follow the Bayesian optimal interval design and RP2D will be decided after Part B dose exploration in at least 2 dose levels. In Phase 2, patients will receive TRX-221 at the RP2D in at least 2 groups based on EGFR mutational profile. All eligible patients will receive the study treatment at selected oral dose(s) once daily. Patients will be treated continuously until disease progression or any other pre-defined discontinuation criteria are met. Clinical Trial Information: NCT06186076

Keywords: 4th generation EGFR-TKI, Osimertinib resistance, C797X

P3.12D.04 Enhanced vs Standard Dermatologic Management with Amivantamab-Lazertinib in Advanced NSCLC: Phase 2 COCOON Study

Introduction: Amivantamab is an EGFR-MET bispecific antibody with immune cell-directing activity. Lazertinib is a CNS-penetrant, third-generation EGFR tyrosine kinase inhibitor. Amivantamab-lazertinib significantly improved progression-free survival in patients with treatment-naïve, EGFR-mutated advanced non-small cell lung cancer (NSCLC; Cho Ann Oncol 2023;34:S1306). As EGFR-targeted therapies, amivantamab and lazertinib are independently associated with dermatologic adverse events (AEs). Dermatologic AEs are often treated reactively with topical/systemic corticosteroids and/or systemic antibiotics. Given that dermatologic AEs can impact patient quality of life (QoL) and treatment adherence, an enhanced prophylactic management strategy might improve clinical outcomes. Previous studies demonstrated that patients receiving EGFR inhibitors and prophylactic treatment with an oral tetracycline reported significantly fewer grade ≥2 dermatologic AEs (Petrelli Br J Dermatol 2016;175:1135-1136). COCOON aims to evaluate the impact of enhanced versus standard management on dermatologic AEs among patients treated with first-line amivantamab-lazertinib.

Methods: The open-label, global, phase 2, randomized COCOON study (NCT06120140) is currently enrolling patients with treatment-naïve, locally advanced or metastatic NSCLC harboring EGFR Ex19del and L858R substitutions. As background anticancer therapy, all patients will receive intravenous amivantamab (1050 mg or 1400 mg if ≥80 kg) weekly for the first 4 weeks, then every 2 weeks thereafter, plus oral lazertinib (240 mg daily). Prophylactic anticoagulation is mandatory for the first 4 months of treatment.

Eligible patients will be randomized 1:1 to receive enhanced dermatologic management (arm A) starting on the first day of anticancer treatment or standard-of-care (SoC) management without restrictions (arm B) per local institutional guidelines. Enhanced dermatologic management includes four components (Figure 1) and a digital health tool to increase treatment adherence and monitor compliance (arm A only). All patients in both arms will receive general recommendations for skincare and will be eligible to receive additional dermatologic measures as per physician discretion.

The primary objective is to evaluate the incidence of grade ≥2 dermatologic AEs of interest by week 12 with enhanced versus SoC dermatologic management. Secondary objectives include characterizing dermatologic toxicities and their impact on patients' QoL, incidence of venous thromboembolic events, and efficacy of antitumor treatment. Planned enrollment is 180 patients, which is estimated to provide a power of 90% with a 2-sided alpha of 0.05 to detect a treatment difference between arms A and B in the incidence of grade ≥2 dermatologic AEs. Safety will be assessed throughout the study by AE frequency and severity.

Keywords: Amivantamab, lazertinib, dermatologic management

P3.12D.05 Furmonertinib Plus Icotinib as First-Line Treatment in EGFR-Mutated NSCLC: Updated Results in L858R and CNS Metastases Groups

H. Chen, G. Huang, T. Xia, R. Chen, M. Lin, D. Yang, Y. Luo, H. Chen, Z. Yang, Affiliated Hospital of Guangdong Medical University, Zhanjiang/CN

Introduction: Third-generation EGFR-TKI is the preferred first-line treatment for EGFR-mutated non-small cell lung cancer (NSCLC), but for patients with L858R mutation and central nervous system (CNS) metastases, the efficacy and prognosis still remains clinically challenging. Furmonertinib, a highly brain-penetrant, selective EGFR-TKI with activity against EGFR classical, T790M resistant and Ex20ins mutations, plus Icotinib, a first-generation EGFR-TKI, have demonstrated an encouraging ORR of 88.9% (n=18) with acceptable safety in high proportion of CNS metastases patients (15/18,83.3%) (Chen et al., ELCC 2023). Here we present updated results in L858R and CNS metastases groups.

Methods: This ongoing phase II study enrolled untreated advanced NSCLC patients with Ex19Del/L858R/Ex20ins mutation. Patients with stable CNS metastases were allowed to enroll. The regimen consisted of furmonertinib (80 mg p.o, qd) and icotinib (125 mg p.o, tid). The primary endpoint was PFS. Secondary endpoints were ORR, DCR, OS, and safety.

Results: As of the data cutoff date of Feb 29, 2024, 45 patients received study treatment, 22 (48.9%) patients with L858R mutation and 30 (66.7%) patients with CNS metastases. Treatment is ongoing in 32 patients. The baseline characteristics were as follows: the median age 61.8 years (range 42-82), female 55.6%, ECOG PS 0/1/2 15.6%/80.0%/4.4%, never smokers 65.6%. Median follow-up was 14.7 months. In the L858R group, the ORR was 95.5%, DCR was 100%, PFS was 17.6 months (95%CI:14.1-22.5). In the CNS metastasis group, the ORR was 90%, DCR was 100%, CNS ORR was 94.1%, CNS DCR was 100%, PFS was 21.1 months (95%CI:20.4-NR). All treated patients (100%) experienced TEAEs, of whom 6 (13.3%) experienced grade 3 TEAEs, and no grade 4 or 5 TEAEs were observed. The most common TEAEs (≥25%) included rash (44.4%), diarrhea (44.4%), dry skin (31.1%), elevated aspartate aminotransferase (26.7%). Dose interruptions due to TEAEs were reported in 6 (13.3%) patients. There was no incidence of dose reduction, treatment discontinuation or deaths due to TEAEs.

Conclusions: Furmonertinib plus Icotinib as first-line treatment in L858R mutation and CNS metastases groups had an encouraging efficacy and the manageable safety. This study is still ongoing and further analyses will be conducted to evalute longer-term outcomes, which may help define the role of dual EGFR TKI therapy in first-line setting in L858R mutation and CNS metastases.

P3.12D.06 Beamion LUNG-1 And LUNG-2: The Zongertinib Clinical Program in Patients with Non-Small Cell Lung Cancer and HER2 Mutations

Y-L. Wu[1], F. Opdam[2], N. Yamamoto[3], T. Yoshida[4], J. Heymach[5], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]The Netherlands Cancer Institute, Amsterdam/NL ,[3]National Cancer Center Hospital, Tokyo/JP ,[4]National Cancer Center Hospital, Chuo-ku, Tokyo/JP ,[5]MD Anderson Cancer Center, Houston/TX/USA

Introduction: HER2 mutation-positive (HER2m+) non-small cell lung cancer (NSCLC) is relatively insensitive to chemotherapy; thus, there is a substantial unmet need for targeted treatments. Zongertinib (BI 1810631), an oral HER2-selective tyrosine kinase inhibitor, binds to wild-type and mutated HER2, including mutations associated with exon 20 insertions, sparing EGFR. The Beamion LUNG-1 (NCT04886804) phase 1a dose-escalation trial (starting at 15 mg twice daily or 60 mg once daily [QD] and increasing to 150 mg twice daily or 360 mg QD, respectively) enrolled patients with HER2 aberration-positive advanced, unresectable, or metastatic solid tumors refractory to/unsuitable for conventional treatment, or who exhausted treatment options. As of September 29, 2023, zongertinib conferred objective response/disease control rates of 49/91% in patients with pretreated HER2 aberration-positive solid tumors, and 58/97% in patients with HER2m+ NSCLC, with manageable safety and limited EGFR-associated adverse events (AEs). Here we present the study design and other parameters of the ongoing zongertinib clinical development program, including the Beamion LUNG-1 (phase 1b) and Beamion LUNG-2 (phase 3; NCT06151574) trials in patients with HER2m+ NSCLC.

Previously presented at WCLC 2022 (Beamion LUNG-1) and ELCC 2024 (Beamion LUNG-2).

Methods: Beamion LUNG-1 (phase 1b) is a dose-expansion study evaluating early efficacy of zongertinib in patients with NSCLC with or without prior treatment. This study initially enrolled patients with HER2 tyrosine kinase domain (TKD) mutation-positive, pretreated NSCLC (cohort 1, n~70). It was then expanded to include patients with treatment-naïve NSCLC with HER2 TKD mutations (2, n~70), NSCLC with non-TKD HER2 mutations (3, n~30), NSCLC with HER2 TKD mutations and active brain metastases (4, n~30), and NSCLC with HER2 TKD mutations and prior treatment with a HER2-directed antibody-drug conjugate (5, n~30). Beamion LUNG-2 is a phase 3 study that will compare the efficacy/safety of zongertinib with the standard of care in patients with histologically or cytologically diagnosed advanced and/or metastatic nonsquamous NSCLC with TKD HER2 mutation and no prior systemic treatment in the locally advanced or metastatic setting. Key exclusion criteria: tumors that have alterations with available therapy, and radiotherapy/major surgery ≤4 weeks before randomization. Target enrollment, randomization, dosing, and endpoints for both trials are outlined in the Table.

Keywords: Advanced non-small cell lung cancer, HER2, Targeted treatment

	Beamion LUNG-1 (Phase 1b)	**Beamion LUNG-2**
Target enrollment	~230 patients from ~86 sites/18 countries	~270 patients from ~160 sites/30 countries
Randomization and dosing	Single arm • Oral zongertinib 120 mg QD	Randomized 1:1* • Experimental arm: oral zongertinib 120 mg QD (21-day cycles) • Comparator arm: intravenous pemetrexed 500 mg/m^2 chemotherapy plus either cisplatin 75 mg/m^2 or carboplatin AUC 5, plus pembrolizumab 200 mg on day 1 every 3 weeks (q3w) for 4 cycles, followed by pemetrexed 500 mg/m^2 plus pembrolizumab 200 mg q3w for ≤35 cycles
Primary endpoint	Objective response	Progression-free survival
Secondary endpoints	• Number of patients with dose-limiting toxicities throughout the entire treatment period • Pharmacokinetic parameters • Duration of response • Disease control • Duration of disease control • Progression-free survival	• Overall response (defined as best overall response of complete or partial response) • Patient-reported outcomes (changes from baseline to week 25) • Overall survival • AEs during the on-treatment period
*In both arms, treatment will continue until progressive disease (RECIST 1.1), undue toxicity, or other criteria are met

P3.12D.07 Divarasib Versus Adagrasib or Sotorasib in Pretreated KRAS G12C+ Advanced or Metastatic Non-Small Cell Lung Cancer (NSCLC)

S. Gadgeel[1], A. Rahman[2], U. Osaghae[3], T.M. Fernando[3], M.T. Lin[3], K. Koli[3], C. Meyenberg[4], M. Mathisen[3], F. Skoulidis[5], [1]Henry Ford Cancer Institute/Henry Ford Health, Detroit/MI/USA ,[2]F. Hoffmann-La Roche, Ltd, Welwyn Garden City/GB ,[3]Genentech, Inc., South San Francisco/CA/USA ,[4]F. Hoffmann-La Roche Ltd, Basel/CH ,[5]University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: KRAS G12C mutations occur in approximately 12% of patients with NSCLC. Patients with advanced/metastatic KRAS G12C+ NSCLC who have previously received standard-of-care therapies (platinum-based chemotherapy, immunotherapy, or a combination of both) have a poor prognosis. Adagrasib and sotorasib are oral, selective KRAS G12C inhibitors with accelerated FDA and conditional EMA approvals for the treatment of patients with previously treated advanced/metastatic KRAS G12C+ NSCLC. However, an unmet need remains for more effective treatments with acceptable safety and tolerability profiles to improve patient outcomes. Divarasib is an oral, selective, KRAS G12C inhibitor previously shown to be 5-20 times as potent and ≤50 times as selective for KRAS G12C in vitro as adagrasib and sotorasib. Divarasib monotherapy (≤400mg once daily [QD]) previously demonstrated encouraging antitumor activity and an acceptable safety profile in patients with advanced/metastatic KRAS G12C+ solid tumors, including NSCLC (confirmed objective response rate [ORR]: 56.4%, 95% CI 39.6-72.2; progression-free survival [PFS]: 13.7 months, 95% CI 8.1-not estimable, in patients with NSCLC; 400mg dose). The observed adverse events were mostly low grade, manageable, and reversible. The phase 3 trial presented here will evaluate the efficacy and safety of divarasib versus adagrasib or sotorasib in patients with previously treated KRAS G12C+ advanced/metastatic NSCLC.

Methods: This phase 3, randomized, active control, open-label multicenter study (EudraCT: 2024-510908-37-00) will enroll patients aged ≥18 years with histologically/cytologically confirmed, unresectable, advanced/metastatic (stage IIIC or IV) NSCLC harboring a KRAS G12C mutation (Figure). Patients must have experienced disease progression on ≥1 prior systemic therapy in the metastatic setting, have measurable disease per RECIST v1.1, and Eastern Cooperative Oncology Group performance status (ECOG PS) 0/1. Prior KRAS inhibitor therapy is not permitted. Patients will be randomized 1:1 to receive divarasib or either adagrasib or sotorasib (based on local approval status and investigator's choice) until disease progression, intolerable adverse events, consent withdrawal, death, or study termination. Tumor assessments will occur at screening, every six weeks for the initial 48 weeks, and every nine weeks thereafter. The primary endpoint is PFS per RECIST v1.1. Secondary endpoints include: overall survival; patient-reported outcomes (time to confirmed deterioration of cough [EORTC QLQ-LC13], dyspnea, or physical functioning [both EORTC QLQ-C30]); ORR and duration of response per RECIST v1.1; and safety.

Introduction: The inhibition of the RAS/MAPK pathway activates autophagy, a cellular stress response that recycles nutrients, to promote cancer cell survival. Unc-51-like autophagy activating kinases 1 and 2 (ULK1/2) are critical regulators of autophagy and are tonically inhibited by signaling through the RAS/MAPK pathway; inhibitors of this pathway, such as those that target KRAS, have consequently been shown to release ULK to mediate an autophagy pro-survival resistance response. Therefore, ULK1/2 inhibition represents a potential targeted approach to selectively inhibit autophagy and is an attractive strategy for combination with RAS/MAPK pathway inhibitors. Additive or synergistic anticancer effects were observed with combination RAS/MAPK pathway and ULK1/2 inhibition in mouse xenograft models. Sotorasib is a KRASG12C inhibitor approved for the treatment of adult patients with KRASG12C-mutant locally advanced or metastatic non-small cell lung cancer (NSCLC) who have received ≥1 prior systemic therapy. DCC-3116 is an investigational, selective, potent, switch-control kinase inhibitor of ULK1/2 in clinical development for combination with targeted therapies that activate autophagy, such as sotorasib. Here, we describe a first-in-human, phase 1/2, multicenter, open-label study of DCC-3116 in combination with sotorasib in patients with advanced or metastatic solid tumors harboring KRASG12C mutations (NCT04892017).

Methods: This study includes a dose escalation (part 1) and a dose expansion (part 2) phase. In the ongoing part 1, eligible patients ≥18 years must have a pathologically confirmed diagnosis of an advanced or metastatic solid tumor with a documented KRASG12C mutation of any histology. Daily oral DCC-3116 is administered in 28-day cycles in combination with sotorasib, using a modified 3+3 design, to patients with advanced KRASG12C-mutant solid cancers, irrespective of prior KRASG12C inhibitor treatment. Patients with previous sotorasib treatment resulting in therapy discontinuation due to a drug-related adverse event are excluded. In the planned part 2 expansion, patients ≥18 years with pathologically confirmed NSCLC with a documented KRASG12C mutation will be enrolled. Patients must have received at least 1 prior line, but no more than 3 prior lines, of systemic therapy in the advanced or metastatic setting and must have not previously received sotorasib or other KRASG12C inhibitors. Exclusion criteria for both parts include use of other anticancer treatments, any investigational therapies, or strong or moderate inhibitors or inducers of cytochrome P450 3A4 or P-glycoprotein within 14 days of the first dose. Proton pump inhibitors and H2 receptor antagonists must be discontinued at least 3 days prior to study drug. Additional exclusion criteria include the presence or history of central nervous system metastases or leptomeningeal disease. Safety is the primary endpoint in part 1. Objective response rate by local read using Response Evaluation Criteria in Solid Tumors version 1.1 in patients with KRASG12C-mutant NSCLC is the primary endpoint in the planned part 2 global expansion. Secondary endpoints for both parts include progression-free survival, duration of response, and pharmacokinetics; exploratory endpoints include pharmacodynamics. Part 1 of this study is currently enrolling patients.

P3.12D.09 Trial in Progress: A Phase Ib Study of HMBD-001, An Anti-HER3 Antibody, in Advanced Squamous Non-Small Cell Lung Cancer

N. Pavlakis[1], G. Kichenadasse[2], G. Richardson[3], S. Bowyer[4], V. Andelkovic[5], V. Ganju[6], A. Tan[7], J. Samol[8], D. Thomas[9], A. Mas Fernandez[10], K. Paszkiewicz[10], P. Ingram[10], J. Boyd-Kirkup[10], K.Y. Kwek[10], [1]GenesisCare North Shore, Sydney/AU ,[2]Southern Oncology Clinical Research Unit, Adelaide/AU ,[3]Cabrini Health, Melbourne/AU ,[4]Linear Clinical Research Ltd, Perth/AU ,[5]ICON Cancer Centre South Brisbane, Brisbane/AU ,[6]Peninsula & South Eastern Haematology and Oncology Group, Frankston/AU ,[7]National Cancer Centre Singapore, Singapore/SG ,[8]Tan Tock Seng Hospital, Singapore/SG ,[9]Omico, Sydney/AU ,[10]Hummingbird Bioscience, Singapore/SG

Introduction: Squamous non-small cell lung cancer (sqNSCLC) accounts for approximately 30% of lung cancers, with poorer prognosis compared to other subtypes of NSCLC. There is a significant unmet need for effective treatments following combined or sequential use of immune checkpoint inhibitors (ICIs) and platinum-based chemotherapy. Squamous cell carcinomas (SCCs) exhibit common genetic alterations such as Chr 3q amplification and Chr 3p loss, which increase signaling through human epidermal growth factor receptor (HER) 3 and epidermal growth factor receptor (EGFR) during early oncogenesis. Despite the high expression of EGFR in sqNSCLC, combinations of EGFR-targeting agents and chemotherapy have shown limited clinical activity. Upregulation of HER3 activity has been implicated in resistance to EGFR inhibitors such as cetuximab. Inhibition of HER3 signaling, alone or in combination with EGFR inhibitors, may confer therapeutic benefit in sqNSCLC. HMBD-001 is a humanized IgG1 monoclonal antibody that specifically targets the dimerization interface of HER3, thereby inhibiting both ligand-dependent and -independent HER3 activation. Initial data from the first-in-human dose escalation study supports a highly tolerable safety profile for HMBD-001, suggesting that HMBD-001 can be combined with other targeted agents and/or standard of care chemotherapy.

Methods: HMBD-001 is being evaluated in a multicenter, open label, Phase Ib trial in advanced sqNSCLC. The study evaluates two treatment regimens (Arm A: HMBD-001 + docetaxel; Arm B: HMBD-001 + cetuximab + docetaxel) in patients with advanced or metastatic sqNSCLC following progression on platinum-based chemotherapy and ICIs. A Simon 2-stage optimal design with an initial safety lead-in using a 3+3 design is employed for each treatment arm. The primary objectives are to determine the safety and tolerability of both treatment regimens and to assess their preliminary anti-tumor activity in terms of objective response rate (ORR) by RECIST v1.1. Secondary endpoints include duration of response (DOR), disease control rate (DCR), progression free survival (PFS) and overall survival (OS), as well as characterization of the pharmacokinetic (PK) and immunogenicity profile. Exploratory analysis of genomic alterations in the MAPK and PI3K pathways will be performed and correlated with ORR. Enrollment of patients into the first stage of the study is currently ongoing.

Keywords: HMBD-001, squamous NSCLC, HER3

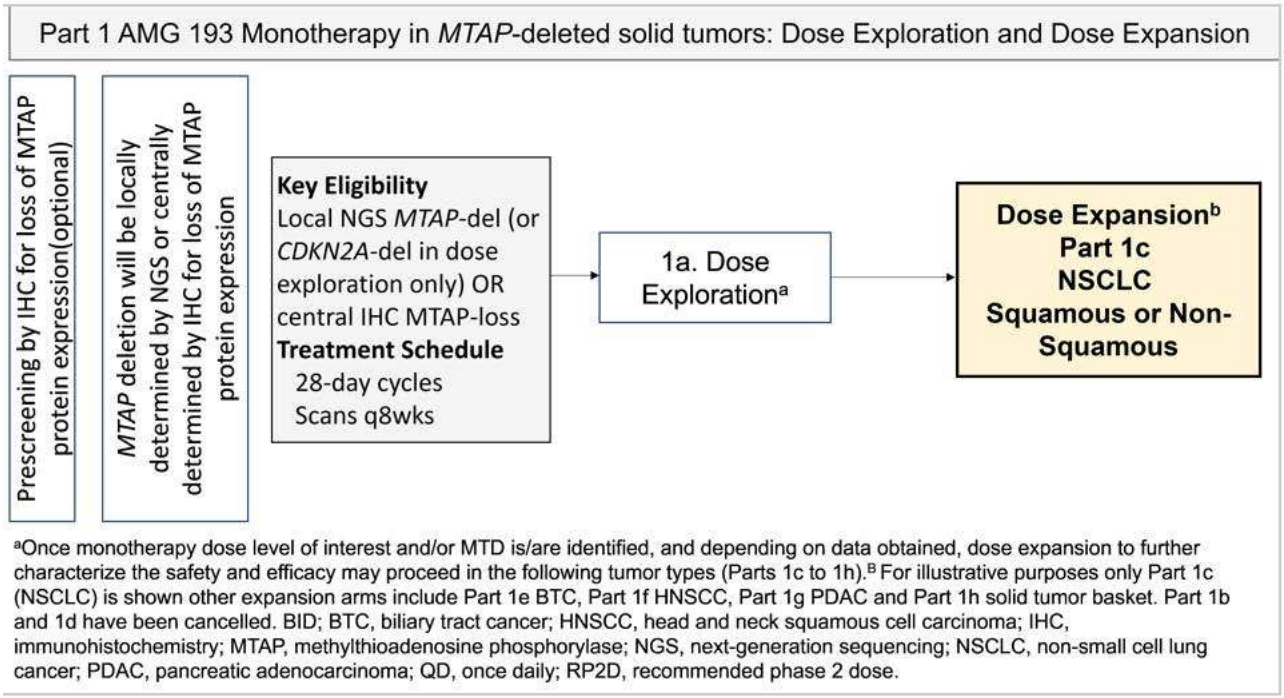
Hummel[13], A. Itsara[14], T. Eggert[14], B. Besse[15], [1]Virginia Cancer Specialists, Fairfax/VA/USA ,[2]Princess Margaret Cancer Centre, University of Toronto, Toronto/ON/CA ,[3]Hospital Doce de Octubre, Madrid/ES ,[4]Vall d'Hebron University Hospital, Barcelona/ES ,[5]Hospital Clinic Barcerlona, Barcelona/ES ,[6]Radboud University Medical Center Nijmegen, Nijmegen/NL ,[7]NYU Langone's Perlutter Health, New York/NY/USA ,[8]Roswell Park Comprehensive Center Institute, Buffalo/NY/USA ,[9]Sarah Cannon Research Institute, London/GB ,[10]National Cancer Center Hospital East Japan, Kashiwa/JP ,[11]Queen Mary Hospital, Hong Kong/CN ,[12]University Hospital of Verona, Verona/IT ,[13]University Hospital Wurzburg, Wurzburg/DE ,[14]Amgen, Thousand Oaks/CA/USA ,[15]Gustave Roussy, Orsay/FR

Introduction: AMG 193 is an oral S-methyl-5'-thioadenosine (MTA)-cooperative protein arginine methyltransferase 5 (PRMT5) inhibitor designed to induce synthetic lethality in cancers harboring deletion of methylthioadenosine phosphorylase (MTAP). MTAP is deleted in many solid tumors (squamous NSCLC [16-20%]; non-squamous NSCLC [12-16%]), often with CDKN2A, and leads to the accumulation of MTA, which binds to and inhibits PRMT5, an enzyme responsible for methylation and gene silencing of proteins commonly dysregulated in cancer. Thus, MTAP-deleted cancers have reduced PRMT5 activity, and as a result, they are susceptible to further inhibition of PRMT5 activity. AMG 193 preferentially targets and inhibits the MTA-bound state of PRMT5 which is enriched in MTAP-deleted tumor cells. In preclinical models, AMG 193 demonstrated selective antitumor activity in MTAP-deleted versus wild type NSCLC with in vitro cell line assays and NSCLC cell line-derived xenograft mouse models (Belmontes, 2023 AACR-NCI-EORTC). Furthermore, combining AMG 193 with cytotoxic chemotherapy and/or checkpoint inhibitors, as well as the KRAS G12C inhibitor sotorasib, may significantly augment antitumor activity. AMG 193 also demonstrated CNS penetrance with PK models in vivo. In the first-in-human dose escalation study, AMG 193 demonstrated antitumor activity with objective responses observed in multiple tumor types with no evidence of clinically significant myelosuppression, confirming a differentiated benefit-risk profile from first-generation PRMT5 inhibitors. (Rodon, 2023 AACR-NCI-EORTC). This promising therapeutic profile of AMG 193 is being further evaluated in combination with other therapies in patients with MTAP-deleted advanced thoracic tumors, including NSCLC.

Methods: This is a master protocol (subprotocol A-C), phase 1, open-label study of AMG 193, alone or in combination with other therapies, in patients with MTAP-deleted advanced thoracic tumors. Subprotocol A-C will enroll patients with MTAP-deleted NSCLC. Central pre-screening NGS testing will be offered to all participating sites. Subprotocol A (N ~ 312) will evaluate AMG 193 in combination with pembrolizumab with (arm A and B) or without (arm C) platinum-based doublet chemotherapy in NSCLC. Subprotocol B (N ~ 94) will evaluate AMG 193 plus sotorasib in MTAP-deleted and KRAS G12C-mutated NSCLC. Subprotocol C (N ~ 94) will evaluate AMG 193 alone in MTAP-deleted NSCLC with active brain metastases. Primary objectives are identification of the maximum tolerated dose and safety of AMG 193. Secondary objectives include antitumor activity by investigator-assessed RECIST and pharmacokinetics of AMG 193. Key eligibility criteria include adult patients (> 18 years of age) with MTAP-deleted NSCLC. Patients will be required to have PD-L1-positive tumors in subprotocol A arm C, KRAS G12C-mutated tumors in subprotocol B, and active brain metastasis in subprotocol C. AMG 193 will be administered daily continuously. The study is expected to start recruitment in April 2024.

Keywords: AMG 193, MTA-cooperative PRMT5 inhibitor, MTAP-deleted NSCLC



[a]Once monotherapy dose level of interest and/or MTD is/are identified, and depending on data obtained, dose expansion to further characterize the safety and efficacy may proceed in the following tumor types (Parts 1c to 1h).[B] For illustrative purposes only Part 1c (NSCLC) is shown other expansion arms include Part 1e BTC, Part 1f HNSCC, Part 1g PDAC and Part 1h solid tumor basket. Part 1b and 1d have been cancelled. BID; BTC, biliary tract cancer; HNSCC, head and neck squamous cell carcinoma; IHC, immunohistochemistry; MTAP, methylthioadenosine phosphorylase; NGS, next-generation sequencing; NSCLC, non-small cell lung cancer; PDAC, pancreatic adenocarcinoma; QD, once daily; RP2D, recommended phase 2 dose.

Keyvanjah[13], S. Gadgeel[14], [1]Princess Margaret Cancer Centre, Toronto/ON/CA ,[2]Hopitaux Universitaires de Geneve, Geneva/CH ,[3]National Cancer Center Hospital East, Chiba/JP ,[4]Cross Cancer Institute, University of Alberta, Edmonton/AB/CA ,[5]Queen Mary Hospital, Hong Kong/CN ,[6]UPMC Hillman Cancer Center, Pittsburgh/PA/USA ,[7]University Hospital Antwerp, Edegem/BE ,[8]MD Anderson Cancer Center, Houston/TX/USA ,[9]Indiana University Health Medical Center, Indianapolis/IN/USA ,[10]Centre Oscar Lambret, Lille/FR ,[11]Community-Health Network of Indianapolis, Indianapolis/IN/USA ,[12]Roswell Park Comprehensive Center Institute, Buffalo/NY/USA ,[13]Amgen, Thousand Oaks/CA/USA ,[14]Henry Ford Health System, Detroit/MI/USA

Introduction: AMG 193 is an oral S-methyl-5'-thioadenosine (MTA)-cooperative protein arginine methyltransferase 5 (PRMT5) inhibitor being evaluated for the treatment of methylthioadenosine phosphorylase (MTAP)-deleted cancers. MTAP deletion occurs in 16-20% of squamous and 12-16% of non-squamous non-small cell lung cancer (NSCLC). Deletion of MTAP leads to the accumulation of MTA, which binds to and inhibits PRMT5, an enzyme responsible for methylation and gene silencing of cell-essential proteins. Thus, in the context of MTAP-deleted cancers, MTA accumulation creates an additional vulnerability to further inhibit PRMT5 activity. AMG 193 preferentially targets and inhibits the MTA-bound state of PRMT5. In preclinical models, AMG 193 demonstrated selective antitumor activity in in vitro and in vivo MTAP-deleted compared to MTAP-wild type NSCLC cell line assays and NSCLC cell line-derived xenograft mouse models (Belmontes, 2023 AACR-NCI-EORTC). AMG 193 also demonstrated central nervous system penetrance with pharmacokinetic models. In the ongoing first-in-human (FIH) study with AMG 193 monotherapy, RECIST responses have been observed in a variety of MTAP-deleted tumors without dose-limiting myelosuppression and a favorable safety profile (Rodon, 2023 AACR-NCI-EORTC), demonstrating differentiated safety from the first generation indiscriminate PRMT5 inhibitors. This study will enroll up to 40 previously treated NSCLC patients in dose expansion (Part 1c), currently open for enrolment.

Methods: This is a FIH, open-label, phase 1/2, dose escalation and expansion study of AMG 193 administered continuously in 28-day cycles in patients with advanced MTAP-deleted tumors (FIGURE). Up to 40 previously treated patients with NSCLC (squamous and non-squamous histology) will be enrolled in Part 1c. Central prescreening NGS will be offered to all participating sites. One interim futility will be conducted by using Simon's minimax two-stage design. The primary objectives are safety and tolerability; secondary objectives include antitumor activity by investigator-assessed RECIST, pharmacokinetics, and pharmacodynamics. Key eligibility criteria for patients with NSCLC (Part 1c) include adult patients (≥ 18 years of age) with MTAP-deleted advanced tumors (determined by NGS or evidence of MTAP depletion determined by IHC); treatment with 1-3 prior lines of systemic therapy in the advanced/metastatic setting including platinum-based chemotherapy. Additionally, patients without actionable mutations must have received treatment with a PD(L)-1 inhibitor (unless contraindicated or PD-L1 < 1%), and patients whose tumors harbor actionable genomic aberrations (i.e. EGFR, ALK, MET, RET, ROS1, KRASG12C) should have disease progression on approved systemic therapies for these aberrations.

P3.12E.02 MEK Inhibitor Combined with RTK Inhibitor (Trametinib Plus Anlotinib) In Non-g12c KRAS-Mutant Non-Small Cell Lung Cancer: A New Strategy

B. Han[1], J. Lu[2], H. Zhong[2], T. Chu[2], W. Zhang[2], M. Hu[2], C. Shi[2], L. Xiong[2], A. Gu[2], H. Wang[2], [1]Shanghai Chest Hospital, Shanghai Jiaotong University School of Medicine, Shanghai/CN ,[2]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: It remains as a big challenge to provide therapeutic regime for the non-G12C KRAS-mutant non-small cell lung cancer (NSCLC) patients. The strategy of co-inhibition of MEK/RTKs pathways via trametinib and anlotinib showed preliminary activity in non-G12C KRAS-mutant NSCLC. However, whether the strategy is effective in clinic remains elusive.

Methods: To determine whether trametinib in combination with anlotinib will be effectiveness and safety in patients with advanced non-G12C KRAS-mutant NSCLC patients. This phase I clinical trial enrolled patients with advanced non-G12C KRAS-mutant NSCLC patients from April 13, 2021, to May 13, 2023. The trial was divided into 2 parts including phase Ia and phase Ib. Phase Ia involved dose escalation, while phase Ib consisted of expansion cohorts. The data cutoff date for this analysis was March 26, 2024. Trametinib and anlotinib were administered orally once daily, with anlotinib being used for every two weeks followed by a one-week discontinuation cycle. The primary endpoint of phase Ia was to evaluate the determine the recommended phase 2 dose (RP2D), and the primary endpoint of phase Ib was to evaluate the objective response rate (ORR). The secondary endpoints were progression-free survival (PFS), disease control rate (DCR) and safety.

Results: The phase Ia containing 13 patients showed that the RP2D is trametinib (2 mg) plus anlotinib (8 mg), the ORR is 69.2%, the PFS is 6.9 months, DCR is 92% and the rate of adverse events (AEs) ≥ grade 3 is 23%. The phase Ib containing 20 patients showed high efficacy of this combinational therapy (trametinib (2 mg) plus anlotinib (8 mg)), with the ORR at 65%, the PFS is 11.5 months, the DCR at 100%, and the rate of AEs ≥ grade 3 at 35%. An integrative analysis for the phase Ia plus phase Ib (33 patients) indicated that the ORR is 66.7%, the PFS is 10.3 months, the DCR is 97% and the rate of adverse events (AEs) ≥ grade 3 is 30%.

Conclusions: This study provides a potential combinational therapeutic strategy for those non-G12C KRAS-mutant lung cancer patients via oral administration of trametinib and anlotinib.

P3.12E.03 Anti-Tumor Efficacy of HRS-4642 and its Potential Combination with Proteasome Inhibition in KRAS G12D-Mutant Cancer

L. Luo[1], C. Li[2], K. Jia[1], X. Li[3], Z. Zhang[3], F. Li[2], C. Zhou[1], S. Ren[1], [1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]Fudan University, Shanghai/CN ,[3]Shanghai Hengrui Pharmaceutical Co., Ltd, Shanghai/CN

Introduction: KRAS G12D is the most prevalent KRAS mutation subtype in solid tumors. Currently, this subtype lacks effective targeted treatment strategies.

Methods: In this study, we conducted the following explorations: (1) Confirmation of the efficacy and selectivity of HRS-4642 in multiple preclinical in vitro models; (2) Assessment of the efficacy, safety, pharmacokinetics, and pharmacodynamics of HRS-4642 in various preclinical in vivo models; (3) Exploration of the efficacy and safety of HRS-4642 in treating patients with solid tumors harboring KRAS G12D mutations in clinical trials; (4) Generation of a comprehensive CRISPR-based map depicting the synergistic sensitization/resistance profile of HRS-4642 across the entire genome, facilitating the identification of potential targets; (5) Validation of candidate target (proteasome inhibitor) in multiple in vitro and in vivo models to assess their anti-tumor effects when combined with HRS-4642; (6) Investigation of the potential impact of HRS-4642 as a monotherapy or in combination with proteasome inhibitor on the tumor immune microenvironment.

Results: We revealed that: (1) HRS-4642 exhibits high selectivity in inhibiting the viability of KRAS G12D mutant cell lines. (2) HRS-4642 demonstrates significant anti-tumor efficacy in vivo. (3) HRS-4642 exhibits significant anti-tumor activity in two NSCLC patients. (4) Whole-genome CRISPR screening identifies proteasome inhibitor as potential agent for synergistic sensitization with HRS-4642. (5) In vitro and in vivo experiments confirm the synergistic killing of KRAS G12D-mutant cells by HRS-4642 and the proteasome inhibitor (carfilzomib). (6) Flow cytometry and immunohistochemical analysis reveal that HRS-4642 as a monotherapy or in combination with carfilzomib significantly increases the infiltration of CD4+ and CD8+ T cells in tumors.

Conclusions: (1) HRS-4642 exhibits high selectivity for KRAS G12D. (2) HRS-4642 synergizes with proteasome inhibitor carfilzomib again KRAS G12D-mutant tumors. (3) HRS-4642, or in combination with carfilzomib, has the potential to reshape the tumor immune microenvironment.

P3.12E.04 Long-Term Outcomes with Sotorasib in KRAS G12c-Mutated Advanced NSCLC from the Global Expanded Access Program (EAP) Study-436

S. Novello[1], N. Maimon[2], J. Stevenson[3], W. Petty[4], C.G. Ferreira[5], I. Morbeck[5], A. Zer[6], J. Bauman[7], S. Kalmadi[8], C. Xia[9], A.R. Meloni[9], B. Mehta[9], C. Ardito-Abraham[9], W. Kormany[9], M. Awad[10], [1]University of Turin, AOU San Luigi – Orbassano (TO)/IT ,[2]LungOncology Service, Division of Oncology, Meir Medical Center, Sackler School of Medicine, Rishon LeZion/IL ,[3]Cleveland Clinic Taussig Cancer Institute, Cleveland/OH/USA ,[4]Wake Forest University School of Medicine, Winston-Salem/NC/USA ,[5]Oncoclínicas & CO - Medica Scientia Innovation Research (MedSir), São Paulo/BR ,[6]Davidoff Cancer Center, Rabin Medical Center, Petah Tikva/IL ,[7]Fox Chase Cancer Center, Philadelphia/PA/USA ,[8]Ironwood Cancer and Research Centers, Chandler/AZ/USA ,[9]Amgen Inc., Thousand Oaks/CA/USA ,[10]Dana Farber Cancer Institute, Boston/MA/USA

Introduction: Sotorasib, a first-in-class KRASG12C inhibitor, was available under an EAP to treat KRAS G12C-mutated advanced non-small cell lung cancer (NSCLC), which included a global study protocol (Study-436). We previously reported outcomes from this study including real-world progression-free survival (rwPFS) and overall survival (OS) after 1 year of follow-up. Here, we describe outcomes with approximately 2 years of follow-up from Study-436.

Methods: Starting January 29, 2021, patients with KRAS G12C-mutated advanced NSCLC and ECOG PS ≤ 2, who had exhausted standard of care treatments, enrolled across 50 centers in 6 countries (USA, ARG, BRA, ISR, SAU, TWN) and received oral sotorasib 960 mg once daily. Patients could be included if they had asymptomatic CNS metastases. Safety was the primary endpoint. OS and duration of treatment were key secondary endpoints. rwPFS was evaluated as an ad hoc endpoint.

Results: At the primary analysis, 150 patients (median age, 66 years; 52.7% female) received sotorasib. At baseline, 38 (25.3%) patients had ECOG PS 2 and 50 (33.3%) had a history of CNS metastases. Median prior lines of anticancer therapy was 2 (range, 0-8). Consistent with previously reported outcomes, and with median study follow-up of 23.8 (95% CI, 19.5-27.1) months, median OS and rwPFS were 9.5 (95% CI, 8.6-12.0) months and 6.3 (95% CI, 5.0-7.3) months, respectively. Kaplan-Meier (KM) estimated OS at 2 years was 27.0% (95% CI, 19.5-35.1). Median duration of treatment, which considers end of treatment for any reason, was 5.2 (95% CI, 4.3-6.9) months with a range of 0.3 to 27.3 months. Efficacy was also observed in subgroups with historically poorer outcomes including those with CNS metastases, where median OS in patients with and without CNS metastases was 9.4 (95% CI, 7.2-12.7) and 10.3 (95% CI, 8.4-13.9) months, respectively (Table 1). KM estimated OS at 2 years was similar to the overall population in patients with (27.8%) and without (26.2%) CNS metastases. Safety was consistent with previously reported data. Treatment-related adverse events (TRAEs) were reported in 97 (64.7%) patients with Grade ≥ 3 TRAEs occurring in 32 (21.3%). Discontinuation due to TRAEs occurred in 10 (6.7%) patients.

Conclusions: In this long-term follow-up of 150 patients from a global EAP, real-world outcomes were consistent with the sotorasib CodeBreaK clinical trials. Approximately a quarter of patients were still alive after 2 years. Efficacy was demonstrated across subgroups including those with poorer prognostic indicators such as CNS metastases.

P3.12E.05 Real-World Comparative Effectiveness of Sotorasib vs Docetaxel as 2L/2L+ Treatment of KRAS G12c-Mutated Advanced NSCLC

M.L. Johnson[1], D. Younan[2], S. Kent[2], A. Balasubramanian[2], M. Mesa-Frias[2], B. Stollenwerk[3], B.E. Sylvester[2], B. Mehta[2], V. Chia[2], M.A. Brookhart[4], A. Spira[5], [1]Sarah Cannon Research Institute, Nashville/TN/USA ,[2]Amgen Inc., Thousand Oaks/CA/USA ,[3]Amgen EUROPE GmbH, Rotkreuz/CH ,[4]Duke University Department of Population Health Sciences, Durham/NC/USA ,[5]Virginia Cancer Specialists Research Institute, Fairfax/VA/USA

Introduction: Sotorasib, a KRASG12C inhibitor, is approved to treat patients with previously treated KRAS G12C-mutated advanced non-small cell lung cancer (NSCLC). While the phase 3 CodeBreaK 200 trial of sotorasib vs docetaxel was not powered to demonstrate an overall survival (OS) benefit, post-marketing real-world data provide an opportunity to further evaluate sotorasib's clinical benefit. We evaluated the comparative effectiveness of sotorasib monotherapy vs docetaxel as monotherapy or in combination for patients with pretreated KRAS G12C-mutated advanced NSCLC in the real-world setting.

Methods: This was a retrospective, active comparator study conducted within the US-based Flatiron Health electronic health record-derived de-identified database. Patients with pretreated KRAS G12C-mutated advanced NSCLC who initiated sotorasib between May 28, 2021 (date of US FDA approval) and September 30, 2022, or docetaxel between January 01, 2019 and September 30, 2022, were included. A longer window for docetaxel was warranted to enhance the sample size in this population. A minimum 12-month opportunity for follow-up was required. Treatment groups were balanced via overlap weighting propensity score methods. Median OS with corresponding 95% confidence intervals (CIs) in the second-line (2L) and 2L+ settings were calculated using Kaplan-Meier estimates. Hazard ratios (HR) were estimated via weighted Cox proportional hazard regression models.

Results: After propensity score weighting, clinical characteristics in sotorasib and docetaxel cohorts were mostly balanced (Table 1). At baseline, most patients were >65 years of age, had ECOG PS of 0-1, were from the community practice setting, had advanced stage at initial diagnosis, and had prior anti-PD-(L)1 treatment and/or platinum-based chemotherapy. In the 2L setting, the weighted median OS (95% CI) for sotorasib (N=102) vs docetaxel (N=59) was 10.2 (7.6-16.3) vs 6.0 (4.2-11.0) months, with a corresponding HR (95% CI) of 0.61 (0.41-0.92). In the 2L+ setting, the weighted median OS (95% CI) for sotorasib (N=164) vs docetaxel (N=118) was 10.2 (8.0-14.6) vs 7.1 (5.0-10.6) months, with a corresponding HR (95% CI) of 0.64 (0.48-0.86). Due to the small sample size, some residual imbalance remained in patients with prior anti-PD-(L)1 treatment and platinum-based chemotherapy. This was further evaluated with sensitivity analysis, and results were consistent with the primary analysis favoring sotorasib.

Conclusions: In this real-world comparative analysis of a US-based population of patients with pretreated KRAS G12C-mutated advanced NSCLC, sotorasib demonstrated a longer median OS vs docetaxel which further supports sotorasib as an important treatment option in this setting.

Introduction: Small cell lung cancer (SCLC) is an aggressive disease with limited treatment options. Immune checkpoint inhibitor (ICI) therapy with concurrent chemotherapy is the preferred first-line treatment for patients with extensive-stage SCLC. However, the addition of ICIs to chemotherapy only modestly improves clinical outcomes while posing a risk of ICI-related toxicities. Thus, identifying patients likely to benefit from ICIs is critical for optimizing treatment decisions. Here, we describe a test derived from a novel computational model that analyzes pretreatment plasma proteomic profiles to predict clinical outcomes in patients with SCLC receiving ICI-based therapies.

Methods: An observational study collected pretreatment plasma samples from 79 patients with extensive-stage SCLC treated with ICI-based therapy (NCT04056247). Proteomic profiling of plasma samples was performed using aptamer-based technology, measuring approximately 7000 proteins per sample. A machine learning model was developed to predict the clinical benefit (CB) from ICI-based therapy, where CB was defined as 6-month progression-free survival. Given the limited cohort size, CB prediction was achieved by integrating two computational models. Model 1, based on 146 plasma proteomic biomarkers, was developed from the SCLC dataset using cross-validation. Model 2, based on a 4-protein signature, was developed from a previously reported NSCLC dataset (Christopoulos et al. JCO prec. onc. 2024). The hybrid model stratified patients into two groups (i.e., 'positive' or 'negative') based on a pre-defined CB probability threshold. Bioinformatic analysis of the SCLC-specific proteomic biomarkers was performed to gain insight into the potential mechanisms driving ICI therapeutic benefit and resistance in SCLC.

Results: The model displayed a robust predictive capability, as demonstrated by the area under the curve (AUC) of the receiver operating characteristic (ROC) plot of 0.63 (p-value = 0.02) and a high correlation between the predicted CB (i.e., model output) and the observed CB rate (R2 = 0.93). Furthermore, overall survival (OS) was significantly longer in patients stratified to the positive group compared to those in the negative group. Median OS was 14 months versus 8.8 months in positive versus negative patient groups (Hazard ratio = 0.47, 95% Confidence interval: 0.25-0.90, p-value = 0.02). Bioinformatic analysis of model proteins revealed significant enrichment of lung tumor-associated proteins, poor prognostic factors in lung cancer, extracellular matrix-related proteins, intermediate filaments, and replicative immortality (Fisher exact test; FDR<0.1). Multiple model proteins are also known to be involved in fibroblast growth factor signaling and glutathione metabolism. Given their association with different treatment resistance mechanisms, such proteins represent potential targets for intervention.

Conclusions: We describe preliminary results from a novel pretreatment plasma proteomics-based predictive model that can potentially inform treatment decisions for patients with SCLC. Bioinformatic analysis demonstrates that the model is based on a composite of biologically and clinically relevant biomarkers. The potential clinical utility of this model is being investigated in a large prospective clinical trial.

Paz-Ares[6], M.P. Diz[7], A.L. Moreno[8], Á. Callejo[9], S. Vidal[3], M. Majem[1], [1]Hospital de la Santa Creu i Sant Pau, Barcelona/ES ,[2]Universitat Autònoma de Barcelona, Barcelona/ES ,[3]Institut de Recerca Sant Pau, Barcelona/ES ,[4]Hospital Universitario Lozano Blesa, Zaragoza/ES ,[5]Hospital del Mar, Barcelona/ES ,[6]Hospital Universitario [12] de Octubre, Madrid/ES ,[7]Complejo Asistencial Universitario de León, León/ES ,[8]Hospital Universitario Reina Sofía, Córdoba/ES ,[9]AstraZeneca Farmacéutica Spain S.A., Madrid/ES

Introduction: Prognosis of patients with extensive disease small-cell lung cancer (ED-SCLC) is poor even when treated with first-line anti-PD(L)-1 in combination with platinum and etoposide. Determination of PD-L1 expression in the tumor by IHC does not fully discriminate patients who benefit the most from this treatment. There are factors that could be limiting the efficacy of this treatment, i.e. the expression of PD-L1 in the surface of circulating cells or the anti-inflammatory role of circulating leukocyte-platelet aggregates. Our objectives were to determine basal circulating levels of leukocyte-platelet complexes, levels of PD-L1 on circulating cells, levels of activated platelets and the absolute number of free platelets in ED-SCLC patients before starting treatment with first-line durvalumab-platinum-etoposide, and to compare them to the levels and numbers in healthy donors.

Methods: Patient (p) data and blood samples from 41 consecutive p enrolled in NCT04712903 Trial (EudraCT: 2020-002328-35) were assessed. Blood samples were collected at baseline, lymphocytes were gated according to size and complexity. Samples were analyzed by flow cytometry. We determined circulating levels of leukocyte-platelet complexes, circulating PD-L1+ leukocytes and platelets, activated platelets and the absolute number of free platelets in ED-SCLC patients and compared them with those from healthy donors (HD) (N=22). Descriptive statistics were used to report baseline characteristics. Kaplan-Meier was used to estimate survivals. Comparisons between groups were analyzed with t-test. All p-values are based on a two-sided hypothesis and those under 0.05 are considered statistically significant.

Results: The median age was 64 years (48-84), 27p (65.9%) were male, 11p (26.8%) had an ECOG PS of 0 and 30p (73.2%) had an ECOG PS of 1. 13p (31.7%) had liver metastases and 4p (9.8%) had CNS metastases.

Flow cytometry results are represented in Figure 1: higher percentages of PDL1+ CD4+ T lymphocytes (p<0.01), PDL1+ CD8+ T lymphocytes (p<0.001), PDL1+ CD20+ T lymphocytes (p<0.001), PDL1+ monocytes (CD14+) (p<0.001) and PDL1+ platelets (p<0.05), were observed in ED-SCLC p compared to HD. Levels of activated platelets (CD62P+) also showed higher percentages in ED-SCLC p (p<0.001), as well as the absolute number of free platelets (p<0.001).

No statistically significant differences were observed in the percentages of circulating leukocyte-platelet (PLT) complexes, nor in PDL1+ neutrophils (CD16+) in ED-SCLC p compared to healthy donors.

Conclusions: Our results suggest that the percentages of circulating PD-L1+ leukocytes, PDL1+ platelets and activated platelets were significantly higher in ED-SCLC patients compared to healthy donors before starting first-line durvalumab-platinum-etoposide.

P3.13C.04 Assessing ctDNA using a Methylation-informed Molecular Response Algorithm in Extensive-Stage Small Cell Lung Cancer Patients

J.S. Gheeya[1], L. Bucheit[2], S.R. Solomon[2], A. Yablonovitch[2], C. Pilcher[1], C.J. Presley[1], E. Bertino[3], P.G. Shields[1], K. He[1], V. Sukrithan[1], B. Konda[1], C.F. Verschraegen[1], D. Carbone[1], G.A. Otterson[1], D.H. Owen[1], [1]The Ohio State University Wexner Medical Center, Columbus/OH/USA ,[2]Guardant Health, Inc, Redwood City/CA/USA ,[3]Columbus Oncology and Hematology, Columbus/OH/USA

Introduction: Noninvasive liquid biopsies could be used to assess evolving treatment responses and overall survival (OS) in patients with advanced cancers. We previously reported that an early decrease in ctDNA from the baseline (BL) in ES-SCLC patients treated with nivolumab and temozolomide (N+T) was associated with improved PFS (NCT03728361). Here, we evaluate treatment response and OS via a methylation-based molecular response (MR) algorithm.

Methods: ES-SCLC patients who have progressed on chemoimmunotherapy were treated with N+T. Plasma was collected at BL, cycle 2 day 1 (C2D1), and C5D1 and analyzed using the Guardant360 Infinity assay, which includes genotyping >750 genes and methylation-informed tumor fraction (methyl TF). Molecular treatment response was assessed using the Guardant methylation-informed MR algorithms, where a >50% decrease in ctDNA was defined as achieving MR. Survival curves were compared using the log-rank test.

Results: 36 samples from 20 ES-SCLC patients were analyzed. 34 samples had methylation-based ctDNA successfully profiled, of which 33 (97%) had ctDNA detected. BL methyl TF was available for 18 patients, of which 50% were classified as high methyl-TF (threshold 10.3%). There were no differences in OS based on BL methyl-TF (p=0.32). BL and C2D1 ctDNA samples were available for 15 patients. Genomic and methylation MRs correlated positively (Pearson R=0.957, p <0.01). One patient had discordant results, with genomic non-MR (-33%) but methylation MR (-98%); notably, this patient experienced >700-day OS, suggesting methylation MR may be a good surrogate marker of response. While highly correlated in the 15-patient cohort, methylation MR is more closely associated with OS (p=0.07) compared to genomic MR (p=0.67). TP53, BRCA2, and RB1 were the most common BL genomic alterations (figure 1). Of 12 patients with BL TF > 0.2%, 8 had concurrent TP53/RB1 loss of heterozygosity (LoH) with a median OS of 114 days, while 4 patients without TP53/RB1 LoH had a median OS of 272 days (log-rank p = 0.03).

Conclusions: In this MR analysis of ES-SCLC patients treated with N+T, genomic variance allelic frequency and methyl TF dynamics were associated with OS, though methyl TF was a more robust indicator of OS. BL TP53/RB1 LoH was associated with shorter OS. These data suggest the potential utility of BL and early on-treatment assessment of ctDNA and methyl-TF in predicting treatment response. additional trials should continue to explore these patterns, which can provide valuable insights into the clinical utility of these assays.

P3.13C.05 Relationship Between Tumor Volume and Clinical Outcomes in Relapsed SCLC

M. Lu, H.F. Byrd, H. Chen, W.T. Iams, Vanderbilt University Medical Center, Nashville/TN/USA

Introduction: For stage IA-IIIC SCLC, tumor burden is a predictor of clinical outcomes, but there is no data exploring whether tumor burden is a predictor of clinical outcomes in relapsed SCLC.

Methods: In this correlative study analyzing a Vanderbilt University Medical Center cohort of 93 patients with relapsed SCLC (49% Men, 90% White, 80% ≥ 65 years old, 69% initially ES-SCLC), total body tumor volume (TV), progression free survival (PFS) and overall survival (OS) were calculated and a Cox Proportional Hazards Model was used to evaluate the relationship between TV and PFS/OS.

Results: Our analysis revealed that TV was significantly associated with OS in a non-linear fashion (p 0.0059). Up to a tumor burden of 500cc, there was a nearly linear relationship between tumor burden and overall survival. As tumor burden reached levels higher than 500cc, this relationship plateaued. There was also a significant association between Eastern Cooperative Oncology Group Performance Status (ECOG PS) and overall survival (p=0.0003). When compared, ECOG PS was more strongly associated with OS than TV. When controlling for ECOG PS, the significant association between TV and OS persisted (p = 0.0064). In this cohort, there was no statistically significant association between TV and PFS or ECOG PS and PFS.

Conclusions: We observed that TV is a potential predictor of OS in patients with relapsed SCLC, though not as strong of a predictor as PFS. Further studies are needed to evaluate whether initiation of standard systemic therapy at lower TV is able to consistently improve PFS and OS.

Arriola[2], [1]Vall d'Hebron University Hospital, Barcelona/ES ,[2]Hospital del Mar, Barcelona/ES ,[3]Hospital del Mar Research Institute, Barcelona/ES ,[4]Department of Pathology, IIS-Fundación Jiménez Díaz, Madrid/ES ,[5]Medical Oncology Department, Hospital Clínico Universitario & Instituto de Investigación Sanitaria de Santiago de Compostela (IDIS), Santiago Compostela/ES ,[6]Hospital Universitario Lozano Blesa, IIS Aragón, Zaragoza/ES ,[7]Hospital Universitario [12] de Octubre, Madrid/ES ,[8]Hospital Universitario Sant Joan de Reus, Reus/ES ,[9]Hospital Universitario A Coruña, Health Research Institute, INIBIC, Coruña/ES ,[10]Hospital Universitario Reina Sofía, Cordoba/ES ,[11]AstraZeneca Farmacéutica Spain S.A, Madrid/ES

Introduction: Small-cell lung cancer (SCLC) represents a unique clinical challenge characterized by its aggressive nature, poor prognosis, and limited therapeutic options. Upfront prediction of overall survival (OS) and progression-free survival (PFS) in this disease could impact patient care by refining risk stratification and personalize treatment strategies. Here, we investigate the utility of a deep learning (DL) model using digital pathology to enhance the outcomes prediction of patients diagnosed with SCLC.

Methods: Data from 307 SCLC patients with comprehensive clinical and follow up information, including age, clinical stage, treatment type, and performance status, progression free survival (PFS) and overall survival (OS) and corresponding Whole Slide Images (WSI) at diagnosis were collected. The cohort was divided into a training set (n=263) consisting of patients treated at Hospital del Mar, Barcelona, Spain, and a validation set (n=44) comprising patients included in the CANTABRICO phase IIIB clinical trial (NCT04712903). LT_OS (Long-Term Overall Survival) was defined as OS exceeding 12 months for metastatic patients and 25 months for non-metastatic patients. For LT_PFS (Long-Term Progression Free Survival) prediction PFS was defined as longer than 5 or 14.3 months for extensive-stage-SCLC and limited-stage-SCLC patients, respectively. We built a random forest (RF) model using clinical data and a DL based model using WSI as inputs. Model performance was assessed using the area under the receiver operating characteristic curve (AUC) with 5-fold cross-validation to minimize bias and variance of the performance. We report the mean and 95% confidence interval of the AUC values across the folds.

Results: In the training set, the RF model achieved an AUC of 0.728 (95% CI: 0.662-0.792) for LT_OS prediction, while the combined RF and DL model achieved an AUC of 0.744 (95% CI: 0.680-0.807). For LT_PFS prediction, the RF model achieved an AUC of 0.689 (95% CI: 0.625-0.753), whereas the combined model achieved an AUC of 0.704 (95% CI: 0.640-0.767). Application of the combined RF and DL model to the validation cohort yielded an AUC for LT_OS of 0.604 (95% CI: 0.582-0.626) and an AUC for LT_PFS 0.690 (95% CI: 0.643-0.738), indicating potential clinical applicability.

Conclusions: Our results showcase the feasibility of integrating clinicopathological data with whole slide imaging (WSI) from digital pathology through a deep learning model to enhance prediction outcomes in patients with SCLC. Inclusion of additional biomarkers (i.e. immunohistochemical markers, genomic alterations) might further increase the potential of prediction using deep learning models. This approach holds promise in helping physicians in personalize treatment strategies that better suit individual patient needs.

P3.13C.07 Novel Nomogram Integrating Clinial, Radiomics and Genomics for Prediction of Radiation Pneumonitis in Limited-Stage Small Cell Lung Cancer

L. Li[1], H. Zhu[1], T. Zhou[1], N. Liu[1], S. Yuan[1,2], [1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan/CN ,[2]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, Anhui, China., Jinan/CN

Introduction: Definitive chemoradiotherapy (dCRT) is the standard treatment for limited-stage small cell lung cancer (SCLC), but varying degrees of radiation pneumonitis (RP) occur in some patients. This study aimed to construct a nomogram combining radiomic, genomic, and clinical factors for the prediction of RP after dCRT in individual patients with limited-stage SCLC.

Methods: Totally 150 limited-stage SCLC patients treated with dCRT were divided into training (n=103) and validation (n=45) cohorts. All tumor tissue samples were subjected to gene sequencing, and 851 radiomics features of lung excluding the hilum, atelectasis and tumor were extracted from initial computed tomography images. The least absolute shrinkage and selection operator (LASSO) method was applied to select features and build a radiomic score (Radscore). Combining radiomics, genomics and clinical factors, a nomogram was established by univariate and multivariate analyses. The predictive ability and application value were evaluated based on the area under the receiver operating characteristic curve (AUC), calibration curve, and decision curve.

Results: The Radscore constructed from six selected features was significantly associated with grade ≥2 RP (P<0.01). Multivariate analysis identified NQO1(rs1131341) allele mutation, Radscore, and mean lung dose as independent risk factors for RP. Compared with the individual clinical (AUC=0.717 and 0.641), radiomic (AUC=0.703 and 0.635) or genomic (AUC=0.581 and 0.571) models, the nomogram had the highest AUC values of 0.857 and 0.688 in the training and validation groups, respectively. The calibration curves indicated good agreement between the predictions and actual observations. Moreover, decision curves showed the nomogram had high clinical practicability.

Conclusions: Radiomic and genomic features have potential to assist with prediction of RP. The developed nomogram incorporating radiomic, genomic, and clinical factors provides robust personalized prediction of RP.

P3.13C.08 Optimal Treatment Strategies for Older Adults with Clinical Stage IA Small Cell Lung Cancer

M. Yang, A. Potter, D. Srinivasan, D. Wang, M. McCarthy, J. Sands, D. Kozono, C-F.J. Yang, Massachusetts General Hospital, Boston/MA/USA

Introduction: Data on treatment strategies for early-stage small cell lung cancer (SCLC) in patients aged 80 and older are limited. The objectives of this study are to (1) assess treatment patterns over time and (2) evaluate survival outcomes of different treatment modalities in this patient population.

Methods: Patients aged 80-89 diagnosed with clinical stage IA SCLC from 2004-2021 in the National Cancer Database were identified for analysis. Treatment patterns from 2004-2021 were examined. Overall survival stratified by treatment type was assessed using Kaplan-Meier analysis and multivariable Cox proportional hazard analysis. A subgroup analysis was performed on surgery and SBRT groups.

Results: A total of 553 patients met inclusion criteria. Median follow up was 18.2 months (IQR, 8.7 to 39.9). From 2004 to 2021, the proportion of patients undergoing chemotherapy alone or no treatment decreased, while numbers receiving SBRT increased (Figure 1). The majority (37.3%) of patients underwent chemotherapy alone, 20.3% underwent SBRT, 13.0% underwent surgery, and 10.0% underwent non-SBRT radiation. 11.4% underwent unknown/other treatment, while 8.1% underwent no treatment. Overall survival by treatment type is shown in Table 1. In unadjusted and multivariable-adjusted analysis, SBRT was associated with similar overall survival compared to surgery; chemotherapy alone, non-SBRT radiation, no treatment, and other/unknown treatment were associated with significantly worse overall survival. In a subgroup analysis of patients who underwent surgery or SBRT (n=189), surgery alone, surgery with chemotherapy, SBRT alone, and SBRT with chemotherapy were associated with similar overall survival.

Conclusions: In this national analysis, the use of SBRT for patients aged over 80 years diagnosed with clinical stage IA SCLC has increased over the last two decades and was the most common treatment for this patient population in 2021. SBRT was associated with similar overall survival when compared to surgery; both were associated with better survival than other treatment modalities.

Introduction: Therapeutic strategies for LCNEC are not standardized and are derived from protocols for SCLC and NSCLC, which might not be entirely appropriate due to the unique biology of LCNEC.

Methods: For discovery, we leveraged a multi-institutional retrospective cohort from 23 centers of metastatic pure LCNEC (diagnosed locally). For validation, clinical and molecular profiles of patients with pure LCNEC were obtained from Caris Life Sciences. Patients received 1st-line systemic therapy between 2015-2023 and were either treated with chemotherapy(chemo), immunotherapy(IO), or a combination(chemoIO). Clinical outcomes included progression-free survival(PFS), overall survival(OS), and treatment-related adverse events(trAE). Survival comparisons were made by genomic alteration (TP53/RB1/STK11/KEAP1/KRAS).

Results: The discovery cohort had 190 patients with median age at 1st-line systemic therapy of 66 years; 55% (n=105) were males. First-line treatments were chemoIO(n=72), chemo(n=105), or IO(n=13). Median follow-up time was 54 months(mo), 45 mo, and 26 mo for the chemo, IO, and chemoIO groups, respectively. Of 116 patients with available PD-L1, 74(64%) were negative and 42(36%) were ≥1%. The most common chemo regimen was platinum-etoposide (n=83,72%). The most common chemoIO regimen was carboplatin/etoposide/atezolizumab (n=30,43%). In the IO group, one patient received dual IO. For the validation cohort(n=158), 47, 99, and 12 received chemo, chemoIO, and IO, respectively.

In the discovery cohort, there was no significant difference in PFS across the groups (Figure, top left) on multivariable analysis adjusting for ECOG and "M" stage (p=0.09 and 0.54 for chemo vs. chemoIO; chemo vs. IO comparisons, respectively). Similarly, there was no difference in OS (p=0.77 and 0.23 for chemo vs. chemoIO and chemo vs. IO comparisons, respectively, Figure, top right). In the validation cohort, median OS was not significantly different across treatment groups(p=0.38, Figure bottom). In the discovery cohort with available genomic data (n=129), those harboring TP53 mutations in LCNEC exhibited significantly inferior OS and PFS when treated with chemo (Median OS TP53-mutant:11mo vs. 24.5mo for TP53-WT, p=0.04; median PFS TP53-mutant 10.4 vs.19.2mo for WT, respectively, p=0.008) but not chemoIO. Any grade trAE occurred in 56(54%), 41(57%), and 6(46%) patients treated with chemo, chemoIO, and IO, respectively. There were significantly less grade ≥3 trAEs in the IO-treated group vs. chemo and chemoIO (22% vs. 24% vs. 0%, respectively, p=0.04).

Conclusions: As first-line therapy for mLCNEC, chemo, chemoIO, and IO show comparable survival outcomes with significantly less toxicities in the IO-treated group. The findings underscore the opportunity for further innovation in treatment strategies, prompting the need for future clinical trials.

P3.13D.01 Proteomic Characterization of Antibody Drug Conjugate Target Expression Profiles in Small Cell Lung Cancer (SCLC)

E. Lin[1], A. Khosla[2], N.K. Smrecek[1], A.R. Naqash[3], K. Parikh[1], Y. Boumber[4], M. Khalil[4], A. Desai[4], [1]Mayo Clinic, Rochester/MN/USA ,[2]Corewell Health William Beaumont University Hospital, Royal Oak/MI/USA ,[3]OU Health Stephenson Cancer Center, Oklahoma City/OK/USA ,[4]University Of Alabama At Birmingham, Birmingham/AL/USA

Introduction: Despite advancements in diagnosis and therapy, outcomes for small cell lung cancer (SCLC) remain suboptimal. Recent studies exploring antibody drug conjugates (ADCs) have demonstrated promising preliminary results. However, further characterization of target expression profiles is needed for optimal patient selection. Here, we aim to utilize mass spectrometry to characterize the proteomic patterns of ADC targets within SCLC.

Methods: We analyzed the expression of ADC targets including DLL3 (DLL3), B7H3 (CD276), Trop2 (TACSTD2), and SEZ6 (SEZ6) in patients with treatment-naïve SCLC (n=112) from Clinical Proteomic Tumor Analysis Consortium (CPTAC) database. Isobaric tandem mass tag labeled mass spectrometry (TMT-11 plex) data from SCLC tumor tissue and normal adjacent lung tissue was obtained. Differential protein expression between tumors and normal adjacent tissue was assessed with a threshold Log2 fold change >1 and Benjamini-Hochberg adjusted P-value <0.01. Hierarchical clustering was used to identify transcriptomic and proteomic patterns of ADC target expressions.

Results: A total of 214 samples from 107 patients which passed quality control were used for downstream analyses. Differential protein expression analysis showed significantly increased DLL3 (Log2FC=2.9, P=4.7E-4), decreased Trop2 (Log2FC=-1.9, P=2E-19), and no difference in B7H3 (P=0.50, Log2FC=-0.05) in SCLC tumors compared to normal adjacent lung tissue. SEZ6 expression was missing for over 50% of samples, precluding further analysis. By hierarchical clustering, normal lung tissue could be distinguished from tumor tissue based on high Trop2 expression. Tumor subsets formed clusters based on either increased expression of DLL3 (22.4%) or B7H3 (24%). Interestingly, DLL3 and B7H3 displayed a nearly mutually exclusive pattern of overexpression.

Conclusions: In SCLC, overexpression of DLL3 and B7H3 is seen in approximately one quarter of tumors with these targets being mutually exclusive. Meanwhile, Trop2 was significantly overexpressed in normal tissues. Further prospective research utilizing proteomics-based approach may enable optimal utilization of ADCs in patients with SCLC.

P3.13D.02 DLL3 Expression in Early-Stage SCLC: Comparative Analysis of IHC and mRNA ISH in Tumor and Lymph Nodes

M-L. Meyer[1], H. Yu[2], F. Hirsch[3], [1]Mount Sinai, NEW YORK/NY/USA ,[2]University of Colorado Anschutz Campus, Aurora/CO/USA ,[3]Mount Sinai Hospital, NEW YORK/NY/USA

Introduction: Small cell lung cancer (SCLC) is highly lethal. Delta Like Canonical Notch Ligand 3 (DLL3) is commonly overexpressed in SCLC and is a target for new therapies. 80%-93% of advanced SCLC cases are DLL3 positive, but its expression in early-stage SCLC lacks documentation, and especially the correlation with metastatic lymph node expression. This study aimed to assess DLL3 expression in early-stage SCLC tumors using immunohistochemistry (IHC) and mRNA in situ hybridization (ISH), correlate these assays with matched metastatic lymph nodes, and correlate DLL3 expression with outcomes and characteristics.

Methods: This single-center retrospective study evaluated 248 resected samples from patients with early-stage SCLC between 1978 and 2013. IHC staining was performed using the Ventana Benchmark XT autostainer and SP347 Antibody Assay. For mRNA ISH, the Leica Bond RX autostainer was utilized. IHC positivity was defined as an H-score of ≥1 (ranging from 0 to 300), and mRNA ISH positivity was defined as a score of ≥1 using the ACD-approved method (ranging from 0 to 3). A linear correlation between IHC and mRNA ISH scores was calculated. Univariable and multivariable Cox regression analyses were conducted using the PASW Statistics 22.0 package and R versions 3.5.2 and 4.3.1.

Results: 248 patients with histologically confirmed early-stage SCLC were included, with 32 matched lymph nodes metastasis. Among the tumor samples, 233 were evaluable using IHC, with 58% testing positive. For mRNA ISH, 235 samples were evaluable, with 87% showing positivity. DLL3 positivity in lymph nodes was 69% with IHC and 100% with mRNA ISH. Correlation between IHC and mRNA ISH was significant (Spearman's rank, p<0.001). Additionally, DLL3 positivity was significantly correlated between tumor and lymph nodes metastasis for both IHC (p=0.024) and mRNA ISH (p=0.047). DLL3 positivity in the tumor was not correlated with patients' clinical characteristics. A non-significant trend towards better median overall survival (mOS) was observed for patients with a tumor IHC score <1, showing a mOS of 27.1 months (95% CI: 12.5-59.0) versus 21.0 months (95% CI: 18.2-30.4), p=0.893. A similar trend was observed with an mRNA ISH score <1: mOS of 38.9 months (95% CI: 26.6-NA) versus 18.9 months (95% CI: 14.9-28.8), p=0.221.

Conclusions: In this study of 248 early-stage resected SCLC, DLL3 positivity was 58% with IHC and 87% with mRNA ISH. Both IHC and mRNA ISH showed significant correlation in tumors and lymph node metastasis. An observed trend suggested improved survival in patients with no DLL3 expression.

Keywords: Delta Like Canonical Notch Ligand 3 (DLL3), immunohistochemistry (IHC), mRNA in situ hybridization

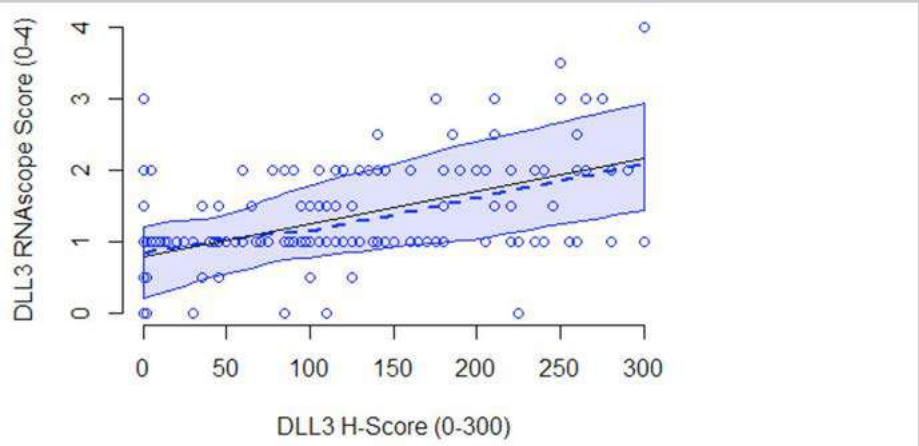

Figure 1. Comparison of DLL3 expression. Linear regression fitted line (black), Loess smoothing line (dashed blue), 95% confidence bands (solid blue). Spearman's rank correlation rho=0.557, p<0.001.

P3.13D SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS - MOLECULAR PROFILING AND MOLECULAR TARGETS

P3.13D.03 Inhibition of LSD1 Prevented Tumor Progression and Recurrence to Radioimmunotherapy in Small Cell Lung Cancer

F. Na, H. Wang, X. Pan, K. Kang, Z. Yao, Y. Zheng, G. Lin, Y. Wu, R. Luo, X. Zhang, R. Tong, C. Chen, Y. Lu, West China Hospital of Sichuan University, Chengdu/CN

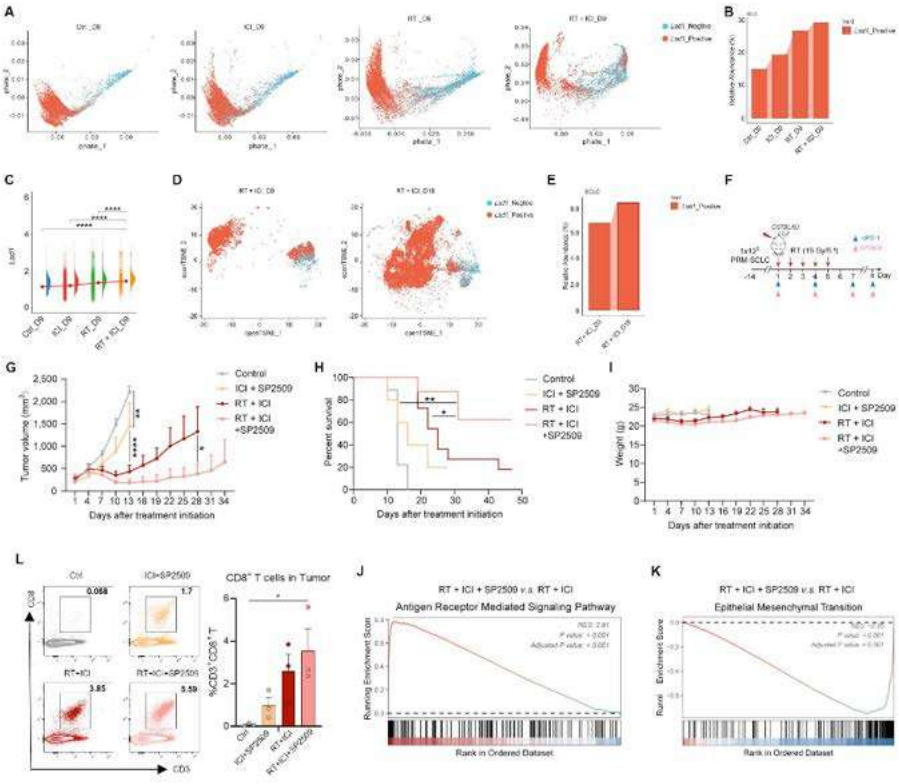
Introduction: Small cell lung cancer (SCLC) remains a highly metastatic neuroendocrine cancer with high lethality. Intratumor heterogeneity and genomic instability are additional features of SCLC. Previous studies revealed radiotherapy (RT) combined with immune checkpoint inhibitors (ICIs) had synergistic anti-tumor effect in SCLC, but tumor recurrence still occurred in the late stage of treatment. Therefore, it's necessary to elucidate the mechanism of recurrence and progression of SCLC in this new combination therapy and explore new therapeutic targets.

Methods: We constructed murine SCLC model and used multi-omics methods to analyze the dynamic changes of SCLC from sensitivity to recurrence after radioimmunotherapy treatment, especially the role and molecular mechanism of lysine-specific demethylase 1 (LSD1) in the process of recurrence. We further evaluate the anti-tumor effect of the triple therapy of RT + ICI + LSD1 inhibitor (SP2509) on SCLC.

Results: Single-cell RNA-Seq (scRNA-Seq) data revealed that according to the expression of Lsd1, the tumor cells from four groups in the murine SCLC model were divided into two clusters: Lsd1 positive and Lsd1 negative. It was observed that despite the synergistic anti-tumor effect of RT + ICI, the proportion of Lsd1 positive tumor cells also increased on Day 9 in the RT + ICI group. Subsequent analysis of tumor tissues in recurrence stage of RT + ICI treatment (Day 18) showed the proportion of Lsd1 positive tumor cells further increased compared to Day 9, indicating these Lsd1 positive tumor cells may be not sensitive to RT + ICI treatment and associated with tumor recurrence and progression in the late stage of treatment. Furthermore, the addition of LSD1 inhibitor (SP2509) into RT + ICI treatment had a superior anti-tumor effect and prolonged the survival of mice. The complete response rate of tumors tripled to 60% with the triple therapy regimen, which was well tolerated with no weight loss observed in mice throughout the experiment. Flow cytometry analysis demonstrate the triple therapy resulted in the most T cell infiltration in tumor. Bulk RNA-Seq data demonstrated that the triple therapy regimen upregulated the antigen presentation pathway and downregulated the epithelial-mesenchymal transition (EMT) pathway.

Conclusions: In our murine SCLC model, Lsd1 positive tumor cells were enriched in the recurrence stage of RT+ ICI treatment. Triple therapy of RT+ ICI + LSD1 inhibitor could delay the tumor progression and recurrence to radioimmunotherapy through upregulating the antigen presentation pathway, downregulating the EMT pathway.

Keywords: Small cell lung cancer, radioimmunotherapy, LSD1



P3.13D.04 Extrachromosomal MYC-Paralogs Amplification Defines Immunosuppressive Microenvironment with Metastatic Potential in Small Cell Lung Cancer

J. Zhang[1], J. Deng[1], Y. Jin[2], H. Lin[2], K. Dai[1], X. Hu[2], K. Sun[1], E. Yang[2], X. Li[1], [1]Peking University People's Hospital, Beijing/CN ,[2]Peking University Health Science Center, Beijing/CN

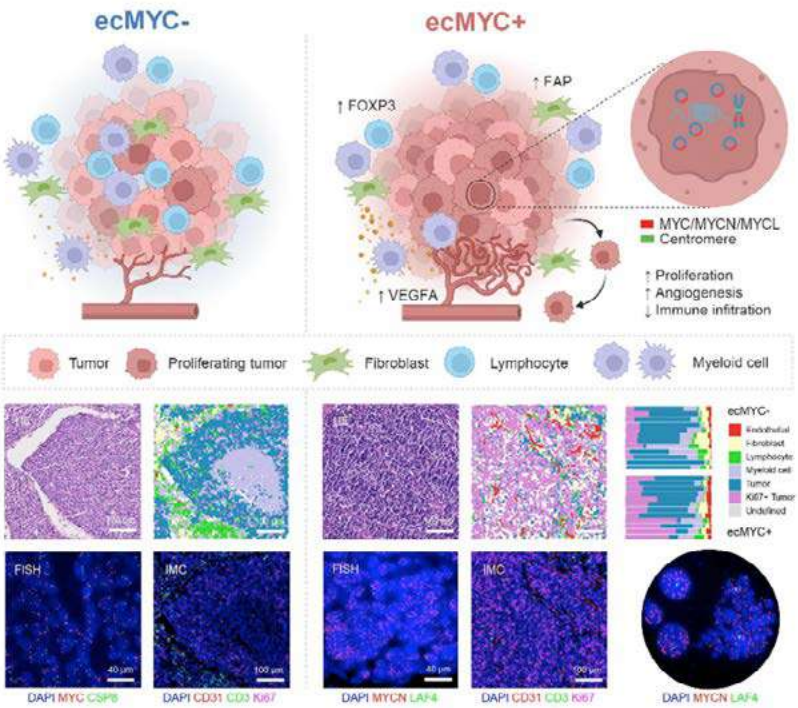
Introduction: Although immunotherapy has demonstrated promise in small cell lung cancer (SCLC), a certain number of patients encounter limited benefits, underlining the necessity for identifying molecular biomarkers of immunosuppressive characteristics. Extrachromosomal circular DNA (ecDNA) promotes amplification of MYC-paralogs (MYC, MYCN and MYCL), which are recognized as recurrent drivers of cross-resistance in SCLC. Nevertheless, it remains unclear whether ecDNA-mediated MYC-paralogs amplification (ecMYC+) denotes immunosuppressive traits in SCLC.

Methods: Whole-genome sequencing (WGS) and bulk RNA sequencing (RNA-seq) data were retrieved from the Cancer Cell Line Encyclopedia (CCLE) database (n = 329), the Cancer Genome Atlas (TCGA) database (n = 1857) and European Genome-phenome Archive (EGAS00001000925, n = 87). The overexpression and amplification of MYC-paralogs were identified by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) in SCLC clinical samples (n = 42). Imaging mass cytometry (IMC) with 40-plex antibody panel was used to characterize the subpopulation frequency and spatial distribution of SCLC tumor microenvironment. The relative copy number of MYC-paralogs was investigated by real-time polymerase chain reaction (qPCR). RNA-sequencing and flow cytometry were performed in controlled and drug-treated SCLC cell lines.

Results: The mean copy number of ecDNAs were higher in SCLC than the other lineages (15.3 vs 8.4), as well as the frequency of ecMYC+ cell lines (SCLC 22/47 vs others 15/282, p = 3.9×10-12). Highly amplified MYC-paralogs (> 20-fold) were detected in resectable SCLC samples, including treatment-naïve T1 stage patient, indicating early relapse and poor prognosis. With 102,008 cells resolved from 24 pathological regions, we identified higher expression of MKI67, VEGFA, FAP and FOXP3 in ecMYC+ samples, and found reduced T cell infiltration along with higher frequencies of endothelial and CD163+ macrophages. Furthermore, ecMYC+ samples exhibited elevated cellular neighborhood dominated by Ki-67+ tumors, with reduced spatial interaction with immune and stroma cells. Various immune-related pathways were downregulated and nucleotide metabolism processes were upregulated in ecMYC+ SCLC, and inhibition of nucleotide metabolism induced by hydroxyurea and gemcitabine led to diminishment of ecMYC, accompanied with activation of antigen presenting pathway. In pan-cancer lineages, ecMYC+ cell lines also exhibited multiple down-regulated immune pathways, higher frequency of metastatic collection sites (p = 1.2 × 10-3) and suspension growth (p = 4.3× 10-4) independent of MYC-paralogs overexpression.

Conclusions: Our findings underscore the significance of extrachromosomal MYC-paralog amplification in shaping the immunosuppressive tumor microenvironment and potentially contributing to metastasis, indicating potential targets for improving immunotherapy outcomes in SCLC.

Keywords: small cell lung cancer, extrachromosomal MYC-paralogs amplification, tumor microenvironment



Schematic model illustrating the proposed role of extrachromosomal MYC-paralogs amplification (ecMYC+) in SCLC (top) and pathological samples images (bottom). The images include hematoxylin-eosin staining (HE), fluorescence in situ hybridization (FISH), imaging mass cytometry (IMC), and cell neighborhood analysis (CN) results for both ecMYC- and ecMYC+ SCLC samples. The bottom right part exhibited the landscape of various subpopulations proportions from 24 SCLC regions of interests (ROIs), while the lower 12 ROIs were from ecMYC+ samples. The circular image demonstrates MYCN (red) amplified outside the metaphase chromosome (in blue) in metaphase cells.

P3.13D.05 Genomics and Immune Infiltration Biomarkers for Short-term and Long-Term ES-SCLC Survivors with First-Line Chemoimmunotherapy

Y. Jiang[1], P. Zhan[1], T. Lv[1], Y. Song[1], [1]Jinling Hosipital, School of medicine, Southeast university, Nanjing/CN

Introduction: First-line chemoimmunotherapy has largely enhanced survival in patients with unselected extensive-stage small cell lung cancer (ES-SCLC). Nevertheless, only a minor subset of ES-SCLC patients are bestowed with prolonged survival, which warrants robust biomarkers. As such, we aim to explore the differences in genomics and spatial distribution of immune cells between long-term and short-term ES-SCLC survivors.

Methods: We retrospectively recruited 11 long-term (>2 years) and 13 short-term (<9 months) ES-SCLC survivors treated with first-line chemoimmunotherapy. Samples were processed using targeted next-generation sequencing (tNGS), programmed death ligand-1 (PD-L1) staining, multiple immunohistochemical staining of immune cells (mIHC) (CD8A, CD68, HLA-DR, CD56, panCK, DAPI), tumor mutational load (TMB) and chromosomal instability (CIN) score testings.

Results: Genomically, a higher proportion of the smoking mutational signature and a heavier TMB suggested better prognoses. The single gene and pathway level's analysis indicated that the amplification of MCL1 and STMN1, as well as apoptotic pathway's alterations accumulated more frequently in short-term survivors, whereas DLL3, KMT2B, HGF, EPHA, and ADGRB3 alterations, and the alterations of the corresponding lysine deprivation and HGF-cMET pathways were commonly detected in long-term survivors. The spatial distribution of immune cells illustrated that long-term survivors showed higher infiltration of parenchymal and stromal M1-like macrophages yet lower levels of CD8+T in the stromal areas. Furthermore, using the public bulk and single-cell transcriptomic databases, we managed to find that high levels of STMN1 and DLL3 typified immunosuppressive phenotypes, whereas HGF, MCL1, and EPHA3 characterized immune-responsive phenotypes. The SCLC-N subtype possessed a higher expression of STMN1 compared to the rest of the subtypes.

Conclusions: The present study revealed that the infiltration of stromal CD8+ T cells and M1-like macrophages in any location differed between long-term and short-term ES-SCLC survivors. Genomic features including alterations of MCL1, STMN1, KMT2B, EPHA3, HGF, DLL3 and ADGRB3, as well as the proportion of smoking mutational signature were proven to be prognosis-related. This may steer us through the maze of selecting suitable ES-SCLC patients benefiting from first-line chemoimmunotherapy and expedite the exploitation of therapeutic targets.

P3.13D.06 Distinct Single-Cell Transcriptomic Characteristics and Responses to the Front-Line Therapy in Patients with Central or Peripheral ES-SCLC

L. Luo[1], R. Xia[2], S. Mao[1], Q. Liu[3], H. Du[1], L. Chen[2], F. Wu[1], S. Ren[1], [1]Shanghai Pulmonary Hospital, Shanghai/CN ,[2]Chinese Academy of Sciences, Shanghai/CN ,[3]Hubei University of Medicine, Xiangyang/CN

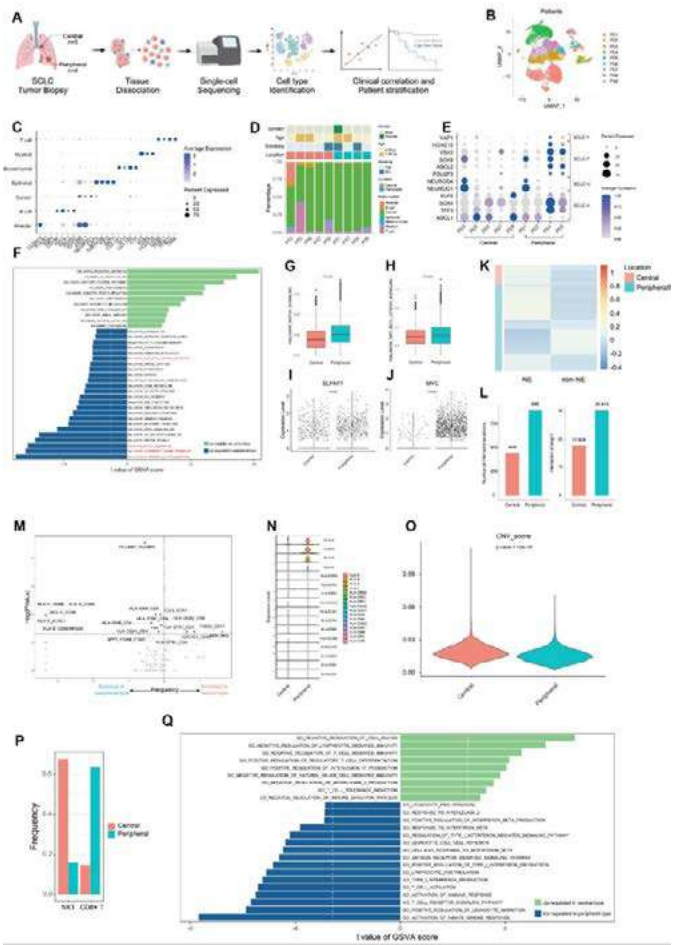
Introduction: Extensive-stage small-cell lung cancer (ES-SCLC) remains a big challenge and in-depth understanding of its biology is urgently needed.

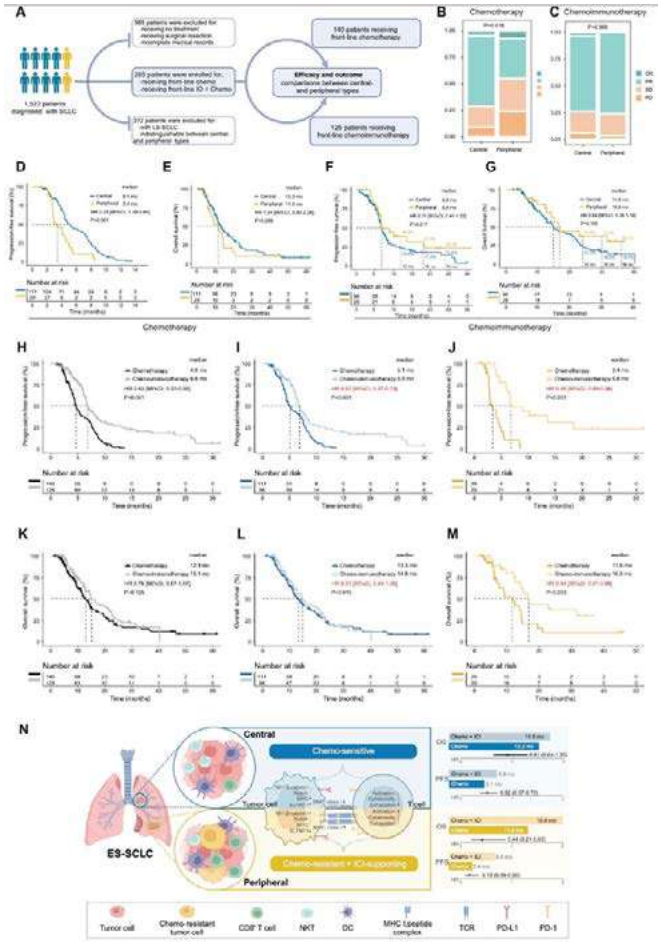
Methods: n this study, we performed scRNA-seq on 9 treatment-naïve samples to investigate the potential prediction for clinical outcomes of front-line therapy, and collected a cohort of 265 ES-SCLC patients for verification.

Results: The scRNA-seq included 12,897 cells. Prominent interindividual heterogeneity was observed in cell-type composition and small-cell lung cancer subtype-specific transcription factor expression, especially between patients with peripheral- and central-type ES-SCLC. The peripheral-type was associated with lower SLFN11 expression, higher MYC expression, activated NOTCH and WNT signaling, non-neuroendocrine components, fewer copy number alterations, higher MHC class I gene expression, and more CD8+ T cell presence. In patients receiving chemotherapy, peripheral-type had lower ORR (44.8% vs. 71.2%, P=0.008), shorter PFS (median 3.4 vs. 5.1 months, P=0.001) and OS (median 11.6 vs. 13.3 months, P=0.268) than central-type. Nevertheless, when comparing chemo-immunotherapy with chemotherapy, peripheral-type subgroup showed the potential to reduce progression (HR, 0.18 and 0.52 respectively) and death (HR, 0.44 and 0.91 respectively) risks than central-type.

Conclusions: The scRNA-seq of ES-SCLC demonstrated that primary location was associated with distinct tumoral and microenvironmental traits, which might associate with distinct responses to the front-line treatment.

Keywords: scRNA-seq, ES-SCLC, Chemo-immunotherapy





P3.13D.07 Longitudinal Tumor Microenvironment Analysis in Extensive Stage SCLC Patients Treated with Dual Checkpoint Inhibitor Blockade

A. Chiang[1], R. Matera[1], K. Ashley[2], B.K. Rajendran[2], K.A. Schalper[2], [1]Yale University School of Medicine, New Haven/CT/USA ,[2]Yale University, New Haven/CT/USA

Introduction: In patients with advanced small cell lung cancer (SCLC), the impact of immunotherapy on the tumor microenvironment and clinical implications of these alterations are very poorly understood with no clear predictive biomarkers to guide patient selection.

Methods: We collected paired baseline (pre-treatment), on-treatment (week 4), and progression biopsies from patients with relapsed extensive-stage SCLC treated with combination nivolumab (nivo) and ipilimumab (ipi) in a single-arm, phase 2 clinical trial (NCT03670056). Nivo 1 mg/kg and ipi 3 mg/kg were administered every 3 weeks for 4 cycles, followed by nivo maintenance until progressive disease (PD) by RECIST 1.1 or treatment-limiting toxicity. Paired pre/on-treatment samples were available from 13/22 patients, as well as 4 biopsies at progression. The tumor samples were studied using multiplexed quantitative immunofluorescence (mQIF) in addition to whole exome DNA sequencing (including germline DNA) and RNA-sequencing.

Results: 9/17 evaluable patients had PD; 8 patients showed clinical activity of treatment (2 with partial response). Among the 9 evaluable subjects that were previously treated with immunotherapy, there was 1 PR and 2 SD (DCR 33%). Median PFS was 1.7 months (95% CI: 1.1 - 5.8) and median OS of 7.3 months (95% CI: 4.9 - 10.1). mQIF analysis showed an increase in both CD8+ effector T cells and CD4+ helper T cells at week 4 compared to baseline samples without significant change in FoxP3+ regulatory T cells. CD4+ helper T cells exhibited the greatest expansion among patients with clinical activity, whereas FoxP3+ regulatory T cells were increased among those with no clinical activity. Tumors at progression showed a notable reduction of TILs, comparable to baseline levels. C to A mutation rate was significantly elevated in patients with clinical benefit. Week 4 tumors showed multiple novel DNA mutations and changes in transcriptional regulation.

Conclusions: Dual checkpoint blockade using ipilimumab and nivolumab has clinical activity in patients with relapsed SCLC, even those previously treated with immunotherapy. Immunotherapy induced changes in TIL number and composition are associated with clinical activity. We identified multiple novel genetic and transcriptional changes in week 4 and progression samples which may be implicated in immunotherapy resistance.

Keywords: SCLC, Tumor Microenvironment, immunotherapy

Figure 1. Longitudinal analysis of tumor microenvironment changes correlated with clinical activity of ipilimumab and nivolumab in extensive stage SCLC patients. A) T cell counts in baseline and on treatment week 4 biopsies and at progression (G). B) T cell counts in patients with clinical activity (CA) vs no clinical activity (NCA). C) Change in T cell density from pre-treatment to week 4 correlated with clinical activity. D-F) Patients with increase in T cells correlated with activity. H) Quantitative immunofluorescence of T cells shows overall increase in T cells at week 4.

P3.13D.08 MYCNOS Epigenetically Regulated by Super-Enhancer is a Potential Predictor to NOTCH Inhibitor in Chemoresistance SCLC

l. guo[1], Y. Niu[2], [1]Zhujiang Hospital, Southern Medical University, guangzhou/CN ,[2]The First People's Hospital of Foshan, Foshan/CN

Introduction: SCLC is an aggressive form of lung cancer that frequently develops resistance to chemotherapy, leading to tumor recurrence and metastasis. A comprehensive understanding the molecular mechanisms of chemoresistance is crucial for identifying effective therapeutic targets. In this study, we aim to investigate the mechanisms underlying super-enhancer-mediated drug resistance for advancing clinical management in small cell lung cancer (SCLC).

Methods: In this study, we employed RNA-Seq to identify highly expressed molecules associated with chemoresistance. To further investigated the potential regulatory mechanism governing the expression of these molecules, we conducted H3K27Ac and ATAC-Seq binding analyses to identify super-enhancers involved and their corresponding transcription factors. Subsequent in vivo and in vitro experiments were performed to assess the impace of these molecules. Clinical samples were also collected to establish the prognostic value for patients. Additionally, we explored the efficacy of NOTCH pathway inhibitors in multiple PDX models and searched for molecular markers that could predict treatment response.

Results: Our findings revealed elevated expression of MYCNOS, demonstrating its chemoresistant properties in both in vitro and in vivo models of SCLC. Furthermore, we identified MYCNOS-SE can directly regulate MYCNOS expression through two key transcription factors, including CTCF and KLF15. Specifically, MYCNOS-SE-E5 was proven to be the most significant constituent of MYCNOS-SE in mediating chemoresistance. Additionally, we showed that MYCNOS binds to MYCN, enhancing its expression to influence chemotherapy sensitivity via the NOTCH pathway. Moreover, we demonstrated NOTCH inhibitors enhance chemotherapy sensitivity both in vitro and in vivo, while MYCNOS emerging as a protein-level predictor of the effectiveness of NOTCH inhibitors in SCLC.

Conclusions: This study highlights the significance of super-enhancer-regulated target genes as distinctive markers for chemoresistance in SCLC. Furthermore, it suggests that MYCNOS as a potential predictor to identify patients who may benefit from NOTCH inhibitors. These findings provide valuable insights for future studies developing therapeutic strategies targeting the identified pathways.

P3.13D.09 Prevalence and Prognostic Impact of SEZ6 Expression in a Real-World Cohort of Patients with Small-Cell Lung Cancer

S. Wang[1], A. Luo[1], N. Choudhury[2], L. Wang[1], D. Xu[1], F. Jiang[1], L. Roberts-Rapp[1], Y.C. Choi[1], M. Cai[1], N. Rudra-Ganguly[1], P. Ansell[1], L. Paz-Ares[3], L.A. Byers[4], [1]AbbVie Inc., North Chicago/IL/USA ,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA ,[3]Hospital Universitario [12] de Octubre, Madrid/ES ,[4]The University of Texas MD Anderson Cancer Center, Houston/TX/USA

Introduction: ABBV-706, an antibody-drug conjugate (ADC) comprising an anti-seizure related 6 homolog (SEZ6) antibody conjugated to a topoisomerase 1 inhibitor payload, is being clinically evaluated in a phase 1 study (NCT05599984) of patients with advanced solid tumors, including small cell lung cancer (SCLC). While recent research has identified SEZ6 overexpression in SCLC and other tumor types with a high unmet need, additional characterization of the prevalence of SEZ6 expression in SCLC, its association with different molecular subtypes of SCLC, and its prognostic value is needed. Herein, we present data from a real-world cohort of patients from the City of Hope (COH) National Medical Center.

Methods: Tissue samples and clinical data pertaining to treatment and outcomes of patients with extensive-stage SCLC were obtained from COH. Tissue samples underwent immunohistochemistry (IHC) testing using an analytically validated clinical trial assay, as well as whole-transcriptome RNA sequencing and whole-exome DNA sequencing analysis. Molecular subtypes were determined on the basis of transcriptional profiles using a proprietary algorithm. Relative timing of tissue acquisition to the line of treatment (LOT) was determined to enable longitudinal biomarker expression analysis along different LOT. Standard-of-care (SOC) treatment consisted of first-line platinum-based chemotherapy with or without immune checkpoint inhibitors and second-line topotecan/irinotecan or lurbinectedin. The abundance of immune cell infiltrates was determined in each sample.

Results: Tissue samples and clinical data were available for 112 patients. The IHC prevalence of SEZ6 using a validated cutoff of ≥25% tumor cells with 1+ staining was 63%; with a cutoff of ≥50%, the prevalence rate was 44%. SEZ6 IHC score distributions of patients' biopsies collected prior to first LOT and in between first and second LOT were similar, indicating the front-line SOC treatment did not alter SEZ6 expression significantly. SEZ6 was enriched in SCLC-A (ASCL1) and SCLC-N (NEUROD1) subtypes; prevalence rates of SCLC-A and SCLC-N subtypes in this real-world cohort were 50% and 24%, respectively. Immune cells were significantly higher in the SCLC-I (inflamed) subtype. In patients with high versus low SEZ6 expression and clinical response status reported, best response rate to first line SOC treatment was 57% and 50%, and clinical benefit rate (CBR) was 100% and 85%, respectively. Hazard ratio for progression-free survival (PFS) was 0.9 (95% confidence interval, 0.44 - 2.00; P=0.872).

Conclusions: In this real-world cohort of patients with SCLC, SEZ6 was a prevalent biomarker, overexpressed in 44 - 63% of patients depending on the selected cutoff, and showed stability across LOT and enrichment in SCLC-A and -N molecular subtypes. Clinical outcomes, including PFS, response rate, and CBR were not significantly impacted by SEZ6 expression levels and thus, SEZ6 is not a prognostic biomarker. Although the sample size was small and the study was limited to a single site, these data support SEZ6 as a potential ADC-targetable biomarker in SCLC. This real-world SCLC cohort could also be used as a borrowed control for the phase 1 single-arm study being conducted in patients with SCLC treated with ABBV-706 to help identify novel predictive biomarkers and interpret the outcomes from the study.

P3.13D.10 Clinical Outcomes of Transformed Small-Cell Lung Cancer Versus Extensive Primary Small-Cell Lung Cancer

L. Chen[1], X-H. Zhang[1], Z-J. Mao[1], D. Wang[1,2], J. Huang[1], H-J. Chen[1], J-J. Yang[1], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [2]School of Medicine, South China University of Technology, Guangzhou/CN

Introduction: The treatments and clinical outcomes of transformed small-cell lung cancer (T-SCLC) were previously considered to be comparable to those of primary SCLC (P-SCLC). Yet, a comprehensive evaluation of prognosis correlating with treatments and biomarkers between the two cohorts remains lacking in the era of chemoimmunotherapy.

Methods: A total of 211 patients diagnosed with T-SCLC (n = 46) and extensive P-SCLC (n = 165) in our hospital from March-2018 to March-2023 were retrospectively enrolled. Patients with T-SCLC had received at least one line of standard treatment with EGFR-TKIs before pathological transformation. In the P-SCLC cohort, 105 were treated with immunotherapy (P-I/O subgroup), while the other 60 with chemotherapy (P-chemo subgroup). In the T-SCLC cohort, 23 with immunotherapy (T-I/O subgroup), and the remaining 23 with chemotherapy (T-chemo subgroup). Clinicopathological data, blood tumor markers and survival outcomes were collected and analyzed. The overall survival (OS) of T-SCLC was calculated since the start of first-line treatment after transformation.

Results: There was no significant difference in median OS (mOS) between the T-SCLC and P-SCLC cohorts (11.7m vs. 12.9m, P=0.0656). In the chemotherapy group, the mOS of T-chemo subgroup was significantly shorter than that of P-chemo subgroup (8.5m vs. 11.0m, P=0.0427). In the immunotherapy group, the mOS of T-I/O subgroup and P-I/O subgroup did not show significant difference (16.5m vs. 13.9m, P=0.6495). Additionally, in the T-SCLC cohort, the mOS of the T-I/O subgroup was significantly longer than that of T-chemo subgroup (16.5m vs. 8.5m, P<0.001). Similarly, in the real-world P-SCLC cohort, the mOS of the P-I/O subgroup was significantly longer than that of P-chemo subgroup (13.9m vs. 11.0m, P=0.0126). Moreover, the optimal cutoff value of baseline neuron-specific enolase (NSE) levels in predicting prognosis differed between T-SCLC (30.8 ng/ml) and P-SCLC (74.8 ng/ml). Higher baseline NSE levels correlated with poorer mOS in both T-SCLC (8.40 m vs. 15.90 m, P<0.0001) and P-SCLC (10.40 m vs. 16.30 m, P=0.0002).

Conclusions: Overall, the prognosis of T-SCLC and P-SCLC was similar. However, chemotherapy yielded significantly poor outcomes with T-SCLC compared to P-SCLC, indicating only chemotherapy could be inappropriate for T-SCLC. Further analysis demonstrated T-SCLC could benefit more from immunotherapy. The baseline NSE levels could be a biomarker in predicting prognosis in both P-SCLC and T-SCLC.

P3.13D.11 SEZ6 Expression in Neuroendocrine Tumors

J.A. Marks[1], K. Sweeney[2], A. Elliott[3], B. Gupta[1], A. VanderWalde[3], S. Puri[4], M.D. Shields[5], J.J. Nieva[6], H.P. Soares[4], P.C. Ma[7], B. Halmos[8], S.V. Liu[1], [1]Georgetown University, Washington/DC/USA ,[2]Caris Life Sciences, Irving/TX/USA ,[3]Caris Life Sciences, Phoenix/AZ/USA ,[4]Huntsman Cancer Institute, University of Utah, Salt Lake City/UT/USA ,[5]Indiana University Simon Comprehensive Cancer Center, Indianapolis/IN/USA ,[6]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles/CA/USA ,[7]Penn State Milton S. Hershey Medical Center, Hershey/PA/USA ,[8]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA

Introduction: Novel treatment options for SCLC and extrapulmonary neuroendocrine (NE) cancers remain an unmet need. Seizure-related homolog 6 (SEZ6) is a cell surface protein with a likely neurosecretory role in SCLC. SEZ6 represents a target for novel SEZ6-targeting antibody-drug conjugates, but SEZ6 expression patterns in SCLC and extrapulmonary NE cancers are poorly understood.

Methods: RNA sequencing (whole transcriptome) was performed for 1312 SCLC and 2231 extrapulmonary NE cancer samples submitted to Caris Life Sciences. Within each of the cancer types, samples were stratified by SEZ6 RNA expression quartile (Q1: low, Q4: high). Samples were additionally classified as SCLC-A, SCLC-N, SCLC-P, SCLC-Y, TF-neg, or Mixed groups based on the expression of ASCL1, NEUROD1, POU2F3, and YAP1. Significance was tested using the Mann-Whitney U test. Real-world overall survival was obtained from insurance claims data and calculated from collection date to time of last contact; associated p-values were calculated using the log-rank test.

Results: SEZ6 expression in SCLC tumors was higher than extrapulmonary NE tumors (1.92-fold, $p < 0.0001$). Comparing primary tumor sites, median SEZ6 expression in SCLC, at 39.9 transcripts per million (TPM) was higher than NE tumors of the bladder (33.6 TPM, $p = 0.0236$), cervix (28.5 TPM, $p = 0.0004$), pancreas (22.6 TPM, $p < 0.0001$), ileum (20.0 TPM, $p < 0.0001$), colon (17.7 TPM, $p < 0.0001$), and adrenal gland (1.2 TPM, $p < 0.0001$) but lower than those of the prostate (52 TPM, $p = 0.0013$) and not significantly different to NE tumors of the rectum (33.6 TPM, $p = 0.465$). Within SCLC tumors, SEZ6 expression was correlated with the expression of ASCL1 (0.43, $p < 0.0001$), NEUROD1 (0.17, $p < 0.0001$), and YAP1 (0.16, $p < 0.0001$), but not POU2F3 (-0.04, $p = 0.1386$). Accordingly, comparing each subtype vs all others, median SEZ6 was greatest in the Mixed group (53.3 TPM, $p < 0.0001$), followed by SCLC-A (48.1 TPM, $p < 0.0001$), SCLC-N (33.5 TPM, $p = 0.4159$), SCLC-Y (32.0 TPM, $p = 0.0002$), TF-neg (25.1 TPM, $p < 0.0001$), and SCLC-P (4.8 TPM, $p < 0.0001$). Among patients with SCLC, median survival was longest for SEZ6-Q2 (13.1 mos.) followed by SEZ6-Q1 (11.0 mos.), SEZ6-Q3 (10.7 mos.) and SEZ6-Q4 (10.1 mos., $p = 0.0327$). Among patients with extrapulmonary NE cancers, median survival was also longest for SEZ6-Q2 (34.2 mos.), followed by SEZ6-Q3 (23.6 mos.), SEZ6-Q1 (21.8 mos.), and SEZ6-Q4 (18.4 mos., $p < 0.0001$).

Conclusions: SEZ6 expression is higher in SCLC than in extrapulmonary NE tumors but there is notable heterogeneity by transcriptional subtype, with the highest expression in the SCLC-A and Mixed groups and lowest expression in SCLC-P. Among extrapulmonary NE tumors, SEZ6 expression varies by site of origin and is highest in prostate neuroendocrine tumors. These data support further exploration of SEZ6- directed therapy in other neuroendocrine tumors.

P3.13E.01 Is Systematic Lymphadenectomy Pivotal for Bronchial Carcinoid Surgical Treatment? A TNM 9th Classification Validation Pilot Study

L. Valentini[1], S. Ceccarelli[2], M. Lugaresi[3], R. Potenza[2], P. Bertoglio[1], S. Bonucchi[1], P. Solli[1], F. Stella[4], F. Puma[2], N. Daddi[1], [1]Thoracic Surgery, Bologna/IT ,[2]Thoracic Surgery, Perugia/IT ,[3]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum, University of Bologna,, Bologna/IT ,[4]Division of Thoracic Surgery, Forlì/IT

Introduction: This study aims to compare systematic nodal dissection, with or without bench dissection of the lymph nodes present along the segmental bronchial branches of the surgical specimen, with nodal sampling according the 9th pTNM lung cancer staging proposal.

Methods: A retrospective study prospectively collected data from two institutional databases were considered. The χ2 test or Fisher's test and the Mann-Whitney test were used to analyze categorical and continuous variables, respectively. Survival analysis was performed using the Kaplan-Meier (KM) method and the Log-rank test. Cancer-specific and disease-free survival analyses were carried out. P-value <0.05 was considered statistically significant.

Results: Between 14/2/1983 and 17/11/2023, 367 patients(297TC and 70AC) were included in the study. FIGURE 1 describes the demographic and results. Sixteen patients(5.38%) with TC and 11 patients(15.71%) with AC had metastatic nodal disease on the pathology report. Overall, KM progression-free survival was achieved at five years with adequate survival in TC compared to AC(p =0.0001) [FIGURE 2].

Conclusions: Performing a systematic lymphadenectomy during surgery for a NET lung tumor is crucial, even if the TC or AC histotype has not been identified before. This helps prevent the risk of recurrence and avoids understaging the disease, which could otherwise delay adjuvant therapy if necessary.

P3.13E.02 Adjuvant Chemotherapy in cT1N0M0 Large-Cell Neuroendocrine Cancer with or without Pathological Upstaging

Y. Suzuki[1], I.S. Sarkaria[2], I.G. Christie[1], S.N. Mazur[1], S. Kim[1], A. Pennathur[1], J.D. Luketich[1], R. Landreneau[3], M.J. Schuchert[1], [1]University of Pittsburgh Medical Center, Pittsburgh/PA/USA ,[2]University of Texas Southwestern Medical Center, Dallas/TX/USA ,[3]Tampa General Hospital, Tampa/FL/USA

Introduction: Large-cell neuroendocrine cancer (LCNEC) is a rare histology associated with poor prognosis. The effectiveness of adjuvant chemotherapy in early-stage LCNEC has been debated but has yet to be concluded. This study aims to analyze the outcomes of clinical T1N0M0 LCNEC (≤ 3 cm) with a focus on their upstaging and adjuvant chemotherapy.

Methods: We performed a single-institution, retrospective study on patients who underwent lobectomy or therapeutic sublobar resection for clinical T1N0M0 LCNEC and its mixed pathology, from January 1, 2002, to December 31, 2022. The patients with pathological upstaging were classified into T-upstage and N-upstage groups. The prognostic value of adjuvant chemotherapy was analyzed for each group.

Results: During the study period, 62 lobectomies and 34 sublobar resections (20 segmentectomies and 14 wedge resections) were performed for clinical T1N0M0 LCNEC. Occult lymph node metastasis was detected in 11 patients (11.5%; N-upstage), and another 24 patients experienced upstage due to T factor (25.0%; T-upstage), leaving 61 patients as pathological Stage IA without upstage (63.5%; No-upstage). The N-upstage group had significantly shorter recurrence-free survival (RFS) compared with the T-upstage and No-upstage groups (RFS; median: 11.4 vs 50.9 vs 40.3 months; p=0.004; Figure 1). Adjuvant chemotherapy was delivered to 35 patients (36.5%) and was associated with significantly better RFS (median: 64.1 vs 19.4 months; p=0.020; Figure 2A). This tendency was seen across the groups (Figure 2B-D) while statistically not significant in the T-upstage group. Of note, even in the No-upstage group (pathological T1N0M0), 11 patients (18%) with adjuvant chemotherapy had significantly longer RFS than those without adjuvant chemotherapy (median: 107.2 vs 18.5 months; p=0.015; Figure 2B).

Conclusions: Upstaging was relatively common in clinical T1N0M0 LCNEC, and a poor prognostic effect of occult node metastasis was noted. Adjuvant chemotherapy was associated with better survival and may be considered even in pathological T1N0M0.

P4.04C.01 Incidental Pulmonary Nodule Management Using Computer Assisted Detection and Patient Tracking: PINPOINT Project, Pilot Data

A. Leliveld[1], B. Willems[1,2], E.J.R. van Beek[3], L. Gorospe[4], A. Veltri[5], J.J. Visser[1], G.V. Scagliotti[5], J.G.J.V. Aerts[1], [1]Erasmus MC, University Medical Center, Rotterdam/NL, [2]AstraZeneca, Den Haag/NL, [3]Edinburgh Imaging, QMRI, University of Edinburgh, Edinburgh/GB, [4]Hospital Universitario Ramon y Cajal, Madrid/ES, [5]Univeristy of Turin, San Luigi hospital, Turin/IT

Introduction: Early detection of lung cancer has a pivotal role in improving lung cancer survival. Incidental pulmonary nodule (IPN) detection can identify patients with early-stage lung cancer, potentially leading to a stage shift in lung cancer diagnosis. Implementing Computer Assisted Detection (CAD) in routine clinical practice has the potential to increase IPN detection rate. Adequate management following detection is equally important and could be achieved through implementation of a virtual nodule clinic (VNC) that allows monitoring of referrals and follow-up. It has been shown that implementation of a VNC can substantially reduce loss-to-follow-up of actionable IPN. In PINPOINT, CAD combined with a VNC is implemented in European medical centers to evaluate its clinical value. This pilot study is performed to assess the impact of the program on clinical workflow.

Methods: CAD software was implemented in 4 medical centers. All consecutive chest CT scans from routine practice were analyzed by CAD-software. No patients were excluded. Radiologists flagged patients with IPN requiring follow-up as "actionable" in the local VNC. (Figure 1a) In each center, a navigator was appointed to supervise referral and management of actionable patients through the VNC. Nodule management was in accordance with the British Thoracic Society (BTS) Guidelines. The impact of the program on clinical workflow was evaluated by collecting aggregated data from the VNC including IPN incidence, referral trends and initial management. In one center, we additionally assessed flagging accuracy and the number of interventions by the navigator.

Results: From July 2022 until January 2024, a total of 60.260 chest CT scans from 36.916 patients were analyzed. The CAD-software detected nodules in 30.839 (51%) scans and in 19.276 (52%) patients. 474 (1.3%) patients had nodules flagged as actionable by radiologists and are being monitored in the VNC.(Figure 1b) Thus far, 4 (0.6%) patients with actionable nodules were diagnosed with clinical stage IA lung cancer. In the center where this data was collected, intervention by the navigator was required for the referral of 5 out of 64 (7.8%) patients with actionable nodules.

Conclusions: IPN detection and adequate management can be optimized by CAD and a VNC in routine clinical practice. Further evaluation of early-stage lung cancer detection and cost-effectiveness of the program are subject of current research.

P4.04C.02 Discrimination of Lung Cancer and Benign Lung Diseases Using BALF Exosomal DNA Methylation Profile

I.A. Kim[1], C. Batochir[2], E. Jo[2], D. Kim[2], H. Park[2], H.J. Kim[1], J.Y. Hur[1], K.Y. Lee[1], [1]Precision Medicine Lung Cancer Center, Konkuk University Medical Center, Seoul/KR, [2]Seasun Biomaterials, Daejeon/KR

Introduction: The early detection of lung cancer utilizing low-dose computed tomography (LDCT) screening holds promise for enhancing treatment outcomes. However, while LDCT effectively identifies lung nodules, its capacity to differentiate malignant potential often leads to unnecessary invasive interventions for benign lesions. This study endeavors to address this diagnostic challenge by leveraging epigenetic insights from DNA methylation patterns in bronchoalveolar lavage fluid (BALF) samples obtained from individuals suspected of having lung malignancies.

Methods: In this retrospective marker screening study, DNAs isolated from 138 exosome isolates purified from clinical BALF specimens of patients suspected of lung cancer via LDCT underwent real-time PCR assays targeting differential methylation regions (DMRs) on approximately 80 tumor suppressor genes linked to early lung cancer development. Seven DMRs exhibiting the highest discrimination rate, with an area under the curve (AUC) of ≥ 0.79 between lung cancer and benign conditions, were selected and a lung cancer prediction model was constructed utilizing logistic regression. The validity of the model was independently verified using 100 BALF exosome DNA collected from 65 patients with lung cancer and 35 patients with benign diseases.

Results: In the screening phase, the combination of the seven epigenetic biomarkers which were identified to be specifically methylated in lung cancer BALF samples demonstrated an AUC of 0.97, with 88.24% sensitivity and 97.14% specificity for discriminating lung cancer and benign conditions . Each individual biomarker exhibited statistically significant and higher Mean Methylation Levels (MML) in both non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC) specimens compared to non-cancer groups, with fold-changes ranging from 1.7 to 13.36. MMLs of these biomarkers were found to be moderately elevated with increasing patient age and smoking history, irrespective of patient sex. Additionally, a higher correlation was observed between MML and NSCLC stage progression, with detection sensitivities of 79% for early-stage (stage I, II) NSCLC and 92% for advanced-stage (stage III, IV) NSCLC. In the validation cohort, testing an additional 100 BALF exosome DNA samples using seven-methylation biomarker model yielded an AUC of 0.95, with clinical sensitivity and specificity rates at 94% each. Furthermore, the sensitivity to discriminate NSCLC early stage (I) patients was increased from 88.00% to 92.00% when evaluating the smoking history as an additional risk factor with the combination of the seven epigenetic biomarkers.

Conclusions: This study highlights the potential of BALF exosomal DNA methylation biomarkers to address the limitations of LDCT screening, facilitating the differentiation between lung nodules and cancer. By exploiting the epigenetic landscape, this innovative approach offers a promising avenue for refining diagnostic precision and advancing personalized treatment strategies. Our findings suggest that BALF exosomes harbor cancer-specific biomolecules and may serve as a potent biomaterial for cancer detection, particularly at early stages. Comprehensive validation and further clinical investigations are imperative to fully establish the clinical utility of this pioneering methodology in managing lung nodules.

P4.04C.03 Nodule Type Classification for Lung Cancer Screening with CT

D. Park, J. Kang, C. Park, J. Kim, VUNO Inc., Seoul/KR

Introduction: The American College of Radiology has periodically updated its lung cancer screening guidelines, known as the Lung Imaging Reporting and Data System (Lung-RADS). Despite these updates, distinguishing nodule types—solid, part-solid, and ground-glass nodules (GGN)—remains clinically important. For instance, patient management guideline varies depending on nodule type, even when nodules have the same size. Therefore, precise classification of lung nodule types lays the groundwork for nodule management. Typically, radiologists assess by comparing adjacent pulmonary vessels, because ground-glass opacity refers to an area of increased attenuation that does not completely obscure the underlying bronchial and vascular structures. However, this method is not objective and can lead to observer variability. This variability emphasizes the need for accurate and automated methods to classify nodule types. In response, this study employs commercial software (VUNO Med-LungCT AI) to evaluate its capability in classifying lung nodule types.

Methods: We collected data on 238 patients with nodules from a referral hospital in the United States. Two radiologists reviewed the images and identified 1,896 nodules by consensus. From these, 11 part-solid nodules were excluded. Out of the remaining 1,885 nodules, 1,413 (75%) were used to update the model, and 472 (25%) were used for testing. The test set included 422 (89%) solid nodules and 50 (11%) GGNs. This study used VUNO Med-LungCT AI for nodule type classification.

Results: The classification of 472 nodules yielded an area under the receiver operating characteristic (ROC) curve (AUC) of 0.972 (95% confidence interval [CI], 0.953-0.991). The accuracy was 98.3% for solid nodules (415 out of 422) and 86.0% for GGNs (43 out of 50). Figure 1.A shows the ROC curve, and Figure 1.B displays axial slice CT images from eight cases, incorrectly classified as the opposite type. The qualitative analysis indicates that most of the incorrectly classified nodules were difficult to categorize definitively even by clinicians, because they are small or have ambiguous HU values. This ambiguity means that while some clinicians might classify such nodules as solid, others could identify them as GGN. The classification of these 472 nodules was completed in under one second, demonstrating the software's efficiency in rapid processing.

Conclusions: VUNO Med-LungCT AI demonstrated impressive performance in nodule type classification. Future studies will expand the part-solid and cystic nodules according to the Lung-RADS 2022. With these enhancements, the VUNO Med-LungCT AI is expected to achieve superior performance in Lung-RADS categorization.

P4.04C.04 Epidemiological Characteristics of Incidental Pulmonary Nodules and in China: A Prospective Multicenter Trial of 10,560 Cases

W. Liang[1], D. Liu[2], C. Hu[3], W. Xiao[4], J. Zhang[5], M. Peng[6], S. Wu[6], B. Wang[6], J. He[1], J-B. Fan[7], N. Zhong[8], O. n Behalf of the NCT[03651986] Trial Investigators[9], [1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN, [2]Department of Respiratory Medicine, West China Hospital of Sichuan University, Chengdu/CN, [3]Department of Respiratory Medicine, Xiangya Cancer Center, Xiangya Hospital, Central South University, Changsha/CN, [4]Department of Respiratory Medicine, QILU Hospital, Shandong University, Jinan/CN, [5]Department of Pulmonary Medicine, Xijing Hospital, Air Force Medical University of PLA, Xi'an/CN, [6]AnchorDx Medical Co., Ltd., Guangzhou/CN, [7]Department of Pathology, School of Basic Medical Science, Southern Medical University, Guangzhou/CN, [8]National Clinical Research Center for Respiratory Disease, State Key Laboratory of Respiratory Diseases, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN, [9]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou Institute of Respiratory Disease & Health, China State Key Laboratory and National Clinical Research Center for Respiratory Disease, Guangzhou/CN

Introduction: We are conducting a large-scale prospective clinical trial study (NCT03651986) for assessment of the performance of ctDNA methylation markers for accurate diagnosis and surveillance of incidental pulmonary nodules screened by low dose computed tomography (LDCT) in China. Here we report the epidemiological characteristics of 10,560 pulmonary-nodule participants enrolled at baseline, and clarify the epidemiological and clinical risk factors associated with malignant features.

Methods: A prospective cohort of 10,560 participants with non-calcified pulmonary nodule sized in 5-30 mm indicated by LDCT or CT at 23 clinical centers in China were enrolled between October 2018 and May 2021. The demographic, clinical, CT imaging features and clinical diagnosis at baseline of all participants were collected. Prevalence and epidemiological characteristics were computed and the potential risk factors associated with lung cancer were evaluated by single and multiple factor binary logistic regression

Results: Females (56.6%) made up the majority of the pulmonary nodule patients and they were also younger (53 [45-62]) than the male patients (55 [46-63]) ($p<0.001$). Although 97.1% females and 37.8% males were non-smokers, up to 70% of them had ever been exposed to second-hand smoking. Increasing smoking and occupational exposing rates were observed in females under 30 years old. Benefited from high sensitivity of LDCT/CT, quite amount of small pulmonary nodules (78.2% at 5-10 mm and 17.8% at 10-20 mm) were detected, including 38.5% pure ground-glass nodules (pGGNs), 24.0% mixed ground-glass nodules (mGGNs) and 37.5% solid nodules (SNs), and most of them were solitary (81.24%). pGGNs and mGGNs dominated in females and non-smokers, whereas SNs dominantly in males and smokers. Both female patients and pGGNs had significantly higher rates of family history of cancers ($p\leq0.003$), indicating their unique genetic associations. Approximately 16.0% high-risk patients (median age 55 ([20-82]) were pathologically diagnosed, with 97.32% as lung adenocarcinoma and 90.35% at very early stages (AJCC stage 0-I). Age, female, education level (college or above), multiple target nodules, nodule size, nodule location (upper lobe), nodule type (mGGN and pGGN) and some CT imaging features were the independent risk factors associated with lung cancers. Notably, according to current NCCN guidelines and Chinese Expert Consensus, 13%-14% lung cancer patients were missed from screening and about 20% misdiagnosis rate was observed in SNs and small nodules.

Conclusions: We describe a representative profile of epidemiological characteristics of pulmonary nodules in a largest cohort from China till now. We identified the features related to different nodule types, and risk factors and trends of lung cancer incidence compared to previous studies, which providing a latest fundamental data for future precise clinical management of pulmonary nodules.

P4.04C.05 AI-Assisted CXR Analysis in the Detection of Lung Nodules and Incidental Lung Cancers

S.H. Kwak[1], H.E. Kim[2], J.S. Choi[1], H.J. Shin[1], E.H. Lee[1], [1]Yonsei University College of Medicine, Yongin/KR, [2]Yonsei University College of Medicine, Seoul/KR

Introduction: The use of artificial intelligence (AI) in chest X-ray (CXR) analysis is growing in recent medical environments, and interest in its application is increasing. This study aimed to investigate whether utilizing AI for CXR analysis could lead to the unexpected detection of lung nodules, and to determine the impact of such detections on actual patient diagnosis and management.

Methods: Patients (> 18 years old) who underwent CXR at Yongin Severance hospital and between March 2021 and January 2023, and were identified to have lung nodules through AI software, were retrospectively included in this study. Commercially available AI-based lesion detection software (Lunit INSIGHT CXR, version 3, Lunit Inc., Korea) was used for lung nodule detection.

Results: During this period, 74,385 X-ray procedures were carried out in outpatient clinics excluding hospitalized patients. Out of 40,191 X-rays performed in other clinical departments, excluding respiratory medicine, thoracic surgery, oncology, health screening centers, and emergency rooms, 1,754 cases (4.4%) had lung nodules detected through AI. In the follow-up on this group, about one-third of these patients underwent a CT scan, while two-thirds did not, despite AI-identified abnormalities. Interestingly, the lung nodule abnormality scores, indicating the likelihood of actual nodules, showed no significant difference between the groups that did and did not undergo CT scans. Of the patients conducted CT scan, 71.5% had true nodules, and among these, lung cancer was incidentally discovered in 36 cases (7% of the CT group). These cancer patients, predominantly male with an average age of 74, mainly had adenocarcinoma (55.5%), with 33.3% at stage I and 44.4% at stage IV. The mean AI score for lung cancer was significantly higher (56.7) compared to the general nodule detection score (around 35), highlighting AI's potential in prioritizing high-risk patients.

Conclusions: This study highlights the potential role of AI CXR in lung nodule finding and incidentally detecting lung cancer. Furthermore, the findings emphasize the need for an improved medical information system to connect AI-detected abnormalities with patient examinations and management strategies.

P4.04C.06 DNA Methylation Analysis in Plasma for Early Diagnosis Inlung Adenocarcinoma

J. Yulin, L. Rongguo, The Affiliated Wuxi People's Hospital of Nanjing Medical University, Wuxi/CN

Introduction: Lung adenocarcinoma (LUAD) is the most common type of lung cancer. SHOX2 and RASSF1A methylation are confirmed to be crucial biomarkers for diagnosis and prognosis of lung cancer. Bronchoalveolar lavage fluid (BALF) has high specificity and sensitivity for the diagnosis of lung diseases, while difficulty obtaining and making patients uncomfortable. Clinically, plasma samples are easier than BALF in collection, but there is little research on the combined detection of SHOX2 and RASSF1A methylation in plasma. The aim of this study is to investigate the diagnosis value of combined promoter methylation assay for SHOX2 and RASSF1A in plasma of early LUAD.

Methods: BALF and blood samples were collected from 36 patients with early LUAD. Ten non-tumor patients served as the control group. The promoter methylation levels of SHOX2 and RASSF1A of all subjects were detected by human SHOX2 and RASSF1A gene methylation kit.

Results: The methylation detection rate of SHOX2 and RASSF1A in plasma was 61.11%, which was slightly lower than that in BALF (66.7%). The Chi-square test showed that there was no significant difference in the methylation rate between BALF and plasma ($p > 0.05$). The AUC of receiver operating characteristic (ROC) curve analysis of blood was 0.806 (95% CI, 0.677 to 0.900), while the AUC analysis of BALF was 0.781 (95% CI, 0.649 to 0.881). We also analyzed the correlation of SHOX2 and RASSF1A methylation level in plasma with gender, age, tumor differentiation, pathologic classification and other clinicopathological variables, which were found no significant correlation between them.

Conclusions: Measurement of SHOX2 and RASSF1A methylation level in plasma can be used as a promising noninvasive biomarker for auxiliary diagnosis of early LUAD, with good sensitivity and specificity.

Keywords: Lung adenocarcinoma, DNA methylation, SHOX2; RASSF1A

P4.04C.07 Improving the Efficiency of Lung Cancer Screening Through a Blood-based Lung Cancer Screening Test Prior to Low-Dose CT

L. Cotton[1], P. Bach[1], E. Kazeroonl[2], C. Cisar[1], D. Tennefoss[1], C. Schonewolf[1], M. Wilson[3], C. Magnuson[3], [1]DELFI DIAGNOSTICS, Baltimore/MD/USA, [2]University of Michigan, Ann Arbor/MI/USA, [3]FiscalHealth Group, Lafayette/CO/USA

Introduction: Wide scale lung cancer screening (LCS) to detect early lung cancer (LC) with low dose computed tomography (LDCT) can strain already taxed health-systems, including the systems' radiology infrastructure, and the professionals and services involved in follow-up and evaluation of LDCT findings, including follow-up of incidental non-malignant actionable findings (NAFs). NAF's are common, occurring in 15-25% of scans, and can lead to specialist consultations, invasive work-up, repeated follow-up, and consume patient's time. It is possible that these burdens dampen the enthusiasm of health systems to ramp up LCS rates, which nationally remain below 20%. We evaluated whether initially evaluating screen-eligible individuals with an accessible blood-based screening test (BBT) could reduce the burden of LCS without reducing cancer detection.

Methods: We adapted the LungPLAN model developed by the American Cancer Society, National Lung Cancer Roundtable and The FiscalHealth Group, to a 2021 USPSTF LCS-eligible population with a 0.7% LC prevalence. We compared an LDCT-only screening strategy (A) to a blood-based test (BBT) first screening strategy (B). The LDCT-only strategy was modeled with 1,000 eligibles screened. We then determined how many individuals needed to be screened with a BBT-first strategy to either: (B1) identify the same number of LDCT screen-detected LCs or (B2) result in the same total number of screening LDCTs. In each, we evaluated the number needed to screen (NNS) to detect a LC, and the associated frequency of NAF detection. LDCT was modeled at 93% sensitivity, 76% specificity (99.9% NPV, 2.2% PPV), with 15% of scans identifying NAFs that required workup. We assumed the BBT had an 80% sensitivity, 58% specificity (99.8% NPV, 1.3% PPV) and that 100% and 0% of BBT positive and negative results followed on to LDCT, respectively.

Results: In strategy A, 1,000 LDCTs identified 7 LCs and 153 NAFs, (NNS=143, NAF:LC=22). In strategy B1, 1,250 BBTs resulted in 525 LDCTs identifying 7 LCs and 77 NAFs (NNS=76, NAF:LC=11). In strategy B2, 2,381 individuals received the BBT, followed by 1,000 LDCTs identifying 13 lung cancers and 147 NAFs (NNS=76, NAF:LC=11).

Conclusions: A BBT-first strategy can screen 2.4x more individuals, drive the same number of LDCTs as an LDCT-only strategy, find 1.9x more cancers and reduce the frequency of NAF detection per LC detected. An initial point of care BBT for LCS has the potential to improve the efficiency of screening and reduce the strain on health-systems.

Keywords: blood-based test, lung cancer screening, low-dose computed tomography (LDCT)

Screening Strategy	# of BBTs	# of LDCTs	# of Screen-detected Lung Cancers	Number needed to screen (NNS)	# Non-malignant actionable findings (NAF:LC)
(A) LDCT-alone	n/a	1,000	7	143	153 (21)
(B1) BBT-first: matched for LC detection	1,250	525	7	76	77 (11)
(B2) BBT-first: matched for LDCTs	2,381	1,000	13	76	147 (11)

P4.04C.08 Sensitivity of Artificial Intelligence in Low-dose Computed Tomography Screening for Lung Cancer

A. Mahovkic[1], J. Borgbjerg[1], K. Neumann[1], T.E. Strand[2], H. Ashraf[1,3], [1]Akershus University Hospital, Lørenskog/NO, [2]The Arctic University of Norway, Tromsø/NO, [3]University of Oslo, Oslo/NO

Introduction: Artificial intelligence (AI)-based techniques have emerged as potential aids in the clinical workflow to reduce the burden on radiological specialist resources. The success of a lung cancer screening program is dependent on correct and timely reporting of CT findings, which places a demand on radiologist resources. Therefore, it is important to investigate the feasibility of using AI to optimize the radiological screening workflow as a primary CT reader or potentially as part of fully autonomous reading. In this manner, we have compared the sensitivity of two commercially available AI systems to an experienced radiologist reader in detecting lung cancer in the Norwegian lung cancer screening trial.

Methods: We included patients in whom lung cancer was detected by one thoracic radiologist reader with 10 years of experience in the first round of the Norwegian lung cancer screening pilot study using low-dose computed tomography (LDCT) reconstructed with a lung algorithm. These cases were blindly reviewed in terms of locating lung nodules retrospectively using two commercially available AI software packages designed to detect lung nodules. All nodules identified by the radiologist or clinically within 12 months with histologically confirmed malignancy were considered the gold standard.

Results: The first round of the Norwegian lung cancer screening pilot included 1000 patients, and 23 lung cancers were identified by the thoracic radiologist and clinically within 12 months of follow-up. The radiologist reader, AI software #1, and AI software #2 failed to detect one, four, and two cases, respectively, yielding sensitivity values of 95.7% (95% CI: 87.7-98.6%), 82.6% (95% CI: 71.7-89.9%), and 91.3% (95% CI: 82.0-96.0%), respectively. AI software #2 successfully detected the cancer missed by the radiologist, whereas AI software #1 did not. Only one cancer was missed by both AI software systems: a solid nodule located between emphysematous bullae. Three lesions overlooked by AI software #1 were larger than 3 cm, corresponding to masses. One lesion overlooked by AI software #2 was a ground-glass lesion.

Conclusions: This study indicates that the evaluated AI systems can fairly reliably assist radiologists in low-dose CT-based lung cancer detection in a screening program. However, they lack the sensitivity for autonomous CT readings to completely replace radiologist assessment.

P4.04C.09 Exhaled VOC Detection in Lung Cancer Screening: A Comprehensive Meta-Analysis

X. Fan, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, Guangdong/CN

Introduction: Lung cancer (LC), characterized by high incidence and mortality rates, presents a significant challenge in oncology. Despite advancements in treatments, early detection remains crucial for improving patient outcomes. The accuracy of screening for LC by detecting volatile organic compounds (VOCs) in exhaled breath remains to be determined.

Methods: Our systematic review, following PRISMA guidelines and analyzing data from 25 studies up to October 1, 2023, evaluates the effectiveness of different techniques in detecting VOCs. We registered the review protocol with PROSPERO and performed a systematic search in PubMed, EMBASE and Web of Science. Reviewers screened the studies' titles/abstracts and full texts, and used QUADAS-2 tool for quality assessment. Then performed meta-analysis by adopting a bivariate model for sensitivity and specificity.

Results: This study explores the potential of VOCs in exhaled breath as biomarkers for LC screening, offering a non-invasive alternative to traditional methods. In all studies, exhaled VOCs discriminated LC from controls. The meta-analysis indicates an integrated sensitivity and specificity of 85% and 86%, respectively, with an AUC of 0.93 for VOC detection. We also conducted a systematic analysis of the source of the substance with the highest frequency of occurrence in the tested compounds. Despite the promising results, variability in study quality and methodological challenges highlight the need for further research.

Conclusions: This review emphasizes the potential of VOC analysis as a cost-effective, non-invasive screening tool for early LC detection, which could significantly improve patient management and survival rates.

P4.04C.10 Validation of LungFlag™ Prediction Model Using Electronic Medical Records (EMR) On Taiwan Data

E.N. Choman[1], A. Lanyado[1], E. Israeli[1,2], N. Olghi[3], Y. Jin[2,4], S-Y. Tsai[4], S-Y. Liu[3,4], M. Obradovic[3,5], P-C. Yang[5], [1]Medial EarlySign, Hod Hasharon/IL, [2]F. Hoffmann-La Roche Ltd, Santa Clara/CA/USA, [3]F. Hoffmann-La Roche Ltd, Basel/CH, [4]F. Hoffmann-La Roche, Taipei/TW, [5]National Taiwan University Hospital and College of Medicine, Taipei/TW

Introduction: Lung cancer (LC) is the leading cause of cancer death according to the WHO. In Taiwan, LC accounted for 9,629 deaths in 2020 and contributed one-fifth of total cancer deaths. More than 50% of those are among non-smokers. To reduce mortality rate, starting 2022, the Ministry of Health and Welfare launched the LC Early Detection Program to provide biennial low-dose computed tomography (LDCT) screening for high-risk groups. Multiple risk-scores were developed to identify high-risk populations, among those are dedicated questionnaire based PLCOm2012 and machine learning (ML) structured EMR based LungFlag™. The model was developed using data from Kaiser Permanente Southern California, USA.

Methods: From the National Taiwan University Hospital (NTUH) a dataset composed of individuals with diagnosed LC (cases) and randomly selected individuals without records of LC (controls) was extracted. To determine if EMR data in Taiwan could be used to identify individuals at higher risk of LC, we tested and compared the LungFlag™ model to the mPLCOm2012 model - both using the mentioned extracted EMR data. Inclusion was for ages 40 to 80 between 2010-2022 with minimal mandatory medical information captured in EMR (e.g., demographics, diagnosis, smoking information). Model performance was evaluated by AUC, Sensitivity, Odds-Ratio (OR) indexes for multiple false positive rate (FPR) cut-offs (top 3% and 10%) using bootstrap methodology.

Results: Total data of 65,882 individuals was extracted, 60,751 met the age criteria (10,557 Cases, 50,194 Controls). Average pack-years for ever smokers were 38 and 30 for cases and controls, respectively. Calculation of mPLCOm2012 and LungFlag™ was performed on the diagnosis date for cases, and on a randomly selected date for controls requiring at least 2 years of follow-up period to reduce the potential false negatives.LungFlag™ demonstrated statistically significant superiority over mPLCOm2012 with OR at 3% FPR of 11.7 vs. 5.9 among ever-smokers and 9.0 vs. 4.3 among USPSTF eligible, respectively. Furthermore, LungFlag™ had an OR of 9.9 at FPR of 3% for never smokers and 2.4 for individuals without smoking status.

Conclusions: LungFlag™ was actionable able to work on Taiwanese EMR data, presented superiority over mPLCOm2021. The results were comparable to the previous validation studies. LungFlag™ can potentially support Taiwan screening program in identifying elevated risk populations among ever- and never- smokers and would benefit from more historic data. A model retraining for never smokers using local data should be considered.

Keywords: AI, screening, Taiwan

Table 1: Performance per sub-population:

Sub-Population	Controls	Cases	Model	AUC	False Positive Rate 3%		False Positive Rate 10%	
					Sensitivity %	*Odds Ratio*	*Sensitivity %*	*Odds Ratio*
Ever smokers	4,986	911	$mPLCO_{20}$	0.697 [0.678 - 0.716]	15.3 [12.3 - 18.2]	5.9 [4.5 - 7.2]	33.2 [30.0 - 36.8]	4.5 [3.9 - 5.2]
			LungFlag	0.769 † [0.750 - 0.788]	26.5 † [23.0 - 31.0]	11.7 † [9.7 - 14.5]	46.6 † [42.8 - 50.7]	7.9 † [6.7 - 9.3]
USPSTF	1,035	342	$mPLCO_{20}$	0.702 [0.670 - 0.732]	11.6 [7.5 - 16.8]	4.3 [2.6 - 6.5]	27.2 [22.0 - 33.0]	3.4 [2.5 - 4.4]
			LungFlag	0.762 † [0.733 - 0.791]	21.6 [15.0 - 28.6]	9.0 † [5.8 - 13.0]	41.8 † [34.3 - 47.7]	6.5 † [4.7 - 8.2]
Never Smokers	19,372	2,207	LungFlag	0.649 [0.638 - 0.661]	13.6 [12.5 - 15.0]	9.9 [8.3 - 12.1]	26.6 [25.0 - 28.5]	3.4 [3.1 - 3.8]
Unknown smokers	26,589	7,439	LungFlag	0.581 [0.574 - 0.588]	6.9 [6.6 - 7.2]	5.9 [4.5 - 7.2]	* NA	* NA

* NA - Most patients only have sex and age information – causing same calculated score. Therefore, unable to select ~10% of the population.

P4.04C.11 Pixel-Wise Pulmonary Nodule Growth Prediction on Low-Dose Computed Tomography with 3D-ConvLSTM Deep Neural Network

H. Li[1], J. Jang[2], M. Tang[2], F. Zheng[2], B. Zhang[3], M. Deng[3], H. Chen[1], X. Lu[3,4], [1]Tsinghua University, Beijing/CN, [2]The First Affiliated Hospital of Xiamen University, Xiamen/CN, [3]Zhuhai Hengqin Sanmed Aitech Ltd., Zhuhai/CN, [4]Zhuhai Sanmed Biotech Ltd., Zhuhai/CN

Introduction: Lung cancer, characterized by high incidence and mortality rates, underscores the importance of early diagnosis for better patient outcomes and prolonged survival. Predicting pulmonary nodule growth through pixel-wise nodule mask forecasting from chest CT scans aids in malignancy assessment and treatment planning, holding significant clinical value. However, current methodologies primarily address tumor growth, neglecting specific nodule growth prediction. To fill this gap, we introduce a dedicated neural network designed for precise nodule growth forecasting using CT scans, aiming to enhance diagnostic accuracy and patient care.

Methods: A novel pixel-wise nodule growth prediction network was proposed, featuring surface and distance guidance branches, as depicted in Figure 1(a). The surface-guidance-branch(SGB) captures nodule surface evolution by predicting post-growth surface contours, alongside key point coordinates extracted via PCA. In the distance-guidance-branch(DGB), we address surface clarity challenges in nodule images by predicting distance maps for segmentation results at subsequent time points. Our network was trained on a dataset of 299 patients, each patient with 3 follow-up CT scans, and tested on an independent dataset of 50 patients. All methods received nodule images and corresponding segmentation results at two-time points, tasked with predicting third-time-point outcomes. Dice, IoU and the MAE of the test set and the growth-only test set (nodules with volume growth over 50%) are calculated.

Results: Compared with existing methods such as 3D ResUNet and GM-AE, the quantitative results presented in Table 1 demonstrate the superior performance of our method over other approaches. This highlights the enhanced predictive capability of our model for nodule growth. Image results are depicted in Figure 1(b), showcasing our method's notably accurate predictions, particularly evident in the areas indicated by arrows.

Conclusions: An innovative method was proposed for pixel-wise pulmonary nodule growth prediction and proved its superiority over existing methods on an independent dataset.

P4.04D.01 Gender Disparities in Lung Cancer Screening: A Systematic Literature Review

E. Shum[1], N. Florez[2], J. Brahmer[3], C. Aggarwal[4], H. Wakelee[5], M. Chau[6], R. Shenolikar[6], R. Salomonsen[6], J. Chaieb[6], L. Luciani-Silverman[6], D. Guy[7], L. Woldmann[7], A-A. Ciritel[7], S. Peters[8], [1]NYU Perlmutter Cancer Center, New York/NY/USA, [2]Dana-Farber Cancer Institute, Boston/MA/USA, [3]Johns Hopkins Medicine, Baltimore/MD/USA, [4]University of Pennsylvania Medical Center - Abramson Cancer Center at Perelman Center for Advanced Medicine, Philadelphia/PA/USA, [5]Stanford University School of Medicine, Stanford/CA/USA, [6]AstraZeneca, Gaithersburg/MD/USA, [7]Amaris Consulting, Barcelona/ES, [8]CHUV, Lausanne University, Lausanne/CH

Introduction: Lung cancer screening can lead to earlier detection and reduced mortality. However, disparities in screening criteria, access, and utilization rates may limit the benefits of screening initiatives. Understanding these disparities is critical for optimizing screening strategies and improving lung cancer outcomes. This study seeks to inform more inclusive and effective lung cancer screening approaches that can benefit all individuals at risk, regardless of their smoking history or demographics.

Methods: A systematic literature review was conducted in January 2024 according to PRISMA guidelines to synthesize published observational or interventional literature reporting on gender differences in screening criteria, access, and utilization rates, considering additional factors such as age, race, ethnicity, histology, and socio-economic status. Embase, MEDLINE, MEDLINE In-Process, and Cochrane library databases were searched. Relevant conference proceedings and additional published literature from experts were also considered. English language studies published between January 2004 and February 2024 that reported statistically significant gender differences were included. Data were assessed before and after 2011, considering potential differences following the publication of the National Lung Screening Trial (NLST).

Results: We found 5,166 unique publications, of which 5,116 were excluded based on titles and abstracts, 50 were reviewed in full, of which, 24 were excluded due to lack of reporting on gender differences outcomes. Twenty-six studies covering over 1.4 million individuals were included. Of these studies, fifteen were from North America (NA), five were from Europe, three covered international regions, and two were from Asia. Screening rates were reported in ten studies, of which seven indicated that men in NA and Europe were more likely to undergo screening compared to women (range of OR 1.11 - 2.57). Five studies reporting on screening eligibility for low-dose computed tomography (LDCT) found that more men were eligible for screening than women using U.S. Preventive Services Task Force (USPSTF) criteria (USPSTF 2013: 56.8% - 70.3% vs 46.7% - 65%, USPSTF 2021: 51.4% - 71.8% vs 41.3% - 64.6 %). Two studies from NA suggested that women who had ever smoked were less likely to meet the 30-pack-year criterion than men who actively smoked or had stopped within six months of diagnosis (65.0% vs. 70.3%, p=0.033). Studies that included cases with 20+ pack-years showed a partial reduction in disparity between women's and men's eligibility criteria. This criteria was consistent with revised 2021 USPSTF criteria. Only one of the five studies reporting on screening eligibility included data from before 2011. Findings remained the same when results were assessed before and after NLST publication.

Conclusions: Fewer women are meeting lung cancer screening eligibility suggesting that current screening guidelines do not adequately capture factors affecting women's lung cancer risk. Further, lung cancer screening rates were found higher among men compared to women in NA and Europe. These exploratory findings suggest that further investigation into gender differences is needed.

P4.04D.02 Lung Cancer in Never Smokers and Individuals with a Family History of Lung Cancer: Missed Opportunities for Screening

R. Yip, T. Holton, J. Zhang, H. Chan, S. Kantor, J. Zhu, S. Woode, L. Lentini, D.F. Yankelevitz, C.I. Henschke, Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: Although smoking is the primary risk factor for lung cancer, a significant proportion of lung cancer cases occur in people who have never smoked. Recent research from Taiwan suggested that a family history of lung cancer among first-degree relatives significantly increases risk of lung cancer, particularly for women, and rate of invasive lung cancer with increasing age. However, current lung cancer screening eligibility criteria do not consider these factors. This study aims to examine the prevalence of people who have never smoked and individuals with a family history of lung cancer in the cohort of patients diagnosed and treated for lung cancer.

Methods: 1110 patients diagnosed with first primary lung cancer were enrolled in the prospective cohort, Initiatives for Early Lung Cancer Research on Treatment (IELCART), between 2016 and March 2024. We determined the prevalence of patients who have never smoked, those with a family history of lung cancer, and smokers who do not meet current screening guidelines, their demographic characteristics, and tumor histology.

Results: Among the 1110 patients with first primary lung cancer (45% male, 55% female; median age 70.5), 696 (62.7%) did not meet the current eligibility criteria for lung screening; 192 (27.6%) were never smokers, 333 (47.8%) smokers with <20 pack-years of smoking, and 171 (24.6%) former smokers with 20 or more pack-years but quit more than 15 years ago. Of these 696 patients, 126 (18.1%) had a family history of lung cancer, including 106 (84.1%) with one, 19 (15.1%) with two, and 1 (0.8%) with three or more first-degree relatives with lung cancer. 33 (26.2%) of the 126 were individuals who have never smoked, 57 (45.2%) smokers <20 pack-years, and 36 (28.6%) former smokers who quit more than 15 years ago. Tumor histology among these 126 patients were 13 (10.3%) squamous cell carcinoma, 3 (2.4%) small cell, 12 typical carcinoma (9.5%), 93 (73.8%) invasive adenocarcinoma, and 5 other (4%). Of the adenocarcinomas, 8 (8.6%) were adenocarcinoma-in-situ or minimally invasive adenocarcinoma, 7 (7.5%) were lepidic predominant adenocarcinoma, and 78 (83.9%) were other subtypes.

Conclusions: Our findings highlight that a significant proportion of diagnosed and treated lung cancer patients have never smoked or have a family history of lung cancer, but do not meet the current eligibility criteria for lung cancer screening. The detection of invasive lung cancers of these patients underscores the missed opportunities for early detection and potentially improved outcomes. This study suggests the need for the identification of more risk factors for lung cancer to inform future screening strategies.

P4.04D.03 Lung Cancer in Those Who Never Smoked Study (luCNeSS) - Preliminary Analysis

M. Aglan[1], M. Tammemagi[2], A. Borondy-Kitts[3], P.J. Hesketh[1], K. Rieger-Christ[1], A.J. Piper-Vallillo[1], [1]Lahey Hospital & Medical Center, Burlington/MA/USA, [2]Brock University, St. Catharines/ON/CA, [3]Rescue Lung Society, Amesbury/MA/USA

Introduction: Despite the increasing prevalence of lung cancer among those without a smoking history (LCNS), there is no proven screening modality approved for this population in the US. The Lung Cancer in those who Never Smoked Study (LuCNeSS) is designed to develop and validate an integrated clinical and biomarker-based risk prediction model for LCNS that will identify those likely to benefit from LDCT screening.

Methods: LuCNeSS aims to enroll at least 300 participants (100 with lung cancer, 200 no lung cancer; all <100 lifetime cigarettes) from the Beth Israel Lahey Hospital network to contribute survey data, blood samples, and nasal swabs. Tumor tissue will be collected when available from affected cases. LuCNeSS employs a survey based on an updated version of the PLCOall2014 risk model optimized for performance among those without a smoking history for the development of a clinical risk prediction model. This clinical risk model will be integrated with a methylation-based nasal epithelial biomarker panel to identify those at high risk for LCNS who may benefit from LDCT screening.

Results: Since November 2021, LuCNeSS has enrolled 26 case and 26 control participants with recruitment ongoing. As of this preliminary March 2024 data analysis, the average age of participants is 65 years, 63% are female. Among case participants, the average age at lung cancer diagnosis was 66 years with adenocarcinoma (ADC) histology predominant (69%). 62% of case participants presented with stage I-III disease (14/16 stage I/II) versus 35% with metastatic disease. Of those with ADC histology and advanced disease, 8/9 had actionable driver alterations (5 EGFR mutant; 2 MET exon 14 skipping; 1 ALK fusion). 9/26 case participants (vs 5/26 control) reported 1st or 2nd degree relatives with lung cancer history and 12/26 reported 1st degree relatives with non-lung cancer diagnoses (versus 11/26 among control participants). Reported environmental exposures linked to lung cancer risk were similar among case and control participants (9 case vs 7 control) as was reported exposure to secondhand smoke (18 case and 18 control). Blood and nasal swab epithelial samples were collected from 51 participants and tumor tissue from 10 case participants. Nasal swab epithelial sample methylation analysis is planned to begin once enrollment has reached 30 case and 60 control participants.

Conclusions: Preliminary results from LuCNeSS are presented here to highlight an ongoing effort to identify a clinical and biomarker-based risk profile for LCNS, emphasizing the role of environmental and potential genetic factors and strengthened by the case-control design. Continued accrual will allow for refining the clinical model (PLCOall2014) and integrated clinical and biomarker risk model (PLCOall2014PLUS) for prospective assessment in identifying a LCNS high-risk population likely to benefit from LDCT.

P4.04D.04 Efficiency of the Annual CT Screening Interval for Those at a Lower Risk of Lung Cancer - A CISNET Comparative Modelling Study

K. de Nijs[1], H.J. de Koning[1], P. Cao[2], H. Mahmoudi[3], M. Diasporra[4], R. Garner[4], J. Jeon[5], E.J. Feuer[6], J.H.E. Yong[7], S. Gazelle[3], R. Meza[8], K. ten Haaf[1], [1]Erasmus University Medical Center, Rotterdam/NL, [2]Unversity of Texas MD Anderson, Houston/TX/USA, [3]Massachussets General Hospital, Boston/MA/USA, [4]Statistics Canada, Ottawa/ON/CA, [5]University of Michigan, Ann Arbor/MI/USA, [6]National Cancer Institute, Bethesda/MD/USA, [7]Canadian Partnership Against Cancer, Toronto/ON/CA, [8]BC Cancer Research Institute, Vancouver/BC/CA

Introduction: The United States Preventive Services Task-Force (USPSTF) recommends individuals aged 50-80 with 20 pack-years of smoking history and less than 15 years since smoking cessation to be screened annually. Other countries are issuing similar recommendations, with some opting for biennial screening out of concern for radiological capacity. Modelling studies have shown benefits and harms of annual relative to biennial screening, but it is unknown whether the benefits of annual screening can be preserved when adapting the screening interval to the age, sex and smoking exposure of participants.

Methods: We perform a comparative modelling study with models from the Cancer Intervention and Surveillance Modeling Network (CISNET) lung working group. We evaluate screening strategies that adapt screening between annual and biennial intervals according to the age, sex and smoking exposure of participants. We consider a 1965 U.S. birth cohort, stratified by sex and smoking exposure at age 50 (<20, 20-30, 30+ packyears). Various age-adaptive strategies using USPSTF smoking eligibility criteria are simulated: annual screening ages 50-80, biennial screening ages 50-80, starting (ages 50-60) or ending (ages 70-80) with 10 years of biennial screening, or both starting and ending with 10 years biennial screening, but annual screening otherwise. To study cost-effectiveness, we calculate Quality-Adjusted Life-Years (QALYs) gained, and SEER-Medicare derived costs of treatment as well as costs of computed-tomography (CT) and follow-up. We assumed a willingness-to-pay threshold of $100k/QALY gained for cost-effectiveness.

Results: We find that starting with biennial screening for ages 50-60, followed by annual screening, retains most benefits with fewer CT scans (Figure 1). Particularly for those meeting USPSTF criteria at lower smoking exposure (e.g., 20-30 pack-years for women), this strategy preserves 95% of lung cancer deaths prevented from this strategy, compared to annual screening, with 27% fewer screens. Annual screening is cost-effective for men ages 50-80 with >30 pack-years (ICER $89,829). For females and males who smoked less, 10 years of biennial screening ages 50-60, followed by annual screening ages 61-80, is preferred over annual screening from ages 50-80.

Figure 1 reports estimated deaths prevented and required CT screens for annual screening (ages 50-80 per USPSTF), biennial screening ages 50-60 followed by annual screening, and biennial screening. Results are stratified by sex and smoking exposure at age 50, and scaled per 100,000 individuals alive at age 45.

Conclusions: In resource-constricted settings, CT scans every two years instead of annually for younger participants with less than 30 pack-years maintain screening effectiveness.

Introduction: Lung cancer screening (LCS) with low dose computed tomography (LDCT) chest confers a mortality benefit in individuals at risk due to cigarette smoking. The importance of family history of lung cancer (FHx) has not been well-defined in this setting. We evaluated FHX as a predictive factor for lung cancer detection in participants in the International Lung Screen Trial (ILST), a prospective, multi-centre cohort study of LDCT in LCS (NCT02871856).

Methods: A post-hoc analysis of all Australian and Canadian participants compared lung cancer detection rates stratified by sex and family history. Univariable logistical regression was used to determine risk factors to include in the multivariable model from the following: age, body mass index (BMI), chronic obstructive pulmonary disease (COPD), personal history of cancer, FHx, smoking pack-years, years since smoking cessation and current smoking status. Risk factors with p-value<0.1 were included in the multivariable analysis to determine independent predictors of lung cancer detection. Continuous and categorical variables were reported as mean±standard deviation and count (%) respectively. Comparison of continuous and categorical variables were conducted using the Mann-Whitney U-test or Chi-Squared test respectively. A p-value <0.05 was deemed statistically significant.

Results: 4309 ILST participants were included of which 3941 (92%) were Caucasian and 2040 (47%) were female. 155 lung cancers were detected with an overall detection rate of 3.6%. There were no significant differences in detection rate based on sex [male 71 (3.1%) vs female 84 (4.1%), p=0.082] or FHx [Fhx 49 (4.3%) vs No Fhx 106 (3.3%), p=0.126]. The results of univariable and multivariable logistic regression analysis are presented in Table 1. Multivariable analysis identified two independent predictors of lung cancer detection in men: age [OR 1.06, 95% CI 1.04 -1.08, p=0.003] and smoking history [OR 1.01, 95% CI 1.01 - 1.02, p=0.001]. Multivariable analysis identified three independent predictors of lung cancer detection in women: age [OR 1.07, 95% CI 1.05 - 1.09, p<0.001], smoking history [OR 1.01, 95% CI 1.01 - 1.02, p=0.033] and FHx [OR 1.58, 95% CI 1.26 - 1.99, p=0.047].

Conclusions: Family history of lung cancer is an independent predictor of lung cancer detection in female participants of the ILST. The inclusion of family history in LCS selection criteria may optimize equity of access to future screening programs.

P4.04D.06 Improving Lung Cancer Risk Prediction in Asbestos Exposed Individuals: An Ensemble Approach

C. Kumarasamy[1], K. Betts[1], R. Norman[1], A. McWilliams[2], E. Stone[3], D.C-L. Lam[4], R. Manser[5], P. Fogarty[6], H. Marshall[7], S. Lam[8], M.C. Tammemägi[9], K.M. Fong[7], S. Atkar-Khattra[8], F. Brims[1], [1]Curtin University, Perth/AU, [2]Fiona Stanley Hospital, Perth/AU, [3]St Vincent's Hospital, Sydney/AU, [4]The University of Hong Kong, Hong Kong SAR/CN, [5]The Royal Melbourne Hospital, Melbourne/AU, [6]Epworth Internal Medicine Clinical Institute, Melbourne/AU, [7]The Prince Charles Hospital, Brisbane/AU, [8]BC Cancer, Vancouver/BC/CA, [9]Brock University, St Catharines/ON/CA

Introduction: Most lung cancer (LC) risk prediction models do not adequately account for risk due to asbestos exposure and none for the relative excess risk due to interaction (RERI) of asbestos and tobacco smoking. The aim of this study was to develop a LC risk model specific for asbestos exposed populations, by modelling complex interactions through ensemble machine learning.

Methods: Lung cancer risk models were trained on 1,357 participants from the Western Australian Asbestos Review Program (ARP), aged 45-90, with a smoking history (42 with lung cancer). All participants had ≥3 months asbestos exposure and underwent LDCT screening over 10-years. Validation was performed on 469 participants from the International Lung Screening Trial (ILST) with ≥3 months of asbestos exposure. Variables for risk prediction included: age, sex, body mass index (BMI), chronic obstructive pulmonary disease, tobacco exposure variables, family lung cancer and personal cancer history, and asbestos exposure duration.

Logistic regression and gradient boosted trees were used to build risk models in the training data using 10-fold cross-validation, with the 'best' performing model selected according to the AUC-ROC. Selected models were benchmarked against the performance of the PLCOm2012 model in the validation cohort. The predictions from the best performing models were selected and combined using weighted averaging to develop the ARP-1 ensemble model.

Results: The gradient boosted tree model was the best performing individual model in the validation data (AUC:0.797; 95%CI 0.693-0.901), improving over the PLCOm2012 model (AUC:0.687, 95%CI 0.502-0.872) in predicting the 12 cancers in ILST validation cohort. The logistic regression (LR) model performed better with asbestos exposure duration included solely as an interaction with smoking intensity (AUC:0.771; 95%CI 0.588-0.954), than as an independent variable (AUC:0.763; 95%CI 0.582-0.944). The variables: age, education, BMI, asbestos exposure duration and tobacco exposure duration/ intensity provided the strongest performance benefit in validation.

The best performing gradient boosted tree and LR models were combined using weighted averaging of predicted probabilities to develop the ARP-1 ensemble model: This model demonstrated improved performance over its constituent models in validation (AUC:0.816; 95%CI 0.698-0.935; Figure 1), with good mean calibration.

Conclusions: The ARP-1 model is the first LC prediction model to account for the RERI of asbestos and tobacco exposure. Given the widespread asbestos exposure in many countries, ARP-1's performance highlights the need for cohort specific models that account for interactions in lung cancer. Further external validation is required due to the small validation cohort.

P4.04D.07 Lung Cancer Biomarkers in Nonsmokers: Diagnostic and Prognostic Use of Liquid Biopsy for Metabolites Found in the Urine

B. Dalal[1], T. Tada[1], D.P. Patel[1], S.R. Pine[2], M. Khan[1], T. Oike[1], Y. Kanke[1], A.L. Parker[1], M. Haznadar[1], L. Toulabi[1], K.W. Krausz[1], A.I. Robles[1], E.D. Bowman[1], F.J. Gonzalez[1], C.C. Harris[1], [1]National Cancer Institute, Bethesda/MD/USA, [2]University of Colorado Anschutz Medical Campus, Aurora/CO/USA

Introduction: Ten to thirteen percent of lung cancer cases in the United States are caused by nonsmokers. Etiology is linked to several risk variables, such as exposure to secondhand smoke, asbestos, environmental pollution, and radon, but these exposures are not within the current eligibility criteria for early lung cancer screening by low-dose computed tomography (LDCT).

Methods: The urine samples were collected from two independent cohorts comprising 846 participants (exploratory cohort) and 505 participants (validation cohort). Liquid chromatography-mass spectrometry was used to analyze and quantify the cancer urine biomarkers, creatine riboside (CR) and N-acetylneuraminic acid (NANA), to identify and distinguish non-smoker cases from sex and age-matched controls in comparison with tobacco smoker cases and controls. This could lead to more precise eligibility criteria for LDCT screening.

Results: Urinary levels of CR and NANA were significantly higher and comparable in non-smokers and tobacco smoker cases as compared to population controls in both cohorts as shown in Figure 1. Receiver Operating Characteristics (ROC) analysis for combined CR and NANA levels in non-smokers of the exploratory cohort resulted in better predictive performance with the area under the curve (AUC) of 0.94, whereas the validation cohort never-smokers had an AUC of 0.80. Kaplan-Meier survival curves demonstrated that high levels of these biomarkers corresponded with an increase in cancer-specific mortality in both non-smokers and tobacco smokers. Biomarkers metabolite category factor and stage were significant independent predictors of survival in multivariate analyses for both cohorts as shown in Figure 2.

Conclusions: Prospective investigations of these biomarkers are warranted, since measuring them in urine liquid biopsies may identify nonsmokers at high risk for lung cancer and make them candidates for LDCT screening.

P4.04D.08 Natural History Model for Second Primary Lung Cancer Among Lung Cancer Survivors: Utilizing the U.S. SEER Cancer Registries

E. Choi[1], V. Ritter[2], J.H. Lee[2], J.T. Wu[3], K. ten Haaf[4], C.C. Su[2], L.M. Backhus[2], A.N. Leung[2], H.A. Wakelee[2], S.S. Han[2], [1]Weill Cornell Medicine, New York/NY/USA, [2]Stanford School of Medicine, Palo Alto/CA/USA, [3]Veterans Affairs Palo Alto Health Care, Palo Alto/CA/USA, [4]Erasmus Medical Center, Rotterdam/NL

Introduction: Recent advances in early detection and treatment have doubled survival rates for lung cancer patients. This extended survival gives rise to a subsequent risk of second primary lung cancer (SPLC), which may require tailored screening strategies. Evaluating the potential benefits of computed tomography screening for SPLC relies on the ability to ascertain when tumors are detected at a curable size. A natural history model (NHM) can provide a mechanistic framework that predicts the expected time course of tumor growth of SPLC, which may differ from initial primary lung cancer (IPLC). Further, an NHM can be incorporated into a microsimulation model that can evaluate efficient screening strategies by simulating individual-level outcomes in the absence or presence of hypothetical screening strategies. However, at this time, SPLC lacks an NHM, with existing NHMs for lung cancer developed using survival data that include patients with both single and multiple primary lung cancers for model parameter estimation. This study aims to develop a separate NHM for SPLC vs. IPLC and to compare their tumor characteristics.

Methods: We utilized data from 250,380 patients diagnosed with primary lung cancer between 1992-2013 in SEER database for 13 registries (i.e., SEER-13). The original Stanford NHM for lung cancer—that did not separate IPLC and SPLC—was previously developed using SEER for 9 registries (i.e., SEER-9; 1988-2003). Using SEER-13, we re-fitted the NHM for IPLC using lung cancer survival data (by stage and tumor size) from patients who had a single diagnosis (i.e., IPLC) in their lifetime, thus separating out SPLCs. Then, we newly developed an NHM for SPLC using data from patients who developed SPLC after ≥5 years from IPLC. The model parameters were estimated using a stepwise maximum-likelihood by histology and sex. We compared the estimated outcomes (survival, stage, tumor size) using the NHMs vs. observed data from SEER-13.

Results: The estimated survival using the NHMs from IPLC and SPLC closely resembled those observed in SEER-13 (log-rank P>0.1). After separating out SPLCs, the TVDT of the IPLC-specific NHM was shorter (i.e., fast-growing) vs. the original NHM (e.g., 65 vs. 128 days for male-adenocarcinoma), which was expected because the latter NHM included those who survived extended time (≥5 years) until developing SPLC. When comparing the NHMs for SPLC vs. IPLC, we observed a larger proportion of SPLCs that were clinically detected at an early-stage vs. IPLC (e.g., 71.0% vs. 56.6% in male-adenocarcinoma in SEER), with a smaller median tumor size at clinical detection (e.g., 2.5cm vs. 3.8cm in male-adenocarcinoma in SEER). However, the TVDT of SPLC was similar to IPLC (e.g., 64 vs. 67 days for male-adenocarcinoma), suggesting that once SPLC is developed, its tumor growth rate may be similar to IPLC.

Conclusions: We developed an NHM for SPLC by separating it from the natural history of IPLC. The tumor growth rate of SPLC may be comparable to IPLC, although SPLC tends to be detected earlier potentially due to post-diagnosis surveillance. This work can serve as a foundation for future microsimulation studies to evaluate tailored screening for SPLC.

P4.04D.09 Assessing the Risk of Second Primary Lung Cancer in Women after Previous Breast Cancer

J. Huang, Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: Advances in early diagnosis and treatment have improved breast cancer (BC) patients' prognosis and prolonged survival, also increased risk for developing a new (second) cancer compared to non-BC survivors. Lung cancer (LC) is of particular concern as it is the most common cancer among BC survivors, but it is unclear whether a history of BC is an independent risk factor for LC.

Methods: Women aged 54 to 75 were identified from prostate, lung, colorectal, and ovarian (PLCO) screening trial. Pre-PLCO BC diagnosis as well as incident breast cancer during follow-up through 2017 were ascertained. We then calculated unadjusted incidence rates of LC among BC survivors. BC was then included as a time-updated exposure in a multivariable Cox regression modeling LC incidence, adjusting for established LC risk factors

Results: The study included 75,951 female PLCO participants, of whom 8,504 (11.2%) were BC survivors, including 5,808 with BC diagnosed after enrollment in PLCO and 2,696 with BC diagnosed prior to enrollment. The median follow-up for BC survivors was 13.37 years. BC survivors were slightly older (p<0.0001), more likely to be white non-Hispanic (WNH), college graduates or with advanced degree, former cigarette smokers (all p<0.05) than non-BC survivors. Overall, unadjusted incidence rate (IR) of 191.7 per 100,000 person-years (95% confidence interval [CI]; 167 -219) compared to IR of 143 per 100,000 person-years non-BC survivors (95% CI; 136 -150). The adjusted hazard ratio (HR) associated with BC for LC was 1.26 (95%CI: 1.09, 1.45) compared to female subjects without BC.

Conclusions: Our results suggest that the history of BC is an independent risk factor for the incidence of LC. BC survivors may therefore have increased benefit from LC prevention interventions including low-dose computed tomography screening.

P4.04D SCREENING AND EARLY DETECTION - REVISING LUNG CANCER SCREENING ELIGIBILITY
MONDAY, SEPTEMBER 9, 2024 - 18:30 - 20:00

P4.04D.10 Risk-Based LDCT Screening for Non-smokers in Taoyuan, Taiwan, Y-L. Liu1, C-y. Yeh1, Y-c. Yu1, T-M. Huang1, H-H. Lin1, K-J. Chuang2, 1Department of Public Health, Taoyuan, Taoyuan/TW, 2Taiwan Association of Medical Screening, Taipei/TW

Introduction: Lung cancer poses a significant challenge to global health, affecting not only smokers but affecting never-smokers, especially in Asia Female. While current evidence supports the use of LDCT for heavy smokers, the design and implementation of LDCT screening for non-smoker remain in debate, even in the face with soaring disease burden among this group. To address this issue, a risk-based low-dose computed tomography (LDCT) screening program was initiated for non-smokers in Taoyuan, Taiwan.

Methods: The Taoyuan City lung cancer screening program targets non-smokers aged 40 to 74 with specific risk factors such as long-term occupational exposure to carcinogens (asbestos, arsenic, cadmium, nickel, and dust), family history of lung cancer, personal breast cancer history, and household passive smoke exposure. It provides triennial LDCT scans for early lesion detection. Eligibility extends to individuals in industrial areas or exposed to pollution, including Police, Fire Department, Funeral Management Office personnel, night market workers exposed to cooking oil fumes, and temple workers exposed to incense, with over a decade of exposure. Utilizing the Lung-RADS system, it identifies positive scans (category 3 and above) for further diagnostics to confirm lung cancer diagnoses, aiming to enhance early detection and management in Taoyuan.

Results: The Taoyuan City lung cancer screening program for non-smokers, conducted from March 1 to December 31, 2023, accessed 13,446 residents, with 949 testing positive (7.06% positivity rate) and 74 diagnosed with lung cancer (0.55% detection rate). Notably, females, older residents (55+ years), and those with junior to senior high school education had higher detection rates. A significant risk increase was observed in individuals with a family or personal history of cancer, specifically lung (0.93% vs. 0.53%) and breast cancer (2.05% vs. 0.51%). Long-term exposure (10+ years) to cooking oil fumes and carcinogenic substances, along with household passive smoke exposure, also correlated with elevated detection rates. Multivariable logistic regression analysis revealed a statistically significant higher risk of lung cancer among attendees with a family history (aOR: 3.27, 95% CI: 1.43-7.50) and a history of breast cancer (aOR: 4.63, 95% CI: 1.86-11.5). Occupational exposure to carcinogenic substances (aOR: 4.06, 95% CI: 0.52-31.9) and exposure to cooking oil fumes (aOR: 1.58, 95% CI: 0.60-4.16) showed increased risks, albeit not statistically significant. Similar trends were observed for industrial workers (aOR: 1.58, 95% CI: 0.82-3.03) and field personnel of the Police and Fire Departments (aOR: 1.36, 95% CI: 0.48-3.82), indicating a need for targeted screening in high-risk groups. The results Bayesian Hierarchical model taking into account relevant factors with the concentration of PM2.5 as a township level factor showed the significant risk of lung cancer detection in the five townships (Guishan, Luzhu, Taoyuan, Bade, Dayuan) for female and two townships for male (Taoyuan, Daxi), showing the necessity of a gender-specific strategy to enhance lung cancer screening for residents in these areas.

Conclusions: The Taoyuan risk-based LDCT screening program proves the effectiveness in identifying lung cancers among non-smokers. This informs targeted LDCT screenings to address increasing lung cancer rates in Asia, aiming to improve early detection and reduce mortality.

Keywords: Lung cancer, Low-dose CT screening, non-smoker

P4.07D.01 Neoadjuvant Osimertinib Followed by Radiation And/or Surgery in Stage III EGFR-Mutant NSCLC: An Open-Label, Single-Arm, Phase 2 Study

N. Peled[1], W. Kian[2], B. Krayim[1], J. Dudnik[3], S. Keren-Rosenberg[4], I.S. Granot[1], H. Nechushtan[5], N. Heching[1], O. Rotem[6], E. Dudnik[7], I. Lazarev[2], E. Chernomordikov[7], W. Shalata[3], D. Levin[3], Y. Krutman[3], K. Lavrenkov[3], P. Blumenfeld[5], A.M. Allen[1], L.C. Roisman[1], [1]Helmsley Cancer Center, Shaare Zedek Medical Center, Jerusalem/IL, [2]Assuta Ashdod Medical Center, Ashdod/IL, [3]Legacy Heritage Center & Dr Larry Norton Institute, Soroka Medical Center & Ben-Gurion University of the Negev, Beer Sheva/IL, [4]Lin Medical Center, Haifa/IL, [5]Hadassah Medical Center, Jerusalem/IL, [6]Thoracic Cancer Unit, Davidoff Cancer Center, Beilinson Campus, Rabin Medical Center, Petach Tikvah/IL, [7]Assuta Medical Center, Tel Aviv/IL

Introduction: The standard treatment for unresectable, locally advanced stage III non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (EGFR) mutations involves concurrent chemoradiation therapy (cCRT) followed by durvalumab. The consolidation treatment might change to osimertinib following the announced positive results of the LAURA study. This study aimed to assess the potential advantages of using neoadjuvant osimertinib as an alternative therapeutic option and to minimize the radiation field.

Methods: This ongoing study is an open-label, single-arm, phase 2, prospective, proof-of-concept, investigator-initiated study. The study focused on patients diagnosed with treatment-naïve unresectable, stage III EGFR+ NSCLC. Participants received 80 mg of oral osimertinib daily for 12 weeks before undergoing definitive radiation therapy (RT) and/or surgery. Response assessments occurred at weeks 6 and 12, with responders proceeding to sequential definitive RT and/or surgery and nonresponders transitioning to cCRT. Patients were monitored for 2 years following RT ± surgery or CRT. The primary endpoint is the objective response rate (ORR), for which data collection will continue until March 31, 2024. The secondary endpoints included safety evaluations and measurements of gross tumor volume (GTV), planned tumor volume (PTV), and the percentage of total lung volume minus the GTV exceeding 20 Gy (V20%) before and after osimertinib treatment. Exploratory analyses involved assessing the presence of plasma circulating tumor-free DNA before osimertinib treatment, at weeks 6 and 12, at RT completion, and at 6 weeks post-RT.

Results: The study enrolled 34 patients, including 26 women, with a median age of 71 years (range: 48-83). Of these, 18 had EGFR exon 19 deletions, and 16 had EGFR exon 21 mutations. Participants had stage IIIA (13), IIIB (10), or IIIC (11) disease. Three patients withdrew from the study and were consequently excluded from the analysis. The ORR to osimertinib was 94% (26 partial responses, 3 complete responses, 1 stable disease, and 1 progressive disease). Initial assessment of 19 patients revealed that the median GTV, PTV and V20% before osimertinib treatment were 47.4 ± 76.9 cm3, 227.0±258.8 cm3, and 27.1±16.4%, respectively. After osimertinib treatment, these values changed to 27.5 ± 42.3 cm3 (representing a reduction of 48 ± 20%; P = .02), 181.9 ± 198.4 cm3 (representing a reduction of 31 ± 20%; P = .01), and 21.8 ± 11.7% (representing a reduction of 24 ± 40%; P = .04), respectively. The reduction in PTV/GTV/V20% correlated with tumor size and central location. No significant adverse events were reported during the osimertinib or radiation phases.

Conclusions: Neoadjuvant osimertinib in stage III EGFR+ NSCLC patients who received definitive radiation and/or surgery was shown to be feasible in this pilot study, achieving an impressive ORR of 94% along with a favourable safety profile. The 12-week induction of osimertinib before definitive radiation (without chemotherapy) notably decreased the radiation field by almost 50%, demonstrating a direct correlation with tumor size. Additional studies are necessary to evaluate the long-term efficacy of this chemotherapy-free strategy.

P4.07D.02 Furmonertinib as Adjuvant Therapy in Postoperative EGFR-Mutated Stage IB-IIA NSCLC with High-Risk Pathological Factors

X-L. Li, X. Wang, J. Fan, Shanghai General Hospital, Shanghai/CN

Introduction: Non-small cell lung cancer (NSCLC) patients with high-risk pathological factors such as micropapillary (MP), solid (S), and spread through air spaces (STAS) have shown poor prognosis in previous studies. Furmonertinib (AST2818) is a novel, promising oral third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), which has demonstrated efficacy in tumors harboring sensitive EGFR mutations and T790M resistance mutation. Here, we investigated the efficacy and safety of furmonertinib as adjuvant therapy in postoperative EGFR-mutated NSCLC patients with high-risk pathological factors.

Methods: Patients who underwent radical lung cancer surgery with both EGFR mutations and MP/S/STAS were enrolled and received furmonertinib 80mg daily. The disease-free survival (DFS), safety and tolerability were evaluated.

Results: This study has prospectively enrolled 52 patients who were pathologically confirmed adenocarcinoma, EGFR mutation positive (exon 19 deletion/L858R), stage IB-IIA NSCLC. All of them had at least one high-risk pathological factor. There were 37 patients with MP, 6 with S, and 33 with STAS. By the cut-off date of March 1, 2024, all patients were alive and with no radiographic recurrence. The median follow-up time was 16.5 months. During therapy, 15 (28.8%) patients had treatment-related adverse events (TRAEs) of any grade. The most common TRAEs were rash (13, 25%), diarrhea (4, 7.7%) and mouth ulcer (1, 1.9%). Only 1 (1.9%) patient had TRAEs of grade 3 or higher.

Conclusions: This is the first prospective study to demonstrate that furmonertinib has good efficacy and a tolerable safety profile as adjuvant therapy in EGFR-mutated early NSCLC patients with high-risk pathological factors who underwent radical lung cancer surgery.

P4.07D.03 Phase 2 Peri-Operative Study of Fianlimab+Cemiplimab+Chemotherapy vs Cemiplimab+Chemotherapy in Resectable Early-Stage NSCLC

L. Paz-Ares[1], N. Girard[2], A. Spira[3], U. Chaudhry[4], M. Ghattas[4], S. Li[4], M. Salvati[4], I. Lowy[4], M.G. Fury[4], L. Paoluzzi[4], [1]Complutense University of Madrid, Madrid/ES, [2]Curie-Montsouris Thorax Institute, Paris/FR, [3]Virginia Cancer Specialists, Fairfax/VA/USA, [4]Regeneron Pharmaceuticals, Inc., Tarrytown/NY/USA

Introduction: Co-blockade of lymphocyte-activation gene 3 (LAG-3) may enhance the efficacy of anti–programmed cell death-1 (anti–PD-1) therapies. Fianlimab (anti–LAG-3) and cemiplimab (anti–PD-1) are high-affinity, fully human, IgG4 monoclonal antibodies. In a Phase 1 study (NCT03005782), fianlimab + cemiplimab showed promising clinical activity with durable responses and an acceptable risk-benefit profile in patients with advanced non-small cell lung cancer (NSCLC) who were anti–PD-1/L1-naïve. The use of IO + chemotherapy in the peri-operative setting is established as a new standard of care, but is still under active investigation to potentially improve outcomes in early-stage disease.

Methods: This is a randomized, multicenter, double-blind, Phase 2 peri-operative study (NCT06161441) in patients with early-stage resectable stage II to stage IIIB (N2), squamous or non-squamous histology, operable, treatment-naïve NSCLC, to be treated with neoadjuvant therapy, followed by surgery and subsequent adjuvant therapy. The aim of this study is to investigate the efficacy and safety of fianlimab + cemiplimab + chemotherapy versus cemiplimab + chemotherapy as peri-operative treatment. The study will be conducted globally at approximately 130 sites. Key inclusion criteria: 1) age ≥18 years; 2) newly diagnosed, histologically confirmed, fully resectable stage II to IIIB (N2) NSCLC; 3) for patients with evidence of mediastinal adenopathy on imaging, mediastinal lymph node sampling is required; 4) no evidence of distant metastases on imaging; 5) evaluable PD-L1 immunohistochemistry results; 6) no cancer treatment within the prior 3 years, except adjuvant hormone therapy for hormone-sensitive cancers in long-term remission; 7) Eastern Cooperative Oncology Group Performance Status ≤1; 8) no known EGFR mutations or ALK aberrations; 9) adequate organ and bone marrow function. All patients enrolled in the study will be stratified by clinical TNM stage at randomization (stage II versus stage III), histology (non-squamous versus squamous), and PD-L1 expression (<1%, 1–49%, ≥50%). Approximately 180 patients will be randomized (1:1:1) to the following study arms for the neoadjuvant period (up to 4 cycles; each cycle is every 3 weeks): Arm A: placebo + cemiplimab 350 mg + platinum doublet chemotherapy; Arm B: fianlimab Dose 1 + cemiplimab 350 mg + platinum doublet chemotherapy; Arm C: fianlimab Dose 2 + cemiplimab 350 mg + platinum doublet chemotherapy. After surgery, in the adjuvant period (up to 14 cycles), all arms will continue study treatment at the same dose and schedule according to prior randomization, without platinum doublet chemotherapy. Patients will be treated for up to approximately 12 months (12 weeks of neoadjuvant therapy + 42 weeks of adjuvant therapy), or until recurrence of disease, unacceptable toxicity, patient's decision, or investigator's decision. The primary endpoint is pathological complete response by blinded independent pathological review (BIPR). The key secondary endpoints are event-free survival by investigator assessment, major pathological response by BIPR, tumor response by investigator assessment, safety, pharmacokinetics, immunogenicity, and patient-reported outcomes. In addition, there are two Phase 2/3 studies (NCT05785767 and NCT05800015) exploring fianlimab + cemiplimab ± chemotherapy in first-line patients with metastatic NSCLC.

P4.07D.04 Trofuse-019: A Phase 3 Study of Adjuvant Pembrolizumab with or without Sac-TMTfor Resectable Stage II-IIIB (N2) NSCLC

J.M. LEE[1], B-C. Liao[2], J. Spicer[3], T. Newsom-Davis[4], R. Hui[5], Y. Xu[6], A. Song[6], A. Samkari[6], M. Hochmair[7], [1]David Geffen School of Medicine at UCLA, Los Angeles/CA/USA, [2]Department of Medical Oncology, National Taiwan University Cancer Center, Taipei/TW, [3]Division of Thoracic Surgery, Department of Surgery, McGill University Health Centre, Montreal/QC/CA, [4]Department of Oncology, Chelsea and Westminster Hospital, London/GB, [5]Centre of Cancer Medicine, University of Hong Kong, Hong Kong and University of Sydney, Sydney/AU, [6]Merck & Co., Inc., Rahway/NJ/USA, [7]Department of Respiratory and Critical Care Medicine, Karl Landsteiner Institute of Lung Research and Pulmonary Oncology, Vienna/AT

Introduction: The phase 3 KEYNOTE-671 study demonstrated significantly improved clinical outcomes with neoadjuvant immunotherapy plus chemotherapy followed by surgery and adjuvant immunotherapy versus neoadjuvant chemotherapy alone followed by surgery in patients with resectable early-stage non-small-cell lung cancer (NSCLC). However, patients in both treatment arms in KEYNOTE-671 who did not achieve a pathological complete response (pCR) had worse outcomes. Additional treatment in the adjuvant setting may improve long-term outcomes in patients who do not achieve pCR following neoadjuvant immunotherapy plus chemotherapy followed by surgery and adjuvant immunotherapy. Trophoblast cell-surface antigen 2 (TROP2; cell-surface glycoprotein) is overexpressed in several cancers, including NSCLC. Sacituzumab tirumotecan (sac-TMT; formerly MK-2870/SKB264) is an antibody-drug conjugate composed of humanized anti-TROP2 monoclonal antibody, a hydrolytically cleavable linker, and the cytotoxic drug KL610023. In a phase 2 study, sac-TMT demonstrated encouraging antitumor activity and manageable toxicity in patients with advanced NSCLC. Here, we describe the phase 3 TroFuse-019 study (NCT06312137) evaluating adjuvant pembrolizumab with versus without sac-TMT in patients with resectable stage II-IIIB (N2) NSCLC who did not achieve pCR after neoadjuvant pembrolizumab and platinum-based doublet chemotherapy followed by surgery.

Methods: In this global, randomized, open-label, phase 3 study, patients will be enrolled into an initial neoadjuvant study period. Initial eligibility criteria include histologically confirmed stage II-IIIB (N2) NSCLC without EGFR mutations, ECOG PS 0 or 1, and ability to undergo surgery and neoadjuvant treatment with pembrolizumab plus platinum-doublet chemotherapy. Documented ALK gene rearrangements are not permitted (if ALK status unknown/undetermined, testing not required). Patients will receive 4 cycles of neoadjuvant therapy with pembrolizumab 200 mg Q3W and platinum-doublet chemotherapy and then undergo potentially curative resection. Approximately 780 patients who complete definitive surgery (with postoperative radiation therapy for R1 resection status as indicated), do not achieve pCR by local review, and are disease-free per radiologic assessment by blinded independent central review (BICR) will be randomized in the adjuvant study period. Eligible patients must also have a tumor tissue sample from the surgical resection for biomarker analysis and ECOG PS 0 or 1. Patients will be randomized 1:1 to receive either sac-TMT 4 mg/kg Q2W for 20 doses plus pembrolizumab 400 mg Q6W for 7 doses or pembrolizumab 400 mg Q6W as monotherapy for 7 doses. Randomization will be stratified by histology (squamous vs nonsquamous), PD-L1 tumor proportion score (<50% vs ≥50%), disease stage (stage II vs stage III), and TROP2 expression (no or low vs medium vs high vs unknown). Tumor imaging will be performed within 2 weeks before surgery, within 28 days before randomization in the adjuvant period, then Q12W after randomization. The primary endpoint is disease-free survival (time from randomization to any recurrence, occurrence of new primary NSCLC, or death) as assessed by BICR. Secondary endpoints include OS, distant metastasis-free survival (time from randomization to first documented distant metastasis by investigator review or death), disease-free survival by investigator review, lung cancer-specific survival (time from randomization to death due to lung cancer), safety, and patient-reported outcomes. Enrollment into this study will begin in April 2024.

P4.07E.01 A Revised International Association for the Study of Lung Cancer Grading System: The Inclusion of Invasive Mucinous Adenocarcinomas

H. Li, L. Xu, W. Fang, Shanghai Chest Hospital, Shanghai/CN

Introduction: The International Association for the Study of Lung Cancer (IASLC) grading system doesn't include lung invasive mucinous adenocarcinoma (LIMA). However, we encounter mixed lung adenocarcinoma and LIMA in clinical work. Our study proposed to introduce the LIMA into the IASLC grading system, and aimed to measure the validity of its modification in lung invasive adenocarcinoma (ADC).

Methods: This retrospective study included 553 patients with lung invasive adenocarcinoma with or without LIMA components (stage I-III) from Shanghai Chest Hospital and 6962 patients in the SEER database. We introduced the LIMA and re-classified the IASLC grading system. The validity of the revised grading, derived from the training cohort, was measured in the validation cohort (the SEER database), using the concordance index (Harrell C-index), time-dependent receiver operating characteristic (ROC) curves and area under the curves (AUCs). Overall survival (OS) curves were estimated by a Kaplan-Meier method and log-rank test was performed to compare differences.

Results: The LIMA was classified as predominant tumor patterns in the IASLC grading system, and mucinous predominant tumors with no or less than 20% of high-grade patterns (solid, micro papillary, and/or complex glandular patterns) were classified as the Grade 2 (moderately differentiated, Table 1). The C-index and AUCs of the revised IASLC system were 0.754 and 0.729 in the training cohort and 0.716 and 0.682 in the validation cohort, respectively. Moreover, the revised grading showed a 5-year OS rate of 88.6% in Grade I group, 76.1% in Grade II group, 65.5% in Grade III group in the training cohort (P<0.001, Table 2). The revised grading also showed a promising performance in distinguishing patients in the validation cohort (5-year OS rate: 85.4% vs. 69.8% vs. 60.1%, P<0.001, Table 2).

Conclusions: The revised IASLC grading system was practical and prognostic for lung invasive adenocarcinoma with or without LIMA component, and the introduction of LIMA could improve its applicability.

Keywords: Lung Cancer, Mucinous Adenocarcinoma, Pathologic Grading

Table 1. The Revised Grading Scheme for Invasive Pulmonary Adenocarcinomas.

Grade	Differentiation	Patterns
1	Well-differentiated	Lepidic predominant with no or less than 20% of high-grade patterns
2	Moderately differentiated	Acinar or papillary or **mucinous** predominant with no or less than 20% of high-grade patterns
3	Poorly differentiated	Any tumor with 20% or more of high-grade patterns

Table 2. Performance Measurements of Revised Grading Scheme in Overall Survival.

Scheme	Training cohort				Validation cohort			
	C-index (95%CI)	AUC (95%CI)	5-year OS rate	P value	C-index (95%CI)	AUC (95%CI)	5-year OS rate	P value
Revised Grading	0.754(0.727-0.783)	0.729(0.696-0.754)		< 0.001	0.716(0.682-0.745)	0.682(0.656-0.711)		< 0.001
Grade 1			88.6%				85.4%	
Grade 2			76.1%				69.8%

P4.07E.02 Genomic Profiling of Pre-invasive and Early-Stage Lung Adenocarcinoma Delineates Gene Signatures of Different Adenocarcinoma Subtypes

Y-H. Luo[1,2], H-C. Huang[1,2], C-J. Huang[2], C-L. Chiang[1,2], H-S. Hsu[1,2], Y-C. Yeh[1,2], Y-C. Wang[2], Y-M. Chen[1,2], [1]Taipei Veterans General Hospital, Taipei/TW, [2]National Yang Ming Chiao Tung University, Taipei/TW

Introduction: Adenocarcinoma represents the predominant type of lung cancer. The major non-mucinous subtypes are acinar, papillary, micropapillary, lepidic, and solid. The presence of solid, and micropapillary patterns is associated with a poor prognosis. Understanding the genomic landscape of preinvasive lung adenocarcinoma (LAD) and subtypes of early-stage invasive LAD might provide important insight and promote development of novel strategies for early intervention and adjuvant treatment. This study explored clinical features and genomic landscape of preinvasive LAD and different subtypes of early-stage invasive LAD.

Methods: Patients with non-small cell lung cancer were prospectively recruited at Taipei Veterans General Hospital from May 2021 to December 2022. The tumor tissues and paired peripheral blood specimens were sequenced using whole-exome sequencing (WES). De-identified data, including genomics, pathology findings, and patients' clinical features were reviewed. For WES analysis, a predefined pipeline was utilized for sequence quality control, alignment, and variant calling, which was conducted using GATK Mutect2, MuSE, VarScan, and Pindel. A mutation was annotated when identified by at least two callers.

Results: This study enrolled 180 patients, of whom 58 and 122 patients had stage 0 and stage I LAD, respectively. Patients with stage I LAD were older than those with stage 0 LAD (64.7 vs. 55.0 years, p<0.001). In patients with stage I LAD, there were more ever-smokers(p=0.013), and more tumors in peribronchial site (p=0.025) compared to stage 0 LAD. As for WES analysis, EGFR was the most common mutation among both groups(41% and 70% for stage 0 and stage I LAD, respectively). Patients with family history of lung cancer had lower tumor mutation burden (TMB) compared to those without(p=0.033). Stage I LAD had a significantly higher TMB compared to stage 0 LAD (p<0.001). TMB of minimally invasive adenocarcinoma (MIA) was higher than that of adenocarcinoma in situ (AIS)(p<0.001). TMB of MIA was lower than that of acinar-, and solid-predominant adenocarcinoma(p=0.0026, and 0.027, respectively). The TMB of micropapillary-predominant adenocarcinoma (MPA) was higher than that of AIS, and MIA(p<0.001, and p=0.0053, respectively). Tumors with spread through air space (STAS) exhibited a higher TMB than those without(p<0.001). The gain and loss proportion of copy number variation (CNV) were higher in stage I LAD compared to stage 0 LAD(both p<0.001). Significant differences in the gain and loss proportion of CNV among different adenocarcinoma subtypes (p<0.001) were also found. Tumors with STAS had higher gain and loss proportion of CNV compared to those without (both p<0.001). Oncogene pathways enrichment analysis for MPA demonstrated the main signaling pathways, including RTK-RAS, WNT, and NOTCH. The mutational enrichment analysis for MPA showed an enrichment of mutations in PCLO, ZNF831, TP53, and PLEKHO1, warranting further research.

Conclusions: The stage I LAD is characterized by a higher TMB, and more significant copy number variations compared to stage 0 LAD. These genetic differences are linked to clinical features, and specific functional morphologies of tumor cells. WES analysis revealed significant genomic disparities between stage 0 LAD and various subtypes of stage I invasive LAD, warranting further investigation into the underlying pathophysiology.

P4.07E.03 Real-World Data on Early Lung Cancer in Never-Smokers and Light Smokers-Prevalence, Family History, and Molecular Alterations

L. Gros, R. Yip, H. Chan, J. Zhu, S. Kantor, D.F. Yankelevitz, C.I. Henschke, Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: The proportion of early-stage lung cancer patients who are never-smokers or have a history of light smoking is on the rise. This study aims to explore the prevalence of never-smokers and light smokers among patients undergoing surgical resection for early-stage lung cancer, along with their family history and the frequency and type of molecular alterations.

Methods: We analyzed data from the Initiative for Early Lung Cancer Research for Treatment (IELCART), a prospective multi-institutional cohort study initiated in 2016. This study included patients who underwent surgery for lung tumors measuring 30 mm or smaller. Our objective was to describe the frequencies of never-smoker patients and light smokers (≤ 20 pack-years), and to report their family history of lung cancer, as well as the distribution of molecular alterations. Additionally, we aimed to compare these distributions among different racial groups.

Results: In the prospective treatment cohort of 957 patients diagnosed with lung cancer, who underwent surgery for tumors measuring 30 mm or less in maximum diameter in the Initiative for Early Lung Cancer Research on Treatment (IELCART), 354 (37%) were never-smokers or had a smoking history of less than 20 pack-years.

Among the 354 patients, 65 (18.4%) reported a family history of lung cancer. Among these, 27 out of 65 patients (41.5%) had a father diagnosed, 33.8% had a mother diagnosed, and 26.2% had a sibling affected. For five out of 65 patients (7.7%), the specific family relationship was not specified.

Oncogenic driver mutation analysis was performed in 248 out of 354 patients (70.1%). Clinically actionable variants were identified in 159 (64.1%) out of 248 patients Among them, 108 out of 248 patients (43.5%) showed EGFR gene mutations, including 82 (75.9%) patients harboring classical mutations such as deletions of exon 19 (39 patients) and the L858R mutation in exon 21 (43 patients). Additionally, 24 (9.7%) presented with a KRAS G12C mutation. Furthermore, there were 12 (4.8%) with MET exon 14 deletions, five patients (2%) with targetable ROS1 mutations, four (1.6%) with RET fusions, three (1.2%) with ALK fusion and three (1.2%) and three with a BRAF V600E.

Our cohort comprises 15.5% patients self-identifying as Asian, 18.4% as Afro-American, 55.9% as White, and 10.2% identifying as other races. The distribution of oncogenic driver mutations varied significantly based on patient race, with a notably significantly higher prevalence of EGFR mutations observed among Asian patients (28/42 patients, 66%) (Fisher test, p-value <0.01).

Conclusions: Among 957 patients with resected lung cancer ≤30mm, 37% were never- or light-smokers. 18.4% had a family history of lung cancer. EGFR mutations were prominent (43.5%), with a higher prevalence of 66% observed among Asian patients. This rate remains below the 85% reported in a Taiwanese cohort dominated by never-smoking patients, mostly females, with early-stage NSCLC, emphasizing the racial heterogeneity of our cohort. Our results underline that many never- or light smokers with lung cancer harbor driver alterations, suggesting an alternative model of carcinogenesis. These patients are not targeted by traditional screening programs, necessitating further studies on screening in these populations.

P4.07E.04 Pathological Grading of Early-Stage Lung Cancers Through CT-to-PET Translation and Co-Learning Model

H. Zhou[1], Z. Huang[1], M. Weng[1], L. Yao[1], W. Zhan[1], M. Li[2], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [2]School of Medicine, South China University of Technology, Guangzhou/CN

Introduction: The wide application of chest CT screening is increasing the detection of early-stage lung cancer. Early-stage lung cancers vary in morphology, progression, and prognosis depending on different stages. However, CT screening has limits, such as high false-positive rates and overdiagnosis. Positron emission tomography (PET) examination can help stratify the pathological subtype of nodules, but it is expensive, radioactive, and technically demanding. We propose a new methodology that may accomplish pathological grading for patients with lung cancer by producing PET pictures and the accompanying metabolic characteristics with CT images.

Methods: We have 642 individuals who had preoperative chest CT scans, PET/CT examinations, and matching nodules (≤30 mm and ≥4 mm) with surgically proven definitive pathology, with a 1:2 distribution between the train cohort (cohort A) and the validation cohort (cohort B). Additionally, we proposed a generative adversarial networks-based image-to-image translation model to achieve CT-to-PET translation (CPT) and predict tumor metabolic characteristics. Thus, to accomplish lung cancer pathological grading, we integrate the metabolic features and the CT and PET pictures into the multi-modal co-learning model.

Results: The synthetic images and real target images in the CPT model show a low mean square error (MSE = 0.015, p<0.01) and a high similarity structural index measure (SSIM = 0.956, p<0.01). Furthermore, we evaluated and computed the metabolic parameters, including SUVmax, using synthetic PET. The correlation plot shows a strong connection (r = 0.79) between the projected SUVmax and the actual data. And the evaluated SUVmax achieved an AUC of 0.658 in cohort A, performed similar efficacy with the one using real SUVmax in cohort A (AUC:0.660), and evaluated SUVmax in cohort B (AUC:0.654) (see Figure1.a-c). Based on the CPT model, we developed a multimodal co-learning model for lung cancer pathological grading. The proposed model using CT, synthetic PET, and evaluated SUVmax achieve an AUC of 0.942 ([95%CI 0.936-0.952], p< 0.0001), performed similar efficacy with the one using CT, real PET, and real SUVmax (0.941 [95%CI 0.939-0.9444], p< 0.0001), better than the one using only CT (0.929 [95%CI 0.924-0.930]) and the one using only PET (0.853[95%CI 0.850-0.869])(ROC curves see Figure1.d).

Conclusions: By expanding the capabilities of CT scans, this model broadens the boundaries of CT images, providing a more accurate, economical, and noninvasive approach for improving early detection and providing appropriate treatment approaches.

P4.07E.05 Insights from Molecular Profiling after Second Lung Surgeries in Early-Stage NSCLC - Recurrence or New Primary Tumor?

L. Gros[1], R. Yip[1], R. Veluswamy[2], D.F. Yankelevitz[1], C.I. Henschke[1], [1]Department of Diagnostic, Molecular, and Interventional Radiology, Icahn School of Medicine at Mount Sinai, New York/NY/USA, [2]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: In patients with early-stage non-small-cell lung cancer (NSCLC), surgery aims to be curative; however, local recurrence may occur, posing challenges in distinguishing between a new primary tumor and an intrapulmonary metastasis. This study aims to investigate the role of genomic profiles of tumors from patients who underwent curative surgery twice.

Methods: We utilized data from a prospective multi-institutional cohort study, the Initiative for Early Lung Cancer Research for Treatment (IELCART), and included patients treated twice surgically with curative intent and subjected to genomic testing between 2014 and 2022. Next-generation sequencing (NGS), histopathological characteristics, demographics and outcomes of patients were collected. NGS profiles were compared and correlated with outcomes.

Results: 30 patients (17 females) underwent surgery after previous resected NSCLC with pathological and genetic analyses. The majority were white (77%), current or former smokers (90%) and had median age of 68.6 years. Mean time between the two procedures was 27 months (SD 21). None had germline mutations.

For their first surgery, 34 adenocarcinomas were resected (4 patients had 2 distinct adenocarcinomas). All patients had stage I NSCLC and none received adjuvant treatment. The mean tumor size was 1.72 cm (SD 0.84). The most frequently mutated genes were KRAS (56%), TP53 (18%), and EGFR (15%). For the 4 patients with 2 separate NSCLC, NGS was discordant in 3 cases.

For the second surgery, 33 adenocarcinomas were resected (3 patients had 2 distinct adenocarcinomas). 7 patients underwent resection in the same lobe and 23 in a different lobe. The mean tumor size was 1.75 cm (SD 0.97). 16/30 patients presented a concordant NGS result between the first and second surgeries. 4 patients received adjuvant chemotherapy.

For patients re-resected in the same lobe, NGS profiles were similar to the first in 6/7 patients. 2 patients subsequently developed a third lung tumor in another lobe, with the same NGS profile (KRAS in both cases).

For patients re-resected on a different lobe, NGS was similar to the first tumor for 10/23 and discordant in 13/23. 10 patients developed a third lung tumor in another lobe, and 2 patients developed distant metastasis.

The localization of the second cancer showed no significant correlation with NGS similarity (exact Fisher test, p=0.086), however with a trend of higher NGS concordance (86% versus 43%) among patients who underwent surgeries in similar lobes.

The size of the initial tumor demonstrated a significant correlation with a concordant NGS profile identified in the tumor from the second surgery (Welch Two Sample t-test, p=<0.05).

Post-surgical outcomes were similar between patients with NGS concordance and discordance (recurrence: 44% vs 50%).

Conclusions: In a cohort of 30 patients with early-stage NSCLC undergoing sequential surgeries, NGS revealed concordance within the same lobe but discrepancies across lobes. Tumor size correlated with NGS concordance, suggesting potential in distinguishing a new primary tumor from intrapulmonary metastasis. Post-surgery outcomes showed no significant difference based on NGS concordance, and the optimal integration of clinical, pathological, radiological, and molecular features for differentiation remains unclear. Future NGS studies may help evaluate its predictive role.

P4.07E.06 Distinct Genomic and Immune Microenvironment Features of Solid or Micropapillary Predominant Subtype in Stage I Lung Adenocarcinomas

L. Zhang[1], H. Qiang[1], J. Luo[1], C. Ji[1], Y. Zhang[1], Y. Wang[1], S. Cao[1], H. Du[1], J. Wang[2], B. Li[2], Y. Zhou[1], H. Zhong[1], [1]Shanghai Chest Hospital, Shanghai/CN, [2]Burning Rock Biotech, Shanghai/CN

Introduction: Lung adenocarcinomas (LUAD) exhibit histological heterogeneity among various pathology patterns. Numerous studies have indicated that the solid or micropapillary predominant subtypes (S/MP+) are associated with unfavorable prognoses in LUAD patients. However, limited research has specifically focused on the S/MP+ subtype in stage I LUAD, and the molecular factors contributing to malignant potential and tumor immune microenvironment in this high-risk subgroup remain poorly understood.

Methods: In this study, we collected clinical information and survival data from 2382 patients diagnosed as stage I LUAD. Patients are defined as S/MP+ if the total proportion of solid and micropapillary subtypes exceeds any other subtypes. To further explore the genetic signatures of S/MP+ pattern, whole exome sequencing and RNA sequencing were performed on another 36 patients with sufficient tissue samples. Multiple immunofluorescence staining (MAP) for PD-1, PD-L1, CD3, CD8, and panCK was also performed to investigate the tumor immune microenvironment. Immune cell infiltration was assessed using Cibersort, Xcell, and single-sample gene set enrichment analysis (ssGSEA).

Results: We found that S/MP+ patients showed significantly poorer overall survival (HR: 0.24 [95% CI: 0.13-0.44], P<0.001) compared to those grouped as S/MP-. This difference remained significant after adjusting for covariates such as gender, smoke, surgery type and adjuvant chemotherapy (HR: 0.22 [95% CI: 0.13-0.44], P < 0.001). In 36 LUAD cases with multi-omics data, 47.2% (N=17) were classified as solid or micropapillary predominant (S/MP+). We found significant differences in driver mutation profiles and immune characteristics between S/MP+ and S/MP- subtypes. S/MP- patients had a significantly higher prevalence of EGFR activating mutations, while S/MP+ subtype showed more RAS(G12X/13X/Q61X) and MAPK pathway mutations, higher tumor mutation burden (TMB) (median, 2.71 mut/MB vs 0.89 mut/MB), tumor neoantigen burden (TNB), and chromosomal instability (P<0.05). Signature 4, a smoking-related signature, was also significantly enriched in S/MP+ patients, suggesting a potential link between high TMB and smoking in this subtype. In total, we identified 1284 differentially expressed genes (DEGs) through RNA sequencing, including 715 upregulated genes and 569 downregulated genes in S/MP+ group. The biological processes of most upregulated DEGs were associated with chromosome organization, cell division and nuclear division. The immune cell infiltrates were comparable between the two groups, but S/MP+ patients exhibited higher tumor proliferation rates, stromal remodeling, and epithelial-mesenchymal transition features (P<0.05). Additionally, S/MP+ patients had significantly higher numbers of cancer-associated fibroblasts (CAF), NK cells, M1 and M2 macrophages, while CD4+ immune cell count was lower (P<0.05).

Conclusions: Our findings suggest that the S/MP+ histologic subtype demonstrates distinct genomic and immune characteristics compared to the S/MP- patients, indicating a worse prognosis in patients with surgically resected stage I LUAD. These findings contribute to defining prognostic subgroups and identifying specific LUAD treatment population that may benefit from evolving therapeutic strategies.

P4.07E.07 Spatial Memory B Cells Activation by CXCL13+ Th Cells via the MIF(CD74-CXCR4) Axis may Improve Immunotherapy Efficacy in HER2 Mutant NSCLC

H. Hong, C. Zhang, L-X. Yan, S-y. Liu, H-J. Li, B-Y. Jiang, H-Y. Tu, Y-L. Wu, W-Z. Zhong, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN

Introduction: The clinical benefits and underlying mechanism of neoadjuvant PD-1 blockade plus chemotherapy (nICT) or Trastuzumab Deruxtecan (nT-Dxd) remain unclear for HER2-mutant non-small cell lung cancer (NSCLC).

Methods: We reported the clinical results of nICT or nT-Dxd in resectable NSCLC patients with HER2 mutation, including objective response rate (ORR), major pathologic response (MPR) and complete pathologic response (PCR) rate. We combined spatial transcriptomics (ST) with single-cell RNA (scRNA) sequencing and multiplexed immunofluorescence (mIHC) of HER2-mutant NSCLC after nICT or nT-Dxd treatment to identify the specific tumor microenvironment (TME) factors related to treatment efficacy. Lasso regression was performed to construct a prognostic risk model and validated by external cohort in TCGA.

Results: Overall, 14 patients treated with nICT and 2 with nT-Dxd were enrolled. The ORR for nICT and nT-Dxd group were both 50.0%. Fifteen out of sixteen patients underwent a complete resection. Among them, 42.9% (6/14) of patients in nICT group and 0% (0/2) in nT-Dxd group achieved MPR, while the PCR rate in patients treated with nICT was 28.6% (4/14). Furthermore, we performed combined analysis of ST (n=5) and scRNA (n=6) data and revealed the enrichment of CD27+ memory B cells (Bm) in tumors with better response to nICT, which is characterized by increased immunoglobulin production and antigen presentation activity. Spatial analysis demonstrated a phenomenon of mutually exclusive distribution between Bm and tumor cells. Then, we dissected the ligand-receptor networks between T and B cells to elucidate the Bm cell activation process; that is, CXCL13+ T helper (Th) cells activate Bm cells via MIF (CD74-CXCR4) crosstalk, which subsequently stimulate the secretion of Immunoglobulin (Ig) G and A, thereby enhancing the antitumor immune response. CXCL13+ Th cells in this process show an elevated ability of CXCL13 production and MHC II binding. A predictive model was developed based on this crosstalk genes, which was associated with favorable outcome. Additionally, the nT-Dxd-treated patient displays a paradoxical TME characterized by significant infiltration of both effector and suppressive immune cells. Immune checkpoint genes are upregulated in the boundary of the tumor.

Conclusions: Our findings demonstrate the potential feasibility of nICT or nT-Dxd for resectable NSCLC with HER2 mutation. Bm cells may serve as a predictor biomarker for favorable outcome in HER2-mutant NSCLC treated with nICT. Furthermore, we have uncovered a novel mechanism of Bm cell activation and provided a fresh insight into the nT-Dxd-treated TME.

P4.07E.08 Single-Cell TCR Barcoding and RNA Sequencing Illuminate Distinct Tumor-Draining Lymph Node T Cell Responses to Neoadjuvant PD-1 Blockade

R. Honigsberg[1,2], T. Cruz[2], L. Yoffe[2], G. Markowitz[2], D. Ozgenel[2], O. Elemento[2], N. Altorki[2], V. Mittal[2], J. Villena-Vargas[2], [1]Cornell University, New Ithaca/NY/USA, [2]Weill Cornell Medicine, New York/NY/USA

Introduction: Leveraging insights from Phase III trials on the efficacy of PD-1 targeted immune checkpoint inhibitors (ICIs) in early-stage NSCLC, the precise mechanisms driving primary tumor responses remain elusive. In this study, we apply advanced machine learning algorithms to analyze single-cell sequencing data of TCR-barcoded CD8+ T cells, aiming to unravel the tissue and treatment-specific clonal dynamics within our "live T cell" biobank from patients receiving neoadjuvant ICIs. This approach illuminates the pivotal role of tumor-draining lymph node-derived T cells in mediating the tumor's pathologic response to therapy.

Methods: At Weill Cornell Medicine, we profiled four early-stage NSCLC patients undergoing surgical resection, with three receiving anti-PD-1 and platinum-based chemotherapy. Treatment outcomes varied: one non-responder (90% viable tumor), one partial responder (30% viable tumor), and one complete responder. We analyzed four tumors and five lymph nodes from these patients, utilizing pathological evaluation, flow cytometry, and scRNA/TCR-seq of CD3+CD8+ T cells. Employing single-cell TCR barcoding and RNA sequencing, we traced T cell responses to PD-1 blockade. Through machine learning, we elucidated the impact of neoadjuvant anti-PD-1 therapy combined with chemotherapy on T cell dynamics.

Results: In our analysis of 19,059 CD8+ T cells from nine tissue samples, we combined single-cell TCR CDR3 amino acid sequencing with the transcriptional profiling of 24,500 genes per cell. T cells from tumor-draining lymph nodes (tdLN) that were clonally related to the tumor predominantly resided in quiescent clusters, characterized by high expression levels of SELL, TCF7, and CCR7. Conversely, tumor-associated T cells from the tumor were localized in clusters indicative of a more differentiated, activated, and exhausted state, marked by the expression of effector-like markers and inhibitory receptors, such as TOX and PDCD1. By applying a mix of supervised and unsupervised machine learning techniques, we identified a transcriptional signature associated with a favorable primary tumor response to PD-1 blockade in T cells within the tdLN ($p < 0.05$). This signature was further validated in an immunocompetent murine model, demonstrating an initial tumor response to neoadjuvant PD-1 treatment ($p < 0.05$).

Conclusions: Employing single-cell TCR barcoding for comprehensive multi-tissue deep clonal tracking in conjunction with single-cell RNA sequencing, we reveal that T cells originating from draining lymph nodes exhibit a unique response to PD-1 blockade, potentially impacting the primary tumor's response to neoadjuvant immune checkpoint inhibitors (ICI).

P4.07E.00 The Impact of PD-1/PD-L1 Inhibitor on GGN Lesion: An Exploratory and Retrospective Study

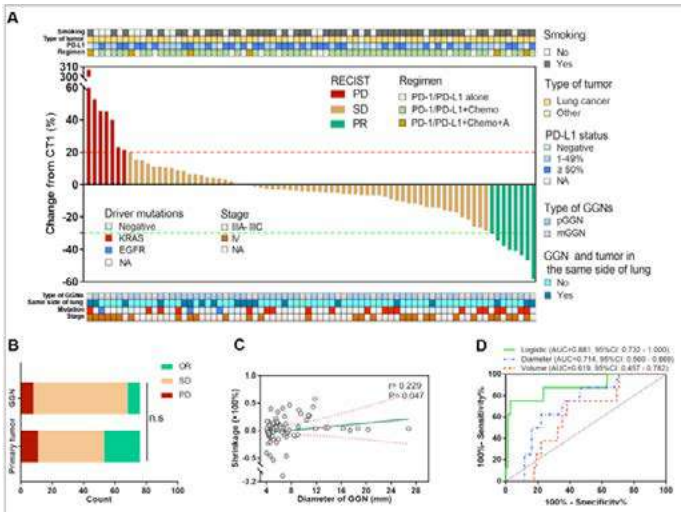
F. Wu[1,2,3,4], J. Liu[1], L. He[1,5], X. Liu[1], Y. Zeng[1], S. Shi[1], Y. Peng[1], [1]The Second Xiangya Hospital of Central South University, Changsha/CN, [2]Hunan Cancer Mega-Data Intelligent Application and Engineering Research Centre, Changsha/CN, [3]Hunan Key Laboratory of Tumor Models and Individualized Medicine, The Second Xiangya Hospital, Central South University, Changsha/CN, [4]Hunan Key Laboratory of Early Diagnosis and Precision Therapy in Lung Cancer, The Second Xiangya Hospital, Central South University, Changsha/CN, [5]Graduate School of Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing/CN

Introduction: Ground-glass nodules (GGNs) are common early signs of lung cancer in CT imaging. Immunotherapy improved the prognosis for patients with advanced lung cancer. However, clinical evidence for the effectiveness of immunotherapy in GGNs is insufficient, especially for cases presenting with GGNs as multiple primary lung cancers.

Methods: Patients receiving PD-1/PD-L1 inhibitors for primary malignant tumors coexisting with GGNs at the Second Xiangya Hospital from January 1, 2016, to June 30, 2021 were included. The inclusion criteria are as follows: 1. Received PD-1/PD-L1 inhibitors for ≥ 2 cycles; 2. Underwent thin-slice (1 mm) chest CT before immunotherapy; 3. Pre-immunotherapy CT suggested the presence of GGNs measuring 4-30 mm in maximum diameter; 4. Underwent CT imaging within 1 month after completing PD-1/PD-L1 inhibitor treatment. The last CT images before (CT1) and after (CT2) PD-1/PD-L1 inhibitor treatment were collected to evaluate changes in GGNs.

Results: A total of 76 GGNs from 39 patients were included. Although almost all GGNs exhibited changes after immunotherapy, there were no significant changes in their maximum diameter, maximum solid proportion, volume, density, or the maximum of the solid component. After PD-1/PD-L1 inhibitor treatment, 74.6% of GGNs classified as Lung-RADS 2 or 3 remained unchanged, while 80% of GGNs classified as Lung-RADS 4 were downgraded to category 2 or 3. When evaluating the efficacy of immunotherapy for GGNs, the objective response rate was 11.8%, with 9 GGNs achieving partial response, 59 achieving stable disease, and 8 achieving progressive disease (Figure 1). The ORR for primary malignant tumors was 36.8%, and the efficacy of 44.7% of GGNs was consistent with that of the primary tumors. The maximum diameter and volume of GGNs were positively correlated with the efficacy of immunotherapy ($p<0.05$), and GGNs ≥8 mm could benefit from PD-1/PD-L1 inhibitor. GGN density ($p=0.012$) and volume ($p=0.039$) were independent predictors of the efficacy of PD-1/PD-L1 inhibitor treatment, with GGNs having a volume ≥70 mm^3 achieving more significant efficacy.

Conclusions: PD-1/PD-L1 inhibitors show limited activity on GGNs in patients with malignant tumors. GGNs with a maximum diameter ≥8 mm and with a volume ≥70 mm^3 may potentially benefit from immunotherapy.



A, Overview of clinicopathological charteristics and clinical outcome of GGNs treated with PD-1/PD-L1 inhibitor.

MONDAY, SEPTEMBER 9, 2024 - 18:30 - 20:00

P4.07F.01 Real World Characteristics and Distant Metastasis Free Survival of Patients with Early NSCLC Treated with Chemoimmunotherapy

K. Schwed[1,2], L. Kalesinskas[1], Q. Yuan[1], C.A. Keane[1], E.L. Fidyk[1], E. Castellanos[1,3], A.B. Cohen[1,4], K. Harrison[1], G. Ho[1], A. Marinescu[1], A. Desai[5], [1]Flatiron Health, New York/NY/USA, [2]Memorial Sloan Kettering Cancer Center, New York/NY/USA, [3]Fox Chase Cancer Center, Philadelphia/PA/USA, [4]NYU Langone Schoo of Medicine, New York/NY/USA, [5]University of Alabama Birmingham, Birmingham/AL/USA

Introduction: Chemoimmunotherapy (CIO) is an established treatment option for resectable early non-small cell lung cancer (eNSCLC) in both the adjuvant and neoadjuvant setting. However, little is known about its real world (rw) utilization. We described adjuvant and neoadjuvant CIO use and rw outcomes in eNSCLC patients.

Methods: Patients with stage II-IIIA, surgically resected NSCLC diagnosed 1/1/2020-7/31/2023 were selected from the Flatiron Health nationwide electronic health record (EHR)-derived, de-identified database, and categorized based on neoadjuvant (CIO prior to surgery) or adjuvant (CIO within 12 weeks post surgery) therapy receipt. Data cut off was 1/31/2024. Clinical characteristics were extracted via machine learning models and compared with chi-square and Wilcox tests. Rw distant metastasis free survival (DMFS), defined as time to distant metastasis or death from first neoadjuvant or adjuvant chemoimmunotherapy, was estimated for both cohorts by the Kaplan Meier estimator. Hazard ratios (HRs) within treatment groups were evaluated using Cox models adjusted for age, race/ethnicity, gender, practice type, smoking status, stage, PD-L1 status and histology.

Results: Among 256,269 patients diagnosed with NSCLC, 4771 patients with stage II-IIIA NSCLC underwent surgical resection in the relevant time period, of which 1008 received CIO in the neoadjuvant or adjuvant setting. Baseline characteristics are shown in the Table; notably biomarker testing rates were lower prior to neoadjuvant than adjuvant CIO. CIO was uncommon among resected stage II-IIIA patients in 2022, but increased in 2023 from 9.0% to 17.0% and 18.9% to 23.9% for neoadjuvant and adjuvant CIO, respectively. DMFS at 18 months for neoadjuvant patients was 77.6% (95% CI, 70.0%-86.2%), compared to 83.2% (95% CI, 79.7%-86.9%) for adjuvant patients. DMFS did not differ by clinical covariates, except for non-squamous versus squamous histology in neoadjuvant patients (HR, 2.96; 95% CI, 1.13-7.73) and stage IIIA versus stage II in adjuvant patients (HR, 2.62; 95% CI 1.58-4.37). Both neoadjuvant (n=19) and adjuvant (n=57) patients who developed distant disease had similar distribution of brain, bone and liver metastasis.

Conclusions: CIO use was associated with favorable rwDMFS, in line with clinical trial outcomes. While rw CIO usage increased in 2022 and 2023, fewer than half of surgically resected patients received CIO at end of study period, and biomarker testing was inconsistently done particularly in the neoadjuvant setting. Further study of factors influencing clinical adoption of CIO and biomarker testing in eNSCLC is needed.

P4.07F.02 Invasiveness Diagnosis by Intraoperative Frozen Section Guides Resection Strategy Amomg ≤2cm Non-Small-Cell Lung Cancer

J. Li, Y. Feng, X. Lu, S. Zhan, J. He, W. Liang, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: The JCOG (Japan Clinical Oncology Group) studies, including JCOG0804, JCOG1211, and JCOG0802, suggest a more favorable long-term survival trend for ≤2cm non-small-cell lung cancer (NSCLC) with sublobar resection, despite increased risks of recurrence and metastasis. This implies that not all nodules within this size range may be suitable for sublobar resection. Therefore, this study aims to determine if intraoperative frozen section diagnosis can accurately identify candidates benefiting more from lobectomy over sublobar resection among individuals meeting JCOG study criteria.

Methods: This retrospective study involved patients diagnosed with NSCLC who underwent surgical resection at the Department of Thoracic Surgery, First Affiliated Hospital of Guangzhou Medical University, between September 2009 and January 2019. Patient data, including preoperative CT images, surgical procedures, frozen section, and follow-up information, were collected from the hospital's electronic medical record system. Kaplan-Meier survival analysis was utilized to compare overall survival (OS) and lung cancer-specific survival (LCSS) between patients with invasive and pre-invasive NSCLC. Meanwhile, based on frozen section diagnosis, OS and LCSS were evaluated in patients undergoing sublobar resection versus lobectomy.

Results: A total of 1,539 patients who underwent surgical resection for NSCLC were included in this study, with a median follow-up time of 54 months. The frozen section diagnosis and the final pathological diagnosis were consistent for both pre-invasive NSCLC and invasive NSCLC, with a concordance rate of 80.90%. Among patients with ≤2cm NSCLC, those whose frozen section indicated invasive lung cancer exhibited inferior overall survival (OS) (HR=19.737, P<0.001) compared to patients with pre-invasive NSCLC, and the patients diagnosed with pre-invasive NSCLC, the LCSS rate is 100%. Among patients with intraoperative frozen section indicated pre-invasive NSCLC, there were no lung cancer-related deaths observed in either sublobar resection or lobectomy group. Among patients with intraoperative frozen section indicated invasive NSCLC, those who underwent lobectomy demonstrated better LCSS compared to those who underwent sublobar resection (HR=0.378, P<0.001). When the invasion status could not be determined by intraoperative frozen section, there was no significant difference in survival between sublobar resection and lobectomy (OS: HR=3.906, P=0.063; LCSS: HR=4.867, P=0.11).

Conclusions: In summary, intraoperative frozen section significantly influences the choice of sublobar resection for ≤2cm NSCLC. Lobectomy demonstrates superior survival for patients with intraoperative frozen section indicating invasive NSCLC, while both sublobar resection and lobectomy show favorable outcomes for those with pre-invasive NSCLC.

P4.07F.03 A Cost-Effective Tumor-Informed ctDNA Analysis for MRD Detection in Resected NSCLC With Common Driver Genes

R. Zhong, H. Liang, Y. Jiang, Y. Lin, J. He, W. Liang, The 1st Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: The potential of Circulating Tumor DNA (ctDNA) for Molecular Residual Disease (MRD) detection in predicting relapse among resected Non-Small Cell Lung Cancer (NSCLC) patients is promising. Digital droplet PCR (ddPCR) has been shown to be highly specific in detecting individual mutations in cell-free DNA (cfDNA). This study aims to identify specific driver gene mutations for MRD monitoring using ddPCR, focusing on epidermal growth factor receptor (EGFR) or Kirsten rat sarcoma viral oncogene homologue (KRAS) mutations in ctDNA from resected NSCLC patients.

Methods: This is an ongoing prospective observational study that enrolled patients with stage I to III resected NSCLC. The study only included patients who were confirmed to have EGFR or KRAS G12 C/D mutations, which were pathologically confirmed through whole exome sequencing (WES) or PCR. Plasma samples were collected from the patients at regular intervals, every 3 or 6 months postoperatively depending on patients' MRD results. A single point assay according to patients' specific gene mutation (EGFR or KRAS) was used to detect ctDNA by ddPCR. The results of MRD analysis in each blood sample were evaluated along with possible influencing factors such as patient age, type of lung cancer, type of gene mutation, postoperative time, and TNM stage.

Results: As of Jan 2024, 695 blood samples were included in our MRD analysis. A total of 300 NSCLC patients were enrolled; 54% of the patients had EGFR L858R mutation, 34% had the EGFR 19del mutation, 10% had KRAS mutation, and the remaining 1% had more than two of the aforementioned mutations. The majority of the participants were diagnosed with Stage IA NSCLC (72%), while 14% had Stage IB, 7% had Stage II, and 7% had Stage III. The follow-up time lasted 3 years, with a median time of 40 months, and 12 patients relapsed. Subgroup analyses of MRD positivity rates were conducted based on different MRD time points, TNM stage, adjuvant therapy and gene type.

Conclusions: Our updated findings from different subgroup analyses the feasibility of utilizing ddPCR technology for evaluating ctDNA MRD in patients with resected NSCLC harboring common mutations such as EGFR L858R, EGFR 19del, KRAS G12C, or KRAS G12D. Considering the high prevalence of the aforementioned mutations within the Chinese population, our targeted, tumor-informed strategy that focuses on specific mutations could offer a cost-effective tool for MRD monitoring. Further research is needed to validate its effectiveness and practical utility in clinical settings.

Keywords: MRD, NSCLC, ctDNA

P4.07F.04 Ground Glass Nodules with Scattered or Eccentric Island-Shaped Consolidations may have Poor Outcomes

M. Li, J. Xi, M. Feng, Q. Wang, Zhongshan Hospital Fudan University, Shanghai/CN

Introduction: To explore the effect of scattered or eccentric shaped types of ground glass opacity (GGO) on outcomes of patients with solid-dominant peripheral lung adenocarcinoma.

Methods: We evaluated patients with solid-dominant peripheral lung adenocarcinoma, who underwent radical surgery at Zhongshan Hospital, Fudan University, between January 2013 and December 2015. Morphologically heterogeneous solid-dominant lung adenocarcinoma in imaging findings was based on the last preoperative computed tomography (CT) scans. Endpoints were recurrence-free survival (RFS) and overall survival (OS). Kaplan-Meier analysis and the log-rank test were used to estimate survival differences. Impact factors were assessed by univariable logistic regression analysis.

Results: We retrospectively collected data from 200 patients, including 170 patients with central island-shaped CT imaging, 18 patients with scattered shaped CT imaging, and 12 patients with eccentric shaped CT imaging. Eleven patients experienced recurrence or metastases. Kaplan-Meier survival curves showed significant survival differences between the central island-shaped type and scattered shaped or eccentric shaped type for OS (c-stage IA: 5-year OS: 100% vs. 92.1%; HR = 0.019, p = 0.0025; p-stage IA: 100% vs. 95.2%; HR = 0.146, p = 0.1139) and RFS (c-stage IA: 5-year RFS: 100% vs. 59.7%; HR = 0.001, p < 0.0001; p-stage IA: 100% vs. 64.5%; HR < 0.001, p < 0.0001). Univariable logistic regression analysis showed that scattered and eccentric shaped types were related to poor outcomes (p < 0.012, odds ratio = 18.8).

Conclusions: Relative spatial position of GGO and solid components may affect patient outcomes. Patients with scattered or eccentric shaped GGO may have a poor prognosis.

Keywords: ground glass opacity, scattered or eccentric island-shaped, prognosis

P4.07F.05 Low OLFM1/BMP6 Expression Identifies High-Risk Stage I Non-Squamous Non-Small Cell Lung Cancer after Pulmonary Resection

K. Suda[1], Y. Yoshida[2], H. Sato[3], A. Hamada[1], M. Yotsukura[2], K. Shiraishi[4], R. Hamamoto[4], Y. Chiba[5], T. Kohno[4], Y. Yatabe[2], S-I. Watanabe[2], Y. Tsutani[1], T. Mitsudomi[1], [1]Kindai University Faculty of Medicine, Osaka-Sayama/JP, [2]National Cancer Center Hospital, Chuo-ku, Tokyo/JP, [3]Yamagata University Well-Being Institute, Yamagata/JP, [4]National Cancer Center Research Institute, Chuo-ku, Tokyo/JP, [5]Kindai University Hospital, Osaka-Sayama/JP

Introduction: Pathological stage I (pStage I) non-small cell lung cancer (NSCLC) is the representative of lung cancers with good prognosis; however, it is also true that a certain number of pStage I NSCLC patients experience disease recurrence after surgery. Identification of poor prognostic markers in pStage I NSCLC may facilitate further personalized perioperative treatment by expanding the candidates for novel adjuvant treatment. Because NSCLC patients with ground-glass opacity have excellent survival outcomes, in this study, we explored prognostic biomarkers focusing on pure solid non-squamous NSCLC.

Methods: RNA sequence was performed using frozen tumor specimens obtained from 33 non-squamous NSCLC patients who experienced disease recurrence (recurrence group) and 33 counterparts (control group) who were extracted from patients without disease recurrence for at least 5 years using propensity score matching (Cohort 1). The prognostic role of candidate genes (either expression or mutation) was evaluated using an independent Cohort 2a (N=125). Furthermore, survival analysis was performed in patients with EGFR mutation after adding an independent Cohort 2b (N=24).

Results: We identified 101 differently expressed genes between recurrence group and control group in Cohort 1. In addition, we found 5 genes of which mutation frequencies were different between these two groups. In the validation analysis using Cohort 2a, we found that lower expression of 6 genes (BMP6, KCNK3, NFASC, OLFM1, PEG3, and TNXB) was associated with disease recurrence. Prognostic impact of these 6 genes were also confirmed using TCGA lung adenocarcinoma database. Multivariable proportional hazard analysis further revealed that lower expression of BMP6 and OLFM1 were independent prognostic factors, and expression status of these two genes was significantly associated with recurrence-free survival in Cohort 2a (Figure 1A). In addition, we observed that the expression status of these two genes was also prognostic in EGFR mutation positive group extracted from a combined cohort (Figure 1B).

Conclusions: In pure solid non-squamous NSCLC patients, low BMP6/OLFM1 status will identify high risk pStage I NSCLC patients after pulmonary resection.

Keywords: Prognostic biomarker, lung adenocarcinoma, pathological stage I

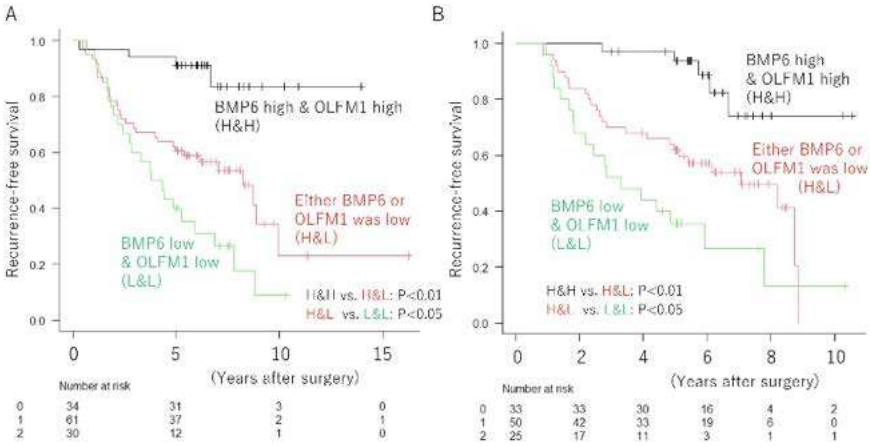

Figure 1. Recurrence-free survivals based on BMP6 and OLFM1 expression status in Cohort 2a (A) and in the EGFR mutated cohort obtained from Cohort 1, Cohort 2a, and Cohort 2b (B).

P4.07F.06 CT-Based Deep Learning Model for Predicting Visceral Pleural Invasion in NSCLCs with Tumor Diameter Less Than 3cm

M-W. Lin, L-W. Chen, M-S. Hsieh, Y-C. Chang, J-S. Chen, C-M. Chen, National Taiwan University, Taipei City/TW

Introduction: Sublobar resection is significantly associated with poor prognosis in early-stage non-small cell lung cancer (NSCLC) with visceral pleural invasion (VPI). Therefore, preoperative VPI prediction is crucial for guiding surgical strategies. The utilization of deep learning models for VPI prediction remains limited with suboptimal performance. This study aims to develop a computed tomography (CT)-based VPI deep learning (VPI-DL) prediction model for NSCLC with tumor sizes less than 3 cm.

Methods: This study consecutively retrospectively enrolled NSCLC patients with tumor size less than 3cm who underwent complete lung resection at Institute 1 from 2011 to 2015 and Institute 2 from 2017 to 2019, respectively (Figure). A CT-based VPI-DL model was developed for predicting VPI. The proposed VPI-DL model underwent external validation and was compared with the three other methods: the previously established DL model, consolidation-to-tumor (C/T) ratio, and assessment by three board-certified thoracic surgeons. The performance of the models was evaluated using the area under the curve (AUC), accuracy, and specificity.

Results: Among the total 835 enrolled patients from two institutes, 127 patients (15.2%) had positive VPI. We included 691 patients (VPI +/- = 104:587) from institute 1 in the training and internal validation sets, and 144 patients (VPI +/- = 23:121) from institute 2 in the external validation set. The proposed VPI-DL model outperformed other methods on the external validation set, achieving an AUC of 0.91 and an accuracy of 83.0%. The AUC of this proposed model in the external validation cohort was significantly superior to the other three methods, including the previously established DL model (0.77), C/T ratio (0.85), and the thoracic surgeons' average (0.74) (Table).

Conclusions: The proposed VPI-DL model exhibited expert-level performance and shows significant promise in preoperatively predicting VPI, providing valuable assistance in surgical planning for early-stage NSCLC.

Keywords: Visceral pleural invasion, non-small cell lung cancer, computed-tomography

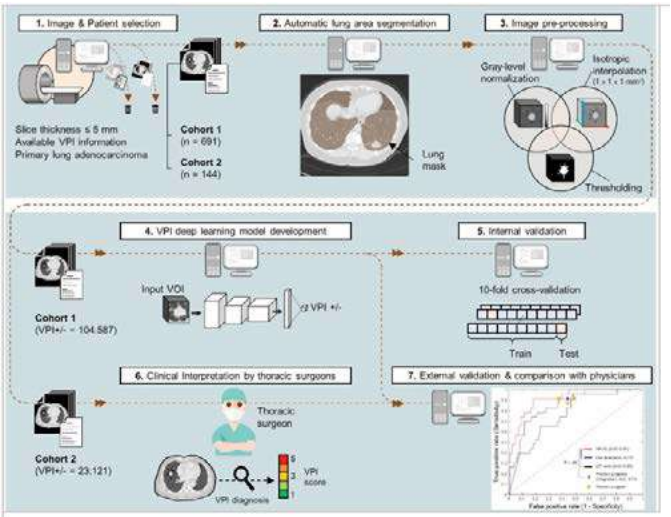

Table. Performance of the proposed VPI-DL prediction model and other methods in training set and external validation set.

A. Performance of three methods based on 5-fold cross-validation in training set. (while operating with 89% [93/104] sensitivity)

	Methods		
Parameters	The proposed VPI-DL model	The previously established DL model	C/T ratio
Accuracy	66.0 (318/691) [62.0, 69.0]	38.0* (507/691) [35.0, 42.0]	62.0* (348/691) [58.0, 65.0]
Specificity	62.0 (362/587) [58.0, 65.0]	29.0* (173/587) [26.0, 33.0]	57.0* (334/587) [53.0, 61.0]

P4.07G.01 Incidence of and Outcomes of Second Primary Lung Cancer after Resection for Screen-Detected Lung Cancer

A. Potter, S. Venkateswaran, Q. Guo, P. Senthil, D. Wang, P. Furlow, M. Lanuti, C-F.J. Yang, Massachusetts General Hospital, Boston/MA/USA

Introduction: Patients who undergo surgery for initial primary lung cancer (IPLC) detected via lung cancer screening remain at risk for the development of second primary lung cancers (SPLC); however, the incidence and outcomes of SPLC in this population are unknown. We evaluated the incidence of, and long-term outcomes associated with, SPLC among patients with resected IPLC detected via screening in the National Lung Screening Trial (NLST).

Methods: Patients who underwent surgery and were diagnosed with pathologic stage I IPLC detected via screening in the NLST from 2002-2009 were identified for analysis. The NLST collected data on the incidence of any SPLC diagnosed among study participants through the end of 2009. For the present study, we obtained an updated dataset with mortality data extended through 2015. The incidence rate of synchronous SPLC and of metachronous SPLC were evaluated. The 5-year cumulative incidence of metachronous SPLC was examined; subgroup analyses were performed by IPLC histology, pack-year smoking history, smoking status, and age at IPLC diagnosis. Lastly, 5-year overall and lung cancer-specific survival after the date of SPLC diagnosis were assessed.

Results: Of 337 patients in the study cohort, 23 patients were diagnosed with SPLC. The incidence of synchronous SPLC was 3.0% (n=10). During a median follow-up of 4.8 years after surgery for IPLC, 13 patients were diagnosed with metachronous SPLC, representing an incidence rate of 0.8 (95% CI: 0.5-1.5) per 100 person-years. The 5-year cumulative incidence of metachronous SPLC in the overall cohort was 3.5% (95%: 1.9-5.7), but varied notably by patient subgroup (Figure). The majority of synchronous (80.0%, n=8) and metachronous (61.5%, n=8) SPLCs were diagnosed at stage I. Five-year overall survival, from the date of SPLC diagnosis, was 80.0% (95% CI: 40.9-94.6) for synchronous SPLC and 53.9% (95% CI: 24.8-76.0) for metachronous SPLC. Five-year lung cancer-specific survival, from the date of SPLC diagnosis, was 88.9% (95% CI: 43.3-98.4) for synchronous SPLC and 61.5% (95% CI: 30.8-81.8) for metachronous SPLC.

Conclusions: In this analysis of patients who underwent surgery and were diagnosed with pathologic stage I IPLC in the NLST, the incidence of synchronous SPLC was 3.0% and the 5-year cumulative incidence of metachronous SPLC was 3.5%. There were notable differences in the stage at diagnosis and long-term survival of synchronous vs. metachronous second primaries.

P4.07G.02 Prediction of Relapse-free Survival of NSCLC Patients Through Multimodal Data Fusion Using Deep Learning Model

H.R. Kim[1], K. Beck[2], J.H. Kang[2], H. Hong[1], [1]Seoul Women's University, Seoul/KR, [2]Seoul St. Mary's Hospital,College of Medicine, The Catholic University of Korea, Seoul/KR

Introduction: The use of deep learning(DL) models has emerged as a superior approach for the diagnosis, treatment, and prognosis of lung cancer. However, current DL models predominantly rely on a single modality, such as textual clinical data, CT images, or omics data, each offering a restricted viewpoint of lung cancer. The aim of this study is to improve the prediction of relapse-free survival by integrating CT images and clinical data through a proposed DL model, namely IC-TCA-Net.

Methods: The dataset used in this study included clinical variables and preoperative chest CT images of 166 NSCLC patients who underwent curative surgical resection (Figure 1(a)). A total of 17 clinical variables, recognized for their prognostic significance, were collected from patient's basic information, laboratory results, and pathology examinations. Initially, univariate, and multivariate analysis were conducted to identify the optimal set of clinical features significantly associated with recurrence. Subsequently, IC-TCA-Net extracted deep image features, which are multi-scale features focused on tumor location, through the tumor-centric attention module and dual branches from CT images and tumor masks. Finally, clinical features and deep image features were concatenated for multimodal feature fusion, and provided recurrence prediction using a classifier composed of two fully connected layers (Figure 1(b)).

Results: We conducted 3-fold cross-validation to assess the performance of our proposed network using the entire dataset. In comparison to TCA-Net, which utilizes only CT images and tumor masks, IC-TCA-Net achieved the overall performance improvement in accuracy, balanced accuracy, sensitivity and AUC by 5.46%p, 4.3%p, 12.86%p and 0.05, respectively. Additionally, the Kaplan-Meier curves of IC-TCA-Net showed better separation than those of TCA-Net.(Figure 2)

Conclusions: This study demonstrated the effectiveness of deep learning-based data fusion, such as IC-TCA-Net. (This work was supported by the NRF grant funded by the Korea government MIST (No. RS-2023-00214043) and the Ministry of Education (No. 2021R1F1A1051297))

P4.07G.03 Real-World Clinical Outcomes and the Association Between EFS and OS in Early-Stage NSCLC Treated with Primary SBRT

M.E. Daly[1], P. Rai[2], S. Zhang[3], Y. Song[3], A. Jiang[3], J. Li[3], P. Jiang[3], C. Gao[3], J. Signorovitch[3], A. Arunachalam[2], A. Song[2], A. Samkari[2], [1]University of California Davis Comprehensive Cancer Center, Sacramento/CA/USA, [2]Merck & Co., Inc.,, Rahway/NJ/USA, [3]Analysis Group Inc.,, Boston/MA/USA

Introduction: Stereotactic body radiotherapy (SBRT) is the standard of care for unresectable early-stage non-small cell lung cancer (NSCLC), yet there are limited real-world clinical outcomes data. While intermediate endpoints (e.g., event-free survival [EFS]) have shown good correlation with overall survival (OS) in NSCLC clinical trials, few studies have quantified this correlation using real-world data. This study assessed clinical outcomes and association between real-world EFS (rwEFS) and OS among patients with early-stage NSCLC treated with SBRT.

Methods: This retrospective, observational analysis of SEER-Medicare database (2007-2020) included patients with newly diagnosed, stage I-II (N0) NSCLC (AJCC 8th edition) who received primary SBRT, with index date defined as initiation of SBRT. Patient characteristics were summarized. rwEFS and OS, overall and by stage, were described using Kaplan-Meier analyses. Data by recurrence status will be presented in the poster. Correlation between rwEFS and OS was assessed using the normal scores rank correlation.

Results: 3,014 patients with stage I-II NSCLC met eligibility criteria with a median follow-up of 2.4 years. Median age at diagnosis was 77.0 years; 37.7 % males, 86.9% whites, and mean Charlson comorbidity index was 2.4. The median rwEFS for the overall population was 26.2 months with 5-year rwEFS survival rate of 23.8%; data by stage shown in Figure 1. The median OS for the overall population was 48.9 months with 5-year OS survival rate of 42.3%; data by stage shown in Figure 2. The normal scores rank correlation demonstrated moderate but statistically significant correlation between rwEFS and OS (0.74; 95%CI: 0.72-0.77; P<0.001).

Conclusions: Among patients with early-stage NSCLC who received primary SBRT, modest survival outcomes were observed, highlighting the potential for novel strategies such as the incorporation of immunotherapy to augment outcomes for this patient population. Additionally, significant positive correlation between rwEFS and OS suggests rwEFS may predict OS.

P4.07G.04 BML is Associated with Potential Survival Advantages in Patients with Solid-Dominant Stage I NSCLC

W. Wang, L. Zhang, Sun Yat-sen University Cancer Center, Guangzhou/CN

Introduction: The optimal lymphadenectomy approach for solid-dominant stage I non-small cell lung cancer (NSCLC) is controversial. We compared postlobectomy survival outcomes to elucidate.

Methods: Patients diagnosed with solid-dominant stage I NSCLC between 2008 and 2015 were included and grouped according to the mode of lymphadenectomy. Disease-free survival (DFS) and overall survival (OS) were compared, and survival analysis was performed among the groups. Cox analysis was used to identify independent prognostic factors. Nomograms for survival prediction based on the lymphadenectomy mode were constructed and internally calibrated. Propensity score matching (PSM) was used to account for potential confounders. Subgroup comparisons between bilateral mediastinal lymphadenectomy (BML), systematic nodal dissection (SND), lobe-specific lymph node dissection (LSND) and systematic nodal sampling (SNS) were conducted.

Results: In total, 983 patients were included. The 5-year OS rates were 98.2%, 86.9%, 86.4%, and 82.8% (p=0.006), and the 5-year DFS rates were 87.1%, 76.4%, 69.5%, and 70.9% (p=0.008) in the BML, SND, LSND and SNS groups, respectively. Given PSM, patients who underwent BML had longer OS (HR, 0.358; 95% CI, 0.127-1.008; p=0.052) and DFS (HR, 0.563; 95% CI 0.295-1.074; p=0.081) than patients who underwent SND with marginal significance. Compared with L-SND and SNS, BML was associated with significantly improved OS (HR=0.343; 95% CI=0.123-0.958; p=0.041 and HR=0.250; 95% CI=0.088-0.709; p=0.009, respectively) and DFS (HR=0.474; 95% CI=0.258-0.868; p=0.016 and HR=0.467; 95% CI=0.232-0.938; p=0.032, respectively). Subgroup analyses demonstrated that in male patients and those whose tumours were larger or more advanced, BML was associated with significantly better OS and DFS than other types of lymphadenectomy.

Conclusions: BML may be associated with improved survival in patients with solid-dominant stage I NSCLC, and BML is recommended for such patients, especially those with large tumours or more advanced disease.

P4.07G.05 Prediction of Quality-of-Life Results after Lung Stereotactic Body Radiotherapy Using Functional Mapping on Gallium-68 Perfusion PET/CT

F. Lucia[1], J. Lamour[2], M. Geier[1], V. Bourbonne[1], U. Schick[1], M. Nebbache[1], F. Pinot[1], O. Pradier[1], G. Le Gal[1], S. Hennebicq[1], M. Mauguen[1], K. Kerleguer[1], F. Blanc-Beguin[1], D. Bourhis[1], P-Y. Salaun[1], P-Y. Le Roux[1], [1]University Hospital of Brest, Brest/FR, [2]University of Brest, Brest/FR

Introduction: The PEGASUS trial was the first study to evaluate and demonstrate the benefits of 68Ga-perfusion PET/CT in the lung stereotactic body radiotherapy (SBRT) planning process in preserving functional lung volumes while respecting target volume coverage and doses to other organs at risk. Here we report the prespecified exploratory endpoint of SBRT on health-related quality of life (HRQoL).

Methods: In this a single-center prospective study, we recruited patients planned to be treated in the radiotherapy department at the Brest University Hospital, France, with SBRT for primary or secondary lung tumors. PROs were assessed at the first visit, 1 month, 3 months and every 3 months until 12 months after SBRT using the European Organisation for the Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire Core 30 items (QLQ-C30), the EORTC Quality of Life Questionnaire Lung Cancer 13 items (QLQ-LC13), and the European Quality of Life 5 Dimensions-5 Level (EQ-5D-5L) questionnaire. The key exploratory HRQoL endpoints (analyzed for all patients who completed at least QLQ-C30 at least one time point after SBRT) were baseline-to-early change (between 1 month and 3 month) and baseline-to-late change (between 6 month and 12 month) in the QLQ-C30 global health status (GHS)/quality-of-life (QoL) score and in the deterioration of the dyspnea (patient-reported lung toxicity). Explorative analysis of the impact of baseline HRQoL, patient- and SBRT-related characteristics, including PET perfusion-based functional parameters, on the change in QoL from baseline was analyzed using univariate analysis.

Results: Of the 60 patients included, 39 were analyzable as early-onset and 22 as late-onset. Thirteen (33%) and 7 (32%) patients had a deterioration of QoL. In univariate analysis, maximal dose to the heart, doses to the functional lung volume and pulmonary functional test parameters were significantly associated with the early deterioration of HRQoL. Only doses to the functional lung volume were significantly associated with the late deterioration of HRQoL.

Conclusions: In our study, increased radiation doses in functional lung volume PET bases dose parameters were significantly associated with decreased of HRQoL unlike anatomic lung parameters. Functional lung avoidance planning guided by perfusion PET/CT may be a simple and noninvasive method to improve HRQoL in patients treated with lung SBRT.

P4.11D.01 TRITON: Tremelimumab + Durvalumab + Chemotherapy (CT) vs Pembrolizumab + CT in mNSCLC with STK11, KEAP1 and/or KRAS Mutations

F. Skoulidis[1], H. Borghaei[2], E.B. Garon[3], T.A. Leal[4], J. Kaufman[5], S.V. Liu[6], E. Nadler[7], S.P. Patel[8], S. Peters[9], V. Velcheti[10], A. Gautam[11], U. Emeribe[11], L. Luciani-Silverman[11], J.V. Heymach[1], [1]The University of Texas M.D. Anderson Cancer Center, Houston/TX/USA, [2]Fox Chase Cancer Center, Philadelphia/PA/USA, [3]David Geffen School of Medicine at UCLA, Los Angeles/CA/USA, [4]Winship Cancer Institute, Emory University, Atlanta/GA/USA, [5]Ohio State University, Columbus/OH/USA, [6]Georgetown University, Washington/DC/USA, [7]Baylor University Medical Center, US Oncology Network, Dallas/TX/USA, [8]University of California San Diego Moores Cancer Center, La Jolla/CA/USA, [9]Centre Hospitalier Universitaire Vaudois, Lausanne University, Lausanne/CH, [10]NYU Grossman School of Medicine, New York/NY/USA, [11]AstraZeneca, Gaithersburg/MD/USA

Introduction: Mutations in STK11 and KEAP1, present in approximately 20% and 15% of patients respectively with non-squamous metastatic NSCLC (mNSCLC), lead to an immunosuppressive tumor microenvironment and are associated with inferior clinical outcomes with anti-PD-(L)1-based chemo-immunotherapy, especially when co-mutated with KRAS. Patients with tumors bearing STK11, KEAP1 and/or KRAS mutations may benefit from combinations with CTLA-4 inhibitors, aimed at increasing immune responses. In the phase 3 POSEIDON trial (NCT03164616), first-line tremelimumab (T) + durvalumab (D) + CT significantly improved overall survival (OS; HR 0.77 [95% CI 0.65-0.92]; P=0.0030) vs CT. These results were maintained after a median follow-up of >5 years. Subgroup analyses showed sustained OS improvement with T+D+CT vs CT in patients with mNSCLC with STK11 (non-squamous), KEAP1 (all histologies, due to small sample size), and KRAS (non-squamous) mutations (HR [95% CI] 0.57 [0.32-1.04), 0.43 [0.16-1.25], and 0.55 [0.36-0.83], respectively). The TRITON study will further investigate the signal of efficacy observed in the POSEIDON subgroup analysis. TRITON will compare T+D+CT vs pembrolizumab (P) + CT (a standard treatment for non-squamous mNSCLC) in patients with STK11, KEAP1 and/or KRAS mutations. The results will help to inform clinical practice and to establish a biomarker-driven treatment strategy for these difficult-to-treat patients.

Methods: TRITON (NCT06008093) is a phase 3b, multicenter, open-label, 2-arm parallel randomized study. Eligible patients, aged ≥18 years, must have non-squamous mNSCLC (no EGFR or ALK alterations), with STK11, KEAP1, or KRAS mutations/co-mutations, no prior systemic therapy for mNSCLC, and ECOG performance status of 0/1. Approximately 280 patients will be randomized 1:1 to receive either T+D+CT or P+CT. In the T+D+CT arm, patients will receive T (75 mg) + D (1500 mg) + carboplatin (AUC 5 or 6)/cisplatin (75 mg/m2) + pemetrexed (500 mg/m2) every 3 weeks (Q3W) for 4 cycles (a fifth dose of T [75 mg] will be given in combination with D, post-platinum at week 16), followed by maintenance D (1500 mg) + pemetrexed (500 mg/m2) Q4W until disease progression. In the P+CT arm, patients will receive P (200 mg) + carboplatin (AUC 5 or 6)/cisplatin (75 mg/m2) + pemetrexed (500 mg/m2) Q3W for 4 cycles, followed by maintenance P (200 mg) + pemetrexed (500 mg/m2) Q3W until disease progression, for up to 24 months.

Randomization is stratified by mutation type (KRAS [without STK11 or KEAP1] mutations are capped at 33% of the total sample) and tumor PD-L1 expression (≥1% vs <1%). Primary endpoints are OS in all patients and in the subset with STK11 or KEAP1 mutations/co-mutations. Key secondary endpoints include OS rates at 12 and 24 months, progression-free survival, objective response rate, duration of response (all RECIST v1.1; investigator-assessed) and safety/tolerability (CTCAE v5.0). The study will include up to 75 sites across the USA; as of April 5, 2024, there are 10 active sites and the first patient has been enrolled.

MONDAY, SEPTEMBER 9, 2024 - 18:30 - 20:00

P4.11D.02 Phase 3 Trofuse-007 Study: Sacituzumab Tirumotecan Plus Pembrolizumab vs Pembrolizumab Alone for NSCLC with PD-L1 TPS ≥50%

N. Frost[1], R. Ghori[2], A. Roy[2], A.T. Nunes[2], J.C-H. Yang[3], [1]Department of Infectious Diseases and Respiratory Medicine, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin/DE, [2]Merck & Co., Inc., Rahway/NJ/USA, [3]National Taiwan University Hospital and National Taiwan University Cancer Center, Taipei/TW

Introduction: Pembrolizumab (anti-PD-1) monotherapy is a standard of care first-line treatment for advanced or metastatic non-small-cell lung cancer (NSCLC) with PD-L1 TPS ≥50% without actionable genetic alterations; however, some patients do not respond to therapy or experience disease progression. Trophoblast cell-surface antigen 2 (TROP2) is another candidate for anticancer treatment and overexpression of TROP2 is associated with poor prognosis in patients with NSCLC. Sacituzumab tirumotecan (sac-TMT; also known as MK-2870/SKB264) is an antibody-drug conjugate (ADC) composed of the humanized TROP2 monoclonal antibody, a hydrolytically cleavable linker, and the cytotoxic drug KL610023. In patients with relapsed or refractory locally advanced or metastatic NSCLC, monotherapy with sac-TMT showed encouraging antitumor activity with a manageable safety profile. The complementary mechanisms of action of sac-TMT and pembrolizumab may provide more potent antitumor activity when given in combination compared with each therapy alone. To investigate this further, the TroFuse-007 study will evaluate the efficacy and safety of the addition of sac-TMT to pembrolizumab vs pembrolizumab alone in patients with previously untreated metastatic NSCLC with PD-L1 TPS ≥50%.

Methods: Approximately 614 eligible patients aged ≥18 y with previously untreated histologically or cytologically confirmed stage IV (per American Joint Committee on Cancer version 8.0) NSCLC, PD-L1 TPS ≥50% and no EGFR, ALK, or ROS1 alterations (nonsquamous only); ECOG PS 0 or 1; and measurable disease per RECIST version 1.1 will be enrolled. Patients with well-controlled HIV are permitted. Patients will be randomized 1:1 to receive either pembrolizumab 400 mg Q6W for up to 18 cycles plus sac-TMT 4 mg/kg Q2W or pembrolizumab 400 mg IV Q6W alone until progressive disease, intercurrent illness, patient withdrawal, unacceptable toxicity, prolonged interruption of study drug, or until maximum number of cycles (18 cycles for pembrolizumab). Randomization stratification factors include ECOG PS (0 vs 1), histology (squamous vs nonsquamous), TROP2 expression (low vs medium vs high), and geographic region (East Asia vs North America/Western Europe/Australia vs Rest of World). The primary endpoint is OS. Secondary endpoints include PFS, ORR, and duration of response per RECIST v1.1 by blinded independent central review, patient-reported outcomes (PROs), and safety. Tumor imaging will occur at baseline, Q6W until week 48, and Q12W thereafter until PD, start of new anticancer treatment, or withdrawal of consent. PD-L1 TPS will be assessed centrally using PD-L1 IHC 22C3 pharmDx (Agilent Technologies, Carpinteria, CA). PROs will be assessed using the European Organisation for Research and Treatment of Cancer (EORTC) Quality of life questionnaire core 30 (QLQ-C30); EORTC quality of life questionnaire and lung cancer module 13 (QLQ-LC13); NSCLC symptom assessment questionnaire (NSCLC-SAQ); and EuroQol 5-dimension, 5-level (EQ-5D-5L) questionnaires. AEs will be graded according to National Cancer Institute Common Terminology Criteria for Adverse Events version 5.0. Enrollment began in December 2023 and is currently ongoing.

P4.11D.03 Trial in Progress: Phase 1/2 Study of OBX-115 Engineered Tumor-Infiltrating Lymphocyte (TIL) Cell Therapy in Patients with Advanced Solid Tumors

A.J. Schoenfeld[1], A. Betof Warner[2], J.A. Chesney[3], S.S. Thomas[4], J.T. Moyers[5], G.K. In[6], A.N. Shoushtari[1], Y. Samhouri[7], P. Hari[8], G. Ramsingh[8], C. Renard[8], P. Prabhakar[8], L. Mclaughlin[8], K. H, [1]Memorial Sloan Kettering Cancer Center, New York/NY/USA, [2]Stanford University School of Medicine, Stanford/CA/USA, [3]UofL Health – Brown Cancer Center, Louisville/KY/USA, [4]Orlando Health Cancer Institute, Orlando/FL/USA, [5]The Angeles Clinic and Research Institute, Cedars-Sinai, Los Angeles/CA/USA, [6]Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles/CA/USA, [7]Allegheny Health Network Cancer Institute, Pittsburgh/PA/USA, [8]Obsidian Therapeutics, Inc., Cambridge/MA/USA, [9]The Ohio State University Comprehensive Cancer Center, The Ohio State University College of Medicine, Columbus/OH/USA

Introduction: Immune checkpoint inhibitors (ICI) have improved outcomes for patients with solid tumor malignancies; however, most patients relapse, after which options are limited. Non-engineered TIL cell therapy has shown promising efficacy in patients with ICI-resistant melanoma (Rohaan NEJM 2022, Chesney JITC 2022) and non-small cell lung cancer ([NSCLC] Creelan Nat Med 2021, Schoenfeld Cancer Discov 2024), but requires co-administration of systemic high-dose IL2, which has well-described high-grade toxicity frequently requiring specialized management and limiting patient eligibility. OBX-115 is a tumor-derived autologous T-cell immunotherapy (TIL cell therapy) expanded from patient tumor tissue and engineered with a transgene to express membrane-bound human IL15 (mbIL15), regulated by acetazolamide (ACZ), eliminating the need for high-dose IL2 (Figure 1). A first-in-human single-institution study (NCT05470283) evaluating the safety of OBX-115 in metastatic melanoma is ongoing (Amaria AACR 2024). The current study (NCT06060613) is enrolling patients with NSCLC and melanoma at multiple US sites using centralized manufacturing.

Methods: This phase 1/2, single-arm, open-label, nonrandomized, multicenter study will assess the safety, tolerability, and efficacy of the OBX-115 engineered autologous TIL cell therapy regimen in patients with metastatic NSCLC previously treated with an approved systemic therapy for metastatic disease (including an ICI-based regimen and/or targeted therapy where applicable) and progressed, no longer deriving benefit, or unable to continue due to treatment intolerance OR histologically confirmed unresectable Stage IIIC, IIID, or Stage IV metastatic melanoma (excluding uveal) with documented radiographic progression after systemic therapy containing an anti-PD-1/PD-L1 agent (if adjuvant, progression during or within 12 weeks after the last dose) and received a BRAF inhibitor ± MEK inhibitor if BRAF V600 mutation-positive. Patients may have treated and asymptomatic brain metastases. Patients must have ECOG PS of 0 or 1 and life expectancy >~6 months. Patients must have ≥1 lesion suitable for OBX-115 manufacturing (≥1.5 cm) and ≥1 RECIST v1.1-measurable lesion remaining after tumor tissue procurement. Primary objectives of Phase 1 are to characterize safety and tolerability and identify a recommended Phase 2 dose of OBX-115 + ACZ; Phase 2 will evaluate efficacy of the regimen (ORR using RECIST v1.1 per investigator). Cryopreserved OBX-115 is generated from the patient's own tumor tissue procured by surgical excision or core needle biopsy and is infused after standard- or low-dose lymphodepletion (cyclophosphamide and fludarabine), based on clinical status and prior treatments (Figure 2). No systemic high-dose IL2 is administered. ACZ is administered at cohort-defined doses once daily for up to 14 days starting day of OBX-115 infusion, with additional ACZ dosing at Week 6 for up to 14 days; patients with NSCLC with investigator-assessed suboptimal response may receive additional ACZ dosing at Weeks 12 and 18. ACZ may be redosed (melanoma or NSCLC) upon progression when new anticancer therapy is not immediately warranted. Four sites are open and recruiting, with additional sites being activated.

P4.11D.04 A Phase 1/2 Study of REGN7075 (EGFRÃ-CD28) Combined with Cemiplimab (anti-PD-1) In NSCLC: Trial in Progress Update

M.L. Johnson[1], E. Girda[2], D. Sohal[3], N.J. Lakhani[4], A.J. Olszanski[5], L. Fong[6], M. Kinnaman[7], H. Han[7], A. Moesta[7], Y. Hao[7], S. Li[7], S. Ganguly[7], F. Seebach[7], M. Mathias[7], N.H. Segal[8], [1]Sarah Cannon Research Institute, Tennessee Oncology, Nashville/TN/USA, [2]Division of Gynecologic Oncology, Rutgers Cancer Institute of New Jersey, New Brunswick/NJ/USA, [3]Division of Hematology/Oncology, University of Cincinnati Cancer Center, Cincinnati/OH/USA, [4]START Midwest, Grand Rapids/MI/USA, [5]Department of Hematology/Oncology, Fox Chase Cancer Center, Philadelphia/PA/USA, [6]Division of Hematology and Oncology, University of California San Francisco, San Francisco/CA/USA, [7]Regeneron Pharmaceuticals, Inc., Tarrytown/NY/USA, [8]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: There is a need to develop novel immunotherapies to enhance response rates to immune checkpoint blockade and in patients who progress on epidermal growth factor receptor (EGFR)-targeted therapies. REGN7075 is a human costimulatory bispecific antibody that bridges EGFR-expressing tumor cells with CD28+ T cells to further support T-cell activation by endogenous tumor antigens.

Methods: Open-label, Phase 1/2, first-in-human, global study to evaluate the safety, pharmacokinetics (PK), and efficacy of REGN7075 + cemiplimab in patients with advanced solid tumors (NCT04626635). Here, we focus on three non-small cell lung cancer (NSCLC) cohorts in the dose expansion phase. The study includes a dose escalation (Part 1) and dose expansion (Part 2) phase. Part 2 consists of tumor-specific expansion cohorts, including three cohorts of patients with metastatic/locally advanced NSCLC who are not candidates for curative surgery/radiation: (1) patients who are treatment-naïve with no targetable driver mutation (ALK/ROS1/EGFR/RET-fusion/MET exon 14 skipping) with any programmed cell death-ligand 1 expression level (cohort 1; n=95); (2) patients with an EGFR mutation (exon 19 deletion/L858R/exon 20 insertion/exon 18/21 atypical mutation) who received a third generation tyrosine kinase inhibitor (TKI; cohort 2; n=61); and (3) patients with an EGFR mutation who received a third generation TKI and prior platinum-doublet chemotherapy (cohort 3; n=56). Patients in cohorts 1 and 2 will receive four cycles of platinum-based chemotherapy concurrently with REGN7075 + cemiplimab. Eligible patients must have an Eastern Cooperative Oncology Group performance status of 0/1 and have received no prior immunotherapy. Primary objectives: safety and tolerability of REGN7075 ± cemiplimab (Part 1); objective response rate (REGN7075 + cemiplimab ± chemotherapy; Response Evaluation Criteria in Solid Tumors v1.1; Part 2). Secondary objectives: PK for REGN7075; overall survival, progression-free survival, duration of response, complete response, and disease control rates; patient-reported outcomes per the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire-Lung Cancer 13 (Part 2). As of February 23, 2024, 122 patients were enrolled in Part 1. The study is ongoing and open to enrollment.

P4.11D.05 EGFR Neoantigen Peptide Vaccine Combined with Tislelizumab and Chemotherapy for Advanced NSCLC Resistant to EGFR-TKI Therapy

L. Wang[1], S. Su[2], X. Lv[2], Y. Liu[2], F. Chen[2], J. Shao[2], B. Liu[2], [1]The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, Nanjing/CN, [2]The Comprehensive Cancer Centre of Nanjing Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School., Nanjing/CN

Introduction: The therapeutic efficacy of PD-1 monoclonal antibody combined with chemotherapy in EGFR-TKI resistant patients is still controversial. At present, neo-antigen vaccine shows a good prospect in NSCLC treatment. The neo-antigens produced by EGFR mutations have strong immunogenicity and are ideal antigens for vaccine. The combination of ICI and neo-antigen vaccine is expected to have a synergistic effect which can improve the immune suppression microenvironment and further enhance the anti-tumor immune response. This study aimed to explore the efficacy and safety of neo-antigen vaccine with tislelizumab (TIS) and chemotherapy in the treatment of advanced NSCLC resistant to previous EGFR-TKI treatment(NCT06095934).

Methods: This is a single arm, open, single center study with plans to enroll 20 patients. Eligible participants were adults aged ≥18 years with stage IIIB-IV EGFRmut NSCLC progressed after EGFR-TKI based treatment. Participants received chemo-immune induction (TIS plus pemetrexed or nab-paclitaxel plus carboplatin), combination(chemo-immune and 9 doses neo-antigen vaccine), and maintenance treatment (TIS with or without pemetrexed or nab-paclitaxel) until disease progression or intolerable toxic effects. Primary endpoint were safety and objective response rate (ORR); secondary endpoints included progression-free survival (PFS), disease control rate (DCR), 6-month and 1-year PFS rate and overall survival (OS). The study will also explore the prediction of biomarkers as well as antigen-specific response.

Results: At present, 15 patients have been enrolled in the study and a total of 11 patients have been vaccinated with EGFR neoantigen vaccine. 5 patients achieved PR (partial response) and 6 achieved SD (stable disease) according to RECIST-v1.1, within 45.45% of ORR and 100% of DCR. The longest PFS was over 21 months till present. Aside from transient fever, rash, and fatigue observed in 5 patients, no severe adverse events related to vaccine injection were observed. The 1-2 grade TRAEs are consistent with known immuno and chemotherapy, while no ≥3 grade AEs were observed. 7 patients have been explored biomarkers related to immune response. Notably, immune monitoring showed that 6/7 patients (85.7%) demonstrated vaccine-induced T cell responses against EGFR neo-antigen peptides and up-regulation of Th1 cytokines including IL-2,IFN-α,TNF-α post vaccination in serum of patients with PFS >4.9 months. Furthermore, the percentage of effect-memory T cells (CD45RO+CD62L-) increased in both peripheral blood CD4+T cells (P=0.0424,P<0.05) and CD8+ T cells (P=0.0242,P<0.05) post vaccination.

Conclusions: This ongoing study with small samples has shown that EGFR neo-antigen vaccine with tislelizumab and chemotherapy for TKI resistant EGFRmut NSCLC has preliminarily confirmed safety and feasibility. The clinical and immune responses were observed following the combination therapy, suggested that shared immunogenic EGFR neoantigen are promising immunotherapeutic strategy for large population of EGFR-TKI resistant NSCLC patients and further efficacy needs to be evaluated in the future.

P4.11D.06 A Phase II Trial of Restorative Microbiota Therapy with Chemoimmunotherapy in Metastatic Non-Small Cell Lung Cancer

A. Kulkarni, S. Kagalwalla, N. Fujioka, B. Manning, R. Kratzke, A. Khoruts, M.R. Patel, University of Minnesota, Minneapolis/MN/USA

Introduction: Immune checkpoint inhibitors (ICI) with or without platinum doublet chemotherapy form the backbone of treatment in advanced or metastatic non-small cell lung cancer (NSCLC). Despite the success of ICI in lung cancer treatment, only a fraction of patients have durable response to ICI and others develop treatment resistance. Pre-clinical and clinical studies provide compelling evidence that the composition of the gut microbiome modulates immunotherapy response and clinical outcomes of ICI in metastatic melanoma and lung cancer. Recently, studies in patients with melanoma have provided preliminary evidence that manipulating the gut microbiome using fecal microbiota transplant is feasible and has demonstrated promising results that may overcome resistance to ICI. We hypothesize that adding microbiota transplant therapy i.e restorative microbiota therapy (RMT), which involves repeated oral administration of encapsulated healthy donor microbiota to immunotherapy improves the gut microbiome diversity and augments anti-tumor efficacy and improves treatment outcomes.

Methods: This is a multicenter, randomized, double-blind Phase II trial of oral RMT or placebo combined with durvalumab plus tremelimumab and platinum doublet chemotherapy in patients with advanced or metastatic NSCLC (NCT04105270). RMT is administered as an oral encapsulated formulation of freeze-dried fecal microbiota (compound MTP-101C) prepared from the stool of healthy donors and manufactured using GMP protocols at the University of Minnesota Microbiota Therapeutics Program. The clinical trial will run in 2 phases. The first phase is the open-label safety component where 10 patients are directly assigned to the RMT capsules with durvalumab and tremelimumab plus standard platinum-doublet chemotherapy. If no safety concerns are noted, the study then moves to the second phase i.e double-blind randomized (RMT vs Placebo) portion where approximately 69 patients are randomized 2:1 to receive either RMT or placebo capsules. In the study, all patients receive RMT or placebo capsules weekly for 16 weeks, along with durvalumab and tremelimumab with platinum doublet chemotherapy every 3 weeks for 4 cycles followed by maintenance durvalumab and pemetrexed every 4 weeks until disease progression, treatment intolerance or up to 2 years whichever occurs earlier. Patients are evaluated for treatment response at 6 weeks and 12 weeks, and then every 8 weeks thereafter with radiographic imaging until disease progression. The primary objective of the study is to evaluate the safety and efficacy of RMT in combination with durvalumab plus tremelimumab and chemotherapy using progression-free survival (PFS) per Response Evaluation Criteria in Solid Tumors (RECIST v1.1) as assessed by the investigator. We will collect stool and blood samples at baseline and longitudinally during treatment.

P4.11D.07 A Single Arm, Exploratory Study Oftislelizumab Intrapleural Therapyin NSCLC Patients with Malignant Pleural Effusion

C. Chen, The First Affiliated Hospital of Soochow University, Soochow/CN

Introduction: Lung cancer is the most frequent cause of cancer worldwide, about 85% are non-small-cell lung cancer (NSCLC). Malignant pleural effusion (MPE) occurs in approximately 40% of advanced NSCLC patients and more frequently in adenocarcinoma. The presence of malignant effusion causes significant symptoms and result in decrease the quality of life and a poor prognosis. Herein, we conduct this study to evaluate the efficacy and safety of Tislelizumab intrapleural therapy combine immunochemotherapy in NSCLC patients with MPE.

Methods: This is a phase II, single arm, exploratory study conducting in the first affiliated hospital of Soochow University in China. Key inclusion criteria: stage IV NSCLC patients with symptomatic MPE, age≥18,ECOG PS 0-2, with EGFR/ALK sensitizing mutations patients should be failed to prior TKIs treatment. Patients who have received prior PD-1 or CTLA-4 immunotherapy will be excluded. All enrolled patients will receive Tislelizumab intrapleural administration in Day1 cycle 1 followed by Tislelizumab plus chemotherapy IV Q3W. We perform this study initially six enrolled patients in safety run-in phase followed by enrolled 14 patients in expansion phase. If 2 or less out of 6 patients experienced DLT in safety run-in phase, the trial will continue. All enrolled patients will receive immunochemotherapy until progression or unacceptable toxicity, consent withdraw or death. Primary endpoint: objective response rate (ORR) for controlling MPE. (WHO therapeutic criteria for pleural effusion).Secondary endpoints: Progression-free survival(PFS), objective response rate(ORR), duration of response(DoR) and safety.

P4.11D.08 Tislelizumab in Combination with Anlotinib as First-Line Treatment for Advanced Pulmonary Sarcomatoid Carcinoma: A Phase II Study

Z. Zeng, L. Xiong, Y. Zheng, X. Zhang, X. Zhang, A. Liu, Second Affiliated Hospital of Nanchang University, Nanchang/CN

Introduction: Pulmonary sarcomatoid carcinoma (PSC) is a rare non-small cell lung cancer (NSCLC) subtype with a poor prognosis. The phase II trial aims to evaluate the efficacy and safety of tislelizumab in combination with anlotinib in patients with stage III and IV PSC.

Methods: This is a single-arm, prospective, open-phase II trial conducted at the second affiliated hospital of Nanchang University to assess the efficacy and safety of tislelizumab in combination with anlotinib in patients with stage III and IV PSC. All patients received first-line treatment with tirelizumab in combination with anlotinib. The primary endpoint was objective response rate (ORR), secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety.

Results: Total 21 patients were enrolled from August 2021 to December 2023. In this study, the median age was 71 years (range 64.0-74.0), 76.2% were male, and 28.6% had a ECOG score of 2. The ORR was 85.7%, meeting the primary endpoint. Partial response (PR) and stable disease (SD) occurred in 10 (42.8%) and 8 (38.1%), respectively, and 1 (4.8%) achieving complete response (CR) (Fig.1A). The median PFS and OS were 8.0 months (95%CI: 0.38-0.82) and 13.4 months (95%CI: 0.29-0.78), respectively (Fig.1B-C). The main adverse events were immune-related toxicities associated with immunotherapy (irAEs), with an incidence rate of 52.4%. The incidence rate of treatment-related adverse events of grade 3 or higher (TRAE3) was 23.8% (5/21). No treatment-related deaths occurred.

Conclusions: Tislelizumab in combination with anlotinib as first-line treatment for PSC appears to be a safe and effective regimen. However, further confirmation through larger-sample studies is warranted. (ClinicalTrials.gov ID: NCT05375734).

Introduction: Fianlimab (anti-lymphocyte activation gene 3) and cemiplimab (anti-programmed cell death-1) are high-affinity, fully human IgG4 monoclonal antibodies. Cemiplimab has shown promising clinical efficacy in patients with non-small cell lung cancer (NSCLC) and no actionable mutations, alone (programmed cell death ligand-1 [PD-L1] expression ≥50%) and in combination with chemotherapy (regardless of PD-L1 expression). However, many patients do not respond or only respond for a limited time. Although the standard of care for NSCLC continues to evolve, one approach to potentially improve outcomes is combination therapy with multiple checkpoint inhibitors with or without chemotherapy. In a previous Phase 1 study of fianlimab plus cemiplimab (NCT03005782), clinically meaningful activity and an acceptable risk-benefit profile were observed in patients with advanced melanoma.

Methods: Two parallel, randomized, multicenter, Phase 2/3 studies are ongoing. In Study 1 (NCT05785767), investigators are evaluating fianlimab + cemiplimab versus cemiplimab monotherapy as first-line treatment in patients with advanced NSCLC and tumors expressing PD-L1 ≥50%. In Study 2 (NCT05800015), investigators are evaluating fianlimab + cemiplimab + platinum-doublet chemotherapy versus cemiplimab + chemotherapy in patients with advanced NSCLC regardless of PD-L1 expression. Eligibility criteria for either study include: patients with histologically confirmed squamous/non-squamous stage IIIB/C (not candidates for surgical resection or definitive chemoradiation) or stage IV NSCLC (no prior systemic treatment for recurrent/metastatic NSCLC); ≥1 radiographically measurable lesion per Response Evaluation Criteria in Solid Tumors v1.1; Eastern Cooperative Oncology Group performance status ≤1; and adequate organ and bone marrow function.

In the Phase 2 part of Study 1, patients will be randomized 1:1:1 into three treatment arms (IV every 3 weeks [Q3W]): fianlimab high dose + cemiplimab 350 mg (Arm A); fianlimab low dose + cemiplimab 350 mg (Arm B); or cemiplimab 350 mg + saline/dextrose placebo (Arm C). Similarly, the Phase 2 part of Study 2 will be used to determine the fianlimab dose selected for the Phase 3 part. Patients will be randomized 1:1:1 to receive fianlimab high dose + cemiplimab 350 mg + chemotherapy (Arm A), fianlimab low dose + cemiplimab 350 mg + chemotherapy (Arm B), or cemiplimab 350 mg + chemotherapy + placebo (Arm C), IV Q3W. In the Phase 3 part of both studies, patients will be randomized 1:1 into either Arm A or B, or the comparator Arm C.

For both studies, the primary endpoint of the Phase 2 part is objective response rate (ORR) per blinded independent central review. In the Phase 3 part, the primary endpoint is overall survival (OS). Secondary endpoints for both studies include tolerability, safety, ORR per investigator assessment, disease control rate, time to tumor response, duration of response, progression-free survival, OS (Phase 2), patient-reported outcomes, pharmacokinetics, and immunogenicity.

Both studies are currently open for enrollment, along with a third Phase 2 study in which fianlimab + cemiplimab + chemotherapy versus cemiplimab + chemotherapy will be evaluated as perioperative therapy in patients with stage II/III NSCLC (NCT06161441).

P4.11D.10 A Phase II Trial of Tiragolumab with Carboplatin, Pemetrexed, And Atezolizumab in Non-Squamous NSCLC and Brain Metastases

B. Schluger, T.F. Burns, H. Wang, D.P. Petro, J. Ohr, S.A. Burton, N. McCall, S. Choi, K.G. Abdullah, A. Niranjan, C.G. Hadjipanayis, L.C. Villaruz, University of Pittsburgh, Pittsburgh/PA/USA

Introduction: Registrational trials that have led to the approvals of immunotherapy alone or in combination with chemotherapy in patients with metastatic non-small cell lung cancer (NSCLC) have excluded patients with active brain metastases. There are encouraging phase II data supporting the antitumor activity of pembrolizumab monotherapy and the combination of carboplatin, pemetrexed and atezolizumab in patients with untreated NSCLC brain metastases. Tiragolumab, a monoclonal antibody that blocks TIGIT (T Cell Immunoreceptor with Ig and ITIM domains; an immune inhibitory receptor expressed on T cells and natural killer cells that interacts with CD155), can enhance anti-tumor activity when combined with immunotherapy and is currently being evaluated in combination with carboplatin, pemetrexed and atezolizumab in patients with newly diagnosed non-squamous NSCLC (SKYSCRAPER-06). We are conducting a phase II single arm investigator initiated clinical trial of this regimen in patients with newly diagnosed metastatic NSCLC and untreated brain metastases (NCT05746481).

Methods: Patients must have histologically or cytologically confirmed non-squamous NSCLC, with asymptomatic brain metastases with at least one untreated evaluable (modified RANO-BM) brain metastasis of 5 mm or more. Symptoms related to brain metastases requiring CNS radiation ≤ 2 weeks, steroids greater than prednisone 10 mg/d or equivalent or anti-epileptic therapy ≤ 2 weeks of treatment initiation are exclusionary. Patients must have adequate marrow function and an ECOG PS of 0 or 1. Tiragolumab 600mg IV is administered on day 1 of a 21-day cycle for 4 cycles in combination with atezolizumab plus carboplatin and pemetrexed, and then on day 1 of a 21-day cycle in combination with atezolizumab plus pemetrexed for up to 2 years as maintenance therapy until loss of clinical benefit, unacceptable toxicity, death or withdrawal of consent. MRI brain is performed at three weeks to assess safety and restaging MRI brain and CT will be done every nine weeks, thereafter. The primary end point is the proportion of patients that require salvage radiation therapy to the CNS within 18 weeks of study initiation. The proportion of participants requiring salvage therapy will be calculated with a 95% exact (Clopper-Pearson) confidence interval. Thirty-five patients will be enrolled with power in excess of 80% if the true P (salvage therapy) is less than or equal to 0.27. A stopping rule for excess toxicity, as measured by Grade 2 or worse CNS adverse events, will be employed after every five participants have received four cycles of treatment. Secondary endpoints include frequency of symptomatic CNS related adverse events, brain metastasis response rate (modified RANO-BM), ORR (RECIST v1.1), PFS, OS, PFS2 (PFS after salvage radiotherapy.) Accrual is ongoing.

P4.11D.011 Evaluating the Impact of Performance Status on Outcomes in Advanced Lung Cancer: A Phase II Clinical Trial

M.F. Porebski[1], S.C. Grant[2], W.J. Petty[3], J. Ruiz[3], P. Triozzi[3], B.J. Levine[4], J.N. Atkins[5], K. Khan[6], D.R. Soto-Pantoja[7], T.W. Lycan[3], [1]Department of Internal Medicine, Wake Forest School of Medicine, Winston Salem/NC/USA, [2]Section of Hematology and Medical Oncology, Tulane University School of Medicine, New Orleans/LA/USA, [3]Department of Hematology & Oncology, Wake Forest School of Medicine, Winston Salem/NC/USA, [4]Social Sciences and Health Policy, Wake Forest School of Medicine, Winston Salem/NC/USA, [5]Atrium Health Wake Forest Baptist Hematology and Oncology, North Wilkesboro/NC/USA, [6]Atrium Health Wake Forest Baptist Hematology and Oncology, High Point/NC/USA, [7]Wake Forest School of Medicine, Winston Salem/NC/USA

Introduction: The majority of metastatic non-small cell lung cancer (NSCLC) cases, lacking actionable tumor genetic alterations, are treated with immunotherapy with or without chemotherapy. Although NCCN guidelines include ECOG Performance Status (ECOG) 2 patients as candidates for systemic therapy, most registration trials for frontline therapy are limited to ECOG 0-1 patients. While ECOG performance status (PS) can be predictive for outcome, its value may be confounded by its subjectivity or by comorbidity (e.g., COPD). Additionally, PD-L1 is limited in predicting efficacy and is non-predictive for toxicity. Clinical trial data are needed to better define the first-line treatment approach for this large subgroup of patients and to develop better predictive assessments (e.g., patient-reported outcomes [PROs]) and circulating biomarkers). Our study objective is to test the use of standard first-line systemic regimens in patients with advanced NSCLC and compare outcomes between PS 0-1 versus PS 2 after three months of treatment. Exploratorily, we will longitudinally collect PROs and analyze key metabolomic factors in the transcriptional activity of peripheral blood mononuclear cells to compare patients with/without treatment response and high-grade immunotherapy toxicity, guided by prior studies.

Methods: The present study is a non-randomized phase II clinical trial (NCT04253964) that assigns advanced NSCLC patients to a standard first-line treatment regimen, stratifying outcomes per baseline ECOG PS: good (0-1) vs borderline (2). Eligibility criteria include: pathologically confirmed advanced NSCLC with no standard curative options, measurable disease, and no prior systemic therapy. Exclusion criteria include a high-level targetable tumor alteration, uncontrolled or autoimmune comorbidity, and pregnancy. Standard regimens are: pembrolizumab (PD-L1 ≥50%); carboplatin, pemetrexed, and pembrolizumab (PD-L1 <50%, non-squamous); or carboplatin, paclitaxel, and pembrolizumab (PD-L1 <50%, squamous). The primary outcome is progression-free survival (PFS) at three months, and we estimate our planned sample size of 105 patients will have 62% power to declare non-inferiority given no difference between two PS groups (90% CIs, margin -0.15, -0.05). Secondary outcomes include incidence of grade 3-5 treatment-related adverse events, change in quality of life by overall EORTC QLQ-C30 score, and deterioration of symptoms by ≥10 points on the QLQ-LC13 PRO measure. Exploratory outcomes will assess mitochondrial respiratory capacity of circulating mononuclear cells, mitochondrial function, plasma metabolomics, changes in COPD-specific PRO measures (i.e., COPD Assessment Test, mMRC dyspnea scale), and differences in PS assignment between treating physicians with an algorithmic assessment by the study team. Currently at 61% accrual (64/105), the study is anticipated to complete enrollment in 2025.

P4.11D.12 Phase 3 Trial of OSE2101 Versus Docetaxel in Patients with Non-Small Cell Lung Cancer & Secondary Resistance to Immunotherapy

S.V. LIU[1], J. SINGH[2], X. YANG[3], J. D'OLIMPIO[4], F. CAPPUZZO[5], R. DZIADZIUSZKO[6], S. VITERI[7], C. CHEVALIER[8], S. COMIS[8], T. VANDEWALLE[8], V. GABARRE[8], F. MONTESTRUC[9], B. VASSEUR[8], J. REMON[10], B. BESSE[10], [1]Georgetown Lombardi Comprehensive Cancer Center, Washington/WA/USA, [2]Alliance for Multispecialty Research (AMR) - Kansas City Oncology, Merriam/KS/USA, [3]Bons secours Hematology and Oncology, Greenville/SC/USA, [4]Clinical Research Alliance, Male Success/NY/USA, [5]IRCCS Regina Elena National Cancer Institute, Rome/IT, [6]Department of Oncology & Radiotherapy and Early Phase Clinical Trials Center, Medical University of Gdansk, Gdansk/PL, [7]UOMI Cancer Center, Clínica Mi Tres Torres, Barcelona/ES, [8]OSE Immunotherapeutics, Paris/FR, [9]eXYSTAT, Malakoff/FR, [10]Paris-Saclay University, Institut Gustave Roussy, Villejuif/FR

Introduction: OSE2101 is a therapeutic cancer vaccine composed of multiple peptides restricted to HLA-A2 phenotype targeting tumor-associated antigens (CEA, HER-2, MAGE-2, MAGE-3, P53) frequently expressed in non-small cell lung cancer (NSCLC). In a prior phase 2 study in heavily pretreated patients with NSCLC, OSE2101 strongly induced T cell immune responses, with higher immune responses associated with longer survival (OS). In the prior randomized ATALANTE-1 study, OSE2101 significantly improved OS with a better safety profile and quality of life (QoL) compared to third-line chemotherapy (CT) in patients with NSCLC with progressive disease (PD) after at least 12-weeks of second line anti-PD(L)1 monotherapy. The aim of the phase III ARTEMIA study is to confirm the benefit of OSE2101 versus CT in second-line treatment of patients with NSCLC and secondary resistance to immune checkpoint inhibitor (ICI) given in the first line setting.

Methods: HLA-A2 positive patients with metastatic NSCLC without known EGFR, ALK, ROS1 or other targetable mutations, no brain metastases, ECOG PS 0 or 1, who had a PD after 24 weeks or more of first line CT-ICI including at least 12 weeks of maintenance ICI without cytotoxic therapy, will be randomized 2:1 to receive either OSE2101 or docetaxel. Randomization will be stratified by histology (squamous vs non-squamous), and ECOG PS (0 or 1). Patients will receive subcutaneous OSE2101 every 3 weeks for 6 injections, then every 8 to 12 weeks up to end of year 2. In the control group, patients will receive docetaxel at 75mg/m2 per standard of care. Primary endpoint is OS defined as time from randomization to death of any cause. Secondary endpoints include QoL Physical, Role, and Global Health Score by EORTC QLQ-C30 questionnaire, and time to ECOG PS deterioration. For sample size calculation, assuming a hazard ratio of 0.70 with a power of 80% using a 2-sided log-rank test, 363 patients will be enrolled to reach 269 events. An interim analysis is planned.

Conclusions: The ARTEMIA phase 3 study aims to confirm the benefit on survival and quality of life of the therapeutic cancer vaccine OSE2101 compared to docetaxel in second-line treatment of HLA-A2 positive patients with NSCLC and secondary resistance to immune checkpoint inhibitor.

P4.11E.01 Real-World First-Line Maintenance Immunotherapy for Nonsquamous Advanced/Metastatic NSCLC without Targetable Mutations

M. Shah[1], U. Tapan[2], K.F. Bell[1], A. Aziez[3], X. Sun[4], M. Du[5], E. Du[5], Q. Hua[5], H. Yang[5], [1]GSK, Collegeville/PA/USA, [2]Section of Hematology and Medical Oncology, Boston University Chobanian & Avedisian School of Medicine and Boston Medical Center, Boston/MA/USA, [3]GSK, Basel/CH, [4]GSK, Research Triangle/NC/USA, [5]Analysis Group, Boston/MA/USA

Introduction: Real-world data comparing first-line maintenance (1LM) immunotherapy (IO)±pemetrexed for patients with nonsquamous (NSQ) advanced/metastatic non-small cell lung cancer (a/mNSCLC) are lacking. This retrospective study compared effectiveness and safety of 1LM IO vs IO+pemetrexed for patients with NSQ a/mNSCLC.

Methods: Physician-provided data, collected via chart review, included patients from Canada, France, Germany, Italy, Spain, the UK, and the US who had NSQ (including mixed squamous/NSQ) a/mNSCLC without targetable mutations, completed 4-6 cycles of 1L chemotherapy (platinum-based chemotherapy+IO, ±pemetrexed) between January 2019 and March 2021, were ≥18 y, and had achieved stable disease or complete or partial response on completion of 1L therapy. Patients who received 1LM of either IO monotherapy or IO+pemetrexed were selected for the current analysis. Progression-free survival (PFS; time from 1LM initiation to progression, death, or second-line maintenance initiation), overall survival (OS; time from 1LM initiation to death), safety, and time to treatment discontinuation (TTD) were assessed.

Results: By selecting patients with NSQ a/mNSCLC receiving 1LM achieving stable disease or complete or partial response, 469 were eligible (median age 64.0 y, 70.1% male, 85.7% current/former smokers, 75.3% PD-L1 ≥1%), 283 received IO, most commonly pembrolizumab monotherapy, and 186 received IO+pemetrexed, most commonly pembrolizumab+pemetrexed. Patients receiving IO monotherapy vs IO+pemetrexed had longer median PFS and median OS (Table; similar efficacy results were seen for patients with PD-L1 ≥1%), had longer median TTD (20.0 vs 11.0 months, P<0.001), and were less likely to experience fatigue (28.3% vs 39.8%, P<0.05) and anemia (16.6% vs 31.2%, P<0.001) while on 1LM therapy.

Conclusions: Among the selected patients with NSQ a/mNSCLC who achieved stable disease or complete or partial response to 1L therapy, the addition of pemetrexed to IO for 1LM did not appear to confer additional clinical benefit.

Keywords: amNSCLC, non-squamous, maintenance immunotherapy

Table. Real-world PFS and OS stratified by IL maintenance therapy

1L maintenance therapy	IO n=283	IO + pemetrexed n=186	Hazard ratio (95% CI)[a]
Adjusted median PFS, mo	21.1	11.1	0.56 (0.37–0.76)
Adjusted median OS, mo	35.3	27.3	0.70 (0.41–0.98)

[a]The adjusted survival curve were estimated using standardized mortality ratio weighting method. 95% CIs were estimated using bootstrapping.

P4.11E.02 Efficacy of Pembrolizumab Plus Pemetrexed in Older Patients with Non-squamous NSCLC According to PD-L1 Status from the CJLSG1901 Study

Y. Kogure[1], H. Hashimoto[1], S. Ikeda[2], T. Harada[3], A. Hino[4], S. Miura[5], Y. Goto[6], K. Fujiwara[7], N. Kaktakami[8], K. Kubota[9], N. Murata[10], M. Mori[11], T. Abe[12], N. Yamamoto[13], H. Saka[1,14], M. Kondo[6], [1]NHO Nagoya Medical Center, Nagoya/JP, [2]Kanagawa Cardiovascular and Respiratory Center, Yokohama/JP, [3]JCHO Hokkaido Hospital, Sapporo/JP, [4]Chiba University Hospital, Chiba/JP, [5]Niigata Cancer Center Hospital, Niigata/JP, [6]Fujita Health University, Toyoake/JP, [7]NHO Okayama Medical Center, Okayama/JP, [8]Takarazuka City Hospital, Takarazuka/JP, [9]Graduate School of Medicine, Nippon Medical School, Tokyo/JP, [10]Japanese Red Cross Aichi Medical Center Nagoya Daini Hospita, Nagoya/JP, [11]NHO Osaka Toneyama Medical Center, Toyonaka/JP, [12]Ogaki Municipal Hospital, Ogaki/JP, [13]Wakayama Medical University Graduate School of Medicine, Wakayama/JP, [14]Matsunami General Hospital, Kasamatsu/JP

Introduction: Pembrolizumab combined with pemetrexed and carboplatin is the standard of care for patients with metastatic non-squamous non-small cell lung cancer (NSCLC); however, its efficacy and safety remain unclear in older patients with metastatic non-squamous NSCLC.The CJLSG1901 phase 2 study suggested pembrolizumab plus pemetrexed was a promising candidate as a novel first-line treatment strategy for patients aged ≥75 years with metastatic non-squamous NSCLC. Previous studies also revealed that pembrolizumab efficacy varied with PD-L1 status in advanced non-squamous NSCLC. Therefore, this study aimed to evaluate the efficacy and safety of pembrolizumab plus pemetrexed according to PD-L1 status in this patient population.

Methods: We investigated the efficacy and safety of pembrolizumab combined with pemetrexed in older patients with metastatic non-squamous NSCLC according to PD-L1 status (< 1% vs 1-49%) in the post-hoc subgroup analysis from CJLSG1901. The Clopper-Pearson method was used to estimate the 95% confidence interval (CI) of objective response rate (ORR). The Kaplan-Meier method was used to estimate survival functions, and the Brookmeyer-Crowley method was used to estimate the 95% CIs of median survival time.

Results: A total of 49 patients were enrolled between July 2020 and May 2022. The median age was 79 years (range, 75-91). The primary endpoint of ORR was 36.7% (95% CI: 23.4-51.7). The median progression-free survival (PFS) was 7.6 months (95% CI: 4.8-16.2), and the median overall survival (OS) was 19.4 months (95% CI: 11.8- not reached). Overall, 21 patients had PD-L1 < 1% and 28 patients had PD-L1 1-49%. Characteristics such as median age, sex, Eastern Clinical Oncology Group performance status, and stage were similar between the groups. ORR of the patients with PD-L1 < 1% and 1-49% was 23.8% (95% CI: 8.2-47.2), and 46.4% (95% CI: 27.5-66.1), respectively. The median PFS of patients with PD-L1 < 1% and 1-49% were 4.4 months (95% CI: 2.9-24.1) and 7.8 months (95% CI: 5.5-18.2), while the median OS was 19.4 months (95% CI: 6.4-not reached) and 19.1 months (95% CI: 11.8-not reached), respectively. All patients experienced adverse events (AEs) of any grade, regardless of PD-L1 status. AE severities were similar between groups. Serious treatment-related AEs were observed in five (25%) patients with PD-L1 < 1% and seven (25%) patients with PD-L1 1-49%.

Conclusions: The ORR and median PFS of patients with PD-L1 1-49% were numerically higher than those of patients with PD-L1 < 1%; however, OS were similar in both groups. AE proportions and severities were similar among all patients with PD-L1 <50%. Thus, pembrolizumab plus pemetrexed may be effective in older patients with non-squamous NSCLC with PD-L1 <1% and 1-49%.

P4.11E.03 Safety and Efficacy of AL2846 Combined with TQB2450 In NSCLC Patients with Previous PD-(L)1 Inhibitor Treated (NCT06116240)

D. Huang[1], Z. Song[2], J. Qin[3], D. Zhong[4], Y. Chen[5], W. Huang[6], G. Li[7], L. Lin[1], L. Wang[1], [1]Tianjin Medical University Cancer Institute & Hospital, Tianjin/CN, [2]Affiliated Hospital of Hebei University, Baoding/CN, [3]Tianjin Chest Hospital, Tianjin/CN, [4]Tianjin Medical University General Hospital, Tianjin/CN, [5]Henan Key Laboratory of Cancer Epigenetics, Cancer Hospital, The First Affiliated Hospital, College of Clinical Medicine, Medical College of Henan University of Science and Technology, Luoyang/CN, [6]Jiangmen Central Hospital, Jiangmen/CN, [7]Tianjin Fifth Central Hospital, Tianjin/CN

Introduction: For patients who have failed first-line treated by PD-1/PD-L1 inhibitors and platinum-containing chemotherapy, there is currently no higher-level evidence of more effective treatment options other than single-agent chemotherapy.

Methods: This open-label, multicenter study include two phases of dose-escalation and dose-expansion. In dose-expansion phase, patients with locally advanced or metastatic NSCLC were enrolled and previous treated with PD-(L)1 inhibitors, either singly or in combination with platinum-based chemotherapy. The primary endpoints were safety and objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), disease control rate (DCR), duration of response (DOR) and overall survival (OS). Patients received a fixed dose of TQB2450 (PD-L1 inhibitor) 1200mg/Q3W, and AL2846 (multi-target tyrosine kinase receptor inhibitor) 120mg/QD, every 3 weeks in a treatment cycle, and imaging assessment every 6 weeks. Efficacy was evaluated according to RECIST 1.1/iRECIST evaluation criteria, mainly RECIST 1.1.

Results: As of January 31, 2024, 44 patients have been enrolled in the study, 39 patients can be evaluated for efficacy. The number of prior systemic lines of therapy was range1~3. In terms of histopathologic subtypes, most of them were squamous cell carcinoma. Preliminary efficacy results showed that ORR assessed by the investigators was 25.6% (10/39), the median PFS was 5.72 months (95% confidence interval [CI], 4.07~8.21), DCR was 94.9%(37/39), the median DOR was 5.54 months (95% CI, 3.52~NR), the median OS was 13.44 months (95% CI, 7.98~21.26). Most PR were achieved at the first time of efficacy evaluation. Among the best response was evaluated as SD, 22 patients had tumor shrinkage, of which 8 patients had tumor shrinkage to more than 20%. Regarding safety, Grade ≥3 treatment related adverse events (TRAEs) occurred in 59.1% (26/44) of patients, the most common events involved hypertension (22.7%, 10/44), diarrhea (4.5%, 2/44), palmar and plantar redness syndrome (2.3%, 1/44), proteinuria (2.3%, 1/44). 11.4%(5/44) of patients occurred dose reduction because of TRAEs, mainly were caused by hypertension, diarrhea, proteinuria.

Conclusions: AL2846 combined PD-L1 inhibitor showed promising clinical activity in patients with locally advanced or metastatic NSCLC who previous treated with PD-(L)1 inhibitors. Based on the good efficacy and safety results of this study, the phase III study is currently being recruited.

P4.11E.05 A Phase II, Randomized Trial of Trilaciclib Plus Chemotherapy and Tislelizumab as First-Line Treatment for Advanced SqNSCLC

Y. Wang, H. Shi, West China Hospital,Sichuan University, Chengdu/CN

Introduction: Immune checkpoint inhibitors (ICIs) combined with chemotherapy has been established as the standard first-line treatment for advanced squamous non-small cell lung cancer (sqNSCLC), regardless of PD-L1 expression levels. However, chemotherapy-induced myelosuppression (CIM), resulted in reduced neutrophils, platelets, and anemia, seriously affecting patients' quality of life and survival. Trilaciclib, a CDK4/6 inhibitor administered prior to chemotherapy for multilineage myeloprotection, has been commercialized in America and China as a myeloprotective agent for specific SCLC chemotherapy regimens. This study aimed to explore the myeloprotective effects of trilaciclib in patients with squamous NSCLC receiving a combination therapy of chemotherapy (carboplatin+paclitaxel) and ICI (tislelizumab).

Methods: This is a prospective, randomized, multi-center, phase II clinical study (NCT05900921). Eligible patients with advanced, untreated squamous non-small cell lung cancer, ECOG PS of 0-1 were randomly assigned 1:1 to two groups. The patients in the treatment group received trilaciclib (240 mg/m2) plus paclitaxel (175 mg/m2), carboplatin (AUC=5), and tislelizumab (200mg,Q3W) for 4-6 cycles (induction period), followed by maintenance treatment with trilaciclib plus tislelizumab (200mg,Q3W) until disease progression or unacceptable toxicity. The patients in the control group received the same chemotherapy plus ICI treatment without trilaciclib. The primary endpoint was the occurrence of grade ≥3 neutropenia during induction period. Secondary endpoints included other myeloprotective indicators, such as the incidence of thrombocytopenia and anemia, anti-tumor efficacy such as objective response rate, progression-free survival, and overall survival. If subsequent chemotherapy is indicated for patients after first-line progression, trilaciclib will be provided to observe the myeloprotective effect in second-line treatment.

Results: Between August 9, 2023 and March 31, 2024, 11 patients were randomized into 2 groups (treatment group, n=4; control group, n=7). 7 patients completed ≥1 cycle follow-up (3 in the experimental group and 4 in the control group). Baseline demographic characteristics were similar between the two groups. All the 7 patients were male, ECOG score 0-1, 49-70 years old, and stage IV squamous non-small cell lung cancer. In the treatment group: the reported CIM were neutropenia (1 patient had grade 2 and 1 patient had grade 3), thrombocytopenia (1 patient had grade 1), anemia (2 patient had grade 1,assessed according to CTCAE 5.0). One patient was administrated with granulocyte colony-stimulating factor (G-CSF) to treat grade 3 neutropenia. All 3 patients achieved partial responses. In the control group, The reported CIM in the 4 patients were neutropenia (1 patient had grade 3 and 2 patient had grade 4), thrombocytopenia (1 patient had grade 1), anemia (2 patient had grade 2, 1 patient had grade 1). All the 3 patients reported grade ≥3 neutropenia were treated with G-CSF. The anti-tumor efficacy of 3 patients was evaluable, 1 patient achieved partial responses and 2 patients achieved stable disease.

Conclusions: Preliminary results revealed that trilaciclib-based combination therapy demonstrated potential improvement of the tolerability of chemotherapy in patients with sqNSCLC. The study is currently recruiting.

P4.11E.06 Envafolimab Combined with Recombinant Human Endostatin and Chemotherapy as First-Line Treatment for Advanced Squamous NSCLC

L. Liu[1], J. Liu[2], Y. Liu[1], X. Yu[2], S. Li[1], B. Li[1], S. Guo[2], Y. Zhang[3], Y. Wang[1], T. Zheng[1], W. Han[1], Y. Xie[2], L. Zhou[2], J. Zhang[2], Y. Zhao[2], Y. Li[2], Y. Hu[1], J. Wang[1], H. Cao[1], [1]Qilu Hospital of Shandong University, Jinan/CN, [2]Shandong Public Health Clinical Center, Jinan/CN, [3]Shandong Cancer Hospital, Jinan/CN

Introduction: In recent years, immunotherapy combined with chemotherapy has been established as the standard first-line treatment for patients with advanced squamous NSCLC (sq-NSCLC). Antiangiogenic drugs can enhance the efficacy of immunotherapy and chemotherapy by normalizing blood vessels and improving the tumor microenvironment. However, antiangiogenic agents have a high risk of hemorrhage in the treatment of sq-NSCLC. Recombinant Human Endostatin (Rh-endostatin) has previously been proven to prolong survival in patients with sq-NSCLC without increasing the risk of hemorrhage, and is currently the only approved antiangiogenic agent for first-line treatment of sq-NSCLC. Envafolimab, the first approved single-domain anti-PD-L1 antibody, represents a potential advance because it can be conveniently administered subcutaneously. This study aimed to investigate the efficacy and safety of envafolimab plus Rh-endostatin and chemotherapy as first-line treatment for advanced sq-NSCLC.

Methods: This was a single-arm, multi-center, prospective, phase II clinical study (NCT05243355). Between December 2021 and January 2024, consecutive patients with histologically or cytologically confirmed sq-NSCLC were enrolled. Patients received envafolimab (300mg, subcutaneous, day 1,) and Rh-endostatin (210 mg, continuous intravenous infusion over 72 h, day 1-3) combined with platinum-based chemotherapy every 3 weeks for 4-6 cycles, followed by maintenance treatment with envafolimab until disease progression (PD), unacceptable toxicity, or patient refusal. The primary endpoint was the 1-year PFS rate, and secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), safety, and tolerability.

Results: Overall, 26 patients with previously untreated stage IIIB/IIIC or IV sq-NSCLC were screened in this study. As of January 29, 2024, 24 patients were included for safety evaluation with 21 patients for efficacy analysis. According to RECIST v1.1, the ORR was 81% (95% CI, 58.1-94.6), and the DCR was 100% (95% CI, 83.9-100). Survival data were not mature at present. Adverse events (AEs) of any grade were reported in 95.8% (23/24) patients, the most common AEs were myelosuppression, alopecia, nausea, which were more related to chemotherapy. 45.8% (11/24) patients experienced immune-related AEs (irAEs), the most common irAE was rash (7/24, 29.2%). Grade ≥ 3 irAEs occurred in four patients, which were mainly skin-related toxicities. There were no unexpected AEs identified in this study.

Conclusions: Envafolimab plus Rh-endostatin and chemotherapy resulted in a favorable clinical efficacy with tolerable safety profile in advanced sq-NSCLC, representing a promising treatment regimen for this population.

P4.11E.07 Envafolimab Combined with Recombinant Human Endostatin and Chemotherapy for NSCLC, C. Miao1, S. Yuan2, 2Provincial Hospital Affiliated to University of Science and Technology of China, Hefei/CN

Introduction: In recent years, the integrated treatment modality of immunotherapy combined with anti-angiogenesis has achievedgratifying therapeutic effects in the second-line treatment of lung cancer. Envafolimab is the first PD-L1 drug to be injected subcutaneously. This study aimed to investigate the efficacy and safety of the combined first-line treatment modality involving Envafolimab, a subcutaneously injected PD-L1 inhibitor, with Recombinant Human Endostatin (Rh-endostatin) and chemotherapy in patients with driver gene-negative advanced Non-Small Cell Lung Cancer (NSCLC).

Methods: This was a single-arm, single-center, prospective, phase II clinical study. Between April 2022 and August 2023, consecutive eligible patients with histologically or cytologically confirmed with untreated stage IV NSCLC (excluding driver mutations) were enrolled. Patients received 4-6 cycles of Envafolimab (300 mg, subcutaneous, Day 1, every 3 weeks) and Rh-endostatin (210 mg, continuous intravenous infusion over 72 h, every 3 weeks) combined with platinum-based dual-agent chemotherapy, followed by maintenance therapy with Envafolimab and Rh-endostatin until disease progression or intolerable toxicity. The primary endpoints were the objective response rate (ORR) and disease control rate (DCR), and secondary endpoints included progression-free survival (PFS), overall survival (OS), safety, and tolerability.

Results: As of December 1, 2023, the median follow-up was 11.8 months (95% CI, 9.4-12.6). Twenty-nine patients with advanced NSCLC were enrolled at Shandong First Medical University Affiliated Cancer Hospital. Of the 29 patients, 14/29 were squamous cell carcinoma, and 15/29 were non-squamous non-small cell lung cancer. The ORR was 72.4% (95% CI, 56.1%-88.7%), and the DCR was 93.1% (95% CI, 76.8%-109.4%), showing statistically significant differences compared with data from previous results. Median PFS and OS were not reached yet. Safety was manageable with no ≥ grade 3 treatment-related adverse events (TRAEs) or immune-related adverse events (irAEs).

Conclusions: Envafolimab in combination with Rh-endostatin and chemotherapy as a first-line treatment for lung cancer exhibits favorable therapeutic efficacy with a manageable safety profile, which might represent a promising treatment regimen and warrant further investigation.

P4.11E.08 Integrated PK/PD Modeling for Ulileldlimab, an Anti-CD73 Monoclonal Antibody, In Non-Small Cell Lung Cancer Patients

J. Yanez[1], V. Wang[1], M. Khali[2], Y. Zhang[3], Y. Li[3], C. Xu[1], J-K. Chung[1], [1]I-Mab Biopharma, Rockville/MD/USA, [2]The University of Alabama, Birmingham/AL/USA, [3]TJ Bio, Shanghai/CN

Introduction: Ulileldlimab is a CD73 antagonistic monoclonal antibody designed to inhibit CD73 enzymatic activity leading to suppression of adenosine production. Adenosine has been shown to cause immunosuppression and PD-1/PD-L1 checkpoint inhibitor resistance. Complete inhibition of CD73 function across a wide range of expression and potentiation of PD-1/PD-L1 inhibitor activities in vivo supported Phase 1 clinical evaluation with combination therapies for non-small cell lung cancer (NSCLC) patients.

Methods: To evaluate the impact of ulileldlimab dosage after Phase 1 study, an integrated approach leveraging nonclinical and clinical results was applied, including target threshold estimation, PK/PD, population PK (popPK) modeling & simulation, and exposure-response (E-R) analyses. The target threshold in human serum was derived from functional activity inhibition and PK/PD analyses with consideration of tumor penetration rate. PK data from three previous clinical studies with ulileldlimab monotherapy or in combination with atezolizumab or toripalimab were used to construct the popPK model. The simulated exposure of ulileldlimab in humans was used to evaluate trough concentrations against the target threshold of different dosing regimens. Serum exposure, overall response rate (ORR), and progression free survival (PFS) data from the patients with treatment-naïve metastatic NSCLC who received ulileldlimab 20 and 30 mg/kg Q3W (in combination with toripalimab) were included in the E-R analyses.

Results: A target threshold of 80 μg/mL was derived from EC80 of the functional CD73 activity inhibition and the assumed tumor penetration rate. The 2-compartment popPK model with parallel linear and nonlinear eliminations captured adequately the ulileldlimab pharmacokinetics in human serum. It was observed that the 30 mg/kg Q3W dose was superior to the 20 mg/kg Q3W dose to provide ulileldlimab trough concentrations achieving and maintaining above 80 μg/mL after the third dose in the majority (95%) of the simulated population. The relationship between Ctrough after the first dose or at the steady state and the probability of ORR was explored. A clear trend of higher ORR probability was associated with higher trough concentration after the first dose or at the steady state. The Kaplan-Meier (K-M) curves of the longitudinal PFS stratified by a target threshold of 80 μg/mL after the first dose and at steady state reported a clear separation. The patients who achieved ulileldlimab exposure equal to or above 80 μg/mL showed a greater median PFS than those below. These PFS analyses by Ctrough further supported that the target threshold of 80 μg/mL may be clinically meaningful.

Conclusions: A population PK model was established and the integrated PK/PD analyses were performed. The E-R analysis showed a positive relationship between ulileldlimab concentration and the probability of ORR in patients with NSCLC. The K-M analysis indicated that the ulileldlimab Ctrough threshold of 80 μg/mL may be associated with PFS benefit and is likely clinically meaningful. The non-traditional integrated PK/PD coupled with modeling & simulation and exposure-response analyses and findings support and inform further ulileldlimab development in NSCLC patients.

P4.11E.09 The Efficacy of PD-1/PD-L1 Inhibitors Combined with Chemotherapy and Anti-Angiogenesis Therapy in Driver Gene-Negative NSCLC Brain Metastases

Y. Yi, Z. Zeng, Z. Lu, A. Liu, The Second Affiliated Hospital of Nanchang University, Jiangxi/CN

Introduction: The IMpower150 study suggest that immune checkpoint inhibition combined with chemotherapy and anti-angiogenic therapy may delay the onset of brain metastases, highlighting the urgent need for further clincial and preclinical investigations to explore optimal treatment modalities for driver-gene negative lung adenocarcinoma brain metastases. Theoretically, anti-angiogenic agents hold the potential to promote the normalization of tumor vasculature structure and function, correcting the immune-suppressive microenvironment, restoring drug penetration in the tumor core, and sensitizing to combined therapies. This study combined clinical restrospective analysis and precilinical experiments to elucidate the potential mechanisms underlying the therapeutic effects of PD-1 inhibitor combined with chemotherapy and anti-angiogenic treatment on driver gene-negative lung adenocarcinoma brain metastasis, focusing on alterations in the immune microenvironment and vascular normalization.

Methods: Clinical data of patients with driver gene negative lung cancer brain metastases who received PD-1/PD-L1 inhibitors at the Second Affiliated Hospital of Nanchang University between May 2020 and July 2022 were collected. Univariate and multivariate analyses were performed to identify independent prognostic factors. Overall survival (OS) and intracranial progression-free survival (iPFS) was analyzed. Animal model of driver gene negative lung adenocarcinoma brain metastases (LLC-BM) was established. The anti-tumor effect, blood-brain barrier permeability and immune microenvironment of mice treated with immunotherapy were detected by in vivo imaging, immunohistochemistry and EB/FITC staining.

Results: 179 patients were included. PD-1/PD-L1 inhibitors combined with chemotherapy and antiangiogenic therapy (n=37) versus PD-1/PD-L1 inhibitors combined with chemotherapy (n=54), PD-1/PD-L1 inhibitors combined with anti-angiogenic therapy (n=53), and PD-1/PD-L1 inhibitors alone (n=35) showed median OS of 21.20 vs 16.00 vs 16.53 vs 9.30 months (P=0.013) and median iPFS of 15.20 vs 11.30 vs 9.03 vs 8.10 months (P=0.118), respectively. In the LLC-BM animal model, the mice in the PD-1 inhibitor combined with bevacizumab and pemetrexed group exhibited the lowest tumor fluorescence intensity, sustained tumor area reduction, and the longest average survival time, suggesting the best inhibitory effect of PD-1/PD-L1 inhibitors combined with chemotherapy and antiangiogenic therapy, which reduced infiltration of M2 macrophages and increased PD-L1 expression, normalized vascular morphology (linear, less bending) and increased CD8+ T cell infiltration, improved tumor hypoxia, enhanced blood-brain barrier permeability and increased perivascular coverage.

Conclusions: PD-1/PD-L1 inhibitors combined with chemotherapy and antiangiogenic therapy may represent the optimal combination regimen for driver gene negative lung adenocarcinoma brain metastases. PD-1 inhibitor combined therapy with chemotherapy and anti-angiogenic treatment activates the immune microenvironment, ameliorate hypoxia, enhance blood-brain barrier permeability and promote vascular normalization.

P4.11E.10 Safety and Efficacy of Sintilimab Combined with Anlotinib in Patients with KRAS-Mutant Advanced Non-Small Cell Lung Cancer

F. Wang, F. Jin, C. Wang, S. Wang, Peking University Shenzhen Hospital, Shenzhen/CN

Introduction: The KRAS mutation is prevalent in non-small cell lung cancer (NSCLC), emphasizing the urgency for effective treatments. Specific KRAS G12C inhibitors are in development, with their clinical efficacy eagerly anticipated. Immune checkpoint inhibitors (ICIs), either alone or in combination with chemotherapy, represent the current standard of care for the treatment of advanced NSCLC lacking targetable oncogenic mutations, including those with KRAS mutations. Anti-angiogenesis agents have shown potential to enhance the efficacy of immunotherapy. This study aims to evaluate the efficacy and safety of the combination of sintilimab with anlotinib in previously treated patients with advanced KRAS-mutant NSCLC.

Methods: Patients who had disease progression on at least one line of systemic therapy were included. Participants received sintilimab (200 mg intravenously on day 1) and anlotinib (12 mg orally from day 1 to day 14) once every three weeks. The primary endpoint was progression-free survival (PFS). The secondary endpoints included overall survival (OS), objective response rate (ORR), disease control rate (DCR) and safety. Subset with KRAS G12C mutations and non-G12C subtypes were identified. This study is registered with the Chinese Clinical Trial Registry (ChiCTR2000032266).

Results: Thirty eligible patients were enrolled from April 2019 to June 2022 at Peking University Shenzhen Hospital. Most had stage IV (76.7%) adenocarcinoma (93.3%), with 53.3% having non-G12C mutations. Frontline treatment included anti-angiogenesis (20.0%), anti-PD-(L)1 (63.3%), and chemotherapy (90.0%). The ORR and DCR were 23.3% and 76.7%, respectively. The median PFS was 7.4 months (95% CI: 3.3 - 11.5), while the median OS was 15.1 months (95% CI: 4.9 - 25.2). Both G12C and non-G12C subtypes demonstrated comparable outcomes (PFS, 9.0 vs. 7.4 months, P = 0.80; OS, 15.1 vs. 10.8 months, P = 0.64, respectively). Patients who did not receive prior anti-angiogenesis therapy exhibited longer PFS (12.8 vs. 2.7 months, P < 0.001) and OS (18.5 vs. 4.3 months; P = 0.008) compared to those who did. Treatment-related adverse events (TRAEs) occurred in 93.3% of patients, with 23.3% classified as grade 3 - 4. The most common grade 3 - 4 TRAEs included hypertension (10.0%), hand and foot skin syndrome (6.7%), rash (3.3%), elevated alanine aminotransferase (ALT) levels (3.3%), and proteinuria (3.3%). No deaths were attributed to TRAEs.

Conclusions: The combination of sintilimab with anlotinib shows promising efficacy and manageable toxicities in previously treated patients with advanced KRAS-mutant NSCLC. Further study in phase 3 trials is warranted.

Aerts[11], [1]Genmab, Plainsboro/NJ/USA, [2]Genmab, Utrecht/NL, [3]Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology, Barcelona/ES, [4]Military Hospital Begin, Saint-Mandé/FR, [5]The Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw/PL, [6]Gustave Roussy, Villejuif/FR, [7]Hospital Universitario [12] de Octubre, Madrid/ES, [8]Merck & Co., Inc., Rahway/NJ/USA, [9]BioNTech US Inc., Cambridge/MA/USA, [10]BioNTech SE, Mainz/DE, [11]Erasmus MC, Rotterdam/NL

Introduction: Acasunlimab (DuoBody®-PD-L1x4-1BB) is an investigational bispecific antibody immunotherapy designed to elicit an antitumor response via conditional 4-1BB activation that is strictly dependent on simultaneous PD-L1 binding. The PD-L1 arm of acasunlimab also functions as an immune checkpoint inhibitor (CPI) by blocking the PD-1/PD-L1 axis. A semi-mechanistic pharmacokinetics/pharmacodynamics (PK/PD) model was used to determine acasunlimab 100 mg Q3W as the expansion dose, allowing optimum trimer (PD-L1:acasunlimab:4-1BB) formation and 4-1BB activation, with partial PD-L1 blockade. Acasunlimab is currently being evaluated in a randomized phase 2 trial (NCT05117242) in patients with CPI-experienced PD-L1+ metastatic non-small cell lung cancer as monotherapy (100 mg Q3W x2 cycles, then 500 mg Q6W), or combination (100 mg + pembrolizumab 200 mg Q3W or 100 mg + pembrolizumab 400 mg Q6W), allowing maximum blockade of the PD-1 pathway. Initial results indicate acasunlimab combination with pembrolizumab shows promising efficacy with durable disease control in patients treated Q6W (Aerts J et al. ASCO 2024). Here we describe PK/PD, exposure-response (E-R), and peripheral PD analyses used for dose-optimization of acasunlimab plus pembrolizumab.

Methods: Acasunlimab exposures (average concentration over first dosing cycle) predicted from population PK model were used in the E-R analyses of efficacy (objective response rate [ORR]), safety (standardized MedDRA query [SMQ]-hepatic events) or PK/PD model describing soluble 4-1BB (s4-1BB) levels. Additionally, a quantitative systems pharmacology (QSP) model was developed to predict conditional 4-1BB engagement and PD-1/PD-L1 complex disruption, by combining a physiologically based PK model for acasunlimab distribution and relevant immune system components. Baseline and on-treatment peripheral blood analyses determining serum s4-1BB and cytokine levels by immunoassays and assessing T-cell proliferation and functionality by flow cytometry were utilized to support dose selection.

Results: Model predictions showed that while acasunlimab 500 mg Q6W resulted in >90% PD-L1 receptor occupancy, trimer engagement was approximately 50% compared with 100 mg Q3W. In combination with pembrolizumab, E-R analyses showed no apparent trend for probability of ORR (efficacy) and SMQ-hepatic events (safety) at range of acasunlimab exposures evaluated at 100 mg Q3W or Q6W, indicating less-frequent administration leading to lower average exposure may be sufficient. Peripheral s4-1BB, a surrogate for target engagement, showed intermittent on-treatment induction in patients treated with combination Q6W compared with sustained induction with Q3W. Further PD analyses showed a more intermittent T-cell proliferation (as predicted in the QSP model) and cytokine modulation in patients treated with combination Q6W compared with Q3W. Reduced on-treatment induction of the coinhibitory marker TIM-3 was observed on CD8 T-cell subsets in patients treated with combination Q6W, with retained T-cell proliferation/activation observed in later cycles in patients with long-term treatment benefit.

Conclusions: Less-frequent acasunlimab dosing (Q6W) in combination with pembrolizumab leading to intermittent engagement of 4-1BB showed more durable clinical activity and peripheral immunomodulation in patients. PD results support the hypothesis that intermittent 4-1BB engagement reduces chronic T-cell stimulation, potentially mitigating T-cell dysfunction by allowing a resting interval and resetting of T-cell function. This may improve the magnitude and quality of antitumor immune responses and result in improved durability in the clinical setting.

Introduction: Several retrospective studies showed preliminary effectiveness of immunotherapy plus radiotherapy in brain metastases (BM) of NSCLC. However, prospective RCTs remain lacking for further validation. CTONG 2003 is the first RCT to compare first-line camrelizumab with placebo for BM.

Methods: CTONG 2003 was a multicenter, randomized, double-blind, placebo-controlled trial conducted at 15 sites in China. Adult treatment-naïve NSCLC patients with BM and no EGFR/ALK alterations were randomized at 1:1 to receive camrelizumab (200mg) or placebo, plus platinum-doublet chemotherapy on day 1 of each 3-week cycle for 4-6 cycles, followed by maintenance camrelizumab or placebo ± pemetrexed (500mg/m^2) for up to 31 cycles. SRT or WBRT, if performed, was administered for BM within 42 days of the first dose. Randomization was stratified by histology (squamous versus non-squamous), number of BM lesions (1-5 versus ≥6) and radiotherapy (yes versus no). The co-primary endpoints were intracranial PFS (iPFS) and PFS. Totally 200 cases were needed but recruitment was prematurely terminated owing to therapeutic paradigm shifts rendering placebo inapplicable.

Results: Between May 28, 2021, and July 21, 2023, 60 eligible patients were assigned: 32 to the camrelizumab group and 28 to the placebo group. Twenty-one (65.6%) patients in the camrelizumab group and 23 (82.1%) in the placebo group received radiotherapy. As of February 20, 2024, median follow-up duration was 17.4 months (95%CI:12.9-20.5). As shown in Figure below, median iPFS was 12.7 months (95%CI: 7.1-19.4) in the camrelizumab group versus 8.4 months (95% CI:5.7-14.6) in the placebo group (HR:0.46, 95%CI:0.22-0.99), and median PFS in the respective group was 9.7 months (95%CI:5.7-12.4) versus 6.7 months (95%CI:4.1-8.6; HR:0.57 [95%CI:0.29-1.11]). A similar improved trend was also observed in OS (HR:0.51, 95%CI:0.21-1.24). The 12- and 18- month OS rates were 79.6% versus 57.2% and 61.3% versus 52.0%, respectively. The confirmed iORR was 56.3% in the camrelizumab group versus 42.9% in the placebo group, with median iDoR of 16.2 months (95%CI:5.3-21.2) versus 5.7 months (95%CI:3.9-15.9). The corresponding ORR and median DoR were 65.6% versus 32.1% and 8.5 months (95%CI:5.7-11.4) versus 4.4 months (95%CI:2.8-7.1), respectively. Grade ≥3 TEAEs occurred in 22 (68.8%) patients in the camrelizumab group and 17 (60.7%) in the placebo group, mainly anemia (34.4% versus 21.4%) and neutropenia (34.4% versus 28.6%). One patient in the camrelizumab group experienced a Grade 5 TRAE.

Conclusions: Although this trial closed early, camrelizumab trended toward improved iPFS and PFS for BM of NSCLC. The toxicity profile was generally manageable.

P4.11E.13 Real-World Treatment Patterns, Healthcare Cost and Resource Utilization in First-Line Treatment of Metastatic NSCLC in the US

D. Chopra[1], D.M. Waterhouse[2], I. Sultan[1], A. Lonshteyn[3], T.E. Delea[3], B. Stollenwerk[4], [1]Amgen, Thousand Oaks/CA/USA, [2]OHC (Oncology Hematology Care), Cincinnati/OH/USA, [3]Avalere Health, Boston/MA/USA, [4]Amgen, Rotkreuz/CH

Introduction: Few studies have reported data on the current treatment landscape and real-world outcomes in the first-line treatment of non-small cell lung cancer (NSCLC). Such information is important to understand the burden of disease in the real-world setting, which is particularly relevant to stakeholders transitioning towards value-based care models. The objective of the current study was to assess real-world treatment patterns, healthcare cost, and healthcare resource utilization (HCRU) associated with the non-targeted first-line treatment of metastatic NSCLC in the US.

Methods: This retrospective observational study used data from the US Optum Clinformatics Data Mart® administrative claims database. Eligible patients were adults (≥18 years) who started non-targeted first-line treatment for metastatic NSCLC between January 01, 2020 and March 31, 2023. Patients were also required to be continuously enrolled in medical and pharmacy benefits for at least 6 months before the NSCLC diagnosis until at least 30 days after starting first-line therapy.

Results: A total of 15,659 patients with metastatic NSCLC met the inclusion criteria. The median age at the start of first-line treatment was 72 years (Interquartile range [IQR]: 67-78 years) and 48% were women; 86% were covered by Medicare Advantage. The median National Cancer Index adapted Charlson Comorbidity index was 2.0 (IQR: 1.0-3.0). The median duration of first-line treatment was 4.2 months, over an average follow-up of 11.2 (Standard deviation [SD]: 9.2) months. The most common treatments administered as first-line were immunotherapy (IO) plus chemotherapy (CT) (48.1%), mono or dual platinum-based CT (PBCT) (26.4%), and mono or dual IO (19.7%). All-cause HCRU during first-line treatment was mainly attributed to outpatient visits (6.6 [SD: 8.9] per patient per month [PPPM]). Inpatient and emergency department (ED) accounted for an average of 0.12 (SD: 0.59) and 0.11 (SD: 0.63) visits PPPM. Mean all-cause total healthcare costs were $32,215 (SD: 44,597) PPPM, incurred mostly in outpatient settings ($28,045 [SD: 37,735]). Healthcare costs were highest for patients receiving IO + chemo ($34,808 PPPM). Among them, IO + non-PBCT (n=176) costs were $38,454 PPPM and $34,721 PPPM for IO + PBCT (n=7,359). Patients receiving IO + non-PBCT also had the highest average outpatient and ED costs ($32,913 and $282, PPPM, respectively), followed by those receiving IO + PBCT ($30,888 and $114, PPPM, respectively).

Conclusions: Despite improvements in the treatment landscape of NSCLC in recent years, non-targeted first-line treatments; particularly IO + chemotherapy continues to be associated with substantial healthcare costs and resource burden. This highlights an unmet need for advancing first-line treatments to reduce the burden of disease in patients with metastatic NSCLC.

P4.11E.14 Anlotinib Plus Penpulimab in Advanced Non-Small-Cell Lung Cancer Previously Treated with PD-1/PD-L1 Inhibitors

L. Wu[1], H. Wang[2], Y. Kong[1], J. Li[1], L. Xu[1], Q. Wang[1], X. Pu[1], Y. Zhou[1], K. Li[1], [1]Hunan Cancer Hospital, Changsha/CN, [2]Henan Cancer Hospital, Zhengzhou/CN

Introduction: Immunotherapy monotherapy or combination therapy, represented by PD-1/PD-L1 inhibitors, has become the first-line standard treatment for driver gene-negative advanced non-small cell lung cancer (NSCLC). However, disease progression is inevitable in most patients, posing challenges for subsequent lines of treatment. Regarding patients with advanced NSCLC who have failed previous PD-1/PD-L1 inhibitor treatment, the question remains whether immunotherapy rechallenge can bring further survival benefits. This study aims to evaluate the efficacy and safety of combining anlotinib hydrochloride with pazopanib monotherapy in the treatment of patients with advanced NSCLC who have previously failed PD-1/PD-L1 inhibitor treatment.

Methods: This open-label, single-arm, multicenter, exploratory study (NCT05460481) enrolled patients with histologically confirmed driver gene-negative advanced NSCLC who had previously failed PD-1/PD-L1 inhibitor treatment. Participants were given 200mg of penpulimab every three weeks and 12mg of anlotinib daily, with a two-week on and one-week off schedule, until disease progression, unacceptable toxicity, or study discontinuation. The primary objective of the study was to evaluate the antitumor activity of the combination therapy using the objective response rate (ORR) as measured by RECIST v1.1. Secondary objectives included evaluating the disease control rate (DCR), progression-free survival (PFS), and overall survival (OS), and the safety and tolerability of the combination therapy.

Results: From September 2022 to present, 13pts aged 38-69 years (median age 60 years) were enrolled. 12 pts (92.3%) were men, 13 pts (100%) ECOG PS=0-1, and 3 pts (23.1%) had brain metastases. Of these, 13 patients were evaluable for RECIST and had an ORR of 23.08% (3/13) and a DCR of 92.31% (12/13). The median PFS was7.54 months, and the median OS were not mature.Two of the 13 patients(15%) experienced grade 3 or higher adverse events. The most common adverse reactions related to anlotinib hydrochloride included hepatic injury, general fatigue, and hand-foot syndrome.

Conclusions: Anlotinib Plus Penpulimab as second-line therapy showed a promising efficacy with a favorable toxicity profile for patients with advanced non-small cell lung cancer. We will report more data in the future.

P4.11E.15 Risk Factors for Ir-AEs in Patients with NSCLC Receiving Chemotherapy Combined with a PD-1/PD-L1 Inhibitor or Nivolumab and Ipilimumab

A. Nomura[1], T. Masuda[1], S. Takao[2], Y. Izumi[3], Y. Araki[4], Y. Takayama[5], K. Masuda[6], K. Yamaguchi[1], S. Sakamoto[1], Y. Horimasu[1], T. Nakashima[1], H. Iwamoto[1], T. Senoo[4], H. Shoda[2], N. Ishikawa[6], M. Yamasaki[3], H. Hamada[1], M. Okada[1], N. Hattori[1], [1]Hiroshima University, Hiroshima city, Hiroshima prefecture/JP, [2]Hiroshima City Hiroshima Citizen Hospital, Hiroshima city, Hiroshima prefecture/JP, [3]Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hiroshima city, Hiroshima prefecture/JP, [4]Kure Medical Center and Chugoku Cancer Center, Kure city, Hiroshima prefecture/JP, [5]Hiroshima City Funairi Citizen Hospital, Hiroshima city, Hiroshima prefecture/JP, [6]Hiroshima Prefectural Hospital, Hiroshima city, Hiroshima prefecture/JP

Introduction: Chemotherapy combined with PD-1/PD-L1 inhibitors is the standard first-line treatment for non-small-cell lung cancer (NSCLC), and chemotherapy combined with nivolumab and ipilimumab is considered effective in patients with low PD-L1 expression. Both regimens are associated with an increased incidence of immune-related adverse events (ir-AEs). Several studies have identified risk factors for ir-AEs and prognostic factors associated with PD-1/PD-L1 inhibitor treatment. To date, prognostic factors associated with chemotherapy combined with ipilimumab immunotherapy remain unclear.This study was performed to identify risk factors for grade 3 or higher ir-AEs and prognostic factors associated with combined immunotherapy with or without ipilimumab in a real-world setting.

Methods: Patients with NSCLC who received combined immunotherapy with or without ipilimumab (IPI or non-IPI groups) between March 2019 and April 2022 were enrolled. Potential risk factors for grade 3 or higher ir-AEs and prognostic factors for combined immunotherapy with or without ipilimumab were retrospectively assessed.

Results: The IPI and non-IPI groups included 66 and 264 participants, respectively. The proportion of patients with low PD-L1 expression in the IPI group was significantly higher than that in the non-IPI group ($p<0.01$). No differences in other patient characteristics were observed between the two groups. The respective incidences of grade 3 or higher ir-AEs in the IPI and non-IPI groups were 46.9% and 21.2% ($p<0.01$). Multivariate logistic regression analysis showed that NLR<5 and CRP≥1 were independent risk factors for severe ir-AEs in the IPI group and the non-IPI group, respectively. Kaplan-Meier analysis showed that overall survival (OS) was not significantly different between patients with NLR<5 and NLR<5 in the IPI group (13.4 months vs. not reached, $p=0.31$). In contrast, OS in patients with CRP-1 was significantly shorter than that in patients with CRP<1 in the non-IPI group ($p<0.01$).

Conclusions: We should be alert for the occurrence of ir-AEs in patients with NLR<5 during combined immunotherapy using ipilimumab. In addition, patients with CR-1 are not expected to benefit from combining chemotherapy with PD-1/PD-L1 inhibitor treatment. The findings of this study will be useful for guiding appropriate treatment choices for clinicians in practice.

P4.11E.16 Clinical Outcome of HER2-mut NSCLC Treated with First-Line Immunotherapy-Based Regimens versus Chemotherapy/HER2-TKIs

K. Yin, L-P. Chen, S-Y.M. Liu, Q. Zhou, Y-L. Sun, E-E. Ke, Y-S. Li, M-M. Zheng, C-R. Xu, J-X. Lin, X-Y. Bai, Z. Wang, H-H. Yan, J-J. Yang, H-J. Chen, B-C. Wang, H-Z. Hong, W-Z. Zhong, Y-L. Wu, H-Y. Tu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Guangzhou/CN

Introduction: The current standard treatment regimen for advanced non-small-cell lung cancer (NSCLC) with HER2 mutations remains the same as for patients without driver genes, due to the absence of approved first-line targeted treatment. However, there is a discrepancy on whether priority should be given to immunotherapy-based regimen over conventional chemotherapy.

Methods: We retrospectively collected patients with primary HER2-mutated locally advanced or advanced NSCLC who received first-line treatment between January 1, 2016 and December 31, 2023 in Guangdong Provincial People's Hospital. Patients with known other oncogenic genes including sensitizing EGFR mutations, BRAF V600E mutation, KRAS G12C mutation, ALK/ NTRK/RET/ROS1 fusion, and MET exon 14 skipping were excluded. Patients were divided into three cohorts based on the first-line treatment regimen: immunotherapy ± chemotherapy (Group I), anti-angiogenic treatment ± chemotherapy (Group C), and targeted treatment (pyrotinib or afatinib) group (Group T). A comparison was made between the median progression-free survival (mPFS) and median overall survival (mOS) of Group I and those of either Group C or Group T.

Results: This study included 160 primary HER2-mutated patients with locally advanced or advanced NSCLC (median age, 57 years; 56% female; 90% stage IV; 24% with brain metastasis). The median follow-up time was 37.1 months (95% CI, 32.2-42.0). In group I (n=55), the majority of patients were treated with a combination of immune-chemotherapy regimens, and only 5 patients used immune monotherapy. The mPFS and mOS were 8.8 months (95% CI, 5.2 to 12.4) and 40.0 months (95% CI, 22.0 to 62.6), respectively. The mPFS of Group I significantly exceeded that of Group C (n=52) (8.8 vs 6.0, p=0.014) and Group T (n=53) (8.8 vs 4.9, p=0.016). The mOS of Group I was significantly longer compared to both Group C (40.0 vs 29.3, p=0.007) and Group T (40.0 vs 26.3, p=0.001).

Conclusions: The first-line immunotherapy-based treatment showed potential improvement for the clinical outcome of HER2 mutated NSCLC patients compared with chemotherapy and existing targeted treatment. Clinical trials comparing first-line novel targeted treatment with immunotherapy and chemotherapy are underway.

Keywords: HER2 mutation, Non-small-cell lung cancer, immunotherapy

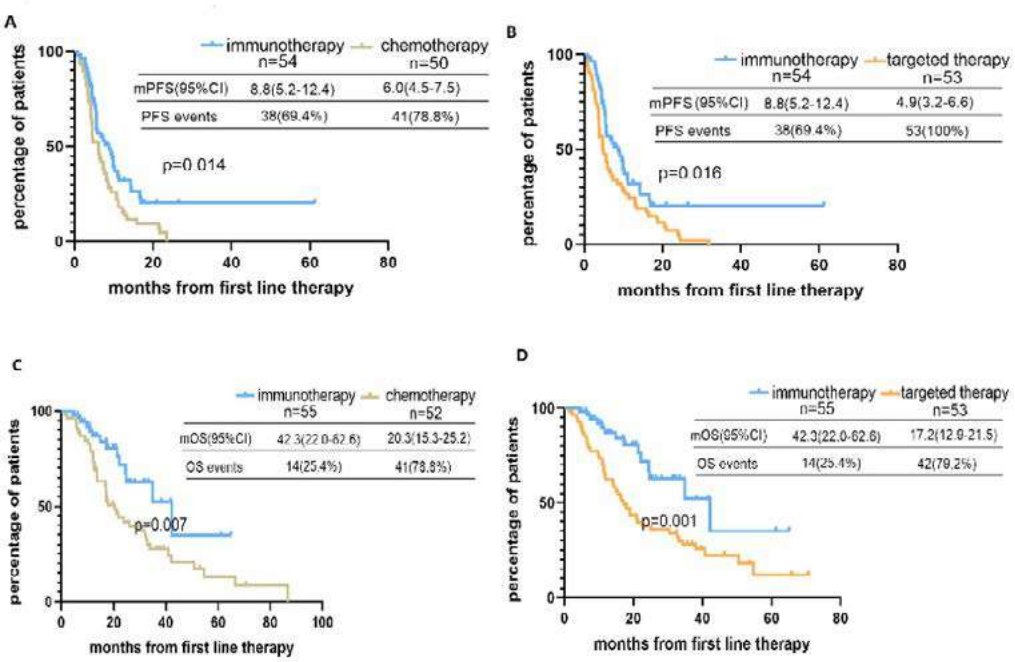

Figure 1: mPFS and mOS of HER2-mutated locally advanced or advanced NSCLC patients treated with different first-line regimens. Group I (Immunotherapy) received ICI-based therapy, Group C (Chemotherapy) received Chemotherapy ± anti-angiogenic treatment and Group T (targeted therapy) received pyrotinib or afatinib as first-line treatment.

Metro[13], N. Vokes[2], M. Awad[1], [1]Dana-Farber Cancer Institute, Boston/MA/USA, [2]MD Anderson Cancer Center, Huston/TX/USA, [3]University of Perugia, Perugia/IT, [44]Hospital Clinic de Barcelona, Barcellona/ES, [5]Memorial Sloan Kettering Cancer Center, New York/NY/USA, [6]Imperial College London, Dana-Farber Cancer Institute/MA/USA, [7]IRCCS Ospedale San Raffaele, Milan/IT, [8]Fondazione Policlinico Universitario Campus Bio-Medico, Rome/IT, [9]Hospital [12] de Octubre, Madrid/ES, [10]Imperial College London, London/GB, [11]Cliniques Universitaires Saint-Luc, Brussels/BE, [12]Hospital Clinic de Barcelona, Barcellona/ES, [13]Santa Maria della Misericordia Hospital, Perugia/IT

Introduction: Immune checkpoint inhibition (ICI) has extended survival in patients with metastatic non-small cell lung cancer (NSCLC). While ICI duration is commonly limited to two years, the optimal duration of ICI, and post-progression treatment outcomes in patients who received at least two years of ICI are unknown.

Methods: We conducted a global, multi-center study of patients with metastatic NSCLC treated with ICI for at least two years to characterize clinical outcomes and post-progression treatment patterns. Log-rank tests were used to test for differences in event-time distributions, and Cox proportional hazards models were used to estimate hazard ratios.

Results: We identified 421 patients with metastatic NSCLC treated with ICI alone (N=320, 76%) or ICI + chemotherapy (N=101, 24%) for least two years. The median age was 63.2, 43.2% were women, 91% had history of tobacco use, 78.9% had adenocarcinoma histology, 48% had a PD-L1 TPS ≥50%. From the start of ICI, the median time to progression (mTTP) was 7.0 years (95%CI 5.6-NR) and the median overall survival (mOS) was 9.5 years (95%CI 8.1-NR).

Patients who achieved a complete response to ICI (N=77) had a significantly longer mTTP compared to those with a partial response (N=242) (HR 0.45, P<0.01) and stable disease (N=93) (HR 0.30, P<0.01). Patients with high PD-L1 ≥50% (HR 0.30, P=0.04 vs PD-L1 <50%), very high tumor mutational burden (TMB) ≥20 mut/Mb (HR 0.70, P=0.03, vs <20 mut/Mb) and ever smoking status (HR 0.52, P=0.03, vs never smokers) had also significantly longer mTTP. Sex, ECOG PS, and number of metastatic sites at baseline were not associated with mTTP. There was no difference in mTTP (HR: 1.19, P=0.28) between patients who stopped ICI after 2 years vs those who continued indefinitely, although mOS was shorter among patients who stopped ICI at 2 years (HR 0.52, P=0.01). Among 158 patients who progressed after ICI, 32.9% (N=52) received local ablative therapies (surgery or radiation), 9.4% (N=15) patients received systemic chemotherapy and 29.1% (N=46) patients received ICI retreatment. Among those retreated with ICI, the response rate was 61.2%, mTTP and mOS from the date of start of ICI retreatment were 22.7 (95%CI 11.2-NR), and 41.7 months (19.3-NR), respectively. Clinico-genomic predictors of response to ICI retreatment included higher TMB at baseline (16.2 vs 7.4 mut/Mb, P<0.001), adenocarcinoma histology (94.4% vs 50.0%, P=0.01), and longer ICI treatment duration prior to retreatment (34.2 vs 24.5 months, P=0.02).

Conclusions: Patients who received a minimum of two years of treatment with ICI experienced unprecedented long-term survival. After completing two years of initial ICI therapy, a large fraction of patients who subsequently experience disease progression and are retreated with ICI experience an objective response, particularly those with longer duration of prior ICI treatment, higher TMB, and adenocarcinoma histology.

P4.11E.18 Impact of Prophylactic use of PEG-rhG-CSF on First-Line Immunochemotherapy in Advanced Non-Small Cell Lung Cancer: A Cohort Study

C.B. Han, L. Sun, Y. Tian, S.L. Zhang, L.T. Huang, J.T. Ma, Shengjing Hospital of China Medical University, Shenyang/CN

Introduction: PEG-rhG-CSF is commonly used as a supportive therapy to prevent neutropenia in patients with malignant tumors undergoing chemotherapy; however, its impact on current immunochemotherapy remains unclear. This study aimed to evaluate the impact of the prophylactic use of PEG-rhG-CSF on the efficacy and safety of first-line immunochemotherapy in patients with advanced non-small cell lung cancer (NSCLC).

Methods: A cohort of patients with advanced NSCLC who received first-line immunochemotherapy (PD-1 inhibitor plus chemotherapy) at Shengjing Hospital of China Medical University between January 2019 and August 2023 were selected for inclusion in this study and divided into two groups: the treatment group, which received prophylactic PEG-rhG-CSF (≥1 cycle) 48 hours after immunochemotherapy, and a control group that did not receive PEG-rhG-CSF. The primary endpoints assessed were PFS, OS, ORR, and safety. A propensity score-matched analysis was performed to reduce potential confounders. The study was approved by the Ethics Committee of Shengjing Hospital (Ethics Approval Number: 2022PS013T).

Results: A total of 127 patients were enrolled in the study, with 48 patients in the treatment group and 79 in the control group. The median duration of follow-up was 14.3 months (range, 3.1-40.9 months). In the unmatched population, the median PFS was 12.7 months (95% CI: 4.9-20.5) for the treatment group and 12.2 months (95% CI: 2.9-21.5) for the control group (HR=0.88, p=0.85). The median OS was not reached (NR) and 33.2 months (HR=0.72, p=0.36). The ORR was 64.6% and 60.8% in the treatment and control groups, respectively (p=0.67), and the DCR was 97.5% and 97.9% (p=0.87), respectively. Following a propensity score-matched analysis (each group contained 34 patients), the median PFS was 9.5 months (95% CI: 3.6-15.4) for the treatment group and 10.8 months (95% CI: 7.7-13.9) for the control group (HR=0.95, p=0.89), and the median OS was NR and 24.9 months (HR=0.71, p=0.47), respectively. Multivariate Cox regression analyses across all 127 patients showed that the lack of antibiotic use (NR vs. 13.0 months; HR=0.43, 95%CI: 0.22-0.86; p=0.016) and a decrease in neutrophil-to-lymphocyte ratio (HR=0.47, 95%CI: 0.24-0.96; p=0.037) were significantly associated with longer OS. Antibiotic usage was less frequent in the treatment group (14.60%) than in the control group (22.80%), and the treatment group experienced a reduced incidence of severe leukopenia and granulocytopenia, without an increase in immune-related adverse events.

Conclusions: The prophylactic use of PEG-rhG-CSF did not adversely affect the efficacy and safety of first-line immunochemotherapy in patients with advanced NSCLC.

Keywords: PEG-rhG-CSF, immunochemotherapy, non-small cell lung cancer

P4.11E.19 The Effect of COVID-19 On Treatment Outcomes in Non-Small Cell Lung Cancer Patients: A Propensity Score Matched Analysis

W.Y. Aung[1], A. Sood[2], L. Hou[2], J. Elengickal[3], S.H. Peketi[4], M. Locke[1], X. Zhou[2], A. Sangari[5], N. Seetharamu[1], [1]R.J. Zuckerberg Cancer Center, New Hyde Park/NY/USA, [2]Northshore University Hospital at Northwell Health, Manhasset/NY/USA, [3]Prisma Health-Midlands, Columbia/SC/USA, [4]Nassau University Medical Center, East Meadow/NY/USA, [5]Stony Brook University, Stony Brook/NY/USA

Introduction: Patients with cancer, particularly those with non-small cell lung cancer (NSCLC), face higher morbidity and mortality from severe COVID-19 infections than the general population. Despite extensive research focusing on outcomes of COVID-19 infection among cancer patients, outcomes related specifically to NSCLC treatment in the context of COVID-19 have not been explored. COVID-19 induced inflammation is hypothesized to adversely impact the tumor microenvironment (TME), with in vitro studies noting T-cell exhaustion with increased expression of PD-1 and PD-L1 in COVID-19 patients, suggesting a tumor-favorable microenvironment. Additionally, inflammatory response associated with COVID-19 infection may enhance T-cell activation and cytokine release, increasing the risk of irAEs. This study seeks to examine the effect of COVID-19 infection on overall survival and treatment outcomes in patients with NSCLC.

Methods: We conducted a propensity-matched, retrospective cohort study utilizing data from the TriNetX database and the US Collaborative Network, encompassing 60 healthcare organizations. The study population comprised patients diagnosed with NSCLC after January 1, 2019. We performed propensity score matching based on stage, age, race, gender, and existing comorbidities to create comparable groups of NSCLC with and without COVID-19 infection. The primary outcome was overall survival at 1 year and 3 years. Secondary outcomes include adverse events from chemoimmunotherapy.

Results: We identified a total of 553 NSCLC patients receiving chemotherapy or immunotherapy who had a positive COVID test, and 3025 similar patients who had a negative COVID test without history of COVID infection. Cohorts had 534 propensity-matched patients. At one year follow-up, overall survival of COVID-19 negative NSCLC cohort was 69.2% compared to 65.6% in COVID-19 positive cohort. There was no significant difference in overall survival at 1 year (HR 0.90, 95% CI 0.75-1.07) and 3 years (HR 1.11, 95% CI 0.97-1.27). There was also no significant difference in incidence of adverse events associated with chemoimmunotherapy (RR 1.09, 95% CI 0.88-1.36) between the matched cohorts.

Conclusions: Our results indicate no significant impact of COVID-19 infection on overall survival or treatment outcomes, contrary to the hypothesis that COVID-19-induced inflammation might exacerbate disease progression and treatment related adverse events. A noteworthy consideration and limitation in our work is the role of widespread implementation of vaccination, which may mitigate the potential negative effects of COVID-19, highlighting the importance of vaccination in maintaining effective cancer treatment outcomes. Future studies are needed to explore the interaction between COVID-19 vaccination status and cancer treatment outcomes.

P4.11E.20 Immune Checkpoint Inhibitors Plus Chemotherapy as First-Line Treatment in Patients with Advanced Pulmonary Sarcomatoid Carcinoma

F. Wu, H. Du, S. Chen, J. Li, G. Gao, Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Immune checkpoint inhibitors (ICIs) have demonstrated promising efficacy in patients with pulmonary sarcomatoid carcinoma (PSC) in retrospective studies. Here, we report a phase II study investigating efficacy and safety of immunotherapy combined with chemotherapy in patients with advanced PSC.

Methods: This was an open-label, single-arm phase II clinical trial (ChiCTR2000031478). Patients diagnosed with advanced PSC received first line anti-PD1 inhibitors plus chemotherapy until progression, unacceptable toxicity, withdrawal, or death. The primary endpoint was the objective response rate. The secondary endpoints included disease control rate, progression-free survival, overall survival, and side effects.

Results: Between October 2020 and January 2024, 38 patients diagnosed with advanced PSC were enrolled. Among them, 3 (7.9%) patients had Met exon14 skipping, 12(31.6%) patients had KRAS mutations and 1 (2.6%) patient had RET fusion. PD-L1 high expression (≥50%) was identified in 45.2% (14/31) patients. Thirty-five patients were available for response evaluation; the objective response rate and disease control rate were 65.7% and 82.8%, respectively. The median progression free survival was 10.5 months (95% confidence interval [CI], 3.5-17.2 months). The median overall survival was not reached and 1-year survival rate was 62.7 %. The most common side effects were chemotherapy associated. The irAEs of any grade were found in 29 (76.3%) patients, and those of grade 3 or worse were found in 8 (21.0%) patients.

Conclusions: Immunotherapy plus chemotherapy showed promising effects in patient with advanced or metastatic PSC.

P4.11E.21 Predictive Value of Longitudinal Systemic Inflammatory Markers for Pathologic Response to Neoadjuvant PD-1 Blockade in Resectable NSCLC

X. Tao, Q. Zhang, P. Yuan, S. Wang, J. Ying, N. Li, W. Guo, J. Li, L. Guo, Y. Liu, Z. Zhang, S. Zhao, S. Gao, N. Wu, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Identifying biomarkers to predict responses for neoadjuvant immunotherapy in resectable non-small cell lung cancer (NSCLC) has become an area of intensive researches. Based on a hypothesis that circulating and imaging inflammatory markers could serve as indicators of anti-tumor immune responses, we conducted an exploratory study to reveal the additional benefit of combining longitudinal systemic inflammatory markers, derived from 18F-fluorodeoxyglucose positron emission tomography-computed tomography (18F-FDG PET/CT) scans and peripheral blood tests, in stratifying the pathologic response to neoadjuvant sintilimab in resectable NSCLC. We also explored the association of tumor-infiltrating immune cells in the microenvironment with systemic inflammatory markers and primary tumor metabolism.

Methods: We retrospectively reviewed 36 patients (29 male and seven female) with NSCLC (stage IA-IIIB) who underwent pre- and post-treatment peripheral blood tests and 18F-FDG PET/CT scans before and after two cycles of neoadjuvant sintilimab. The neutrophil-to-lymphocyte ratio (NLR), immune-related adverse events on PET/CT, and lymphoid organ metabolism (spleen-to-liver SUVmean ratio [SLR] and bone marrow-to-liver SUVmean ratio) were evaluated to examine their predictive value in major pathologic response (MPR) and pathologic regression. Significant variables (ΔNLR% and pre-treatment SLR) were used to classify patients into low, intermediate, and high inflammatory burden groups for stratifying pathologic response and tumor-infiltrating immune cells abundance. Spearman's correlation analysis was performed to explore the correlation between systemic inflammatory markers, primary tumor metabolism, and tumor-infiltrating immune cells abundance at various time points.

Results: Of the 36 patients, 13 (36.1%) exhibited MPR. ΔNLR% was a significant negative predictor of MPR (p=0.047) and pathologic regression (p=0.045). Pre- and post-treatment SLRs were potential negative predictors of MPR (p=0.065; p=0.055) and pathologic regression (p=0.074; p=0.064). The ΔNLR% and pre- and post-treatment SLRs had the best discriminatory ability for MPR, with areas under the receiver operating characteristic curve of 0.702, 0.689, and 0.694, respectively. The high inflammatory burden group (pre-treatment SLR>0.83 and ΔNLR%>-17%) had the lowest pathologic regression (p=0.012) and the highest infiltration abundance of pre-treatment tumor-infiltrating CD68+ macrophage (p<0.05). The emergence of immune-related adverse events on PET/CT did not have significant effects on pathologic response in the overall and per-organ analyses.

Conclusions: The combination of pre-treatment SLR and ΔNLR% demonstrates promising predictive value in stratifying the pathologic response to neoadjuvant sintilimab in resectable NSCLC. The high inflammatory burden group showed the lowest pathologic regression and a pre-treatment immunosuppressive microenvironment with CD68+ macrophage enrichment.

P4.11E.22 Treatment-Free Survival in Advanced NSCLC Patients who Terminated Immune-Checkpoint Inhibitors.

T. Nagai, H. Akamatsu, E. Takase, E. Murakami, T. Sugimoto, R. Shibaki, A. Hayata, T. Shimizu, M. Nakanishi, Y. Koh, N. Yamamoto, Wakayama Medical University, Wakayama/JP

Introduction: Immune checkpoint inhibitors (ICI) are widely used in patients with advanced non-small cell lung cancer (NSCLC) without driver alterations. Although patients sometimes terminate ICI due to various reasons, it remains unclear how long the efficacy of ICI is sustained after termination.

Methods: In this single-centered retrospective study, we reviewed the medical records of patients who received ICI-containing treatment for advanced NSCLC between January 2016 and December 2020 at Wakayama Medical University Hospital and identified those who terminated ICI for reasons other than progressive disease. Patients who received ≥2 years of ICI were defined as the completion group, and patients who discontinued ICI within 2 years were defined as the non-completion group. The primary outcome of this study was treatment-free survival (TFS), defined as the time from the last dose of ICI administration to disease progression or death from any cause.

Results: Sixty-five of 233 patients (28%) met the criteria (median [range] age, 71 [41-91], 58 males [89%]). Of those, 15 patients were in the completion group, and 50 were in the non-completion group. In both groups, about 40% had PD-L1 expression level ≥50%, and almost half received ICI monotherapy. Fifty-two patients (80%) were treated with anti-PD-1 antibody and 13 (20%) with anti-PD-L1 antibody. The median duration of ICI-containing treatment was 3.9 months (range, 0-22) in the non-completion group. The most common reason for ICI termination was irAE (68%).The median follow-up period of TFS was 36.0 months (range, 1.7-93). The median TFS of the entire population was 11.5 months (95%CI, 7.2-20.7 months), and the annual TFS rates were 48% at 1 year, 38% at 2 years, 36% at 3 years, and 29% at 4 and 5 years, respectively: the Kaplan-Meier curve of TFS dropped in the first year and almost plateaued thereafter. Fourteen patients (26%) demonstrated TFS at 3 years. Nine of them discontinued ICI due to irAE, and all had PR as their best response. Univariate analysis showed that tumor shrinkage (CR/PR vs. SD) is the only predictor of TFS at 3 years. Median TFS was not reached in the completion group, while that was 9.4 months in the non-completion group. The TFS rates at each year were better in the completion group compared with those in the non-completion group (80% vs. 38% at 1 year, 64% vs. 30% at 2 years, 64% vs. 27% at 3 years, and 64% vs. 22% at 4 and 5 years, respectively). In both groups, the Kaplan-Meier curve reached at a plateau 1 year after termination.

Conclusions: Our findings showed that 36% of advanced NSCLC patients who terminated ICI had disease-free and treatment-free periods of more than 3 years, and even among patients who did not complete ICI, 27% achieved 3-year TFS. Our study also suggested that the imaging interval can be loosened after 1 year of ICI termination.

Introduction: Cemiplimab, an anti-PD-1 antibody, has been approved for first-line treatment of NSCLC patients. In this scenario, single-agent cemiplimab demonstrated significant survival benefits over chemotherapy for NSCLC patients with high PD-L1 tumor proportion score (TPS) (≥ 50%) in a randomized phase III trial. However, there is limited RWD available on this compound. The aim of this study was to assess the real-world outcomes of NSCLC patients receiving cemiplimab as first-line therapy.

Methods: This multicenter retrospective study was conducted in 16 Spanish institutions and enrolled patients with confirmed advanced NSCLC PD-L1 TPS ≥ 50% who were treated with cemiplimab alone as first-line. Real-world safety, progression-free survival (PFS), overall survival (OS) and their correlation with clinical characteristics were examined. Log-rank tests were used to analyze differences in event-time distributions, and Cox proportional hazards models were used to estimate HR.

Results: A total of 102 patients were included in the study between 05/01/2022 and 07/31/2023. The median age was 70 years, 19.6% were women, 93% had history of tobacco use, 80.4% had a ECOG performance status (ECOG-PS) of 0-1, 69.7 % had a non-squamous histology, 40.2% had single metastatic location, 64.7% had extrathoracic disease and 26.5% had ≥3 metastases. Steroids were administered (>10 mg prednisone) in 24.5%. Hypoalbuminemia was detected in 28.9% of patients at baseline, and a poor lung immune prognostic index (LIPI) was found in 12.5%. Over half of the patients (53.1%) exhibited radiological response, including a 5.1% complete response rate. Immune-related adverse events (irAEs) occurred in 28.7 % of patients (44.8% grade 1-2), and 15.7% of patients discontinued cemiplimab due to immune-related toxicity. With a median follow-up of 9.8 months the median PFS was 8.1 months (95% CI, 3.9-12.2), while the median OS was not reached. Regarding PFS, extrathoracic disease (HR 3.2, p<0.000), poor ECOG-PS (HR 2.3, p<0.000), ≥3 metastatic sites (HR 2.2, p=0.005), hypoalbuminemia (HR 1.8, p=0.046) and specific metastatic allocations including liver (HR 2.1, p=0.026), and adrenal glands (HR 1.9, p=0.041) were significantly correlated with a worse PFS. Conversely, single-site metastasis (HR 0.4, p=0.001), irAEs onset (HR 0.5, p=0.047), as well as treatment discontinuation due to irAEs (HR 0.2, p=0.035) exhibited an increased PFS. On the other hand, a shorter OS was significantly associated with poor ECOG-PS (HR 3.1, p<0.000), extrathoracic disease (HR 3.9, p<0.000), bone metastases (HR 2.1, p=0.019), hypoalbuminemia (HR 2.0, p=0.027), poor LIPI score (HR 1.9, p=0.008), and steroids at the onset of cemiplimab (HR 2.6, p=0.001). Single-site metastasis (HR 0.2, p<0.000) and irAEs occurrence (HR 0.3, p=0.009) were linked to a longer OS. Poor ECOG-PS and extrathoracic disease remained significant for both survival outcomes in multivariate regression analysis: PFS (HR 2.7, p=0.012 and HR 3.7, p=0.001, respectively) and OS (HR 2.8, p=0.015 and HR 4.8, p=0.001, respectively).

Conclusions: The RWD of cemiplimab demonstrated a favorable safety profile and efficacy outcomes consistent with pivotal trial and other RWD of anti PD-1/PD-L1 agents developed in this context. Extrathoracic disease and ECOG-PS emerged as significant factors associated with clinical outcomes in multivariate analysis.

P4.11E.24 Clinical Features of Long-Term Response (LTR) to Immune Checkpoint Inhibitors (ICIs) in Patients with Advanced or Recurrent NSCLC

W. Dohi, H. Kanemura, J. Tanizaki, S. Suzuki, T. Takahama, K. Tanaka, T. Iwasa, K. Yoesaka, H. Hayashi, Kindai University, Faculty of Medicine, Osaka-Sayama/JP

Introduction: Long-term follow-up data from multiple phase III trials of ICIs demonstrate a 5-year overall survival (OS) rate of approximately 15-30% in pts with non-small-cell lung cancer (NSCLC). While biomarkers predicting the initial response to ICIs, such as tumor mutation burden, PD-L1 expression, and microsatellite instability, have been reported, there is currently limited data on the characteristics of pts who experience LTR to ICIs in advanced or recurrent NSCLC.

Methods: This is a retrospective study in which included pts with advanced or recurrent NSCLC who received any ICIs with or without chemotherapy at Kindai University Hospital from 2015 to 2021. LTR was defined as a progression-free survival (PFS) of more than two years on ICI treatment, and the clinical and genetic data were collected.

Results: Among the 388 pts, 57 (14.6%) were identified as patients who achieved LTR. The median age was 70 years (range: 37-86), with males constituting 42 pts (73.7%). Driver gene mutations were observed in 13 pts (22.8%) with the breakdown as follows: KRAS; 5, EGFR; 3, BRAF; 2, and ALK/RET/ROS1; 1 pt each. Clinical characteristics of patients who achieved LTR included non-squamous histology, PD-L1 TPS over 50%, and treatment regimen with PD-1 antibody monotherapy. Among the total of 57 patients, the median PFS was 84.6 months (95% CI: 42.3-not reached), with 5-year PFS rate of 59.4%. The median OS was not reached (95% CI: 69.5-not reached), with 5-year OS rate of 91.3%. Immune-related adverse events (irAEs) were observed in 28 pts (49.1%), with endocrine disorders being the most common, affecting 13 pts (46.4%). Based on the clinical course, they were classified into 3 patterns; continuous administration of ICI for more than two years, which constituted most of the long-term responders (39 pts, 68.4%), early discontinuation of ICI due to irAEs (9 pts, 15.8%), and completion of two years of ICI treatment followed by observation without treatment (9 pts, 15.8%). The median duration of treatment with ICIs was 41.4 months (range: 24.2-91.1), 12.7 months (range: 1.0-20.0), and 23.9 months (range: 22.1-26.5), respectively. The incidence of irAEs according to this classification was observed in 20 (51.3%), 9 (100%), and 3 (33.3%), respectively.

Conclusions: Among patients with advanced or recurrent NSCLC treated with ICI therapy, 14.6% achieved LTR, and those patients demonstrated a markedly favorable prognosis. Non-squamous histology, high PD-L1 expression, and treatment regimen with PD-1 monotherapy were enriched among these LTR patients. Furthermore, LTR patients were shown to be classified into 3 patterns of clinical courses.

Vidal, Corrientes/AR, [17]Fundación Centro de Medicina Nuclear y Molecular, Entre Rios/AR, [18]Centro de Operaciones de Emergencias de San Miguel Arcángel, Buenos Aires/AR, [19]Instituto Multidisciplinario de Oncología, Rio Negro/AR, [20]Centro Oncológico Anna Rocca de Bonatti, Corrientes/AR, [21]Instituto Misionero del Cancer, Misiones/AR

Introduction: The expression of PD-L1 serves as the main biomarker for response to immune checkpoint inhibitors (ICI) in NSCLC. However, approximately 30% of patients do not exhibit PD-L1 expression. This observation emphasizes the necessity to explore complementary biomarkers, particularly within the subgroup of NSCLC patients. The role of the neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) relationship has been evaluated as markers of host inflammation, correlating with poorer response to ICI and overall survival in NSCLC. Therefore, this study aims to assess the predictive role of these two biomarkers together as a score, referred to as NSCLC Immune Hemogram Index (NIHX), in a retrospective cohort of PD-L1 negative patients (REAL-IMPACT).

Methods: Multicenter retrospective study including patients with advanced NSCLC PD-L1 negative (<1% by IHC), without driver mutations (negative test for EGFR and ALK), treated with ICI from 2017 to December 2023 from 21 Argentinian centers. Complete blood cell counts were measured before ICI treatment. NIHX based on NLR greater than 3 and PLR greater than 180 was developed, characterizing 3 groups (good, 0 factors; intermediate,1 factor; poor, 2 factors). The primary endpoint was Progression-free survival (PFS). Secondary endpoints were overall response rate (ORR) and overall survival (OS).

Results: 121 patients were analyzed. Median age at first line was 65 (range 59-73), male gender 88 (58%), previous or active tobacco use 134 (88%), adenocarcinomas 126 (83%). IO schemes: CT + Pembrolizumab 125 (82%), Ipilimumab + Nivolumab 12 (7.9%), CT + Ipilimumab + Nivolumab 11 (7.3%), CT + Atezolizumab + Bevacizumab 3 (2%). Based on the NIXH score, 45 (29%), 34 (22.5%), and 42 (27.8%) patients were categorized as having good, intermediate, and poor prognosis, respectively.Median PFS for good, intermediate and poor NIHX was 14.1 months (95% CI, 8.1 to 20.1 months), 11.3 months (95% CI, 4.6 to 17.9 months) and 6.5 months (95% CI, 2.1 to 10.8 months) and ORR with 66%, 47% and 33% partial responses, in that order (both p<0.004). Median OS was 20.8 months (95% IC, 12 to 28 months), 24.1 months (95% IC, 18.2 to 30 months) and 18 (95% IC 7.7 to 28 months), respectively (p=0.42).

Conclusions: Our study demonstrates that pretreatment NIHX, based on NLR and PLR, serves as a promising predictive tool for treatment response in PD-L1 negative advanced NSCLC patients. NIHX stratification into good, intermediate, and poor groups correlates with PFS and RR, highlighting its potential utility in guiding ICI therapy selection for this patient population.

P4.11E.26 A Multicenter Retrospective Study Reveals High MET Expression Associated with Superior Benefit from Immunotherapy in Advanced NSCLC Patients

H. Li[1], L. Hong[1], Y. Jin[2], P. Rocha[3], R.B. Mora[3], I.I. Wistuba[1], L.M. Solis Soto[1], C.A. Arrechedera[1], C. Young[1], N. Vokes[1], J. Wu[1], W. Rinsurongkawong[1], J.J. Lee[1], D.L. Gibbons[1], A.A. Vaporciyan[1], J.V. Heymach[1], X. Le[1], Y. Fan[2], J. Zhang[1], [1]The University of Texas MD Anderson Cancer Center, Houston/TX/USA, [2]The Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Hangzhou/CN, [3]Hospital del Mar, Barcelona/ES

Introduction: MET has been recently scrutinized due to its association with resistance to chemotherapy and targeted therapy. However, the correlation between MET alterations and the efficacy of immune checkpoint inhibitors (ICIs) remains under explored. We sought to examine the clinicopathologic characteristics associated with high MET expression by immunohistochemistry (IHC) and explore the potential association between MET expression and ICI therapeutic benefits in advanced non-small cell lung cancer (NSCLC) patients.

Methods: We curated a multicenter dataset, encompassing 428 stage IV NSCLC patients who underwent MET IHC testing from MD Anderson Cancer Center (USA), Hospital del Mar (Spain), and Zhejiang Cancer Hospital (China). Among these patients, 382 received ICI treatment between October 2014 and October 2023, while the remaining 46 patients received chemotherapy alone. Experienced thoracic pathologists graded MET IHC results on a scale from 0 to 3+, defining high expression as a staining intensity of 2+ or 3+. The clinicopathological features associated with MET expression were assessed by logistic regression analysis. Kaplan-Meier analysis was conducted to investigate the correlation between MET expression and overall survival (OS) and progression-free survival (PFS) in ICI cohort and chemotherapy-alone cohort. Cox proportional hazards model was utilized for multivariate analysis.

Results: In the ICI cohort, 249 of 382 patients (65.2%) had high MET expression. High MET expression significantly correlated with female gender (P < 0.001), adenocarcinoma histology (P < 0.001), de novo stage IV diagnosis (vs. recurrent stage IV, P < 0.001), biopsy after ICI treatment (P = 0.022), and high PD-L1 expression (P < 0.001), while no significant correlations were observed with age and smoking history. In multivariate analysis, female gender (P = 0.001), adenocarcinoma histology (P = 0.007), de novo stage IV diagnosis (P < 0.001), and biopsy after ICI treatment (P = 0.027) remained significantly associated with high MET expression. Survival analysis revealed that high MET expression was associated with significantly improved OS (HR=0.740, 95% CI [0.556-0.984], p = 0.038), while PFS showed a trend towards improvement (HR=0.867, 95% CI [0.674-1.116], p = 0.269). To mitigate the impact of ICI treatment on MET expression, we conducted Cox regression analysis exclusively in patients who underwent biopsy before ICI treatment, revealing that high MET expression (P = 0.049) was associated with better OS, independent of PD-L1 expression. Additionally, age over 65 (P = 0.006), squamous cell carcinoma histology (P = 0.045), de novo stage IV (P = 0.003), and brain metastases (P = 0.002) were associated with inferior OS. Regarding PFS, only histology and PD-L1 expression were identified as independent factors, while MET expression was not significant (P = 0.538). In the chemotherapy-alone cohort, MET expression showed no correlation with either OS (P = 0.629) or PFS (P = 0.217).

Conclusions: In this real-world multicenter study, our findings indicated that high MET expression, assessed by IHC, was associated with improved OS in advanced NSCLC patients receiving ICI treatment, independent of PD-L1 levels. These results suggest that high MET expression may serve as an independent marker for predicting response to ICIs in advanced NSCLC patients.

P4.11E.27 Comparison of Immunotherapy for Metastatic Non-Small Cell Lung Cancer in Real-World Practice: A Japanese Registry Study

A. Miyazaki, K. Kunimasa, T. Morishima, T. Kawamura, T. Inoue, M. Tamiya, I. Miyashiro, K. Nishino, Osaka International Cancer Institute, Osaka/JP

Introduction: For metastatic non-small cell lung cancer (NSCLC) without driver alterations, several treatment options are available including immune-mono therapy, immune-chemo therapy and immune-combo therapy. The relative effectiveness of these approaches has yet to be determined through direct, prospective comparisons. This study employs real-world data to further investigate these treatment strategies.

Methods: This was a multi-center retrospective cohort study. We used anonymized records in hospital-based cancer registry data from 68 designated cancer care hospitals across Osaka Prefecture, Japan. Patients diagnosed with Stage IV NSCLC and treated with first-line therapy including immunotherapy between 2019 and 2021 were extracted and analyzed. The endpoint of this study was overall survival (OS) and time to treatment failure (TTF).

Results: From the cancer registry data, 2101 patients who were diagnosed with a StageIV NSCLC and treated with first-line therapy including immunotherapy. The distribution of regimens for the 2101 patients was 1173 for Pembro-chemo, 446 for Pembro, 272 for ATZ-chemo, 119 for NIV+IPI-chemo, 85 for NIV+IPI, and 6 for ATZ. First, we compared the immune-mono therapy group and the immune-chemo therapy group. TTF was 248 days (95% CI, 207 to 317 days) for the immune-mono therapy group and 252 days (95% CI, 237 to 275 days) for the immune-chemo therapy group (HR, 0.93 [95% CI, 0.81-1.07]) (P-value=0.33). OS was 492 days (95% CI, 365 days to NA) for the immune-mono therapy group and 829 days (95% CI, 805 days to NA) for the immune-chemo therapy group (HR, 0.62 [95% CI, 0.52-0.73]) (P-value=<0.05). Similar results were observed in the propensity score analysis. Second, we compared the Pembro-chemo therapy group and the ATZ-chemo therapy group. TTF was 267 days (95% CI, 245 days to 288) for the Pembro-chemo therapy group and 211 days (95% CI, 183 days to 245) for the ATZ-chemo therapy group (HR, 0.75 [95% CI, 0.63-0.89]) (P-value=<0.05). OS was NA (95% CI, 805 days to NA) for the Pembro-chemo therapy group and 609 days (95% CI, 437 days to NA) for the ATZ-chemo therapy group (HR, 0.75 [95% CI, 0.60-0.95]) (P-value=0.02). Similar results were observed in the propensity score analysis. Third, we compared the Pembro-chemo therapy group and the NIV+IPI-chemo therapy group. TTF was 267 days (95% CI, 245 to 288 days) for the Pembro-chemo therapy group and 217 days (95% CI, 176 to 322 days) for the NIV+IPI-chemo therapy group (HR, 0.85 [95% CI, 0.65-1.10]) (P-value=0.22). OS was NA (95% CI, 805 days to NA) for the Pembro-chemo therapy group and NA (95% CI, 454 days to NA) for the NIV+IPI-chemo therapy group (HR, 0.93 [95% CI, 0.64-1.36]) (P-value=0.72).

Conclusions: Our findings suggest that immune-chemo therapy, particularly pembrolizumab combined with chemotherapy, significantly enhances OS in stage IV NSCLC patients without driver alterations who are eligible for chemotherapy. This advantage was not observed with the combination of nivolumab and ipilimumab with chemotherapy, highlighting the importance of regimen selection in this patient population.

P4.11E.28 Pharmacological Comparison of Dostarlimab and Pembrolizumab in Metastatic Non-Small Cell Lung Cancer in PERLA

T.S. Samant[1], H. Struemper[2], R.C. Franzese[1], B. Goulooze[3], M. Muliaditan[3], M. Melhem[4], S. Ghosh[1], M. Fastenrath[5], N. Stjepanovic[6], Z. Szijgyarto[7], C. Rathi[1], A. Mantero[1], P. Hanafin[1], S. Zajic[1], N. Yanamandra[1], C-w. Chung[7], G. Vlahovic[4], [1]GSK, Collegeville/PA/USA, [2]GSK, Durham/NC/USA, [3]LAP&P Consultants, Leiden/NL, [4]GSK, Waltham/MA/USA, [5]GSK, London/GB, [6]GSK, Baar/CH, [7]GSK, Stevenage/GB

Introduction: PERLA (NCT04581824) is a randomized phase II trial of dostarlimab + chemotherapy vs pembrolizumab + chemotherapy in non-squamous metastatic non-small cell lung cancer. At median 21 months follow-up, a numerical trend in overall survival (OS) favoring dostarlimab + chemotherapy vs pembrolizumab + chemotherapy was observed (hazard ratio = 0.75 [95% confidence interval (CI): 0.53-1.05]) [1]. Post-hoc analyses were conducted to elucidate the difference in OS based on pharmacokinetics (PK), functional receptor occupancy (fRO), structural binding, and longitudinal tumor response using tumor size-overall survival (TS-OS) modeling.

Methods: PERLA PK for dostarlimab and pembrolizumab was compared with historical data, and fRO was compared between dostarlimab and pembrolizumab. Dostarlimab and pembrolizumab antibody X-ray complexes within the Research Collaboratory for Structural Bioinformatics (RCSB) protein databank were compared and visualized using standard molecular modelling software. A joint mixed-effects TS-OS model was developed from multiple immuno-oncology studies and applied to PERLA data [2]. Individual TS profiles were modelled longitudinally; corresponding TS parameters and baseline patient factors were linked to OS using a log-normal survival model [2]. The TS-OS model was well qualified across multiple studies.

Results: Steady-state PK concentrations observed for PERLA were similar to prior PK data for both dostarlimab and pembrolizumab. fRO was similar between dostarlimab and pembrolizumab, with a slight trend favoring dostarlimab. High-resolution crystal structures show dostarlimab binds to programmed cell death protein 1 at a distinct binding site compared to pembrolizumab. Based on arm-specific population estimates for TS parameters, the TS-OS model predicted a differential TS response for dostarlimab + chemotherapy vs pembrolizumab + chemotherapy: median (95% CI) maximal reduction from baseline was 37.0% (45.8-27.1) vs 27.1% (36.8-17.6) and median (95% CI) time to tumor growth was 8.9 (7.2-10.6) vs 6.6 (5.2-8.2) months, respectively (Figure 1).

Conclusions: The difference in OS between the pembrolizumab + chemotherapy and dostarlimab + chemotherapy arms was not readily explained by PK or fRO. The clinical impact of the dostarlimab distinct binding mode is still unknown. The TS-OS model demonstrated that the numerically deeper/longer response for dostarlimab + chemotherapy vs pembrolizumab + chemotherapy is consistent with the difference in OS.

P4.14C.01 Trends of Asbestos Lung Content in the General Population

E. Taioli[1], S. Visona[2], B. Bertoglio[2], S. Capella[3], E. Belluso[3], [1]Icahn School of Medicine at Mount Sinai, New York/NY/USA, [2]University of Pavia, Pavia/IT, [3]University of Torino, Torino/IT

Introduction: Malignant Mesothelioma (MM) is well-known to be related to previous occupational or non-occupational exposure to asbestos. The existence of a "threshold dose" above which the risk of developing the MM is significantly increased is still under debate. As asbestos and asbestos-like minerals are ubiquitously diffused in urban and natural environments, everyone is potentially exposed during life and, as a consequence, may have asbestos in their lungs. However, there is lack of data about the quantification of this "background exposure", which some scientists (Carbone et al.) considered to be below 500 000 ff/gdw in the lung. Another issue of great interest is represented by the chronological trends of asbestos exposure. Roggli et al. observed a progressive decrease of asbestos lung content in people with MM during the past four decades. Our group reported similar trends in a recent paper. However, there is no data about these trends in the general population. The objective of this study is to quantify asbestos in lung tissue of healthy individuals from the general population and to understand if asbestos exposure changed over the past decades.

Methods: This study was carried out on formalin-fixed lung samples taken during autopsy from 50 healthy individuals deceased between 2001 and 2023 from traumatic causes, according to the following criteria: age above 40 years; no medical history or pathologic evidence of neoplastic or respiratory disease; negative known history for occupational, household or environmental asbestos exposure. Concentration of asbestos uncovered fibers (AF), of asbestos bodies (AB) and of each type of asbestos, as well as the length and width of each detected fiber, were determined using a scanning electron microscope equipped with energy dispersion spectroscopy (SEM-EDS).

Results: AF was detected in 28% of them, while AB in 22%. The mean concentration of AF and AB were, respectively, 3190 ff/gdw (SD=7580) and 2010 ABs/gdw (SD=5630). The maximum concentration of AF was 39000 ff/gdw. Chrysotile was detected in 3 cases (6%), tremolite/actinolite in 12 cases (24%); amosite and anthophyllite were detected in only one case each, crocidolite was never detected. We studied the chronological trends of asbestos lung content comparing subjects born before (n=11) and after (n=14) 1940, frequency matched the on age at death. We found that both AF (5909 vs 1197 ff/gdw) and AB concentrations were significantly lower in people born after 1940, and AF were significantly shorter in people born after 1940 (10.1+4.9 vs 23.2+17.1). Moreover, in people born before 1940 both chrysotile and non-commercial amphiboles tremolite/actinolite were detected, whereas in those born after 1940 we observed only non-commercial amphiboles and, in two cases, commercial amphiboles (amosite and anthophyllite).

Conclusions: In this work we observed a significant decrease in asbestos lung content during the past decades, suggesting that the ban of asbestos mining and use in most western countries led to a considerable decrease of asbestos exposure in the general population.

P4.14C.02 Analysis of Pleiotropic Effects of Nivolumab in Patients with Relapsed Pleural Mesothelioma: A Single Center Retrospective Study

T. Higashiyama, K. Kuribayashi, M. Murakami, N. Kawamura, T. Kondo, T. Fujioka, T. Kandori, M. Tokuda, Y. Negi, D. Fujimoto, T. Otsuki, K. Mikami, R. Takahashi, T. Minami, T. Kijima, Hyogo Medical University, Nishinomiya/JP

Introduction: Nivolumab, an immune checkpoint inhibitor (ICI), became the first therapy approved worldwide by the regulatory authority (Japanese PMDA - Pharmaceuticals and Medical Devices Agency) for previously treated unresectable progressive/recurrent Pleural Mesothelioma (PM), filling a therapeutic gap that previously existed. However, the vulnerability of evidence obtained from the non-blinded single-arm Phase II trial of 34 cases, known as the "MERIT (Multicenter, Open-label, Single-arm, Japanese Phase II study in Malignant Pleural Mesothelioma) Trial," was strongly emphasized.

Methods: At our institution, we aimed to retrospectively confirm the effectiveness and safety of Nivolumab in real-world clinical settings for patients with previously treated unresectable progressive/recurrent PM, while simultaneously analyzing their clinical background.We targeted 83 cases of histologically diagnosed previously treated unresectable progressive/recurrent malignant pleural mesothelioma who received Nivolumab at our institution from August 2018 to May 2022. Effectiveness was assessed based on modified RECIST criteria, and safety was evaluated using CTCAE version 5.0 to assess treatment-related adverse events (TRAE).

Results: Patient demographics were as follows: median age, 73 (range 45-88) years; male/female, 64/19 cases; performance status (PS) 0-1/2 or more, 73/10 cases; smoking history, yes/no, 61/22 cases; asbestos exposure, yes/no, 55/24 cases; stage I/II/III/IV, 47/36 cases; histological subtype, epithelioid/sarcomatoid/biphasic/unknown, 60/15/6/2 cases; treatment line, 2nd/3rd/4th or later, 62/13/8 cases. The effectiveness outcomes were as follows: best treatment response, complete response/partial response/stable disease/progressive disease/not evaluable, 0/16/30/29 cases; overall response rate (ORR), 19.28%; disease control rate (DCR), 55.42%. The median PFS was 5.13 months (95% CI: 3.50-6.27), and the median OS was 12.40 months (95% CI: 8.50-16.37). Regarding safety, treatment-related adverse events (TRAE) occurred in 45 cases (54.22%) of all grades, with 6 cases (7.23%) being grade 3 or higher, and there was 1 case (1.20%) of death.

Multivariate analysis revealed that significant correlations with PFS were male gender, TRAE positivity, and good PS (PS: 0-1), while significant correlation with OS was observed only with good PS (PS: 0-1). Significant correlations with both PFS and OS were observed only with good PS (PS: 0-1).

Conclusions: The effectiveness of Nivolumab administration for PM in real-world clinical settings in this study was comparable to or greater than previous reports in terms of PFS and OS, and the safety profile was tolerable. Additionally, it became evident that even in late-line treatment, Nivolumab administration should be actively considered for patients with good PS.

P4.14C.03 Real-World Prognostic & Predictive Implications of EORTC & MRS Scores for Immunotherapy and Chemotherapy in Pleural Mesothelioma (PM)

F.T.H. Wu[1,2], M-F. D'Amours[1], F. Usman[1], A. Hussein[1], E. Bhang[1], M. Kamali Sarvestani[1], C.W. Lee[2,3], C. Ho[1,2], [1]BC Cancer Vancouver Centre, Vancouver/BC/CA, [2]University of British Columbia, Vancouver/BC/CA, [3]BC Cancer Surrey Centre, Surrey/BC/CA

Introduction: The EORTC prognostic score (EORTC-PS) was derived to classify patients with PM undergoing single-agent chemotherapy into good- versus poor-risk groups based on mainly clinicopathological characteristics. The Mesothelioma Risk Score (MRS) classified PM patients undergoing second-line single-agent anti-PD-1 immunotherapy or chemotherapy after prior platinum-doublet chemotherapy into favorable-, intermediate-, and poor-risk categories based on baseline laboratory values. This study explores the value of the EORTC-PS and MRS in the real-world setting in the modern era of first-line dual anti-CTLA-4 + anti-PD-1 immunotherapy.

Methods: A retrospective analysis was conducted using a cohort of 247 patients who were diagnosed with PM between 2010 to 2022 and received systemic therapy in British Columbia, Canada. Pre-treatment laboratory values (CBC+differential); and clinicopathological characteristics (pre-treatment performance status, sex, histological subtype, definitiveness of diagnosis) were used to calculate EORTC-PS and MRS. Overall survival (OS) from the date of diagnosis was analysed by the Kaplan-Meier method.

Results: Baseline characteristics: male 84%; median age at diagnosis 72 years (IQR 66 to 77); sarcomatoid (12%), epithelioid (66%), biphasic (11%), not otherwise specified (11%); ECOG performance status 0 (10%) and ≥1 (90%). The MRS and EORTC-PS scores were effective differentiators of favorable/good versus poor risk for patients receiving immunotherapy (Table 1). For patients receiving predominantly platinum-doublet chemotherapy, the EORTC-PS did not differentiate OS benefit and the MRS intermediate-risk group had better OS compared to the MRS favorable-risk group (Table 1). Patients in the EORTC-PS good-risk and MRS favorable-risk groups had a greater OS advantage from immunotherapy over chemotherapy compared to their poor-risk counterparts (Table 2), which is suggestive of predictive value.

Conclusions: The MRS showed greater prognostic value than the EORTC-PS in a real-world setting, especially for those receiving immunotherapy. Further evaluation is needed to confirm the utility of EORTC-PS and MRS in predicting immunotherapy advantage over chemotherapy.

P4.14C.04 Exhaled Breath Analysis for the Early Diagnosis of Malignant Pleural Mesothelioma and the Surveillance of Asbestos-Exposed At-Risk Subjects

A. Catino[1], A. Di Gilio[2], J. Palmisani[2], M. Nisi[3], N. Varesano[1], D. Galetta[1], G. De Gennaro[2], [1]Thoracic Oncology-IRCCS Istituto Tumori "Giovanni Paolo II", BARI/IT, [2]Apulian Regional Centre for the Breath Analysis, IRCCS Istituto Tumori 'Giovanni Paolo II', Bari/IT, [3]University of Bari, Bari/IT

Introduction: Malignant Pleural Mesothelioma (MPM) is a rare neoplasm with still a poor prognosis and mainly caused by previous asbestos exposure (both occupational and environmental). The management of MPM is challenging due to the long latency period between the exposure and the diagnosis and due to symptoms appearing only at an advanced stage. Thus, there is an ever-increasing need to equip National Health Systems with a reliable diagnostic tool to integrate into large-scale screening programs. Quite recently, the chemical characterization of Volatile Organic Compounds (VOCs) in human breath and the identification of disease-related metabolites pattern has been recognized as non-invasive and promising approach for the early detection of various neoplastic diseases. In the present study, we report the main outcomes of a cross-sectional study aimed at identifying MPM-related VOCs pattern in human breath. Furthermore, breath analysis potentialities in detection of metabolic alterations in participants with previous asbestos exposure were explored.

Methods: A total of 58 subjects were recruited: 24 patients affected by MPM, 24 healthy controls (HC) and 10 former asbestos-exposed individuals (EXP). The enrollment of volunteers in the clinical trial fulfilled specific criteria, after approval by the Institutional Ethic Committee. The methodological approach was based on the sampling of end-tidal breath directly onto two-beds adsorbent cartridges (Biomonitoring steel tubes, Markes International) by means of the automated sampler Mistral (Predict srl). Ambient air samples (AA) were simultaneously collected at each sampling session. Breath samples (n. 116) were thermally desorbed (Unity Ultra-xr Markes) and analyzed by Gas Chromatography/Mass Spectrometry (GC Agilent 7890/MS Agilent 5975). Experimental data were statistically processed by non-parametric Wilcoxon signed rank test in order to identify the most weighting variables in the discrimination between MPM and HC breath samples. Based on the outcomes of the preliminary statistical treatment, Principal Components Analysis (PCA) and Linear Discriminant Analysis (LDA) were applied to the dataset to validate breath analysis-based methodology in the discrimination among MPM, HC and EXP subjects.

Results: PCA statistical treatment of experimental data, e.g., VOCs abundances in MPM and HC samples, resulted in the identification of two principal components (PC1, PC2) explaining 82% of the total variance and characterized by higher loadings of selected aldehydes, whose increased abundance in MPM breath samples is indicative of promoted lipid peroxidation due to cellular oxidative stress. Leave-one-out cross-validation method was applied to calculate the prediction accuracy obtaining sensitivity equal to 92% and diagnostic accuracy equal to 90% (ROC AUC: 0.905). Finally, LDA output allowed to discriminate among MPM, HC and EXP subjects through clustering of population groups.

Conclusions: The methodological approach applied in this study, e.g., VOCs collection directly onto sorbent tubes by an automated device, represents an advancement in human breath sampling procedure with respect to previous studies carried out by the same authors and in line with research in breath analysis worldwide. Despite the promising results, the size and the homogeneity of the sample population deserves further investigation to validate breath analysis as a helpful tool in the screening and clinical management of MPM.

P4.14C.05 Incidence of Pseudoprogression and Hyperprogression in Patients with Pleural Mesothelioma Treated with Ipilimumab and Nivolumab

O. Mitchell, F. Li, C.M. Straus, G. Porroga, A.N. Husain, M.W. Drazer, S.G. Armato, H.L. Kindler, The University of Chicago, Chicago/IL/USA

Introduction: The immune checkpoint inhibitors (ICI) ipilimumab and nivolumab are now standard of care treatment for patients with pleural mesothelioma (PM). In other malignancies, ICI treatment can lead to an initial increase in tumor burden followed by tumor shrinkage (pseudoprogression), or an accelerated increase in tumor burden (hyperprogression). These phenomena have not been previously quantified in PM. We therefore investigated the clinical characteristics and incidence of pseudoprogression and hyperprogression in PM patients who received this regimen.

Methods: Patients presenting to a high-volume Mesothelioma Clinic were enrolled in an IRB-approved biorepository protocol. Clinical characteristics were abstracted from the medical record. Genomic DNA was assayed on a research-based germline panel. PD-L1 expression was quantified using Tumor Proportion Score (TPS). CT scans were obtained at baseline and approximately 6 and 12 weeks after starting immunotherapy, then every 3 months until treatment discontinuation. CT scans were interpreted and measured using mRECIST 1.1 by a single reference radiologist blinded to the clinical results. Pseudoprogression was defined as an interval increase in tumor burden at the first post-treatment scan that regressed at the next scan. Patients evaluable for hyperprogression had measurable disease per mRECIST 1.1 at baseline; hyperprogression was defined as either >50% growth in target lesions or marked new lesion growth within the first 12 weeks of treatment. Fishers exact and Wilcoxon ranked sum tests were used to determine statistical significance.

Results: Of 682 mesothelioma patients enrolled in the biorepository, 63 patients with pleural mesothelioma who received ipilimumab/nivolumab between January 2017 and February 2024 were included in this analysis. Patient characteristics: male 59%; median age: 70 years (range 23-86); performance status 0 33%, 1 54%, ≥2 13%; histology: epithelioid 62%, biphasic 32%, sarcomatoid 6%; PD-L1 TPS >1% (n=55) 64%; germline mutations (n=55) 14%; probable/definite asbestos exposure 70%; first-line treatment 59%. Of the 15 patients (24%) who had worsening disease at first reassessment, 10 had tumor regression at the subsequent scan, for an overall incidence of pseudoprogression of 16%. Pseudoprogression was more common in women (p=0.012). There was a trend towards higher PD-L1 expression in those with pseudoprogression that did not reach statistical significance (p=0.078). Of 44 patients evaluable for assessment of hyperprogression, 6 (14%) developed hyperprogression. No statistically significant differences in age, performance status, histology, PD-L1 expression, treatment line, asbestos exposure, or somatic or germline mutations were observed between patients with and without either pseudoprogression or hyperprogression.

Conclusions: In PM patients treated with ipilimumab/nivolumab, 67% of patients with worsening disease at first reassessment had subsequent tumor regression, for an overall rate of pseudoprogression of 16%. Women were more likely to experience pseudoprogression. The relatively high incidence of pseudoprogression we observed suggests that in the absence of significant clinical deterioration, PM patients on immunotherapy with suspected disease progression at the initial scan should consider continuing treatment until subsequent imaging is performed. Ongoing analyses evaluate the impact of hyperprogression on overall survival; correlate the incidence of pseudoprogression with objective response rate, response duration, and overall survival; and employ radiomics to discriminate between pseudoprogression and true progression.

P4.14C.06 Effect of Cytotoxic Chemotherapy Following Ipilimumab Puls Nivolumab Combination Therapy for Malignant Pleural Mesothelioma

K. Mikami, T. Otsuki, D. Fujimoto, Y. Negi, A. Tada, T. Higashiyama, M. Tokuda, J. Kiyota, T. Kondo, T. Kandori, H. Oota, T. Murata, H. Wakita, M. Kato, M. Mori, R. Takahashi, T. Minami, K. Kuribayashi, T. Kijima, Hyogo Medical University, Nishinomiya/JP

Introduction: Based on the outcomes of the Checkmate743 trial, ipilimumab and nivolumab combination treatment has been as a first-line regimen for malignant pleural mesothelioma (MPM) in Japan from June 2021. In non-small cell lung cancer (NSCLC), Immune checkpoint inhibitors (ICIs) have been reported to enhance antitumor effects of successive cytotoxic chemotherapy in some studies, which remains unclear in MPM.

Methods: This study aimed to retrospectively assess the effectiveness and safety of second-line cytotoxic chemotherapy in patients with MPM who received ipilimumab plus nivolumab combination treatment as first-line at Hyogo Medical University Hospital starting from June 2021 to January 2024.

Results: A total of 22 patients were analyzed. Patient characteristics were as follows. The median age: 71 (range 42-84), male/female:15/7, stage I/II/III/IV/relapse: 11/0/4/2/5, epithelioid/biphasic/sarcoma: 18/0/4, and CDDP+PEM/CBDCA+PEM: 13/9. Response rate was 9.1% and disease control rate were 50.0%, the median progression-free survival (mPFS) was 4.7 months and 1-year survival rate was 78.8%, respectively. The epithelioid type showed better PFS compared to the non-epithelial type (mPFS: 6.2 months vs. 2.4 months, p=0.035. HR=0.13) but no difference was observed in overall survival (OS) (1yr-OS rate: 79.6% vs. 75.0%, p=0.88. HR=1.18). As for safety, serious adverse events were observed in 3 patients, one anaphylactic shock and two grade 3 or higher renal dysfunction, which compelled treatment discontinuation.

Conclusions: Our findings suggest that the effectiveness of platinum plus pemetrexed successive to ipilimumab plus nivolumab was comparable to the data of first-line cisplatin plus pemetrexed reported in EMPHACIS study in which the mPFS was 5.7 months.

P4.14C.07 A Combination of Routine and Novel Immunohistochemical Markers to Improve the Histological Diagnosis of Mesothelioma in Challenging Biopsies

P. Viola[1], H. Kudo[2], G. Valentine[1], J. Vidak[1], G. Srilal[1], S. Desai[1], N. Gupta[1], J. Nandi[2], M. Al-Sahaf[1], A. Mani[3], [1]Imperial College Healthcare, london/GB, [2]Imperial College London, School of Medicine, London/GB, [3]Manchester University NHS Foundation Trust, Manchester/GB

Introduction: Early diagnosis of malignant mesothelioma (MM) is essential to increase the chance of curative treatment. Unilateral accumulation of haemorrhagic effusion and pleural thickening/nodularity are the earliest clinical manifestations of MM. Despite the fact that effusion is easily accessible, compared to a thoracic surgical biopsy, cytomorphological criteria to diagnose MM are not clear-cut as previously investigated by the authors. Confident histological diagnosis requires a decent amount of material (presence of adipose tissue) which is not always achievable generating diagnostic challenges and requests for more tissue. This work will look into a combination of Immunohistochemical (IHC) markers to look for a diagnostic algorithm to confidently diagnose MM in limited samples.

Methods: We retrieved 37 pleural biopsies with a confirmed clinical and histological diagnosis of MM and 22 cases of benign mesothelial proliferation/reactive pleuritic between January 2016 and December 2021. An IHC panel including BAP1, MTAP, p16, p53 and Merlin was performed on all 59 pleural biopsies to look for a diagnostic algorithm. This algorithm will be prospectively applied to an additional set of 20 consecutive pleural biopsies morphologically suspicious for MM to assess its validity.BAP1 was considered as retained (positive nuclear staining) or lost (negative nuclear staining with a positive internal control). MTAP was considered as retained (positive cytoplasmic staining of same intensity as positive internal control) or lost (negative cytoplasmic staining with a positive internal control). P16 was considered positive when >10% of cells showed block staining (any weak staining will be interpreted as negative). P53 was considered positive when >10% of cells showed strong nuclear staining at 10x (any weak staining will be interpreted as negative). Merlin was considered as retained (crispy membranous staining at 10x objective with same intensity as positive internal control) or lost (nuclear and/or cytoplasmic staining). Statistical analysis were conducted using IBM SPSS Statistics (Pearson Chi-square Tests and Fisher exact bilateral tests).

Results: 64.9% biopsies with a diagnosis of MM showed loss of BAP1, 59.5% showed loss of MTAP and 32.4% showed loss of Merlin. BAP1, MTAP and Merlin were retained in 100% of biopsies negative for malignancy. P53 and p16 were negative in the majority of biopsies regardless the diagnosis (61% and 84.7% respectively) with this scoring system. Statistical analysis showed significant correlation between the type of diagnosis, BAP1 ($p<.001$), MTAP ($p<.001$) and Merlin expression ($p<.002$).

Conclusions: Early detection of MM has a major impact on patient survival however, histological diagnosis can be challenging on limited samples. A combination of well-established and novel IHC markers selected from the literature have been investigated in this work to support a histological criteria. Our preliminary results showed a high level of retention in benign mesothelial proliferation of all three markers BAP-1/MTAP/Merlin. This novel IHC panel, if confirmed by a larger series, could help in diagnostically challenging cases.

P4.14C.08 HIT-MESO: Hemithoracic Irradiation with Proton Therapy in Malignant Pleural Mesothelioma. UK National Proton Radiotherapy Study

C. Hiley[1], A. Gosling[2], K. Durno[2], P. Patrick[3], C. Clarke[3], C. gardiner[4], P. Shaw[5], N. Counsell[6], [1]UCL Cancer Institute, London/GB, [2]UCLH, London/GB, [3]UCL, London/GB, [4]University of Sheffield, London/GB, [5]Velindre University NHS Trust, Cardiff/GB, [6]ULC, London/GB

Introduction: Only 15% of patients with Mesothelioma in the UK receive any radiotherapy and this is predominantly given as a palliative treatment for symptomatic benefit to a limited area of pleural disease. However radical hemi-thoracic radiotherapy with conventional radiotherapy has demonstrated an overall survival benefit but with high rates of toxicity. Several planning studies have shown the potential benefit of proton beam therapy (PBT) in MPM for treatment of the hemi-thorax due to a reduction in the doses to normal tissues, however clinical data is limited to single centre retrospective studies.

Methods: HIT-Meso is a phase III, multicentre, randomised (1:1) controlled trial comparing radical hemi-thoracic PBT to standard of care, in 148 patients with histologically confirmed MPM confined to one hemi-thorax. HIT-Meso aims to explore a PBT as an option to delay the need for systemic anti-cancer therapy in MPM patients suitable for surveillance by evaluating the efficacy and safety of PBT.Trial endpoints: co-primary PFS (i) and OS (ii); safety and toxicity, QoL, health and social care resource use, and incremental cost-effectiveness (secondary); translational research (exploratory). A qualitative sub-study explore participant experience is included.

A sample size of N=148 (i.e. 74 patients per arm) is required to detect an OS hazard ratio of 0.58, equivalent to an improvement in 2-year OS from 30% to 50%, with 85% power and 5% two-sided alpha. Recruitment to complete in 3 years across 20 UK centres with 2 years of additional follow-up and up to 5% dropout. Using a fixed-sequence approach, a difference for OS will only be tested if the co-primary endpoint of PFS is statistically significant ($p<0.05$).The study has been funded by Asthma + Lung UK and Mesothelioma UK, and opened to recruitment in April 2024

Results: NA

Conclusions: NA

Keywords: Trial in Progress, Mesothelioma, Proton radiotherapy

P4.15A.01 Efficacy of Digital Therapeutics for the Perioperative Management in Patients with Lung Cancer: A Randomized Controlled Trial

J. Xu[1], H. Ni[1], H. Zhan[1], H. Yu[2], Z. Lu[1], J. Zhang[1], H. Meng[1], L. Hang[1], L. Mao[1], X. Xu[1], X. Ma[1], Q. Wu[1], W. Xu[1], D. Xiang[1], Y. Zeng[1], D. Meng[1], X. Teng[1], L. Yu[1], L. Zeng[1], P. Ni[1], H. Miao[1], S. Fu[1], L. Wang[1], Z. He[1], C. Zhang[1], X. Lv[1], H. Xu[1], Y. Wu[3], W. Lv[1], K. Chen[4], Q. Shi[2], J. Hu[1], [1]the First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN, [2]College of Biomedical Engineering, Chongqing Medical University, Chongqing/CN, [3]Zhejiang University School of Medicine, Hangzhou/CN, [4]CinoCore Health, Shanghai/CN

Introduction: To evaluate the efficacy of digital therapeutics (DTx) assisted management vs multidisciplinary management (MM) in the perioperative management of patients with lung cancer, an open-label, single-center, non-inferiority, randomized controlled trial conducted in China.

Methods: From July 2022 to June 2023, a total of 186 patients underwent minimally invasive lung surgery were randomized and 147 completed the study. Participants were randomly assigned 1:1 to receive DTx-assisted management (n=72) or traditional MM (n=75). The primary endpoint is the pulmonary function recovery rate measured by forced expiratory volume in the first second (FEV1) three weeks after surgery. Secondary endpoints include hospital stay duration, 90-day unplanned readmission rate, symptom scores, management efficacy and patient satisfaction rate. Exploratory endpoints include factors influencing postoperative lung function recovery.

Results: The lung function FEV1 recovery rate of DTx group was not inferior to that of the MM group (87.18±11.01% vs 84.21±11.75%). There were no significant differences between the two groups in terms of postoperative hospitalization duration and 90-day unplanned readmission rates. The average time required for each patient management in DTx group was significant shorter than that of MM group (P<0.001). Patient symptom scores showed a decreasing trend over time after discharge, the 5 target symptoms included pain, coughing, shortness of breath, disturbed sleep and fatigue. On the 7th day after discharge, the DTx group had a lower occurrence rate of the 5 target symptoms triggering alert threshold (P=0.002). Patients with higher education level achieved better FEV1% recovery rate by DTx-assisted management (P=0.021).

Conclusions: Compared to the MM group, the DTx group achieved non inferior results, therefore providing an alternative digitalized management mode for patients with lung cancer surgery.$$graphic_{0F56E6B4-F259-4DF9-B288-7BE0B90D8315}$$

P4.15B.01 Remote Exercise Program for Patients with Lung Cancer on Immune Checkpoint Inhibitors

P.G. Bergerot[1], C.D. Bergerot[1], J.R.G. Silva[1], J.R. Farias[1], P.S.M. Lages[1], W.H. Fuzita[1], J.N. Matos Neto[1], M.V.d.S. França[1], M.M. Buso[1], M.T. Laloni[1], C.G. Ferreira[1], W.N. William Jr[1], E. Soto-Perez-de-Celis[2], K.H. Schmitz[3], N. Florez[4], [1]Oncoclinicas&Co - Medica Scientia Innovation Research (MEDSIR), Sao Paulo/BR, [2]Instituto Nacional de Ciencias Medicas Y Nutricion Salvador Zubiran, Mexico/MX, [3]University of Pittsburgh, Pittsburgh/PA/USA, [4]Dana-Farber Cancer Institute, Boston/MD/USA

Introduction: Despite advancements in the treatment of lung cancer (LC) with the introduction of immune checkpoint inhibitors (ICI), patients with advanced LC often experience significant physical and psychological challenges that can impact their quality of life, ability to receive therapy and LC outcomes. Physical activity is a promising adjunctive therapy, offering potential benefits in symptom burden, and overall well-being. This prospective study aimed to investigate the efficacy of a remote physical activity program tailored for patients with advanced LC receiving ICI

Methods: This longitudinal study recruited patients diagnosed with LC and receiving ICI within a cancer network in Brazil. Eligible participants were invited to enroll, and those interested underwent screening for symptom burden (Edmonton Symptom Assessment System, ESAS) and quality of life (Functional Assessment of Cancer Therapy-General, FACT-G). Following assessment, a certified fitness trainer prescribed personalized physical activity regimens for home-based implementation. Over a 12-week period, patients engaged in weekly virtual appointments with their assigned personal trainer. During these sessions, the trainer assessed patients' physical capacity and adjusted the intensity of the exercise regimen to the patient's needs. The protocol included resistance exercises, aerobic activities, and mobility exercises, specifically tailored for home-based execution. At the conclusion of the 12-week intervention, patients underwent reassessment for symptom burden and quality of life. Statistical analyses were performed using linear mixed models to evaluate the effectiveness of the remote physical activity program.

Results: A total of 14 patients were recruited for the study, with a mean (M) age of 70 years (SD=6.2). Most participants were male (57%), married (57%), and had at least a college degree (64%). Seventy-one percent of the patients were diagnosed with metastatic disease. At baseline, patients reported experiencing higher levels of fatigue (M=4.2) and anxiety (M=3.7). Following participation in the remote physical activity program, there was a significant decrease in both fatigue (M=1.0) and anxiety (M=1.0 and M=1.5, respectively; P=0.001). Over the course of the intervention, there was a notable improvement in overall quality of life, with scores increasing by almost 10 points from baseline (MT1=84.7 to MT2=91.6, p=0.005). Additionally, there was a substantial reduction in symptom burden, with scores decreasing by almost 10 points over time (MT1=21.6 to MT2=10.7, p=0.01).

Conclusions: Our study highlights the critical role of physical activity interventions in addressing the multifaceted needs of patients with LC, often overlooked in trials due to associated symptoms. Patients with LC frequently present insufficient physical activity, contributing to quality of life impairment, functional decline, and symptoms like fatigue. Our remote program demonstrated significant improvements in symptom burden and overall quality of life, while the remote aspect of the proposed method also substantially increased patient adherence. These findings emphasize integrating tailored exercise programs for patients with advanced LC, warranting further research for validation and comprehensive support.

P4.15B.02 Cardiopulmonary Rehabilitation Exercises Effectively Improve the Radiation-Induced Cardiopulmonary and Patients' Life Quality

Q. Meng[1], H. Li[2], J. Gu[1], D. Sun[1], M. E[1], Y. Jie[2], A. Gu[1], [1]Harbin Medical University Cancer Hospital, Harbin/CN, [2]Fourth Affiliated Hospital of Harbin Medical University, Harbin/CN

Introduction: In the process of radiotherapy for patients with non-small cell lung cancer,normal heart and lung tissues are inevitably exposed to different degrees of radiation,which may cause damage to the cadiopulmonary function.However,current studies about the rehabilitation of cardiopulmonary injury often focused on the heart and lung separately, which cannot simultaneously reflect the characteristics of the cardiopulmonary function in real life of patients.And there is no particularly effective way to prevent and improve the radiation-induced cardiopulmonary injury. In this study,cardiopulmonary rehabilitation exercise methods of common cardiovascular diseases were applied to the study of radiation-induced cardiopulmonary injury, and integrated exercise prescription intervention was used to improve the radiation-induced cardiopulmonary injury and improve the quality of life of patients.

Methods: The study lasted from September 2020 to December 2023. 82 patients with stage I-III non-small cell lung cancer receiving radiotherapy were randomly divided into trial group and control group. These patients received cardiopulmonary exercise test (CPET) and health-related quality of life (HRQoL) score before initial radiotherapy. CPET can reflect the real cardiopulmonary combined function in patients' lives. At the beginning of radiotherapy, the experimental group was given an integrated exercise prescription. The prescription includes aerobic exercise such as walking and traditional Chinese medicine-Baduanjin. It also includes resistance exercises for muscle strength training. The control group was given a fixed routine exercise prescription, and the two groups were followed up daily. The total dose of radiotherapy was 60-66Gy. The CPET and HRQoL score was performed after 45/135/225/315 days,and the results of the these tests were compared to evaluate the intervention effect of cardiopulmonary rehabilitation on radiation-induced cardiopulmonary injury.

Results: The maximum oxygen uptake (VO2max) reflected the maximum aerobic metabolism and cardiopulmonary reserve capacity of human body. After radiotherapy, many indexes of experimental group and control group were significantly decreased compared with those before radiotherapy ($P < 0.05$). However, the experimental group with integrated exercise prescription intervention did not decrease the VO2max and HRQoL score, while the control group significantly decreased the VO2max and HRQoL score($P < 0.05$). This indicates that cardiopulmonary rehabilitation exercise can improve radiation-induced cardiopulmonary injury.

Conclusions: Cardiopulmonary function rehabilitation can improve radiation-induced cardiopulmonary injury and the quality of life of patients by exercise prescription.It is an effective treatment method.

P4.15B.03 Effects of Tai Chi and Qigong Interventions in Lung Cancer Patients: A Systematic Review

T. Franchina[1], V. Franchina[2], E. Sapuppo[1], D. Tessitore[1], N. Silvestris[1], [1]Medical Oncology Unit, Department of Human Pathology "G. Barresi", University of Messina, Messina/IT, [2]Medical Oncology Unit, "Papardo" Hospital, Messina, Messina/IT

Introduction: Exercise plays a crucial role in the journey of patients with lung cancer.

Tai Chi and Qigong have shown promise in improving the quality of life, alleviating symptoms, reducing stress, and enhancing physical functioning in cancer patients, including those with lung cancer.

Methods: Following PRISMA guidelines, electronic databases (MEDLINE, Web of Science, and Scopus) were searched from January 2014 to February 2024 using the MeSH terms, text word synonyms and key words for the topics addressed by the systematic review. Titles and abstracts were reviewed by 2 independent reviewers; disagreements were resolved by a third. All identified full papers were assessed independently by three researchers. Included studies were required to be RCT, and evaluate tai chi or qigong interventions in lung cancer patients.

Results: We found 107 studies through the database; after duplicate removal and eligibility evaluation, we identify 6 studies meeting the selection criteria to analyze in qualitative synthesis (Table 1). These studies included a total of 823 lung cancer patients mainly in advanced setting. The main relevant aspect emerging from the analysis is the interesting multifaced role of tai chi and qigong in alleviating symptoms, promoting an holistic approach.

Conclusions: For patients with lung cancer Tai Chi and Qigong may offer several benefits in palliative care settings including symptom management, improved quality of life and sleep quality, and stress reduction. Multidisciplinary support is crucial to implement lung cancer exercise programs and define interventions tailored to the specific needs of lung cancer patients.

Keywords: advanced lung cancer, tai chi, qigong

Table 1: Analysis of randomized controlled trials on the effects of tai chi or qigong interventions in lung cancer.

AUTHORS	SAMPLE	DESIGN	EXERCISE INTERVENTION	RESULTS
ZHANG LL et al, J Pain Symptom Manage 2016	96 advanced lung cancer patients undergoing chemotherapy	Prospective, randomized, controlled intervention trial	Tai Chi exercise group or low-impact exercise control group	Tai chi was an effective intervention for managing CRF
CHEUNG DST et al, Integr Cancer Ther 2021	30 advanced lung cancer patients	Assessor-blinded, exploratory randomized controlled trial	A tai chi group (both attending 12-week, twice-weekly supervised sessions), or a self-management control group	Tai chi group attained higher adherence than the exercise group
TAKEMURA N et al, Palliat Support Care 2023	99 advanced lung cancer patients	Randomized controlled clinical trial	Aerobic exercise versus Tai Chi intervention	Low fatigue levels contributed to higher attendance in Tai Chi and improves long-term effectiveness of sleep
TAKEMURA N et al, JAMA Oncol 2024	226 advanced lung cancer patients	Assessor-blinded, randomized clinical trial	Aerobic exercise versus Tai Chi intervention	TC demonstrating greater benefits on sleep and survival
MOLASSIOTIS A et al, Integr Cancer Ther 2021	156 lung cancer patients	Randomized controlled clinical trial	Qigong group (6 weeks of intervention) or a waitlist control group receiving usual care	Qigong did not alleviate the symptom cluster experience, but it was effective in managing respiratory symptoms
XU J et al, Support Care Cancer 2023	216 NSCLC postoperative participants	Randomized controlled clinical trial	Routine lung rehabilitation training versus Baduanjin qigong	Baduanjin qigong may have certain advantages in relieving cancer-related fatigue and FEV1%

P4.15C.01 Improving Care Coordination to Address Healthcare Inequities in Lung Cancer

C.S. Lathan, MD, MS, MPH[1], C.B. Smith, MD, PhD[2], K. Finch, PharmD, BCOP[3], J. Modlin, PharmD, BCOP[4], A. Lile[5], L. Meier[5], E. Plotkin[5], M. Kisiel, MSN, FNP-BC[5], [1]Harvard Medical School, Dana-Farber at St. Elizabeth's Medical Center, Boston/MA/USA, [2]Mount Sinai, New York City/NY/USA, [3]Columbus Regional Health, Columbus/IN/USA, [4]St. Luke's Health System, Boise/ID/USA, [5]Association of Cancer Care Centers, Rockville/MD/USA

Introduction: The Association of Cancer Care Centers (ACCC) developed the Improving Care Coordination (ICC) Model between 2016 and 2020, expanding on the Multidisciplinary Care (MDC) Assessment Tool from the National Cancer Institute's Community Cancer Centers Program (NCCCP). These models aimed to enhance multidisciplinary care quality for Medicaid-covered patients, ultimately improving their quality of life and treatment outcomes. The ICC Model consists of 12 assessment areas with 5 levels each, ranging from basic care provision (level 1) to optimal best practices for coordination (level 5). Designed for multidisciplinary teams including oncologists, advanced practice providers, navigators, social workers, and administrators, the Model is a tool for cancer programs to objectively assess how lung cancer care is provided at their institution and as scaffolding for building quality improvement initiatives to improve care coordination for patients with a lung cancer diagnosis. Cancer programs can employ the Model to measure strengths and improvement opportunities while conducting continuous assessment of care coordination in pursuit of optimal patient outcomes.

Methods: In late 2023, ACCC updated the Model with new quality metrics. To refine the Model, a working group was assembled featuring key stakeholders and cancer care professionals, including an oncology pharmacist, two medical oncologists with expertise in thoracic oncology and palliative medicine, and patient advocacy partners. The working group distributed the 12 assessment areas among its members based on expertise and interest, with each member reviewing and updating three sections. ACCC reviewed, consolidated, and collated all quality updates and conducted individual review sessions with each working group member. The final version of the Model was reviewed by the Working Group, editorial teams, and key advocacy partners before publication.

Results: Table 1 (Assessment Areas - Summary of Updates) summarizes the updates made to the Model across assessment areas. Although the Model was originally developed for the lung cancer population, many components may now be used across the cancer care delivery system independent of cancer type.

Conclusions: Continuous quality improvement in healthcare is crucial for enhancing patient care and provider satisfaction. The ICC Model serves as a tool to evaluate strengths and areas for improvement, aiming to achieve optimal patient care. With each assessment area offering five levels of care provision, the ICC Model supports cancer programs and practices in progressing towards their desired target level. Originally tailored for lung cancer, its adaptable components can benefit the broader cancer care delivery system.

Keywords: Care Coordination, Quality Improvement, Assessment Tool

Assessment Area	2023 Updates
Patient Entry into Lung Cancer Program	Added offering of navigation services & second opinion telehealth as high-level metrics.
Multidisciplinary Treatment Planning	Removed strict metrics regarding multi-visits—allowed the use of agreed upon treatment pathways if applicable to the disease state and program type.
Clinical Trials & Biomarker Testing	Moved metrics regarding coordinated portfolio of trials up from Level 3 to Level 4. Reduced percentages of patients screened for clinical trials (very hard to reach and measure, even for NCI cancer centers). Added metrics for biomarker testing, aligned with best practices
Supportive Care	Added prescription of prophylactic antiemetic therapy prior to first cycle chemotherapy as Level 2 metric. Advanced care planning should be in place for patients 65+
Survivorship Care	Added metrics for annual education of staff on providing supportive care services. Added that patients should be referred to resources when available. Added that a survivorship program with coordinator oversight is available for Level 5
Financial, Transportation, and Housing	Recommended visually separating metrics for the 3 areas (such as color-coding). Removed specifics (such as "discussion of bills received") as patients may ask to speak with financial counselors for other reasons.
Tobacco Education	Recommend listing the "assessment" (screening) step as the first bullet for Levels 1, 2 and 3 as assessing tobacco use is the first step prior to advising and assisting the patient and household member to quit (3 As: ask, advise, assist). Added details for clarity (example: changing "formal counseling" to "formal tobacco cessation counseling")
Navigation	Added medical interpreter services & structured education to navigation services. Added responsiveness to telephone inquiries re: medical care within 24 business hours
Treatment Team Integration	No updates needed.
Physician Engagement	Added metrics of physicians' completion of training in inclusivity, social determinants of heath, and barriers to care, either through credentialling program or outside organization.
Electronic Health Records (EHR) and Patient Access to Information	Added metrics for: (1) Increased patient access to EHR, (2) review of Problem & Medication list at every visit, (3) medication documentation via barcode, (4) telemedicine integration with EHR. Recommended use of clinical data sharing repositories or exchanges if possible
Quality Measurement and Improvement	Removing distinction of QOPI/RQRS data when describing Level 3 QI initiatives (to increase flexibility for average programs).

MONDAY, SEPTEMBER 9, 2024 - 18:30 - 20:00

P4.15C.02 Palliative Care Impact on Time Toxicity Among Patients with Advanced Lung Cancer at the End of Life

A. Duffens[1], S. Zhu[2], L. Lyyon[2], A. Shirazi[1], A. Lynch[3], A. Gupta[4], R. Liu[2,5], [1]San Francisco Medical Center, Kaiser Permanente, San Francisco/CA/USA, [2]Kaiser Permanente Northern California, Oakland/CA/USA, [3]Oakland Medical Center, Kaiser Permanente, Oakland/CA/USA, [4]Division of Hematology, Oncology, & Transplantation, University of Minnesota, Minneapolis/MN/USA, [5]The Permanente Medical Group, San Francisco/CA/USA

Introduction: Time toxicity, reflecting the burdensome time commitments required from patients undergoing cancer treatment, is a significant concern in advanced lung cancer care. Patients with advanced lung cancer have frequent and intensive interactions with the healthcare system, primarily driven by the demanding nature of cancer treatments and significant disease burden. Studies have emphasized that early integration of palliative care improves patients' quality of life and leads to a decrease in unnecessary medical interventions, hospitalizations, and emergency department (ED) visits. This study examines the impact of palliative care on time toxicity by analyzing healthcare contact days in patients with advanced lung cancer within the last year of life.

Methods: A retrospective cohort analysis was conducted including patients with advanced (stage 4) lung cancer who died within one year of diagnosis at Kaiser Permanente Northern California between January 1, 2018, and December 31, 2021. The outcome was quantified as the number of days patients had physical contact with the healthcare system, including outpatient visits (lab work, imaging, treatment, provider appointments), ED visits, acute inpatient hospitalizations, and non-acute institutional stays from diagnosis to death (healthcare contact days), presented as both an absolute number and as a proportion of the total survival period (contact %). Our exposure was whether patients had received palliative care, characterized as being seen by outpatient or inpatient palliative care at least once between diagnosis and death. Multivariable negative binomial regression was utilized to model contact days with adjustment for demographic, treatment, and clinical variables.

Results: There was a total of 944 patients with advanced lung cancer (49.5% female, 73.3% White, median Elixhauser score of 4), 486 (51.5%) of which were seen by palliative care. Compared to those who did not receive palliative care, patients who received palliative care were younger (73 years vs 75 years), more likely to have received chemotherapy (46.3% vs 28.2%), radiation (38.7% vs 26.9%), and enrolled in hospice (45.3% vs 31.2%) (all $p<0.01$). Overall, patients receiving palliative care lived longer than those who never received palliative care (median survival, 140.5 days vs 81 days, $p<0.001$). The median percentage of contact % were similar between two groups (29.1% vs 33.2%, $p=0.05$). However, after adjustment and stratifying by types of contact, the palliative care group demonstrated significantly fewer ED or acute inpatient contact days (adjusted rate ratio [aRR] = 0.67, $p<0.001$) with an increased outpatient contact days (aRR = 1.15, $p<0.001$). Additionally, hospice enrollment was associated with significantly less contact days (aRR = 0.68, $p<0.001$).

Conclusions: The integration of palliative care significantly reduces time toxicity for advanced lung cancer patients by decreasing reliance on acute inpatient and ED services and promoting more manageable outpatient and in-home care options, including virtual care. These findings advocate for the broader implementation of palliative care in advanced lung cancer treatment protocols, highlighting its role in improving patient outcomes and quality of life.

Keywords: Palliative care, Time toxicity, Contact days

P4.15C.03 Successful Implementation of a Lung Cancer Navigator Workshop: A Cancer Site-Specific Training Program by GO2 For Lung Cancer

M. Fay, A.M. Barry, J.T. Fathi, GO² for Lung Cancer, Washington/DC/USA

Introduction: Lung cancer is the leading cause of cancer-related deaths worldwide. This highly stigmatized disease is preventable and curable when people receive timely, evidence-based, efficient, and high-quality care. A growing body of evidence demonstrates the value of integrating patient navigation across the care continuum for improved outcomes and a well-accepted practice in lung cancer. Due to the paucity of comprehensive and site-specific training for lung cancer navigators, GO2 for Lung Cancer has initiated the Lung Cancer Navigator Workshop to elevate the standard of care and equitable health outcomes through effective care navigation for people at risk and living with lung cancer.

Methods: The curriculum for this didactic workshop was informed by a navigator advisory board (NAB) comprised of clinical and administrative experts representing the lung cancer continuum. The NAB provided diverse perspectives and insights on content areas that must be included in navigator training. Ten topics were prioritized for the day-long Lung Cancer Navigator Workshop held on October 12, 2023, in Washington, DC.

Results: This inaugural workshop was attended by 85 participants (nurses, pharmacists, social workers, scientists, and administrators) across oncology; A 70% higher attendance than the goal of 50 was appreciated. A post-test and survey were completed by 47% (40/85) of participants, with 100% (40/40) demonstrating competency and earning continuing education credit. Feedback on the workshop's effectiveness revealed high satisfaction levels and perceived competency in the course content, with 100% (40/40) of participants reporting the course was worth their time and would recommend it to others, and 97.5% (39/40) found the faculty effective in delivering the material. The professional value of the workshop content in improving their practice or job function was rated "highly valuable" (82.5%) and "valuable" (17.5%), and 92.5% (37/40) reported that the education and resources provided would be useful in their practice. Finally, upon completing the Workshop, participants rated their knowledge confidence highly in seven key content areas.

Conclusions: This comprehensive site-specific Lung Cancer Navigator Workshop, provided by GO2 for Lung Cancer, is the first of its kind. Providing didactic content orienting cancer navigators to current evidence, practice guidelines, and best practice standards for lung cancer care leverages the opportunity to prepare navigators to address the unique needs of people at risk and living with lung cancer. This ongoing Workshop enhances the provision of quality patient and family-centered lung cancer care, close care gaps, and improve equitable health outcomes critical to the lung cancer community.

P4.15D.01 Beyond Survival: A Pilot Study Analyzing Physician and Patient Perspectives on Lung Cancer Survivorship Care at Weill Cornell Medicine

A. Kulkarni, P. Collins, P. Sadama, A. Saxena, C.A. Garcia, Weill Cornell Medicine / New York Presbyterian Hospital, New York/NY/USA

Introduction: Lung cancer survivors constitute a significant and continually growing segment of the healthcare landscape. This increase can be attributed to the remarkable advancements in treatment modalities, including surgery, targeted therapy, and immunotherapy. These have enabled the 5-year lung cancer survival rate to rise from a meager 13% in the early 1990s to a promising 22% in the 2010s. 1 However, surviving cancer brings its own set of complex needs related to the long-term physical and psychological effects of cancer and its treatment. 2 With the rising number of lung cancer survivors and their unique, multifaceted needs, the demand for structured lung cancer survivorship programs has never been more pronounced.

Methods: Our study aimed to conceptualize and create a lung cancer survivorship program, beginning with a comprehensive understanding of our current approach to survivorship care. To accomplish this, we employed the Plan-Do-Study-Act (PDSA) cycles 1 and 2. In cycle 1, we developed and adapted a survey tool from the validated Concerns Checklist3, specifically tailored to understand the existing approach to the care of lung cancer survivors. This survey was distributed to physicians who treat lung cancer patients, who were then provided with a list of survivorship concerns. In cycle 2, we developed a patient-centric survey tool, which was given to all patients diagnosed with early-stage lung cancer who were eligible for survivorship care. This patient survey evaluates multiple domains of survivorship including symptoms, pain, sexual dysfunction, practical concerns, psychosocial needs, spirituality, nutrition concerns, and use of complementary therapies.

Results: Physician surveys were completed by 12 respondents from various specialties. The most addressed concerns were breathing difficulties, cough, pain, smoking cessation, and fatigue. However, concerns like sexual functioning, fertility, and complementary therapies were areas where most respondents felt uncomfortable addressing. Faith or spirituality, sexual functioning, fertility, and practical concerns like shopping and housework were aspects that most respondents did not routinely address. Thus far, 34 patient surveys have been completed, providing baseline understanding of our current approach and gaps in services for survivorship care in lung cancer.

Conclusions: The results of these surveys will lay the groundwork for a new Thoracic Oncology Survivorship Program designed to best serve the needs of our lung cancer survivors, and our focused training needs for providers. By identifying and addressing the areas of concern, we aim to enhance the quality of life for lung cancer survivors, catering to their unique needs and challenges. In doing so, we hope to transform the landscape of survivorship care, providing a model for comprehensive, patient-centered care for lung cancer survivors.

P4.15D.02 Risk of Osteoporosis and Bone Fracture by Systemic Therapy in Lung Cancer Survivors

M.L. Hsu[1], I. Trinh[2], J.A. Perez[3], E. Harper[3], L. Chiec[1], D.S. Bruno[1], G. Dutcher[1], M. Mirsky[1], A. Dowlati[1], Q. Wang[1], [1]University Hospitals Seidman Cancer Center, Case Western Reserve University, Cleveland/OH/USA, [2]Case Western Reserve University, Cleveland/OH/USA, [3]University Hospitals Center for Clinical Research, Cleveland/OH/USA

Introduction: Increased risk of bone fracture (fx) is reported in survivors of multiple myeloma, lymphoma, and breast cancer. Malnutrition, muscle atrophy, and chemotherapy (chemo) may contribute to increased fx risk in these populations. Limited studies on fx risk in lung cancer survivors (LCS) have mixed findings, with smoking postulated as a risk factor. No studies have reported the impact of type of systemic therapy on osteoporosis and fracture in LCS.

Methods: Data from TriNetX, a de-identified network of over 110 million patients from 78 US health care organizations, was used. All adult patients (pts) diagnosed with primary lung cancer were stratified based on the presence of metastases at diagnosis. Pts with rheumatoid arthritis, pathologic fxs, or secondary malignancies were excluded. We investigated the outcomes of any bone fx and osteoporosis/bone density disorder (O/BDD). 1:1 greedy nearest-neighbor propensity score matching (PSM) based on demographics, smoking, and systemic therapy (chemo, immunotherapy (IO), or targeted therapy (TT)) was used. Independent t-tests were performed for continuous data; chi-square analysis for categorical data. We assessed outcomes using logistic regression with covariates age, sex, race, smoking history (hx), and systemic therapy use, both before and after PSM (doubly robust approach). All tests were two-tailed with alpha 0.05.

Results: Of 474,352 LCS, 43,454 had metastases at diagnosis (LCS-M), and 430,898 did not (LCS-NM). All results reported are after PSM. LCS-M were more likely to have O/BDD (OR 1.14, 95% CI 1.07-1.21, p<.001) and any fx (OR 1.54, 95% CI 1.49-1.59, p<.001) than LCS-NM. Male LCS were less likely to have O/BDD (OR 0.39, 95% CI .36-.41, p<0.001) or fx (OR 0.70, 95% CI 0.67-0.73, p<0.001). LCS with hx of smoking, received chemo, or TT were more likely to have O/BDD (Table). Odds of fx were only elevated in LCS who had smoked, although trended towards significance in those having received TT. Among LCS-M, receiving chemo (OR 1.32, 95% CI 1.14-1.52, p<0.001)) or TT (OR 1.55, 95% CI 1.23-1.93, p<0.001) increased odds of having osteoporosis/BDD; receiving TT increased odds of fx (OR 1.31, 95% CI 1.09-1.55, p=0.003).

Conclusions: LCS-M have increased risk of O/BDD and non-pathologic fracture than LCS-NM. Type of systemic therapy may contribute to these increased risks, with increased risk of O/BDD in LCS treated with chemo, and increased risk of fx and O/BDD in LCS treated with TT. Prospective studies are needed to validate these findings and identify interventions to evaluate and allay these risks.

P4.15D.03 The Lung Cancer Stigma Communications Assessment Tool: Supporting Engagement with the Lung Cancer Community

J. Studts[1], K. Hoover[2], L. Carter-Bawa[3], [1]University of Colorado School of Medicine, Aurora/CO/USA, [2]University of Colorado Cancer Center, Aurora/CO/USA, [3]Hackensack Meridian Health, Nutley/NJ/USA

Introduction: Lung cancer stigma poses a critical barrier to improving lung cancer outcomes, limiting optimal delivery of innovative and effective lung cancer risk reduction, early detection, treatment, and survivorship interventions. Stigma in the context of lung cancer can lead to feelings of shame and blame and prevent individuals from accessing care that can dramatically improve reduce mortality. In developing and disseminating patient- and public-facing educational materials and interventions, it is essential to be aware of how words, imagery, and context have the potential for creating or contributing to stigma in the lung cancer community. The Lung Cancer Stigma Communications Assessment Tool (LCS-CAT) was created to help content developers who are creating or modifying public facing materials to identify, remove, and replace potentially stigmatizing language, imagery, and context that could contribute to societal and individual stigma.

Methods: With support from the American Cancer Society National Lung Cancer Roundtable, a multifaceted tool was developed to assist lung cancer content developers in creating more effective engagement tools by removing and avoiding stigmatizing language and imagery. Additionally, the tool was intended to guide consideration of the context in which lung cancer content and engagement materials are to be used and to provide alternative approaches to replace language and imagery and alter contexts to maximize engagement with the lung cancer community. Leveraging extensive expertise from lung cancer professionals and integrating insights garnered from other health stigmas (e.g., HIV/AIDS, mental health, obesity, etc.), the development team prepared and revised the LCS-CAT.

Results: The development team identified a structure including three essential considerations: language, imagery, and contexts that must be considered when developing and disseminating lung cancer content and engagement materials. Similarly, the development team developed a process for identifying, removing, and replacing potentially stigmatizing language, imagery, and contexts. Following several iterations of feedback and pilot testing, the LCS-CAT Version 1.0 consists of six components and an implementation manual. The six components include: (1) a Language Audit Tool, (2) a Language Alternatives Guide, (3) an Imagery Audit Tool, (4) an Imagery Alternatives Guide, (5) a Context Audit Guide, and (6) a Context Alternatives Guide.

Conclusions: Although innovative and effective lung cancer risk reduction, screening, treatment, and survivorship interventions have the potential to rapidly improve lung cancer outcomes, societal constraints, including lung cancer stigma, can pose barriers to implementation. Building on the influential and impactful work of the IASLC Language Guide Version 1, the LCS-CAT expands consideration of stigma-inducing content to include imagery and contexts and provides alternatives for content developers to consider when developing any effort to engage or educate the community regarding lung cancer. To support the destigmatization of lung cancer, it is critical for communication creators to consider a “stigma biopsy” on all patient- and public-facing lung cancer campaigns to help identify, eliminate, and replace messages that could compromise engagement with the lung cancer community. The LCS-SAT is designed to facilitate these efforts. Ongoing research continues to evaluate the tool, build a web-based dissemination platform, and transcreate the LCS-CAT for other languages and cultures.

P4.15D.04 Association Between Emotional Distress and Immunotherapy Response in Advanced NSCLC (STRESS-LUNG-1): Biomarkers Exploratory Analyses

F. Wu[1,2,3,4], Y. Zeng[1], J. Zhou[1], Z. Qiu[1], C. Deng[1], F. Ma[1], C. Xia[1], A. Liang[1], Y. Peng[1], S. Wang[1], S. Yao[1], J. Liu[1], Y. Zhang[1], X. Zhang[1], X. Wang[1], X. Liu[1], C. Hu[1,2], [1]The Second Xiangya Hospital of Central South University, Changsha/CN, [2]Hunan Cancer Mega-Data Intelligent Application and Engineering Research Centre, Changsha/CN, [3]Hunan Key Laboratory of Tumor Models and Individualized Medicine, The Second Xiangya Hospital, Central South University, Changsha/CN, [4]Hunan Key Laboratory of Early Diagnosis and Precision Therapy in Lung Cancer, The Second Xiangya Hospital, Central South University, Changsha/CN

Introduction: Emotional distress, with hallmarked symptoms of depression and anxiety, is prevalent among patients with cancer. The field of "Psycho-oncology" is gaining increasing attention in cancer management. STRESS-LUNG-1 study is a prospective observational cohort study to investigate the association between emotional distress and efficacy of first-line treatment of immune checkpoint inhibitors (ICIs) in advanced non-small-cell lung cancer (NSCLC). We have previously reported the independent relationship between distress and lower objective response rate and shorter progression-free survival. We here updated the overall survival (OS) and explore the biomarkers including blood distress hormones, tumor microenvironment (TME), and gut microbiota.

Methods: STRESS-LUNG-1 study is a prospective, observational cohort study with the predetermined primary endpoint to explore the association between emotional distress and the efficacy of first-line treatment of ICIs in cancer (NCT05477979). Stage IIIB-IV NSCLC treated with first-line therapy of ICIs were enrolled. Emotional distress was assessed using PHQ-9 and GAD-7 scales. The data was as of November 30, 2023. Tumor microenvironment was detected by multiplex immunofluorescence, and gut microbiota by 16S rDNA sequencing.

Results: A total of 227 NSCLC patients were enrolled with 111 patients (48.9%) presence of distress. The baseline characteristics between distressed and no-distressed groups were well-balanced. With the median follow-up of 16.0 months, and the OS maturity of 30.4%, the distress group had a lower 1-year (70.4% vs. 80.8%) and 2-year survival rate (46.5% vs. 64.9%) with higher risk of OS events of death (HR=1.82, 95% CI 1.12 to 2.97; p=0.016). For biomarkers exploratory analyses, the distressed group had higher serum cortisol levels (443.4 vs 386.0 nmol/L, p=0.019), which is also associated with poor PFS and OS. The TME in the distress group exhibited lower infiltration of M1 macrophages (564 vs 1558 cells/mm2, p=0.035). Notably, patients with distress had the reduced abundance of Genus Bacteroides, especially in species of Bacteroides stercoris (0.7% vs 0.1%, p=0.011). The reduction of Bacteroides stercoris was associated with worse survival outcomes.

Conclusions: The study underscored the association between emotional distress and the worse efficacy of ICIs. Blood cortisol, gut Bacteroides stercoris and TME macrophages may play pivotal roles in the correlation of emotional distress and efficacy of ICIs.

MONDAY, SEPTEMBER 9, 2024 - 18:30 - 20:00

P4.15E.01 Association Between Dynamic Patient-Reported Outcome-Based Symptom Exacerbation and Postoperative Complication in Lung Cancer

S. Huang[1,2], X. Zhou[3], C. Deng[4], H. Liu[4], Z. Li[1], X. Li[1], Y. Chen[1], D. Tang[1], Y. Tang[1], P.M-K. Tang[2], Q. Shi[3], G. Qiao[1], [1]Guangdong Provincial People's Hospital, Guangzhou/CN, [2]The Chinese University of Hong Kong, Hong Kong/CN, [3]Chongqing Medical University, Chongqing/CN, [4]Guangdong Provincial People's Hospital, Guangzhou/CN

Introduction: Recent studies highlight the association of dynamic changes in patient-reported symptoms such as cough and pain in the immediate postoperative period, with recovery outcomes. However, the temporal association between patient-reported outcome-based symptom exacerbation following lung surgery and postoperative (post-op) complications has not been effectively investigated. This study aims to investigate whether there is a transient increase in risk of postoperative complications after symptom exacerbation at post-op Day 2 (POD2) in patients with lung cancer. By focusing on quantifiable, threshold-based symptom management, this study seeks to provide insights into effective strategies for minimizing postoperative complications and enhancing patient recovery.

Methods: A prospective observational study was conducted using electronic health records from the Department of Thoracic Surgery, Guangdong Provincial People's Hospital in China between Jan 06, 2022 and Feb 18, 2023. A multivariable nested case-control study was performed among 405 patients with lung cancer receiving surgery. Postoperative symptom exacerbations are recorded via an electronic Patient-reported Outcome (ePRO) platform. Cases were identified with postoperative complications occurrence defined by Clavien-Dindo classification (Grade≥2). Controls were matched to cases (4:1). Multivariate Cox regression models estimated postoperative complications risk for patient-reported symptom exacerbation at POD 2 with hazard ratio (HR), adjusted for 3.231(95% CI 1.673,6.241). Cox regression analysis was adopted in subgroup analysis to determine the most susceptible cohorts.

Results: The total sample of 405 individuals (median age [IQR], 56 (47 - 64) years) included 81 cases and 324 matched controls. The alterations observed in patient-reported sleep disturbance from postoperative day one (POD1) to postoperative day two (POD2) exhibited a statistically significant difference when comparing the case group to the control group. Amongst the 81 individuals who encountered postoperative adversities, 47 (58.0%) had inpatient complications while 37 (45.7%) experienced outpatient complications. Multivariate Cox regression analysis showed that the combined sleep disturbance and shortness-of-breath is a significantly independent risk factor (HR: 3.231, 95% CI [1.673-6.241], P = 0.0005) for postoperative complications.

Conclusions: In this nested case-control study, combined sleep disturbance and shortness of breath exacerbation at POD2 was associated with higher risk of postoperative complications. These findings suggested that combined symptom exacerbation pattern may serve as an early indicator for postoperative complications and that early interventions to manage sleep disturbances and respiratory symptoms could be implemented to mitigate the risk of complications. Enhanced follow-up procedures might be warranted for patients who exhibit these risk factors, especially after hospital discharge to address outpatient complications.

P4.15E.02 Acceptability and Feasibility of Integrating A Chatbot into Routine Lung Cancer Care: Patient and Clinician Perspectives

J. Wainwright[1], H. Toneff[1], J. Kalman[1], M. Mengesha[1], A. Strazinsky[1], W. Song[1], S. Beucker[1], E.P. Wileyto[1], C. Johnston[2], C. Cambareri[3], D. Yarosh[3], A. Blauch[3], D. Pucci[3], L.A. Jacobs[3], J.E. Bekelman[1], S.E. Kimmel[4], L.N. Shulman[1], S. Takvorian[1], K. Rendle[1], [1]University of Pennsylvania, Philadelphia/PA/USA, [2]Memora Health, San Francisco/CA/USA, [3]Penn Medicine, Philadelphia/PA/USA, [4]University of Florida, Gainesville/FL/USA

Introduction: Across the digital health landscape, technologies that draw upon augmented or artificial intelligence to mimic human conversation (i.e., chatbots) have rapidly increased. Yet, little is known regarding how best to integrate these technologies into clinical practice. This mixed-methods study shares patient and clinician perspectives on the use of a chatbot ("Penny") to support symptom management and oral anticancer agent adherence in lung cancer care and examines factors that shape the acceptability and feasibility of implementing Penny into routine care.

Methods: Penny engages with patients via text messaging and provides reminders and motivational cues to promote medication adherence. Penny also assists with management of disease symptoms and treatment side effects. Following a randomized controlled trial assessing the effects of Penny on medication adherence and symptom management in patients with advanced non-small cell lung cancer who were taking oral targeted therapies, we conducted a mixed-methods study among 18 enrolled patients and 12 clinicians who care for this population. Using the Information-Motivation-Behavioral Skills model and the Consolidated Framework for Implementation Research, we designed interview guides to systematically assess factors shaping the acceptability, effectiveness, and feasibility of future implementation of Penny into routine cancer care. Qualitative data were analyzed using the constant comparative method. Close-ended responses were analyzed using descriptive statistics and triangulated with qualitative findings.

Results: Participants were interviewed between December 2022-February 2023. During the trial, among all patients who were randomized to use Penny and completed the final survey (n=36), the net promoter score (NPS) [From 0 (Not at all likely) to 10 (Extremely likely), how likely is it that you would recommend Penny to a friend or colleague with lung cancer?)] was 6.9. The patient interview sample was stratified to include patients who ranked Penny with low, middle, and high NPS; yet, during the interviews, 17 out of 18 patients said that they would recommend Penny to a friend taking oral cancer medication, and 1 patient said that it would depend on the individual's personal health situation. When asked if they would continue using Penny as part of their personal cancer care, responses were mixed, with some patients stating that Penny wasn't necessary for them. Few patients used Penny to manage symptoms, but they appreciated having another line of communication about their care if needed. Patients also appreciated the emotional support and reminders provided by Penny. Among clinicians (n=12), when asked if they would recommend Penny to their patients, 6 agreed, 5 strongly agreed, and 1 remained uncertain. When asked if Penny would be useful in managing patient care, 7 agreed, 4 strongly agreed, and 1 remained uncertain. Clinicians commented that technological limitations (e.g., not having mobile phones or knowing how to text) would be a key barrier to implementing Penny into routine care among some patient groups.

Conclusions: Our findings show that integrating a chatbot into cancer care is largely acceptable and feasible, can provide needed reminders and emotional support to patients, and can potentially alleviate clinician burden. Further study of chatbots in this context is warranted.

P4.15E.03 Assessing the Utilization of Palliative Care in Advanced NSCLC Patients with Brain Metastases

A. Vyas[1], A. Khosla[2], A. Thomas[3], A. Desai[4], C. Fadul[5], A. Harisingani[6], R. Singh[3], [1]Vanderbilt University Medical Center, Nashville/TN/USA, [2]Corewell Health William Beaumont University Hospital, Royal Oak/MI/USA, [3]University of Vermont Medical Center, Burlington/VT/USA, [4]University of Alabama, Birmingham/AL/USA, [5]University of Virginia, Charlottesville/VA/USA, [6]Loyola Medicine MacNeal Hospital, Berwyn/IL/USA

Introduction: Non-small cell lung cancer (NSCLC) represents a significant global health burden, with stage IV disease presenting particularly challenging clinical scenarios, often accompanied by brain metastases (BMETS). Palliative care (PC) plays a pivotal role in addressing the needs of patients with advanced NSCLC, focusing on improving symptom control, overall quality of life, and survival. This retrospective cohort study aimed to elucidate the influence of PC involvement on outcomes, including survival, advance directives, hospice, and ER visits among patients with NSCLC and BMETS.

Methods: In this retrospective cohort study, data were extracted from electronic medical records of patients with advanced NSCLC who had brain metastases at the University of Vermont Medical Center (UVMMC) between 1/1/2017 and 12/31/2019. Patients with at least six months of follow-up or until death were included, with exclusion criteria comprising patients with leptomeningeal or dural/calvarial metastases. We utilized the Recursive Partitioning Analysis (RPA) prognostic tool to categorize patients into two RPA classifications: class II and class III. RPA is based on age, KPS, and disease status at BMETS diagnosis. Overall survival was calculated from the diagnosis of NSCLC with brain metastasis to death or the last follow-up.

Results: The study comprised 92 NSCLC patients with brain metastasis, including 48 RPA class II and 44 RPA class III. The median age was 67 years with 68% male representation. Palliative care was not received by 38 (41.3%) patients. Analysis revealed that 16/44 (36.3%) RPA class III patients and 22/48 (45.8%) RPA class II patients did not receive palliative care consultation. The median overall survival (OS) for patients without palliative care was 236 days (7.8 months) compared to 224 days (7.4 months) for those receiving palliative care, with no statistically significant difference (p = 0.52). Patients receiving palliative care exhibited higher rates of hospice utilization (78% vs. 47%, p = 0.002) and advanced directive completion (82% vs. 43%, p = 0.003). Although patients receiving palliative care had a seemingly higher number of emergency room (ER) visits, the difference was not statistically significant (p = 0.45).

Conclusions: Our study highlights no survival difference in patients who receive PC care; however, the palliative consult group utilized hospice and advanced directives more. PC involvement can assist patients and clinicians in making better-informed decisions based on the patient's values and realistic outcomes using brain-directed treatment options.

Keywords: Non-small cell lung cancer (NSCLC), Palliative care (PC), Brain metastases (BMETS)

Table 1: Comparing the Effectiveness of the Palliative Care Consultation Group versus the Standard Care Group

OUTCOME	PALLIATIVE CARE (n-54)	NO PALLIATIVE CARE (n-38)	P-VALUE
Median Survival	7.4 months	7.8 months	0.52
Hospice Utilization	75%	47%	0.002
Advance Directives Completed	82%	43%	0.003

MONDAY, SEPTEMBER 9, 2024 - 18:30 - 20:00

P4.17C.01 Clinical Trial Enrollment at a Thoracic Oncology Program at a Single-Academic Institution Serving Primarily Underrepresented Patients

M. Pasquinelli[1], L. Liu[1], W. Ma[1], C. Zazueta[2], A. Guzman[1], M. Russell[1], C. Weldon[3], A. Salahudeen[1], R. Nguyen[1], F. Weinberg[1], [1]University of Illinois Chicago, Chicago/IL/USA, [2]Eastern Virginia Medical School, Norfolk/VA/USA, [3]The Center for Business Models in Healthcare, Glencoe/IL/USA

Introduction: Participation in oncology-directed clinical trials ranges between 2-8% worldwide. A meta-analysis found that barriers contributing to low participation rates included lack of an available clinical trial (56%), ineligibility based on clinical trial criteria (22%) and non-enrollment despite being eligible for study (15%). Additionally, recent studies demonstrated that underrepresented (Black, Hispanic) patients have lower enrollment rates (4% and 6%, respectively) compared to their White counterparts (8%). The Thoracic Oncology Program at UI Health, a tertiary academic center, serves primarily underrepresented individuals from the South and West sides of Chicago. Therefore, we sought to characterize and analyze clinical trial enrollment rates and patterns in our program.

Methods: We retrospectively collected and analyzed data from 249 patients with lung cancer from 2021-2023. Enrollment in clinical trials was defined as: patients who were either successfully enrolled or initially enrolled but subsequently found not to meet eligibility criteria. The demographic and clinical characteristics of enrollees and non-enrollees were compared using two-sample t-tests, chi-square tests, or Fisher's exact tests, as appropriate. Multivariate logistic regression was employed to identify the factors that significantly associated with clinical trials enrollment.

Results: Cohort race demographics: 65% Black, 10% Asian, 16% White, 9% Hispanic. 35% enrolled into clinical trials. When excluding patients for whom no trial was available, 72% of patients enrolled into clinical studies. Additionally, we found that 52% of patients did not have a clinical trial available while 5% enrolled but were later deemed ineligible and 14% of patients declined to participate. A significant association was found between race/ethnicity and enrollment. Of those who enrolled onto a clinical trial, 24% were White, 64% were Black and 12% were individuals of other races/ethnicities. Of those that declined to enroll, 3% were White, 76% Black and 21% other races/ethnicities. After conducting multivariate logistic regression, both race/ethnicity and insurance type were found to be significantly associated with enrollment among all predictors. White patients were significantly more likely to enroll into a clinical study than Black patients (OR, 10.85; 95%CI,1.36-86.47; p=0.0244). Additionally, patients with Medicaid insurance were more likely to enroll onto a clinical study than patients with Medicare insurance coverage (OR, 3.33; 95% CI, 1.19-9.29; p=0.0218).

Conclusions: In the present analysis of clinical trial enrollment at a single-academic institution serving primarily undeserved, underrepresented patients, our enrollment rate far exceeded the national average at 35%. Additionally, we were successful in enrolling underrepresented patients at a far higher rate than what has been reported nationally. Our ineligibility rate is far below what has previously been reported. However, we found that White patients were over 10 times more likely to enroll onto a clinical study compared to Black patients. Therefore, a significant racial disparity exists between those enrolling and declining clinical trials. Future work will focus on evaluating the underlying reasons behind a patient's choice to enroll or decline a clinical study. We hope to utilize this data to develop educational materials for physicians and patients to improve not only our own clinical trial enrollments at UI Health but across the US and world.

P4.17D.01 Incidence Correlation Between Different Diseases and Lung Cancer: A Global Cross-Sectional and Time-series Study

J. Li, R. Wang, B. Cheng, J. He, W. Liang, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Patients with lung cancer often have diverse comorbidities. However, a comprehensive and systematic review exploring the association between different diseases and lung cancer is currently lacking. This study aims to explore the correlation between various diseases and lung cancer, generating a comprehensive correlation map.

Methods: This study collected the incidence of 102 diseases across 204 countries from the Global Burden of Disease (GBD) database (1990-2019). In the cross-sectional analysis conducted each year, adjusted for smoking and SDI, explored the relationship between diseases and lung cancer using Spearman correlation. To mitigate the bias of low diagnostic rates and premature mortality, the study just focused on diseases positively correlated with lung cancer. Additionally, a 30-year time-series analysis employed a distributed lag non-linear model (DLNM) to investigate the lag effects of chronic diseases on lung cancer incidence.

Results: The analysis revealed potential positive correlations between lung cancer and 40 diseases. For instance, non-rheumatic valvular heart disease (correlation coefficient (CC): 0.736-0.789, p<0.001), peripheral artery disease (CC: 0.738-0.766, p<0.001), alopecia areata (CC:0.609-0.631, p<0.001), schizophrenia (CC: 0.561-0.612, p<0.001) and vascular intestinal disorders (CC: 0.548-0.590, p<0.001) demonstrated significant positive associations with lung cancer. Additionally, several chronic diseases such as chronic obstructive pulmonary disease (COPD, CC: 0.531-0.564, p<0.001), diabetes type 1 (CC: 0.343-0.405, p<0.001), Parkinson's disease (CC: 0.490-0.565, p<0.001) and psoriasis (CC: 0.489-0.577, p<0.001) exhibited positive correlations with lung cancer. Specifically, gout (CC: 0.156-0.190, p<0.05) showed a positive correlation in males, while paralytic ileus and intestinal obstruction (CC: 0.253-0.383, p<0.001), hernia (CC: 0.404-0.447, p<0.001) and rheumatoid arthritis (CC: 0.310-0.340, p<0.001) showed a positive correlation in females. Finally, the lag effects of 10 common chronic diseases were evaluated using the distributed lag non-linear model (DLNM). For instance, when the incidence rate of COPD was 207.8 (per 100,000), it exerted the greatest promoting effect on lung cancer risk with a lag of 6 years. Conversely, when the incidence rate of COPD was 213.4 (per 100,000), the impact on lung cancer was minimal, with a lag of 13 years.

Conclusions: By conducting population-level correlation mapping of disease incidences, this study unveiled potential associations between lung cancer and 40 diseases documented in the GBD database. This research could provide hints for studying the mechanism between lung cancer and certain associated diseases, and also established a paradigm for screening risk factors from the populational perspective.

P4.17D.02 Global Trends in Lung Cancer Survival by Morphology: Analysis from 61 Countries During 2000-2014 (CONCORD-3)

H. Zhu[1,2], V. Di Carlo[2], F. Khan[2], C. Allemani[2], M.P. Coleman on behalf of the CONCORD Working Group[2], [1]Fudan University Shanghai Cancer Center, Shanghai/CN, [2]London School of Hygiene and Tropical Medicine, London/GB

Introduction: In 2015, the CONCORD programme established global surveillance of trends in population-based cancer survival as a metric of the effectiveness of health systems, and to inform global policy on cancer control. In 2018, CONCORD-3 updated the worldwide surveillance of cancer survival trends to 2014. The third cycle of the CONCORD programme (CONCORD-3) included data on over 37 million adults (15-99 years) diagnosed with one of 18 common cancers or groups of cancers during 2000-2014, including 6.1 million adults with lung cancer. Anonymised individual records were provided by 290 population-based cancer registries in 61 countries.

Methods: Tumours were categorised in three main groups by ICD-O-3 morphology codes: small-cell lung cancer (SCLC), non-small cell lung cancer (NSCLC) (adenocarcinoma, large cell carcinoma and squamous cell carcinoma) and lung cancer, not otherwise specified (NOS). We estimated trends in 5-year net survival by morphology for patients diagnosed during 2000-2004, 2005-2009 and 2010-2014, using the non-parametric Pohar Perme estimator. To control for background mortality, we used life tables of background mortality rates by single year of age, sex, calendar year and (where possible) race/ethnicity in each country. All-ages survival estimates were standardised with the International Cancer Survival Standard weights.

Results: Overall, 19% of tumours were categorised as lung cancer, NOS, ranging from 8% in Belgium to over 50% in China, India and Thailand. The proportion of NSCLC ranged from 36% in China to over 80% in Guadeloupe, Martinique and Taiwan. Overall, 13% of patients were diagnosed with SCLC (range 3-17%). In 2010-2014, age-standardised 5-year net survival for lung cancer, NOS ranged from less than 1% in Chile to 27% in Belgium. Five-year net survival for NSCLC was lower than 10% in Bulgaria, Chile and Guadeloupe, but reached 39% in Japan. Age-standardised 5-year net survival for SCLC was less than 15% in all countries. Five-year survival trends between 2000-2004 and 2010-2014 were generally flat for each morphology group and in most countries. For NSCLC, 5-year survival increased by 10% or more in Korea (from 16% in 2000-2004 to 29% in 2010-2014) and Taiwan (from 13% to 23%).

Conclusions: The current results represent worldwide survival trends in lung cancer survival by morphology based on data from population-based registries. Together with incidence and mortality, this contributes to a comprehensive picture of the global lung cancer burden, and can support public health strategy to reduce disparities in outcome. Accurate morphology data are crucial to understanding worldwide inequalities in survival from lung cancer. Population-based registries with high-quality data are essential for this purpose.

P4.17D.03 Analysis of Lung Cancer Mortality Trends and Factors Impacting Years of Life Lost: A 20-Year Hospital-Based Cohort Study in São Paulo, Brazil.

A.L. Marcheti, FASM - Faculdade Santa Marcelina, São Paulo/BR

Introduction: Lung cancer stands as the second leading cause of years of life lost (YLL) among the 30 major diseases, surpassing all other cancer types. Its severity is evidenced by the high mortality rate, making it the primary cause of cancer-related death globally. This study aims to analyze the main factors influencing YLL and mortality trends in lung cancer over a 20-year period in São Paulo, Brazil.

Methods: This descriptive hospital-based cohort study utilized data from the Sao Paulo's State Hospital Cancer Registry (SPHCR), managed by the Sao Paulo's Oncocentro Foundation Information and Epidemiology Directorate (FOSP), encompassing 72 institutions. Analyzed variables included both genders, clinical stage, histological type, complexity level in centres in oncology hospitals (CLCOH), disease recurrence, 5-year YLL period and Annual Percent Change (APC - measure of annual variation in YLL based on the first and last year of a given period). YLL correspond to the difference among the estimated years of life expectancy (LE) for the respective year of death and the age of death for the individual. The YLL were described as the mean and median for each variable.Statistical analysis for the mean and median of YLL involved the Wilcoxon Mann Whitney method for two-categorical variables and Kruskal Wallis for three or more categorical variables. The difference between the groups were considered statistically, if p-value < 0.05

Results: The study included 5.419 patients from 2000 to 2019, aged 18 years or older, who died before reaching the mean LE. Analysis revealed that stage IV patients experienced approximately double the YLL compared to stage I (median=15.1 versus 8.6, respectively; p<0.0001). Patients who died in the periods of 2005-2009, 2010-2014, and 2015-2019 exhibited similar YLL rates confirmed with APC (-0.89% versus 0.05% versus -0.01% respectively). In addition, was observed that female had higher YLL than male (median=18.6 versus 11.6, respectively; p<0.0001), and patients without disease recurrence had lower YLL compared to those with disease recurrence (median=14.2 versus 14.9, respectively; p=0.0346). (Table 1). Being diagnosed with large cell lung carcinoma (LCLC) impacted on two and a half more YLL than squamous cell carcinoma (SCC) (median= 14.8 versus 12.3 respectively; p<0.0001).

Conclusions: Our results reveal the APC remained small over 15 years, indicating stable YLL. Significant YLL disparity among lung cancer stages underscores the need for early detection and tailored interventions. Gender differences and disease recurrence highlight the importance of personalized care and active surveillance in improving patient outcomes.

P4.17D.04 Insights into Lung Cancer During Pregnancy: Analysis of the National Inpatient Database (NIS)

N.A. Guevara Rodriguez[1], E. Perez[2], V. Chapiolkina[3], M. Ghimire[4], P. Budhathoki[5], S. Poudel[6], C. Olazagasti[7], N. Florez[8], [1]hematology-oncology, Saint Louis University, Saint Louis/MO/USA, [2]Perez: Montefiore Medical Center/ Albert Einstein College of Medicine at MJH, New York City/ NY/USA, [3]St. Barnabas Health System, St. Barnabas Health System/NY/USA, [4]St. Barnabas Health System, Bronx/NY/USA, [5]Bronx Care Hospital, Bronx/NY/USA, [6]Jhon H Stroger of Cook County, Chicago/IL/USA, [7]University of Miami Health System, Miami/FL/USA, [8]Dana-Farber Cancer Institute, Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Lung cancer (LC) remains the second most diagnosed cancer in both genders and the leading cause of cancer-related deaths in the USA, making up 21% of fatalities. The American Cancer Society estimates 118,270 new cases in women in 2024. While cancer rates are decreasing overall, the decline is more significant in men (2.5%) compared to women (1%). The higher incidence in women, often diagnosed later due to pregnancy-related factors like delayed imaging due to radiation concerns, warrants attention. Notably, lung cancer rates among young women, particularly white non-Hispanic and Hispanic women, surpass those of young men, highlighting an unexplained disparity. Given the knowledge gap, we analyzed NIS data to characterize reproductive-age women, both pregnant and non-pregnant.

Methods: This retrospective cohort analysis focused on women aged 15-49 admitted to USA hospitals from 2016 to 2020 with primary LC diagnosis during pregnancy. Data for this study was obtained from the NIS Database, excluding long-term acute care hospitals and rehabilitation centers. Primary goal: describe LC trends and compare incidence across socio-demographic groups. Secondary goal: assess care settings' impact (teaching vs. nonteaching hospitals) on outcomes and analyze hospital stay length (LoS). We used the Chi-Square-test for categorical variables and the Student's-t-test for continuous variables, with significance defined as $P < 0.05$.

Results: Among 32,405 reproductive-age women meeting the criteria, 80 were pregnant (PP) patients, and 32,325 were non-pregnant (NPP). Lung cancer incidence in reproductive-age-women was approximately 16.38 cases per 1000, and during pregnancy was 0.04 per 1000. PP's average age was 33, significantly younger than NPP's 43.9 ($p<0.001$). The average LoS was 7.5 days for PP and six days for NPP ($p=0.4$). Hospitalization costs were higher for PP: $100,241 vs. $73,119 for NPP ($p=0.4$). PP mortality was 12.5%, higher than NPP's 7.55% ($p = 0.4$). Most patients were white (62.5% PP vs. 64.8% NPP), followed by Black (19% PP vs. 15% NPP), Hispanic (12.5% PP vs. 9.6% NPP), Asian (0 PP vs. 6% NPP), and Native American (0 PP vs. 4% NPP). However, mortality didn't significantly differ by race (p:0.87). The primary hospital location was south (Delaware-Maryland-District of Columbia-Virginia-West Virginia-North Carolina-South Carolina-Georgia-Florida-Kentucky-Tennesse-Mississippi-Alabama-Oklahoma-Texas-Arkansas-Louisiana) (44% PP, 42% NPP). Most hospitals were large (69% PP vs. 60% NPP), followed by medium (25% PP vs. 25% NPP) and small hospitals (6% PP vs. 15% NPP) ($p=0.59$). PP documented complications: acute MI (6%, $p = 0.38$) and mechanical ventilation (44%). NPP complications: COPD (5%, $p = 0.35$), stroke (4%, $p=0.4$), sepsis (3%, $p=0.4$), and acute MI (3%, $p=0.38$). Thrombosis was more significant in PP than NPP (p:0.002). Income had no impact (p:0.75).

Conclusions: Our analysis of NIS highlights the incredible challenges and outcomes entwined with LC during pregnancy. Pregnant patients endure elevated mortality rates and heightened hospitalization costs compared to their nonpregnant counterparts, possibly attributable to the comprehensive care required for both mother and fetus. The study highlights the necessity for tailored management strategies and heightened vigilance in caring for pregnant patients with LC. Furthermore, further research is essential to optimize care and outcomes for this vulnerable population.

P4.17D.05 Squamous Cell Lung Cancer Still Remains the Most Common Histological Subtype of Lung Cancer in Rural India

J. Grover, P.K. Singh, Pandit Bhagwat Dayal Sharma Post Graduate Institute of Medical Sciences, Rohtak/IN

Introduction: As per the UN population data India is the most populous country in the world. Majority of epidemiological data about lung cancer from India, comes from National Cancer Registry Program (NCRP) steered by Indian council of Medical Research which has 272 sites under its umbrella. However, most of these sites are in metro cities catering predominantly to urban population. Despite the 65% contribution of rural population towards total population, lung cancer data from rural population remains underrepresented in the epidemiological reports. In the current report we have analyzed and reported the demographic and clinical data of the patients treated at a university-teaching hospital from northern India which caters predominantly to rural population.

Methods: Data of all patients managed at thoracic oncology clinic from September 2022 to March 2023 was retrieved and analyzed. Apart from demographic data, smoking profile and clinical information was also collected. Data of patients residing in urban areas was excluded from analysis. We further compared this data with the NCRP report published in 2022 (doi:https://doi.org/10.4103%2Fijmr.ijmr_1364_21).

Results: Over the above-mentioned period 540 subjects of lung cancer were treated at the clinic. Data of 36 subjects with urban residence was excluded. The mean age of the patient population was 59.8±10 years. 82.9% were males and 95.2% were smokers. Among the smoker's group 81.7% were current smokers and the remaining were former smokers. Out of the current smokers, 44.9% were still smoking at the time when they were being evaluated for the diagnosis of lung cancer. Among the smokers, 96.7% were bidi smokers. Bidis are hand rolled, small indigenous cigarettes with tobacco rolled into tendu leaves. They have significantly higher tobacco and tar component as compared to commercial cigarettes. Also, they lack filter. Mean BMI at the time of treatment initiation was 18.4±3 Kg/m2. Majority patients presented with ECOG PS (eastern cooperative oncology group performance status) 1 (41.9%) followed by ECOG PS 2 (32.9%). In 56.2% cases primary lesion was central (defined as location in the medial one third of the axial section, around the trachea and main bronchi). Endobronchial biopsy was used for obtaining tissue in 49.8% whereas Endobronchial ultrasound guided TBNA was employed in 21%. 71.4% of cases were also found to have emphysema on CT thorax. 46.4% were diagnosed with Squamous cell subtype (all p40 or p63 positive on immunohistochemistry- IHC). 28.8% were adenocarcinoma, 11.3% were small cell and the remaining were either NSCLC NOS (not otherwise specific), Large cell, undifferentiated or lacked sufficient tissue for IHC markers. Stage IIIB and IVA were the most common stages of presentation- 39.7% and 33.9%, respectively. As compared to the NCRP data- mean age was similar (61 compared to 59.8 years), male proportion was higher in rural data (76.7% versus 82.9%,) and Squamous cell subtype was distinctly higher in the rural data (23.4% versus 46.4%).

Conclusions: Majority of lung tumors in patients from rural India are central and of squamous histological subtype. Smoking habits of the rural population are also different from what is reported from urban areas.

P4.17D.06 Pan-Canadian Lung Cancer Observational Study (PALEOS): A Multicentre Ambispective Real-World Database Study in a Publicly Funded Health System

S. Kuruvilla[1,2], P. Wheatley-Price[3,4], F. Gwadry Sridhar[5], P. Joubert[6,7], O.I. Aseyev[8,9], L. Young[5], R. Sachdeva[1], B. Sheffield[10], M. Richardson[3], J. Bafaro[6], R. Seeger[3], A. Wojtyk[3], K. Bisson[10], A. Foo[10], G. Liu[11,12], P.K. Cheema[10,12], [1]London Health Sciences Centre, London/ON/CA, [2]Western University, London/ON/CA, [3]The Ottawa Hospital Cancer Centre, Ottawa/ON/CA, [4]University of Ottawa, Ottawa/ON/CA, [5]Pulse Infoframe Inc., London/ON/CA, [6]Institut de Cardiologie et de Pneumologie de Québec-Laval Universit, Quebec City/QC/CA, [7]Universite Laval, Quebec City/QC/CA, [8]Thunder Bay Regional Health Sciences Centre, Thunder Bay/ON/CA, [9]Northern Ontario School of Medicine, Thunder Bay/ON/CA, [10]William Osler Health System, Brampton/ON/CA, [11]Princess Margaret Cancer Centre, Toronto/ON/CA, [12]University of Toronto, Toronto/ON/CA

Introduction: In the dynamic landscape of healthcare decision-making, stakeholders are increasingly relying on real-world evidence (RWE) alongside evidence from randomized controlled trials. Regulatory bodies such as the US Food and Drug Administration, Health Canada and the European Medicines Agency are advocating for increased utilization of RWE to support new indications, signaling a paradigm shift in evidence-based medicine practices. Lung cancer is a heterogeneous disease with diverse subgroups defined by various factors including sociodemographic, molecular, and treatment characteristics. PALEOS aims to address key questions regarding the epidemiology and natural history, treatment patterns and effectiveness, safety, patient reported outcomes and health economic impact in Canadian lung cancer patients.

Methods: PALEOS (NCT04706754) is a multicentre, ambispective observational study conducted across multiple sites in Canada in adult patients with a confirmed non-small cell lung cancer. Patient clinico-demographic information, medical history, diagnostic, pathological and molecular data, treatment details, resource utilization and patient-reported outcomes, are collected retrospectively and prospectively. The study will recruit 25,000 patients over 20 years, with 6 initial sites that comprise a catchment area of approximately 30% of the Canadian population (mix of urban and rural populations), with plans to expand. Descriptive statistics are generated and survival analysis conducted based on primary and secondary objectives.

Results: Since first site initiated in 2019, 1,273 non-small cell lung cancer patients have been enrolled. Median age is 69 years (range 22-97; n-949) at diagnosis, 46% were females, and 19%, 9%, 19%, 53% were stages I, II, III, and IV, respectively (n=706). 48% had first-line metastatic treatment initially involving immunotherapy (24% monotherapy; 24% combination chemoimmunotherapy; n=544). Among all patients tested, 15% had EGFR-mutated (number tested =639) and 5% were ALK-rearranged (n=621) tumours. Median follow-up in Stage I-III patients was 20 months; in Stage IV patients, 9 months. Median OS survival for Stages I, II, III, IV were 35, 20, 12, and 10months, respectively. Annual recruitment rates are growing exponentially, from 69 new cases in 2020 to 835 new cases in 2023.

Conclusions: PALEOS provides a comprehensive framework for evaluating the natural history, treatment patterns, and outcomes of lung cancer patients across Canada. The study aims to enhance understanding of the impact of new diagnostic and treatment modalities in clinical practice and identify gaps in efficiencies within our publicly funded health care system. This initiative will facilitate knowledge translation and inform evidence-based decision-making in the management of lung cancer across disciplines. It is anticipated to support health technology assessments for new therapeutics and have meaningful impact on patient advocacy.

P4.17D.07 Temporal Improvements in Overall Survival in Metastatic Non-Small Cell Lung Cancer in the United States Since 2004

M. Danese[1], A. Lee[2], I-H. Su[3], Y. Yuan[4], [1]Outcomes Insights, Inc, Calabasas/CA/USA, [2]BMS, Uxbridge/GB, [3]University of North Carolina at Chapel Hill, Chapel Hill/NC/USA, [4]BMS, Princeton/NJ/USA

Introduction: In metastatic non-small cell lung cancer (mNSCLC) targeted therapy was first approved in 2003, and immunotherapy was first approved in 2015. To characterize the population-level survival benefit of improved systemic therapy, we estimated the effect of diagnosis year on overall survival. These estimates can also be instrumental to external validation of long-term economic models of new therapies.

Methods: Surveillance, Epidemiology, and End Results data were used to identify adult patients with histologically-confirmed mNSCLC diagnosed from 2004 through 2018 and followed through 2019. Analyses of 2-year overall survival were conducted using flexible parametric survival models. We used g-computation to estimate the effect of diagnosis year on survival accounting for differences in age, sex, race, pleural effusion, marital status, large metropolitan area status, registry, histology, census-tract income. Sensitivity analyses were conducted using the subset of patients known to be treated with systemic therapy, and by projecting expected overall survival in 2024. All analyses were conducted using R.

Results: Among 238,680 patients with mNSCLC diagnosed from 2004-2018, mean age was 68 years and 55% were male. Using an adjusted model of survival for all diagnosed patients based on categorical diagnosis year, the hazard ratios for each diagnosis year (compared to 2004) declined over time and were 0.95 (95% CI 0.91-0.99) in 2010, 0.87 (95% CI 0.83-0.90) in 2014, and 0.76 (95% CI 0.73-0.79) in 2018. In the subset of 118,829 patients receiving systemic therapy, the hazard ratios were 0.91 (95% CI 0.86-0.97) in 2010, 0.77 (95% CI 0.73-0.82) in 2014, and 0.57 (95% CI 0.54-0.61) in 2018.

Overall survival improved over calendar time for all diagnosed patients and for the subset known to receive systemic therapy based on models using continuous diagnosis year (Figure). From 2004 to 2018, 24-month overall survival improved from 13% to 16% in all diagnosed patients, and from 18% to 26% in the systemic therapy subset. Extrapolating to 2024 showed that 24-month overall survival would be 17% for all diagnosed patients and 33% for patients who received systemic therapy.

Conclusions: Overall survival in mNSCLC has improved since 2004, particularly among patients who received systemic therapy who showed a 43% mortality risk reduction in 2018 compared to 2004. However, assuming a continued reduction in mortality risk through 2024, 24-month overall survival in patients receiving systemic therapy was estimated to be only 33%. While these trends highlight the results of meaningful treatment advances, further improvements are still needed.

P4.17E.01 Navigating from Target to Treatment: Early Impact of the Lung Precision Oncology Navigation Program (LPOP)

N. Ghazali, M. Ku, L. Corke, G. Liu, P. Bradbury, F. Shepherd, A. Sacher, L. Eng, L. Le, A. Ramsey, P. Sabatini, P. Pal, J. Schwock, M. Rabey, N. Leighl, Princess Margaret Cancer Centre, Toronto/ON/CA

Introduction: Molecular testing is essential for treatment decisions in non-small cell lung cancer (NSCLC). However, many patients have either missing or delayed results, leading to delays in treatment initiation or lost opportunities to access targeted therapy. The Lung Precision Oncology Navigator Program (LPOP) was developed to ensure and accelerate complete genotyping for patients and enhance access to precision medicine.

Methods: The Princess Margaret Cancer Centre (Toronto, Canada) LPOP entails detailed review of molecular testing results and communication with appropriate pathology, molecular, and treatment teams to facilitate complete molecular testing including through liquid biopsy prior to initial oncology consultation. The Navigator suggests potential targeted therapy trials and special access programs as appropriate based on biomarker results. We compared outcomes pre- and post-LPOP implementation including the: 1. proportion of patients with complete genotyping (non-squamous NSCLC); 2. proportion with results by initial oncology consultation; 3. turnaround time (TAT) for complete molecular results from biopsy; 4. time to treatment (TTT) from initial oncology consultation. Health care providers (HCPs) were surveyed at baseline and at six months to assess program impact and perceived gaps in care.

Results: Between 9/1/2023-11/30/2023, 75 patients were identified prior to LPOP implementation. Another 101 patients were identified post-LPOP implementation (12/1/2023-3/1/2024). Post-implementation of LPOP, we observed a numerical decrease in TAT for complete molecular results from biopsy (post 14.3 days vs. pre 15.9 days, $p = 0.09$) and a trend to reduced time from initial consultation to treatment start (12.6 days vs. 16.9 days, $p = 0.09$). There was a significant increase in the proportion of patients who had complete genotyping by their first consultation (81.2% vs. 44.1%, $p < 0.0001$) after LPOP implementation. When complete results were available for the initial consultation, there was no significant difference in the time to treatment initiation between the two periods (post-LPOP 12.9 days vs. pre-LPOP 15.7 days, $p = 0.60$). Patients without results available at the time of initial consultation had a longer time to treatment initiation in both time periods (17.1 days post, 18.2 days pre). Ten of 24 HCPs surveyed responded, reporting moderate familiarity with the LPOP Navigator's role. Challenges highlighted by respondents include incomplete genotyping and delays in obtaining results. HCPs recommended ongoing proactive review of molecular results, expediting testing and results, and facilitating clinical trial access. Respondents reiterated the importance of ensuring complete genotyping results at the initial oncology consult.

Conclusions: Our results showed an increase in the proportion of patients with complete genotyping by initial consult, indicating improved efficiency with LPOP. Survey feedback emphasized the need for ongoing navigator role refinement. We await results from the planned survey six months post-LPOP for insights into program efficacy and improvement areas.

P4.17F.01 Effective EGFR Testing Rates in Advanced Stage NSCLC Patients Treated in Community Oncology Practices: Impact of a Decision Support Program

G. Dranitsaris[1], S.D. O'Brien[2], A. Carey[2], B. Decker[2], R.D. Page[3], [1]Department of Public Health, Syracuse University, Syracuse/NY/USA, [2]EMOL Health, Inc, Royal Oak/MI/USA, [3]The Center for Cancer and Blood Disorders, Ft. Worth/TX/USA

Introduction: The current standard of care in advanced-stage NSCLC patients who harbor EGFR mutations such as exon 19 deletions is small molecule targeted therapies. However, not all newly diagnosed patients receive biomarker testing before initiating first-line anticancer therapy (i.e. effective testing). Indeed, a proportion of these patients are offered a checkpoint inhibitor, even though such agents are of limited clinical benefit. We hypothesize that an early engagement program to inform oncologists on the importance of biomarker testing on all newly diagnosed patients will improve effective EGFR testing rates. The main objective of the current study was to measure the impact of a decision support program (DSP) on EGFR testing rates in advanced-stage NSCLC patients treated in community oncology practices across the United States (US).

Methods: The DSP consisted of multiple components such as early patient identification prior to their clinic appointment, their candidacy for benefiting from biomarker testing before initiating first-line therapy, and links to NCCN guidelines for treating actionable mutations in advanced NSCLC. Prior to the implementation of the program, a multistage random sampling technique was used to identify 201 control patients who were managed at the Quality Cancer Care Alliance or the National Cancer Care Alliance, for a combined 23 community oncology clinics across the US. The intervention group consisted of a random sample of 174 patients who were diagnosed in the 12 months following the launch of the DSP in participating clinics. The primary endpoint was the effective testing rate, defined as the EGFR test being ordered and the results received by the oncologist before initiating therapy. Secondary endpoints consisted of overall testing rates and test outcomes. Group comparisons were presented as proportions with 95%CI and odds ratios (OR).

Results: Median patient age in the intervention and control group was 72 vs. 68 years, 53.4% vs. 48.4% were female, and 78.2% vs. 92.4% had stage IV disease. EGFR testing rates are presented in the table below. Overall testing rates were comparable between groups (OR = 1.33, p = 0.35). However, effective EGFR testing rates significantly increased over the 12-month intervention period relative to the control period (OR = 1.74, p = 0.014).

Conclusions: The implementation of a DSP significantly improved effective EGFR testing rates across participating community oncology practice sites in the US.

Keywords: Non Small Cell Lung Cancer, EGFR, Biomarker testing

Outcome (95%CI)	Control Group (n=201)	Intervention Group (n=174)
Overall testing rate	84.6% (95%CI: 78.8 to 89.3%)	87.9% (95%CI: 82.1 to 92.4%)
Effective testing rate	62.2% (95%CI: 55.0 to 68.9%)	74.1% (95%CI: 67.0 to 80.5%)

P4.17F.02 Sociodemographic and Clinical Predictors of Diagnosis of Lung Cancer in the Emergency Department in a Large, Integrated Health System

M. Ragavan[1], M.J. Somers[1], M. Reed[1], A. Dang[2], M. Yang[2], T. Huang[2], D. Vinson[3], L. Sakoda[1], C. Triplett[2], R. Liu[4], [1]Kaiser Permanente Northern California, Oakland/CA/USA, [2]Kaiser Permanente Northern California, Santa Clara, Santa Clara/CA/USA, [3]Kaiser Permanente Northern California, Roseville, Roseville/CA/USA, [4]Kaiser Permanente Northern California, San Francisco/CA/USA

Introduction: Between 20-30% of patients with lung cancer (LC) are diagnosed in the emergency department (ED). While ED presentations of LC are sometimes necessary to address life-threatening symptoms or facilitate rapid diagnostic workup, they are time and resource-intensive and often reflect missed opportunities for earlier diagnosis. Patients diagnosed with LC in the ED have been shown to have adverse clinical outcomes, including higher mortality rates. Prior studies have demonstrated that patients of lower socioeconomic status and who belong to racial/ethnic minoritized groups, as well as patients with a higher number of comorbidities, are more likely to be diagnosed with LC in the ED. However, such studies are largely single center and conducted outside of the United States. In this study, we sought to identify sociodemographic and clinical predictors of an ED diagnosis of LC in a large, sociodemographically diverse integrated health system.

Methods: This retrospective cohort study included all adults diagnosed with any stage or histology of primary LC between 1/1/2018-12/31/2021 within Kaiser Permanente Northern California (KPNC), encompassing twenty-one medical centers. Analyses were restricted to patients who had continuous health plan enrollment with KPNC for one year both before and after diagnosis. Sociodemographic and clinical variables were abstracted from institutional databases. An ED diagnosis of LC was defined as an ED visit within 30 days before LC diagnosis. A Quasi-Poisson regression model was developed to identify predictors of an ED diagnosis of LC.

Results: Of the 5443 patients with LC, 2007 (37%) were diagnosed in the ED (Table 1). In the Quasi-Poisson regression model, Black patients were more likely to be diagnosed in the ED compared with Non-Hispanic white patients (RR 1.22, 95% CI:1.07-1.38). In addition, patients with a higher comorbidity burden (RR 1.22, 95% CI: 1.07-1.38), prior or current smoking status (RR 1.11, 95% CI: 1.01-1.22), and Stage IV disease (RR 2.68, 95% CI: 2.4-3.0) were more likely to be diagnosed in the ED. There were no differences in likelihood of ED diagnosis by age, gender, or neighborhood deprivation index.

Conclusions: Even in an integrated health system with universal access to primary care, there remain disparities in rates of diagnosis of LC in the ED. Patients diagnosed with LC in the ED also have a higher rate of medical comorbidities and present with higher stage disease. Future studies should characterize potential diagnostic delays in this patient population to identify opportunities for earlier diagnosis and intervention in the outpatient setting.

Table 1: Demographic and clinical predictors of an ED diagnosis for patients with LC

	Diagnosed in ED (n=2007, 36.9%)	Not diagnosed in ED (n=3436, 63.1%)	Adjusted Relative Risk[2] (95% CI)

P4.17F.03 Utilizing AI for Automated Data Entry and Analysis to Pre-Screen Lung Cancer Clinical Trial Candidates

M. Aldea[1], P. Rolland[2], L. Zullo[1], S. Simon[1], A. Djarallah[2], A. Poplu[2], M. Wartelle[1], L. Chutto[2], B. Vignal[2], J-C. Louis[2], F. Lion[1], S. Platano[2], D. Planchard[2], A. Gazzah[1], C. Baldini[1], C. Robert[1], F. Andre[1], F. Barlesi[1], S. Michiels[1], F. Le Ouay[2], B. Besse[1], [1]Gustave Roussy, Villejuif/FR, [2]Lifen, Paris/FR

Introduction: In cancer research, patient selection for clinical trials mainly depends on physicians identifying eligible participants, a process prone to oversight. Automated, innovative approaches to expand patient screening at an institutional level could enhance trial accrual and shorten inclusion times. Here, we propose an artificial intelligence (AI) tool capable of assessing essential inclusion and exclusion criteria to identify trial candidates.

Methods: This retrospective study involved patients with thoracic cancer seen at Gustave Roussy between February 2021 and June 2023. Utilizing unstructured patient notes, we automated the entry and structuring of 83 variables covering demographic details, disease features (e.g., histology, PD-L1 expression, molecular and metastatic status, central nervous system metastases), comorbidities, systemic treatment history, and life status. Automated data entry (ADE) was performed by large language model actions with prompt engineering and tailored few-shot examples. A cohort of patients with manual data entry (MDE) was used for comparison with ADE. ADE's correctness was measured by data concordance with MDE, including mismatches where ADE was accurate, and considering missing data. ADE's completeness was gauged by the data filled post missing value abstraction. Primary objectives were assessing ADE's correctness and completeness. Secondary objectives included evaluating the correctness of simultaneously entered multiple variables, verified by randomly selecting 20 sets of 3 and 5 variables, respectively, always including life status.

Results: Data from 1,057 patients were processed through ADE, with a subset of 137 patients also undergoing MDE. Within this dual-entry cohort (N=137), ADE achieved an overall correctness of 96% [range: 71.9-100% per variable]. ADE performed best (95-100% correctness) in identifying demographic information, life status, histology, number of prior lines, and classes and types of systemic treatments received. Variable-specific details are presented in the Table. For the entire group of 1,057 patients, ADE automatically filled 144,499 data points, with a median completeness of 96.7% per patient [range: 59.6%-100%] and 3 minutes per patient. Correctness of ADE for randomly selected combinations of 3 and 5 variables was 81.9% [IQR: 77.7-85.4] and 81.3% [IQR: 75-85.7], respectively, leading to an overall combined correctness of 81.6%.

Conclusions: This study highlights the effectiveness of ADE in identifying selected eligibility and non-eligibility criteria for lung cancer clinical trials with over 90% accuracy. It estimates an 80% probability of simultaneously correctly structuring multiple criteria for a patient. ADE may offer scalable solutions for patient matching to trials, a task unfeasible for manual search in the absence of structured data.

Keywords: artificial intelligence, large language model, automated data entry

Correctness range (%)	Variables
95-100%	sex, birthdate, life status, history of cardiac disease, autoimmune disease, HIV, hepatitis B and C, histology, treatment class (immunotherapy, targeted therapy, antiangiogenic, antibody-drug conjugates), number of lines, drugs received
90-95%	Metastatic from diagnosis, metastatic anytime, alterations in *EGFR, BRAF, ROS1, RET, MET, HER2, PIK3CA, SMARCA4, KEAP1, NRG1, NTRK*, treatment class -chemotherapy
85-90%	Thromboembolic events, *TP53* mutations, PD-L1 expression, leptomeningeal metastases

P4.17F.04 Feasibility of Comprehensive Genomic Profiling for Advanced NSCLC in Public Healthcare System - The Hong Kong Experience

K.M. Cheung[1], C.H.L. Wong[2], J.K.S. Fong[2], V.H.F. Lee[2], M.Y. Lim[3], T.Y. Kam[4], S.F. Nyaw[5], C.K. Kwan[6], F.S.T. Mok[7], A.W.M. Lee[2], H.H.Y. Yiu[1], [1]Queen Elizabeth Hospital, Hong Kong/HK, [2]The University of Hong Kong, Hong Kong/HK, [3]Princess Margaret Hospital, Hong Kong/HK, [4]Pamela Youde Nethersole Eastern Hospital, Hong Kong/HK, [5]Tuen Mun Hospital, Hong Kong/HK, [6]United Christian Hospital, Hong Kong/HK, [7]Prince of Wales Hospital, Hong Kong/HK

Introduction: Lung cancer is the most common cancer worldwide. In recent 10 years, there were more than 35 additions to FDA-approved targeted therapies, targeting over 10 oncogenic drivers. Co-mutations predicting response towards targeted therapies and immune-checkpoint inhibitors are also increasingly recognized. In Hong Kong where universal healthcare is provided to citizens, over 90% of lung cancer patients receive testing and treatment in public healthcare. The current lung cancer testing algorithm in Hong Kong public healthcare included sequencing of individual or a small panel of actionable target genes. Upfront comprehensive cancer genomic profiling (CGP) will enable complete understanding of currently actionable and emerging biomarkers in a single testing, but the real-world diagnostic yield, logistics feasibility and clinician acceptance in integrating CGP in routine testing pathway in a public healthcare setting is not well reported.

Methods: The University of Hong Kong-Hospital Authority (HKU-HA) lung cancer CGP project is a territory-wide project which aims to provides CGP testing to all advanced NSCLC cancer patients in Hong Kong since 2021. All 6 public cancer centers in Hong Kong participated. FoundationOne CDx and Liquid CDx were used as the CGP platform. Survey was conducted among thoracic oncologists in all participating cancer centers. The feasibility of routine CGP in advanced lung cancer is assessed and reported in terms of diagnostic yield (success rate and identification rate of druggable mutation), logistic feasibility (report turnaround time and estimates on time spent on explanation) and clinician acceptance.

Results: As of January 2024, 874 patients have been enrolled to the territory-wide CGP project. For diagnostic yield, the success rate for tissue CGP is 63.9%, and 91.2% for liquid CGP. The identification rate of druggable mutation has doubled with the use of CGP in our cohort, amounting to 32.6% in standard assay and 65.3% in CGP. In addition, 72.5% of patients were noted to have other important cancer-associated mutations which could be of predictive and prognostic value. For logistical practicalities, the turnaround time for CGP is 2-3 weeks, which is comparable to current in-house gene-based and small panel testing. The median estimated time taken for informed consent is 5 minutes (IQR 5-10), and the median for the estimated additional time taken to explain the details of CGP to patients was 5 minutes (IQR 5-10). For clinician acceptance, all 22 participating thoracic oncologists are willing to adapt the new CGP approach. 85.7% of clinicians opined that the additional information could improve identification of therapy compared to standard assay, 95.2% expressed CGP could help in prediction of treatment effect and 81% think that CGP helps with prognostication.

Conclusions: The introduction of routine CGP testing in workflow of management of advanced NSCLC into public healthcare setting yields improvement in detection rate of actionable mutations at comparable turnaround time and a high success rate. While a median of additional 10 minutes is required for the additional explanation, thoracic oncologists are willing to adapt routine CGP in management of advanced NSCLC and most find the additional information provided helpful to patient management.

P4.17F.05 Adherence to Clinical Practice Guideline - Analysis of 89 Multidisciplinary Team Discussed Patients with Stage III Lung Cancer

J-T. Zhang[1], Y-C. Zhang[1], W-Z. Zhong[1], B-C. Yin[2], G-W. Che[3], M. Li[4], Y-L. Wu[1], P.J-Y. Cui[5], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [2]Vintura, Paris/FR, [3]Lung Cancer Center, West China Hospital, Sichuan University, Chengdu/CN, [4]Xiangya Lung Cancer Center, Xiangya Hospital, Central South University, Changsha/CN, [5]Vintura, Munich/DE

Introduction: The management of stage III lung cancer patients is complex, involving careful consideration of tumor severity, patient health status, and treatment feasibility. Multidisciplinary teams (MDTs) are pivotal in ensuring tailored treatment decisions that optimize patient survival and quality of life while avoiding over or undertreatment. Guidelines from organizations like ASCO, NCCN, ESMO, and CSCO provide evidence-based recommendations, yet research on patient guideline adherence post-MDT is limited. This study aims to assess stage III lung cancer patient adherence to CSCO guidelines post-MDT and its impact on treatment outcomes, quality of life, and satisfaction.

Methods: We organized over 20 cross-institutional MDT meetings nationwide for lung cancer, involving 89 stage III patients. Data collected included patient medical histories, pre-MDT diagnostic and treatment decisions, MDT recommendations and treatment outcomes. Statistical analysis compared changes in patient plans before and after MDT discussions and assessed MDT's impact on guideline adherence for stage III lung cancer patients.

Results: In terms of staging, approximately half of the cases (49.4%) underwent staging adjustments post-MDT discussions, indicating a prevalent issue of incomplete testing before MDT. Moreover, a considerable proportion (30.3%) of initially deemed unresectable cases were reevaluated as potentially resectable after MDT deliberations. In terms of treatment recommendations, three main categories of alterations were observed post-MDT discussions: 1) shifts in the overall treatment trajectory from Plan A to Plan B, 2) supplementation of treatment strategies from Plan A to Plan A+B, and 3) elimination of redundant interventions from Plan A+B to Plan A. Importantly, patients demonstrated a high satisfaction 98% (87/89) with treatment plans endorsed during MDT discussions, 79.8% (71/89) experienced the improvement of quality of life, and 80.9% (82/89) followed up with tumor examinations, including 64.6% (53/82) using RECIST 1.1 and the remaining 35.4% (29/82) using the physician-reported response method. The majority of MDT discussed cases (n=80, 89.9%) are adherent to 2023 CSCO guideline, with a median follow-up of 8.4 months, during which 66 individuals remained progression-free.

Conclusions: This study underscores the significant impact of MDT discussions on stage III lung cancer. Integrating MDT meetings is crucial for standardizing and customizing the management of stage III lung cancer, leading to advancements in patient prognosis and quality of life. Future research will concentrate on evaluating long-term outcomes, such as five-year survival rates and long-term progression-free survival.

P4.17F.06 Review of State Legislation Mandating Biomarker Coverage in Cancer Care

S. Kalantri[1], R. Singh[2], I. Singh[3], J. Kolesar[4], G. Kloecker[1], [1]Brown Cancer Center, University of Louisville, Louisville/KY/USA, [2]University of Illinois College of Medicine Peoria, Peoria/IL/USA, [3]Suny Upstate Medical University, Syracure/NY/USA, [4]University of Kentucky, Lexington/KY/USA

Introduction: Biomarkers, measurable biological molecules serving as indicators of various processes, conditions, or diseases, including cancer, have revolutionized precision therapy. Particularly in non-small cell lung cancer (NSCLC), precision therapy guided by biomarker testing has demonstrated significant improvements in overall survival compared to conventional treatments. The FDA approval of targeted therapies against biomarkers such as EGFR, ROS1, BRAF, ALK, RET, and PD-L1 has reshaped the landscape of NSCLC treatment. However, despite these advancements, disparities in access to biomarker testing persist, impacting patient outcomes. Our study aims to assess disparities in biomarker testing coverage for NSCLC and explore mechanisms to overcome these disparities.

Methods: We conducted a comprehensive analysis of existing legislation by locating and downloading official legislative documents from respective state government websites. These documents included bills, statutes, regulations, and other policy documents relevant to biomarker testing coverage for NSCLC. We systematically reviewed each document to extract pertinent information into a table regarding biomarker testing legislation, coverage requirements, populations covered, prior authorization, costs, and any other relevant details. This method ensured the inclusion of official and up-to-date legislative information in our analysis.

Results: Our analysis revealed significant disparities in biomarker testing coverage across states (Table 1). As of March 2024, only 13 states - Arkansas (AR), Arizona (AZ), California (CA), Georgia (GA), Illinois (IL), Kentucky (KY), Louisiana (LA), Maryland (MD), Minnesota (MN), New Mexico (NM), New York (NY), Oklahoma (OK), Rhode Island (RI), and Texas (TX) - have enacted legislation mandating coverage. However, many states still lack comprehensive measures, leaving gaps in accessibility. It's worth noting that assessing coverage solely based on legislation may not accurately reflect disparities, as affordability remains a critical issue. Without mandating affordable co-pays, insurance companies retain discretion over cost-sharing, potentially exacerbating disparities. Fifteen additional states, including Colorado (CO), Connecticut (CT), Hawaii (HI), Iowa (IA), Indiana (IN), Florida (FL), Massachusetts (MA), Maine (ME), New Jersey (NJ), Nevada (NV), Ohio (OH), Pennsylvania (PA), Washington (WA), West Virginia (WV), and Vermont (VT), are expected to introduce legislation regarding biomarker testing in 2024.

Conclusions: Our findings underscore the urgent need to address disparities in biomarker testing coverage for NSCLC. While legislative efforts are crucial, ensuring affordability is paramount in reducing disparities. Mandating affordable co-pays alongside coverage requirements may help mitigate disparities and improve access to biomarker testing, ultimately enhancing outcomes for NSCLC patients. These conclusions are supported by data highlighting disparities in coverage and the potential impact of affordability measures.

EP.01A.01 Role of Diet and Exercise in Young Lung Cancer Patients with Driver Mutations (NCT04640259)

A. Wu[1], M. Bittoni[2], A.M. Harper[3], N. Florez[4], C.A. Granville[5], R. Erwin[3], B.J. Addario[6], D.P. Carbone[7], B.J. Gitlitz[8], J. Nieva[1], [1]University of Southern California, Los Angeles/CA/USA ,[2]Ohio State University James Cancer Center, Columbus/OH/USA ,[3]Addario Lung Cancer Medical Institute (ALCMI), San Carlos/CA/USA ,[4]Dana-Farber Cancer Institute – Harvard Medical School, Boston/MA/USA ,[5]GO[2] for Lung Cancer, Washington/DC/USA ,[6]GO[2] for Lung Cancer, San Carlos/CA/USA ,[7]Ohio State University, Columbus/OH/USA ,[8]Roche/Genentech, San Francisco/CA/USA

Introduction: The Epidemiology of Young Lung Cancer Study (EoYLC) is an innovative, virtual case-case study that explores environmental, lifestyle and genetic factors in young persons with lung cancer (LC), and the largest epidemiology study in young lung cancer (YLC) patients to date. Previous EoYLC results showed that relative to ALK rearranged LC, EGFR patients were more likely to be female and older, had increased smoking exposure, lower body mass index (BMI), increased oral contraceptive and antihistamine use, and fewer allergies during adolescence. However, information on dietary and exercise patterns in YLC patients by driver mutations has been largely lacking, and is the focus of this report.

Methods: We are actively recruiting individuals with YLC (<age 50) from our established LC registry and social LC networks using a virtual study strategy. Eligibility criteria include age > 18, primary non-small cell LC (any stage), documented testing of target mutations, plasma collection, and willing to complete a comprehensive 10-module risk factor survey. We analyzed the EGFR and ALK groups regarding usual pre-diagnostic diet and exercise using validated instruments, including the International Physical Activity Questionnaire (IPAQ), which measured frequency, intensity, and amount of activity per week, as well as a Food Frequency Questionnaire (FFQ- nutritionquest.com), from which the Healthy Eating Index (HEI-2015- a validated measure of diet quality) was calculated. Descriptive statistics were calculated and associations between lifestyle factors and driver mutations were assessed using t-tests and chi-squares.

Results: Preliminary results from the first 141 individuals who completed risk factor surveys and donated blood specimens showed that 85% were females, with a mean age of 38, and had adenocarcinoma (95%), Stage 4 (80%), and mostly ALK (42%) or EGFR driver mutations (38%). The IPAQ results classified 69% of participants as engaging in high intensity, 19% in moderate intensity and 12% in low intensity activity. Those with EGFR mutations had significantly higher combined high/moderate activity compared to ALK (p=0.031). EGFR patients also had higher vigorous MET min/week and total MET min/week compared to ALK patients (p=0.007 and p=0.036, respectively). A significantly lower mean BMI was observed for EGFR vs ALK patients (23.9, and 27.3, respectively, p=0.07). The mean HEI-2015 score was 66.7 (range 43.6-91.0) compared to the US average of 58; 4% of participants were in the “good” category (score >80), 69% in the “needs improvement” category (score 51-80), and 26% in the “inadequate” category (score <51). No statistically significant associations were found between genetic mutations and HEI-2015 score.

Conclusions: Younger ALK and EGFR patients (<age 50) had similar HEI-2015 diet quality scores which were better than the US average. However, BMI and physical activity levels appeared to differ significantly between EGFR vs ALK driven lung cancers, with higher physical activity and lower BMI among those with EGFR mutations. Further research on these factors among younger lung cancer populations is ongoing and updated analyses will be presented upon completion of enrollment.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.01A.02 Risk Factors and Nomogram Construction of Early Death in Patients with Stage IV Lung Squamous Cell Carcinoma: A SEER-Based Study

X. Yu[1], X. Chu[1], L. Wang[1], K. Wang[2], C. Su[1], [1]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN ,[2]School of Medicine, Southeast University, Nanjing/CN

Introduction: Stage IV lung squamous cell carcinoma (LUSC) has a poor prognosis and takes the risk of early death. However, risk factors of early death remain to be explored for optimizing decision-making.

Methods: Data on stage IV LUSC patients diagnosed between 2010 and 2015 was extracted from the Surveillance, Epidemiology, and End Result (SEER) database. The least absolute shrinkage and selection operator (LASSO) logistic regression and multivariate analysis were used to select the independent risk factors and build a predictive nomogram. The receiver operating characteristic (ROC) curve, calibration curve, and decision curve analysis (DCA) were performed to assess the performance of the nomogram.

Results: 4,908 stage IV LUSC patients were enrolled and divided into the training (3,436) and validation cohort (1,472). 41.6% had early death and were predominantly attributed to cancer-specific-early death (92.7%). The early death rate exhibited a substantial increase in correlation with advancing age. Independent risk factors for constructing a nomogram included age, T stage, N stage, M stage, tumor size, bone metastasis, brain metastasis, liver metastasis, chemotherapy, and radiotherapy. The AUC was 0.793 (95%CI: 0.778-0.809) and 0.798 (95%CI: 0.775-0.821) in the training and validation cohorts respectively. Calibration and DCA curves both demonstrate the reliability of this model.

Conclusions: We identified the incidence, causes, and risk factors of early death. A comprehensive nomogram was established to predict early death in stage IV LUSC patients. The nomogram revealed excellent discrimination and clinical usability to predict the probability of early death accurately

EP.01A.03 Disparities Inepidemiological Characteristics, Clinical Profiles,and Survival Forever-Smokers and Never-Smokers with Lung Cancer in China

F. Tan, C. Wang, R. Li, W. Yang, N. Li, J. He, China National Cancer Center, Beijing/CN

Introduction: Lung cancer in never-smokers poses a health burden worldwide, particularly in East Asian countries like China. It is crucial to identify epidemiological and clinical characteristics of lung cancer patients between ever-smokers and never-smokers. However, there have been limited related data to date in China.

Methods: This study included lung cancer patients who underwent surgical procedures from January 2014 to December 2021 at 26 hospitals in China. The hazard ratio (HR) with 95% confidence interval (CI) for survival was estimated using the Kaplan-Meier method and multivariable Cox proportional hazard model. This is a part of the nationwide real-world study (NCT06255197).

Results: A total of 24,164 ever-smoking and 100,815 never-smoking lung cancer patients undergoing surgery were included in this study. From 2014 to 2021, the proportion of non-smoking patients increased from 56.5% to 86.8%; a consistent upward trend was observed in the proportion of never-smokers among male patients, from 30.8% in 2014 to 67.8% in 2021. Adenocarcinoma remained the most common histologic subtype, with its proportion increasing from 45.7% to 71.7% for ever-smokers and 83.1% to 95.1% for never-smokers, respectively. Patients who had ever smoked had a significantly higher risk of mortality compared to those who had never smoked (adjusted HR: 1.24 [95% CI: 1.15, 1.34]). Further subset analyses revealed that the increased risk of mortality was observed among ever-smokers patients with adenocarcinoma (adjusted HR: 1.37 [1.24, 1.52]), at stages I (adjusted HR: 1.45 [1.29, 1.64]) and III (adjusted HR: 1.26 [1.11, 1.42]). Female gender was found to be a significant prognostic factor only for non-smoking patients, with an adjusted HR of 0.66 (0.60, 0.72).

Conclusions: The disparities in lung cancer between ever-smokers and never-smokers in China provide further evidence that these two groups are distinct entities. It is crucial to conduct future research focusing on biological explanations and population-based studies.

EP.01A.04 Predictive Value of a Prognostic Model Based on Clinicopathologic Features in Lung Adenocarcinoma

Y. Lv, Shanghai Chest Hospital, Shanghai/CN

Introduction: The presence of tumor spread through air spaces (STAS) was reported to be associated with worse prognosis in early-stage lung adenocarcinoma. However, STAS was also associated with other clinicopathologic features affecting prognosis. This study aims to explore the independent prognostic value of STAS and develop a prognostic model for survival prediction in lung invasive adenocarcinoma.

Methods: The medical records of 2144 stage I to IIIA patients with resectable lung adenocarcinoma who received surgical treatment at our institution from 2015 to 2019 were retrospectively reviewed. Clinicopathological variables that were statistically significant in multivariate Cox regression were included in the nomogram to create a recurrence predictive model.

Results: STAS was observed in 931 patients (43.4%). Univariate and multivariate Cox regression analyses revealed that STAS, adjuvant therapy, stage and risk factors including poorly differentiated tumors, lymphovascular invasion and visceral pleural invasion were independent risk factors for lung invasive adenocarcinoma. A prognostic model based on above features was developed to predict the 1-year, 3-year and 5-year recurrence-free survival. The concordance index (C-index) of the prognostic model was 0.858 in the internal validation cohort.

Conclusions: The presence of STAS, adjuvant therapy, stage and risk factors including poorly differentiated tumors, lymphovascular invasion and visceral pleural invasion were significant prognostic factors for poorer RFS. The prognostic model we developed could effectively predict the recurrence-free survival.

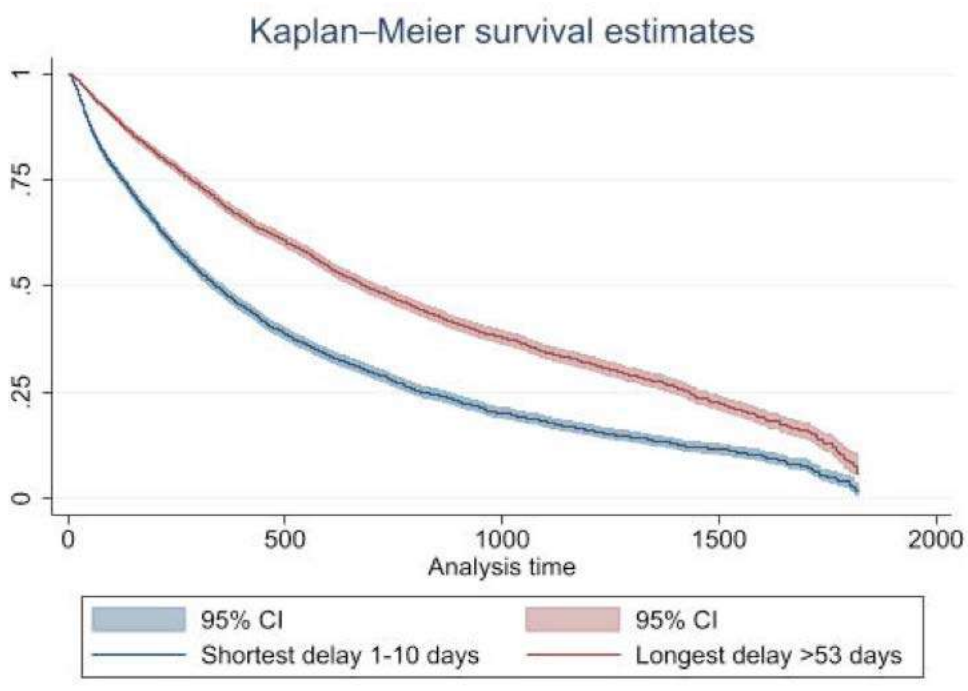
Introduction: Lung cancer is the leading cause of cancer mortality worldwide, and early detection is crucial to improve survival rates. Delays in diagnosis can occur due to various factors and these delays might negatively impact the prognosis of the disease. This study aims to analyze the diagnostic delay in lung cancer patients, examine the characteristics of cases associated with long delay and describe potential associations between delay and survival.

Methods: The data source used was the Thoracic Tumour Registry of the Spanish Lung Cancer Group, a monographic lung cancer registry representative of cancers diagnosed in Spain by age and sex. This analysis was restricted to lung cancer cases with information on the first date of consultation by symptoms or when the patient attended the emergency room as a consequence of an undiagnosed lung cancer and date of diagnosis. The delay was calculated as the number of days between the two dates and categorized as follows: the shortest delay 1-10 days, short delay 11-23 days, long delay 24-53 days and the longest delay >53 days. A descriptive analysis was performed, and ordinal logistic regressions were fitted with the dependent variable being delay. Kaplan-Meier survival analysis and Cox regression were performed.

Results: 22,755 cases were included. Most were men (73.68%), the median age at diagnosis was 66 years (interquartile range 59-73), and most were smokers (44.66%) and ex-smokers (44.70%). Multivariate analysis showed that never smokers were 1.14 (95%CI 1.04-1.25) times more likely to register longer delay than smokers. Stage 0-I-II cases had a 3.09 (95%CI 2.88-3.32) times higher risk of longer delay compared to III-IV stages. Overall, the 5-year survival rate after diagnosis was 23.64% (95%CI 22.88-24.41). In those categorized as having the shortest delay it was 17.67% (CI95% 16.31-19.07) and in the longest delay was 32.96% (CI95% 31.26-34.67) ($p<0.005$). The Cox regression showed a mortality risk higher in men (adjusted Hazard Ratio (HR) 1.20; 95%CI 1.14-1.25), in stage III and IV (HR 3.37; CI95% 3.17-3.59) and in ever-smokers (exsmokers HR 1.25, CI95% 1.16-1.34; smokers HR 1.51, CI95% 1.41-1.63). The mortality risk was higher in those with the shortest delay (HR 1.37, CI95% 1.30-1.45) in comparison with the longest delay.

Conclusions: Diagnostic delays are generally short among Spanish lung cancer patients, indicating a relatively quick diagnostic process. The longest delays appear to be associated with higher survival rates, possibly attributed to slow-growing tumors or early-stage at diagnosis.

Keywords: lung cancer, diagnostic delay, survival



EP.01A RISK FACTORS, RISK REDUCTION & TOBACCO CONTROL - DISEASE PROFILE
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.01A.06 Characteristics of Non-Small Cell Lung Cancer with High Serum CEA Levels

K. Hoshijima[1], S. Shiono[2], J. Suzuki[2], H. Watanabe[2], K. Abe[2], S. Yasuda[2], [1]Yamagata University Faculty of Medicine, Yamagata-City/JP ,[2]Yamagata University Faculty of Medicine, Yamagata City/JP

Introduction: Serum carcinoembryonic antigen (CEA) level is a predictive factor for recurrence, and a high preoperative CEA level is a poor prognostic factor for non-small cell lung cancer (NSCLC). Because serum CEA can be easily examined using blood biochemistry, it is widely used in clinical practice for the preoperative and postoperative management of NSCLC in Japan. However, although serum CEA levels of smokers have been reported to be higher than those of nonsmokers, the characteristics of NSCLC with high serum CEA levels have not fully elucidated. Therefore, we aimed to evaluate the characteristics of patients with NSCLC and high serum CEA levels.

Methods: This retrospective study used a prospectively collected database from two institutions. We examined surgical cases of patients with NSCLC with high serum CEA levels. We determined the cutoff value as 10 ng/ml, which is twice the in-house CEA cutoff value. Between 2004 and 2023, 3482 patients underwent surgery for lung cancer. Among them, we evaluated the characteristics of 297 patients (8.5%) who underwent surgery for NSCLC and had a preoperative serum CEA level ≥10 ng/ml.

Results: The median age of the patients was 72 years (range:41-89), with 220 men (74.1%) and 77 women (25.9 %). The median serum CEA level was 18 ng/ml (range: 10.0-1584 ng/ml). The median smoking index was 780(0-2500), 236 were smokers (79.5%) and 61 (20.5%) were nonsmokers. Regarding history of other cancers, 68 patients (22.9 %) had a history of cancer of other organs, of which gastric cancer was the most common (19 cases), followed by colorectal cancer (15 cases), and prostate cancer (7 cases). Chronic obstructive pulmonary disease was the most common pulmonary comorbidity (109 patients, 36.7%), followed by interstitial lung disease (51 patients, 17.2%). Regarding clinical stage, 148(49.8%) had stage I, 55(18.5%) had stage II, and 149(31.7%) had stage III and IV. A total of 222 (74.7%) patients underwent lobectomy or pneumonectomy, 11(3.7%) underwent segmental resection, and 37 (12.4%) underwent partial resection. The pathological stage was stage I in 140 (47.1%) patients, stage II in 55(18.5%), and stage III and higher in 102 (34.3%) patients. Histologically, 201 cases (67.7%) were adenocarcinoma, 61 cases (20.5 %) were squamous cell carcinoma, and 7 cases (2.4 %) were adenosquamous carcinoma. During the postoperative follow-up, 109 patients (36.7 %) developed recurrence, 20 had locoregional lymph node recurrences, 20 had ipsilateral or contralateral lung recurrences, 19 had pleural dissemination, and 17 had brain metastasis. The overall 5-year survival rate after surgery was 25% in all patients.

Conclusions: Patients with NSCLC with a high serum CEA level tended to be advanced stage of NSCLC and proportion of COPD was approximately 40%. As the percentage of smokers was around 80%, smoking could affect the level of higher serum CEA.

EP.01B.01 Geospatial Characterization of DNA Damage Repair (DDR) Mutations in Lung Cancer Patients in an Underserved Urban Population

J. Kao, M. Pasquinelli, R. Nguyen, A. Hulbert, A. Mallisetty, M.E. Wright, E. Abrol, F. Weinberg, University of Illinois College of Medicine, Chicago/IL/USA

Introduction: DNA-damage repair (DDR) mutations in lung cancer have shown potential for use as therapeutic targets and predictive biomarkers. However, the relationship between DDR mutations and socioeconomic factors remains largely unknown. In this study, we characterize the geospatial distribution of DDR mutations in lung cancer patients at a single academic medical center serving a population of primarily underserved, underinsured patients.

Methods: All lung cancer patients seen at the University of Illinois Chicago (UIC) between 11/2/2015 and 9/11/2023 with TEMPUS genetic data available were included in the study (N = 235). DDR mutations of interest were ARID1A, ATM, ATR, ATRX, BAP1, BRCA1, BRCA2, BRIP1, CHEK2, ERCC3, FANCA, FANCC, MLH3, MRE11, MSH6, MUTYH, NBN, PALB2, and RAD50. The home addresses of each patient were geocoded and DDR mutational status was visualized by zip code across Chicago. DDR mutational status was then correlated with various population-level social determinants of health (SDOH) and cancer risk factors that were compiled by the University of Illinois Cancer Center Data Integration Shared Resource.

Results: The overall frequency of DDR mutations in the population was 28.5% (n = 67). The most common DDR mutations were ARID1A (20.7%), CHEK2 (12.8%), ATM (9.9%), BRCA2 (9.9%), ATRX (7.9%), and MUTYH (7.9%). There was a significant effect in tumor mutational burden (TMB), t(55) = 2.97, p = 0.004, with a higher mean TMB in the DDR positive group (M = 14.4, SD = 11.1) compared to the DDR negative group (M = 9.4, SD = 5.1). The most common zip codes in the DDR positive group were 60629 (9.0%), 60616 (9.0%), and 60608 (9.0%) compared to 60616 (8.4%), 60609 (5.4%), and 60644 (4.8%) in the DDR negative group; all zip codes were located in the West and South sides of the city. Table 1 summarizes the comparison of selected population-level SDOH and cancer risk factors between the two groups.

Table 1. Comparison of selected population-level SDOH based on DDR mutational positivity

	DDR positive (mean) (n = 67)	DDR negative (mean) (n = 168)	p value
Area deprivation index[1]	52.0	54.8	0.27
Median household income (annual)	$56,691	$53,044	0.21
Poverty rate	19.9%	21.5%	0.16
Violent crime (crimes per 100k residents/yr)	1308	1471	0.16
Severe housing cost burden	20.5%	22.0%	0.08
Life expectancy (years)	76.3	75.7	0.21
Obesity (BMI ≥30)	36.3%	37.2%	0.33
Cigarette smoking rate	17.0%	17.7%	0.24
Binge drinking	16.0%	15.3%	0.08
Visited doctor for routine checkup	76.3%	77.3%	0.08
Federally Qualified Health Centers (number)	5.96	4.81	0.05
Lung cancer diagnosis rate (per 100k residents/yr)	70.6	75.4	0.10
Proximity to superfund (toxic waste) sites[2]	0.0712	0.0865	0.17
Proximity to hazardous waste management sites[2]	8.75	8.16	0.47
Proximity to water polluting sites[2]	109	106	0.94
Particulate matter (PM2.5) concentration ($\mu g/m^3$)	10.09	10.07	0.44

[1]Higher values represent more disadvantage.
[2]Higher values indicate closer proximity.

Conclusions: The frequency and distribution of DDR mutations in lung cancer at UIC appears similar to what has been previously reported in the literature. There is a higher tumor mutational burden in lung cancers with DDR mutations, which may suggest greater susceptibility to immunotherapy. There may be associations between the presence of DDR mutations and certain SDOH and cancer risk factors. Future work will involve analysis of correlations between the presence of DDR mutations and individual risk factors, stage at diagnosis, and median survival, as well as a broader array of population-level measures.

EP.01B.02 Association Betweensocial Isolation and Loneliness, and the Risk of Lung Cancer: A Prospective Cohort Study

Y. Zhang, Xiangya Hospital, Changsha/CN

Introduction: Globally, lung cancer is the leading cause of cancer-related mortality. Social isolation and loneliness are growing concerns in the development of lung cancer, while the relationship between social isolation and loneliness, and the risk of lung cancer remains inconclusive.

Methods: The prospective cohort was conducted based on the data from UK Biobank. Social isolation was evaluated based on the number of household members, frequency of social activities, contact with others. Meanwhile, loneliness was assessed by the subjective feeling of loneliness and the willingness to confide in others. The association between social isolation, loneliness and incident lung cancer was estimated by Cox regression models.

Results: A total of 3,692 lung cancer cases were documented among 415,366 participants during a mean follow-up of 13.8 years. Compared with participants with the least social isolation, approximately 10% [Hazard Ratio[HR] 1.10, 95% Confidence Interval[CI] 1.03-1.18] and 21% [HR 1.21, 95%CI 1.10-1.34] increase in risk of lung cancer were identified among individuals with moderate isolated and most isolated, respectively. Meanwhile, we also found that loneliness was associated with 11% increased risk of lung cancer [HR 1.11, 95% CI 1.04-1.18]. In addition, the stratified analysis showed the aforementioned relationship was substantially modified by age, gender, genetic risk, smoking, drinking, and diet behaviors.

Conclusions: Social isolation and loneliness were identified to be associated with significant increased risk of developing lung cancer. The evidence highlights the significance of managing social isolation and loneliness for lung cancer prevention.

EP.01C.01 Evolution of Lung Cancer Mortality Rates in Brazil (1996-2022).

J. Rey Brandariz[1], B. Wanderlei-Flores[1], C. Guerra-Tort[1], C. Candal Pedreira[1], G. García[1], A. Ruano-Ravina[1], L. Martín-Gisbert[1], L. Varela-Lema[2], M. Pérez-Ríos[1], [1]University of Santiago de Compostela, Santiago de Compostela/ES ,[2]University of Santiago de Compostela, Santiago de Compostela/BR

Introduction: Although Brazil is the leading country in South America in the implementation of tobacco control measures, lung cancer is the main cause of cancer-related deaths among men and the second cause among women in Brazil. The objective of this study was to analyze the evolution of lung cancer mortality rates in Brazil from 1996 to 2022.

Methods: Lung cancer mortality data for individuals aged ≥35 years were obtained from the Sistema de Información de Mortalidad del Sistema Único de Salud de Brasil (ICD-10 C33-C34). Crude and age-adjusted rates were calculated by applying the direct method. Trend analysis was conducted using joinpoint regression models. Annual percentage changes (APC) and 95% confidence intervals (95%CI) are presented.

Results: During the period 1996-2022, 570,594 persons aged ≥35 years died from lung cancer in Brazil. Of these deaths, 61.8% (352,577 deaths) occurred in men. The overall crude mortality rate increased by 15.1% during this period, from 24.4 deaths per 100,000 inhabitants in 1996 to 28.1 in 2022. The crude mortality rate for men decreased by 11.6% from 36.6 deaths (1996) to 32.3 (2022). For women the rate increased by 84.4%, from 13.2 (1996) to 24.3 deaths (2022). When analyzing the trend of the overall age-adjusted rates, two periods were identified. The first between 1996-2017 with an increasing trend (APC: 0.4 [95%CI 0.1 to 0.7]) and the second between 2017-2022 with a decreasing trend (APC: -3.7 [95%CI -7.6 to -1.9]). For men, the joinpoint identified three periods. The first period with a stable trend between 1996-2005 (APC: 0.4 [95% CI -0.3 to 3.8]) and the second and third periods with a decreasing trend (APC: 2005-2018 = -1.1 [95% CI -2.0 to -0.5]; APC: 2018-2022= -5.2 [95% CI -9.7 to -2.9]). For women, the analysis of age-adjusted rates showed an increasing trend between 1996 and 2016 (APC: 2.3 [95% CI 2.0 to 2.7]) followed by a decreasing trend between 2016 and 2022 with an APC: -1.7 [95% CI -5.0 to -0.03]) (Figure-1).

Conclusions: Crude lung cancer mortality rates have decreased in men since 2005, while in women they have remained stable since 2016. However, crude mortality rates in women have almost doubled since 1996. Analyzing the trend of age-adjusted rates in women has shown a decrease since 2016, which may explain that the stabilization observed with crude rates is due to the aging of the population. The evolution of lung cancer mortality in Brazil is favorable.

EP.01D.01 Exploring the Association Between Connective Tissue Diseases and Lung Cancer: Analysis of the Mediating Role of Immune and Inflammatory Markers

Y. Feng, B. Cheng, J. He, P. Chen, W. Liang, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Early researches indicate that patients with certain connective tissue diseases (CTDs) may have an increased risk of lung cancer, yet these studies often focus on specific diseases or populations, lacking a systematic analysis. This study examines the relationship between CTDs and lung cancer.

Methods: This study prospectively followed 457,959 participants from the United Kingdom Biobank cohort who were free of lung cancer at baseline. The risk of lung cancer in patients with CTDs was assessed using Cox proportional hazards models, adjusting for 14 covariates including age and gender. Mediation analysis was employed to investigate the connections between thirteen CTDs associated with lung cancer risk and ten key immune and inflammatory markers.

Results: The study included a total of 457,959 participants, with an average follow-up time of 9.21 (SD = 4.06) years. The median age was 57 years and 54.20% female. During the follow-up period, there were 157273 cases of CTDs and 4229 cases of lung cancer. Compared to individuals without CTDs, patients with CTDs had a lung cancer HR of 0.899 (0.842-0.959), p=0.001, which included thirteen CTDS related to lung cancer risk: seropositive rheumatoid arthritis[1.67(1-2.77),p=0.049], other rheumatoid arthritis[1.27 (1.02-1.57),p=0.033], gout[1.3(1-1.69),p=0.049], other acquired deformities of limbs[1.49(1.05-2.11),p=0.024], systemic sclerosis [3.41(1.62-7.16),p=0.001], scoliosis[1.53(1.02-2.31),p=0.041], spondylosis[1.19(1.01-1.41),p=0.038], other spondylopathies [1.26(1.01-1.57),p=0.037], other intervertebral disk disorders[1.37 (1.14-1.63),p=0.001], dorsalgia[1.2(1.05-1.37),p=0.007], fibroblastic disorders [1.37(1.09-1.72),p=0.007], other enthesopathies[1.3(1-1.69),p=0.049], other soft tissue disorders(not elsewhere classified)[1.47(1.29-1.68),p<0.001]. Mediation analysis revealed that among thirteen CTDs associated with lung cancer risk, the associations of specific diseases such as rheumatoid arthritis, gout, acquired deformities of fingers and toes, and systemic sclerosis with lung cancer were predominantly mediated through significant roles of lymphocyte count, monocyte count , neutrophil to lymphocyte ratio, and systemic immune inflammation index.

Conclusions: The findings of this study suggest that CTDs do not increase the risk of lung cancer. However, significant associations were observed between certain CTDs and an elevated risk of lung cancer, with some immune and inflammatory markers playing a key mediating role between CTDs and lung cancer risk. These findings offer new perspectives for the prevention and treatment strategies of both CTDs and lung cancer.

EP.01D.02 Heterogeneous Germline Variants Detected in EGFR-Mutant Familial Lung Cancer Patients and Family Members

Y-C. Zhang, X-W. Wei, Y-D. Lin, Z-H. Chen, Y-L. Wu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN

Introduction: Management of familial lung cancer has gradually become a clinical unmet need in recent years. Lung cancer patients with family history have been reported to demonstrate clinical characteristics including a higher frequency of non-smoker, driver gene-positive. Some previous studies have investigated the prevalence and role of germline EGFR mutation in EGFR-mutant familial lung cancer patients. In addition to germline EGFR mutations, our study aims to comprehensively investigate the germline characteristics of EGFR-mutant familial lung cancer.

Methods: We first retrospectively enrolled EGFR-mutant lung cancer patients who had family history of cancer and underwent tissue next-generation sequencing (NGS) in Guangdong Provincial People's Hospital from November 2020 to 2023, to analyze the clinical characteristics of this subset of patients. Familial aggregated EGFR-mutant lung cancer families who provided consent for whole exome sequencing (WES) of peripheral blood for germline alteration analysis were prospectively enrolled to investigate the germline characteristics. Germline variants were further screened according to ACMG evidence level.

Results: In the retrospective cohort, a total of 110 EGFR-mutant lung cancer patients with family history of cancer were enrolled, with 70% female, median age of lung cancer diagnosis was 56 (25-84) and 84% were never-smoker, 65% presented with multiple lung nodules. For the type of cancer family history, top 4 included 62% of patients with a family history of lung cancer, 13% with liver cancer, 11% with colon cancer and 9% with breast cancer. Nine patients (8.2%) have a family history of ≥3 family members with cancer. Pathogenic(P) and Likely pathogenic (LP) germline variants mutations were detected in 5 patients (2 suspected LP due to no match peripheral blood test) by NGS, involving alterations in DNA repair genes FANCI,FANCA,PALB2 and RAD54L. In our prospective cohort, a total of 25 individuals (10 lung cancer, 1 liver cancer, 13 healthy individuals) from 4 familial aggregated EGFR-mutant lung cancer families underwent WES of peripheral blood nucleated cells. These families have 4 to 9 first-degree family members with cancer diagnosis. Likely pathogenic (LP) variants detected involving multiple DNA repair genes such as RECQL, ATR, and ZRANB1, metabolic pathway genes such as PMVK and CD36 were also identified. In addition, novel germline nonsynonymous mutation (ACMG: VUS) in EGFR exon14, EGFR exon 1 were also detected in two separate families respectively.

Conclusions: Heterogenous germline P/LP variants mostly involving DNA repair genes and metabolic pathway, as well as germline EGFR mutation of unknown significance were detected in familial aggregated EGFR-mutant lung cancer. Our finding indicates that the hereditary trace might differ between individuals in this rare population with high risk of lung cancer and a potential "multiple hit" genetic predisposition.

EP.01D.03 Analysis of Lung Cancer Risk in Never Smokers with a Family History of Lung Cancer: A Cohort Study

Y-G. Lee[1], D. Seo[2], D-Y. Kang[3], [1]Samsung Kangbuk Hospital, Sungkyunkwan University School of Medicinel, Seoul/KR ,[2]Sungkyunkwan University School of Medicine, Suwon/KR ,[3]Samsung Kangbuk Hospital, Sungkyunkwan University School of Medicine, Seoul/KR

Introduction: In Eastern Asia, the incidence of lung cancer among never-smokers is increasing. Therefore, it is necessary to devise alternative screening strategies for individuals at high risk due to factors other than smoking. The aim of this research is to evaluate how familial lung cancer history influences lung cancer risk among individuals who have never smoked.

Methods: The Kangbuk Samsung Health Study is a longitudinal cohort study designed to investigate various factors influencing health and the development of chronic diseases among South Korean adults. This cohort draws its participants from individuals undergoing comprehensive health screenings at the Kangbuk Samsung Hospital Health Screening Centers from 2002 to December 31, 2022. After applying exclusion criteria, our analyses were performed with 216,618 Korean adults who were free of cancer history at baseline and followed up to 18 years. Non-smokers are defined as individuals who have never smoked in their lifetime or have smoked fewer than 100 cigarettes. Diagnosis of lung cancer were ascertained through linkage to Korea National Cancer Incidence Database. Utilizing Cox regression analysis, the study scrutinizes various factors such as sex, average body mass index (BMI) during survival time, average alcohol consumption (g/day), frequency of vigorous exercise per week, alongside family history of lung cancer.

Results: Over a follow-up period of 3,474,970,672 person-years, 31 incident lung cancer cases were identified in 14,156 individuals with a familial history of lung cancer, compared to 172 cases in 202,462 individuals without such a familial history. In univariate analysis, a history of familial lung cancer was significantly associated with elevated risks of lung cancer (HR 1.77, 95% CI 1.21-2.59, p=0.003). In multivariate analysis, a family history of lung cancer was associated with an increased risk of lung cancer (adjusted HR 1.85 95% CI 1.25-2.73, p=0.002) when accounting for other variables like sex, BMI, alcohol consumption, exercise frequency and past medical history. Nortably, lifestyle factors such as average BMI also displayed an association with lung cancer risk, underscoring the multifaceted nature of lung cancer etiology.

Conclusions: In individuals who do not smoke, a family history of lung cancer significantly associated with the increased risk of lung cancer. It highlights the significant role of genetic predisposition, especially in never smokers, and calls for a broader perspective on lung cancer prevention strategies. These findings could guide targeted screening and intervention strategies, potentially leading to early detection and better outcomes for high-risk populations. Further research could explore the mechanisms behind this familial risk.

Keywords: familial lung cancer, never smoker

EP.01D.04 Impacts of Household Tobacco Smoke on Life-Long Non-Smoking Adults: An Internet-Based Population Survey in India.

V. Brunelli[1], D.C. Currow[1], S. Chang[2], T. Buchanan[3], K. Reakes[4], S. Kochovska[1], L. Poulos[5], D. Ferreira[1], R. Iyer[6], S.K. Rajan[7], [1]University of Wollongong, Wollongong/AU ,[2]IMPACCT, University of Technology, Sydney/AU ,[3]Cancer Council Australia and University of Wollongong, Sydney/AU ,[4]Cancer Institute of New South Wales, Sydney/AU ,[5]University of Sydney, Sydney/AU ,[6]The Bhatia and P.D. Hinduja Hospital, Mumbai/IN ,[7]Bombay Hospital Institute of Medical Sciences and Bhatia Hospital, Mumbai/IN

Introduction: In India, tobacco use is highly prevalent. An estimated 28.6% of the population use some form of tobacco. India accounts for 12% of all tobacco users globally. Of the eight million deaths worldwide from tobacco use each year, approximately 16% are in people breathing second-hand tobacco smoke. In India, it is estimated that 39% of adults are exposed to second-hand tobacco smoke at home and 30% in the workplace. Despite the meticulous documentation of the burden of disease-based morbidity and mortality from second-hand tobacco smoke and its associations with cardiorespiratory and cardiothoracic diseases, little is known at a population level about the symptoms with which people live because of this exposure.

The aim of this population-based survey in India was to quantify the prevalence of long-term breathlessness limiting exertion in life-long non-smokers currently living with someone who smokes.

Methods: A national, English language internet survey in India, drawn from population panels. Recruitment was stratified by age, sex and rurality based on the 2011 Indian national census.

Breathlessness limiting exertion was defined as modified Medical Research Council breathlessness scale ≥1. Using the new International Classification of Disease code, long-term was defined as breathlessness for >8 weeks. Respondents were asked if anyone currently smoked in their household.

A multivariable binary logistic regression model explored any associations between long-term breathlessness and currently living in the same house as a smoker.

Results: The survey (February 2023) had 2,989 adult responses when weighted to the 2011 Indian census of whom 1,561 (52.2%) were life-long non-smokers.

One in three non-smokers reported long-term breathlessness with prevalence increasing from 38.5% (age ≤29) to 81.8% (age ≥40; p<0.001 for trend). Younger, urban women were more likely to report currently living with someone who smoked.

The regression showed that non-smokers living with someone who smoked increased the risk of long-term breathlessness compared to non-exposure (AOR=2.06, 95% CI 1.02, 4.16; p=0.04) as did age ≥40 (AOR 2.59 (95% CI 1.22, 5.52; p=0.01).

Conclusions: Living with someone who smokes significantly increases the risk of long-term breathlessness limiting exertion in non-smokers. This long-term symptom burden generated for non-smokers is further evidence of the impact of tobacco smoke on the health of the population. In the clinic setting, in people presenting with long-term breathlessness, it is important for clinicians to ask about exposure to other people's smoke at home or in the workplace. Equally importantly, people who smoke need to be educated on the impact that their tobacco smoke may have on the long-term well-being of people who live in the same household.

Given that the consequences of second-hand tobacco smoke include all the diseases associated with smoking tobacco and thus the risk of premature morbidity and mortality, at a population level, greater efforts need to be made to reduce the risk of exposure to other people's smoke at home, in the workplace, in cars, and places where people congregate such as dining areas, sporting events, transport queues.

EP.01D.05 Environmental Asbestos Exposure and Lung Cancer

G. Ak[1,2], S. Metintas[2,3], S. Ozyavuz[1], M. Metintas[1,2], [1]Eskisehir Osmangazi University, Medical Faculty, Department of Chest Diseases, Eskisehir/TR ,[2]ESOGU Lung and Pleural Cancers Research and Clinical Center, Eskisehir/TR ,[3]Eskisehir Osmangazi University, Medical Faculty, Department of Public Health, Eskisehir/TR

Introduction: Environmental asbestos exposures have been reported with increasing frequency. Apart from living near an asbestos industry site, mine or in an asbestos-contaminated house environmental asbestos exposure is observed in certain regions in the world. The people living in these areas will be exposed while working in the fields (agriculture) and/or when using contaminated soil for whitewhashing, plastering, insulating and waterproofing of their houses. The aim of the study was to determine the relationship between environmental asbestos exposure and lung cancer risk as well as the characteristics of lung cancer patients.

Methods: The study included 6,446 lung cancer patients diagnosed and followed up to death between 1990 and 2022 in rural areas where environmental asbestos exposure is common. The epidemiologic and clinical characteristics of the patients were recorded. The predictive variables among the findings were determined using logistic regression analysis. To calculate the relative risk of lung cancer associated with asbestos exposure, we designated the four districts with asbestos in the soil samples as asbestos-exposed zones, and two other districts without asbestos in the soil samples as control zones.

Results: The mean age of the patients was 62.82±9.48 (21-92) years, and 89.6% were male. Overall, 51.0% of patients had a history of environmental asbestos exposure, 57.7% were active smokers and 32.1% were former smokers, 16.2% had an occupational risk of lung cancer. Radiologic evidence of asbestos exposure was found in 445 (12.9%) of the patients with asbestos exposure. The most common histopathological subtypes were squamous cell carcinoma, adenocarcinoma and small cell carcinoma (37.2%, 28.7% and 18.6%, respectively). A total of 3,344 (51.9%) of the patients were in stage IV. The survival time of patients with asbestos exposure was longer than that of patients without asbestos exposure (9.00±0.21 and 8.00±0.21 months, respectively; p=0.017). The determining variables for lung cancer patients exposed to asbestos are advanced age (p<0.001), male gender (p<0.001), occupational risk (p<0.001), non-smoking (p<0.001) and early stage of disease (p=0.034). In the asbestos-exposed zones, 629 lung cancer cases (559 males and 70 females) were detected. There were 46 lung cancer cases (44 males and 2 females) in the control zones. Thus, the relative risk of lung cancer was 4.34 (95%CI: 3.71-5.08) times higher in the asbestos-exposed zones than in the control zones. No mesothelioma diagnoses were reported in the control zones but there were 235 mesothelioma diagnoses in the asbestos- contaminated zones. The risk of lung cancer versus mesothelioma was 2.68 (95% CI: 2.48-2.89) times higher in the asbestos-exposed zones.

Conclusions: Environmental asbestos exposure is able to increase the risk of lung cancer. The relative risk values are significant. Since rural residents with environmental asbestos exposure in Turkey are part of well-monitored cohorts, they represent a useful group for future studies. It is unlikely that we will be able to prevent environmental asbestos exposure completely, we must increase our efforts to stop smoking especially in asbestos-exposed groups and include people exposed to environmental asbestos in screening programs.

EP.01D.06 Radon Exposure in Colombian Never-Smoker Non-Small Cell Lung Cancer Patients. A Pilot Study

W. Mantilla[1], A. Ruano-Ravina[2], M. Borras-Osorio[3], I. Munevar[3], L. Viola[1], J. Zuluaga[1], L. Rojas[1], A.F. Cardona[1], L.J. Tellez[1], [1]Luis Carlos Sarmiento Angulo Cancer Treatment and Research Center – CTIC, Bogota/CO ,[2]University of Santiago de Compostela, Santiago de Compostela/ES ,[3]Fundación Cardioinfantil-Instituto de Cardiología, Bogota/CO

Introduction: Lung cancer (LC) is the leading cause of cancer-related death globally, with 1.8 million deaths estimated in 2022. In Colombia, up to 74% of patients with LC are diagnosed with stage IV which negatively impacts survival, with 6,000 estimated deaths in 2022. The most critical strategy for reducing LC is the reduction of tobacco exposure; however, up to 38% of LC cases are not related to tobacco. Among other risk factors different from tobacco smoke; indoor radon, a radioactive gas found naturally in closed spaces, stands out and could be the most important one. In Latin America, information on the influence of radon on the incidence of LC is scarce. This study aims to establish the prevalence of Radon exposure in Colombian never-smoker LC patients

Methods: This is a Pilot study, Adult patients with de novo NSCLC diagnosis (<6 mo) were included. Past smokers (≥100 cigarettes in life or ≥1 cigarette daily for 6 mo) or patients with a change in place of living in the last 10 years were excluded. Sociodemographics, clinical, and molecular information were obtained and included in an eCRF using REDCap®, Radon measurement was done using a DTPA-type detector (Alfa-track). The detector was located in the patient's home, (60-140 cm from the floor at the point of least ventilation of the space to be measured), for 90 days, Subsequently an automated count quantification was carried out using the Radosys® system at a certified lab (Universidad Santiago de Compostella Radon Lab). The Radon levels were reported in Bq/m3, using the average value observed during the measurement period (The threshold was 20 Bq/m3)

Results: Between February 2022 to May 2023, 30 patients were included in the study, 86.7% were women, 73% had stage IV disease at inclusion, 53% had an identified driver mutation, with EGFR being the most frequent (62,5%) followed by ALK (31.3%). The mean Radon levels were 25.6 Bq/m3 (5 - 48). No patient had Radon levels ≥100 Bq/m3.

Conclusions: In this pilot study, we didn´t find high radon exposure among never-smoker NSCLC patients. Two other studies on indoor Radon concentrations have been done in Colombia, with only one demonstrating high radon levels (≥100 Bq/m3) in Bogotá. These differences could be explained by the type of house, rainfall adjustment, or underlying rock composition in our study. It´s important to increase the sample size for a definitive conclusion and to explore other risk factors in non-smoker patients as the quality of air or occupation, among others.

EP.01E.01 Understanding the Choices of Those who Smoke Post-cancer Diagnosis

A. Pemmaraju[1,2], M. Neumann[2], S. Rajan[2], N. Seetharamu[2], [1]Great Neck South High School, Lake Success/NY/USA ,[2]Northwell, New Hyde Park/NY/USA

Introduction: Continued smoking after a cancer diagnosis leads to worse morbidity and mortality. Unfortunately, smoking prevalence remains high amongst cancer patients and survivors. Interventions to improve cessation rates amongst cancer patients have been largely unsuccessful. A starting point to designing an optimal cessation program is to understand the demographics of and circumstances that these patients are exposed to. We developed a questionnaire intended to assess patients' demographics, tobacco smoking history, motivation to quit, and their social network dynamics.

Methods: We designed a three-page questionnaire to gain more information about a patient's past and current smoking history, level of nicotine dependence, assessment of their motivation to quit smoking, and their social network. Inclusion criteria included patients who have been diagnosed with lung or head and neck cancer and reported tobacco use at some point in their lifetime. For this abstract, patients who reported continued tobacco use after cancer diagnosis were included. Since these questionnaires were anonymous, Northwell IRB granted an exempt status. Questionnaires completed between June 2022 and December 2023 were included in the analysis. Descriptive statistics was used to analyze and report results.

Results: Of the 140 respondants, 72 patients reoported continued smoking after cancer diagnosis. The mean age of this cohort was 67 years (SD 11.02), and 42 (58.3%) were males. 52 (72%) patients had lung cancer and 20 (28%) head and neck cancer. The majority (47, 65.3%) were diagnosed within six months, with 15 (20.8%) having had the diagnosis more than a year prior. Family dynamics played a significant role, with 31 (43%) being married individuals and 49 (68%) reporting living with someone who smoked for a median of 27.5 years. Educational levels varied, but 61 patients (84.7%) had completed high school or above. The median age of starting smoking was 16 years. 17 (23.6%) patients had successfully quit for a period of time but relapsed. Only 38 (52.8%) patients reported increased motivation post-diagnosis, while others experienced decreased or no change and only 5 (6.9%) patients were enrolled in a tobacco cessation program at the time of survey. Barriers to quitting included stress, a desire to maintain control, and skepticism about the direct link between smoking and cancer.

Conclusions: We believe that this study provides valuable insights into the characteristics and motivations of individuals who continue smoking after a cancer diagnosis. The cohort's diversity in age, marital status, cancer type, and time since diagnosis underscores the need for personalized support strategies. Family and social network are huge influences that should be taken into account in designing cessation programs.

EP.02A.01 Gender-Specific Onset Age Distribution Among Different Driver Mutations in Lung Cancer

H. Wang, S. Xiong, W. Ye, F. Li, C. Li, J. Li, J. He, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Different driver gene mutations play a crucial role in the pathogenesis of lung cancer, and their distribution across ages and genders may exhibit distinct characteristics, current study remains insufficient yet.

Methods: We employed next-generation sequencing to analyze genetic testing results on lung cancer patients from the First Affiliated Hospital of Guangzhou Medical University, including point mutations and gene fusions. Based on their genomic profiles, we categorized patients into 11 distinct gene subtypes, including EGFR, KRAS, ALk, Wild-type and so on. Furthermore, we investigated the distribution characteristics of different types of gene mutations across age and genders as well as age at disease onset.

Results: Cumulatively, 8705 patients were included in our study cohort. Across various age brackets, the distribution of EGFR mutations exhibited consistent rates among males (P=0.927). While in females, a higher enrichment of EGFR mutations was identified (P<0.01), particularly evident in L858R mutations showing significant age correlation(P<0.001). Conversely, 19del mutations in females exhibit a declining trend around the age of 65. The enrichment of Kras mutations in males increases with age(P<0.001), whereas the trend is less pronounced in females(P=0.07). Additionally, the frequency of male wild-type patients gradually increases with age(P<0.05), while in females, it decreases gradually (P<0.05).Regarding the age of onset, Alk (Mean age: 53.96, 95% CI: 52.88 to 55.04), Ros1 (Mean age: 57.47, 95% CI: 56.11 to 58.83), and ERBB2 (Mean age: 55.64, 95% CI: 54.31 to 56.98) were associated with earlier onset compared to the mean age (Mean age: 59.1, 95% CI: 58.86 to 59.34), all P<0.05. Conversely, mutations in RAS family genes (KRAS, NRAS, BRAF, MET) are associated with delayed onset (P<0.01). EGFR 19del mutation was associated with earlier onset in males (Mean age: 57.95 vs. 60.47, 95% CI: [57.18, 58.72] vs. [60.16, 60.78], P<0.01), while EGFR L858R mutations tended to occur later in females (Mean age: 60.66 vs. 57.35, 95% CI: [57.35, 60.09] vs. [56.98, 57.72], P<0.01). Braf mutations are associated with earlier onset in females and delayed onset in males(P<0.01). ERBB2 and ALK were associated with earlier onset in both males and females (P<0.05), while NRAS, KRAS, MET, and wild-type were associated with delayed onset in both genders (P<0.05). The co-mutation of TP53 had minimal impact on the age of onset (Mean age: 58.39 vs. 60.43, 95% CI: [58.09, 58.70] vs. [60.04, 60.81], P=0.25), but ERBB2 co-mutation with tp53 may delay the age of onset in both males and females, meanwhile TP53 co-mutation on the age of onset in ALK patients shows opposite effects between males and females. All in all, the impact of TP53 co-mutation exerting a protective effect in males, not in females.

Conclusions: Different gene subtypes exhibit distinct characteristics of onset age across different gender, Gender and age exert significant and varying influences on lung cancer patients with different gene types.

Keywords: NSCLC, onset age, genetic mutations

EP.02A TUMOR BIOLOGY - PRECLINICAL BIOLOGY - EARLY STAGE DISEASE/STEM CELLS, SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.02A.02 The Stroma Cell Function in the Border Region Between Lung Cancer and Normal Lung

G. Kamimura, M. Aoki, S. Morizono, T. Umehara, A.H. Takeda, K. Maeda, T. Nagata, K. Ueda

Kagoshima University, Kagoshima/JP

Introduction: Stromal cells in the intratumoral microenvironment of lung cancer are important for lung cancer progression. Stromal cells in the normal lungs are stimulated by lung cancer and undergo phenotypic changes. The biological characteristics of stoma cells in lung cancer and normal lung tissues have been previously reported. This time, we defined the margin between lung cancer tissue and normal lung tissue as the "border" and aimed to clarify the biological characteristics of the stromal cells in "border."

Methods: Tissues in lung cancer, normal lung, and border were collected from the excised lungs of three female non-smokers who underwent curative lobectomy for lung adenocarcinoma. By cutting the tissues into small pieces and culturing them in vitro, we observed differences in the morphology and gene expression of stromal cells extending from the tissue pieces. We also used a cytokine array to search for differences in cytokine expression in the second-passage culture supernatants of each stromal cell.

Results: In each cultured tissue sample, Vimenntin-positive and Cytokeratin-negative stromal cells spread and proliferated around the tissue. Morphologically, the stromal cells in the lung cancer region had a thick cytoplasm, while those in the normal lung region had a thin cytoplasm, and the stromal cells in the border region had an intermediate cytoplasm. Polymerase chain reaction showed that the expression of the COL11A1 gene in stromal cells in the lung cancer region was higher than that in the normal lung region, and the expression in the border region was similar to or slightly lower than that in the normal lung region. According to the cytokine array, there were differences in cytokine expression between the lung cancer, normal lung, and border regions. The expression of GM-CSF in the culture medium was highest in the border region, followed by the lung cancer region and then the normal lung region. In addition, the expression of uPA in the culture medium was more than three times higher in the border region and normal lung region than in the lung cancer region.

Conclusions: Stroma cells cultured individually from lung cancer, normal lung, and border regions showed differences in morphology and genes as well as in cytokine expression in the culture medium. It has become clear that there is a "border" between lung cancer and normal lung regions and that stromal cells in this area are involved in the progression and proliferation of lung cancer. Whether stromal cells in this border region contribute to the prevention or promotion of tumor progression depends on cancer histology.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.02B.01 PIK3C2A Potentiates Angiogenesis of Non-Small Cell Lung Cancer by Regulating ADRB2/VEGFA Signaling Pathway

T. Wang[1,2], H. Ge[1], S. Bu[1], X. Wang[1], C. Yang[1], X. Zheng[1], Y. Liu[3], X. Dong[2], [1]The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou/CN ,[2]The Warren Alpert Medical School of Brown University, Providence/RI/USA ,[3]The Affiliated Hospital of Nantong University, Nantong/CN

Introduction: Non-small cell lung cancer (NSCLC) is a aggressive tumor with a unfavorable prognosis, and the potential mechanisms underlying tumor progression is not yet clearly. There is increasing evidence to support that β2AR is responsible for cancer growth, angiogenesis and metastasis in NSCLC. However, the molecular mechanism underlying the cancer angiogenesis of β2AR in NSCLC hasn't been fully clarified.

Methods: We screened proteins that interact with β2AR proteins and are significantly associated with NSCLC angiogenesis by using the TCGA database and STRING database. Through CO-IP and IF experiments, we further verified the proteins that interacted and co-located with β2AR in NSCLC. The interaction between PIK3C2A and β2AR and the effect on NSCLC angiogenesis were explored through WB, PCR, IF and angiogenesis experiments.

Results: We revealed a novel regulation mechanism by which ADRB2 and PIK3C2A cooperated to promote NSCLC angiogenesis. PIK3C2A interacts with β2AR, and its expression is positively correlated with ADRB2 expression in NSCLC. Knocking down the expression of PIK3C2A can also reduce the expression of vascular endothelial growth factor A (VEGFA). Loss-of-function experiments demonstrate that PIK3C2A potentiates HUVEC proliferation, migration and tube formation. Immunohistochemistry (IHC) analysis confirmed that PIK3C2A expression was positively correlated with microvessel density (MVD) expression in patient specimens.

Conclusions: This study not only sheds light on the emerging roles of PIK3C2A/β2AR interaction in the progression of NSCLC, but also offer a new strategy for the inhibition of angiogenesis in NSCLC.

Keywords: PIK3C2A, Tumor angiogenesis, β2AR

EP.02B.02 The Functional Roles of Intergenic ALK Fusions in NSCLC

X. Zhai, M. Wang, G. Che, C. Chen, West China Hospital, Sichuan University, Chengdu/CN

Introduction: ALK fusions are frequent in non-small cell lung cancer (NSCLC). The classic EML4-ALK fusions and several others have been shown to be drivers and therapeutic targets of NSCLC. However, about 15% of ALK fusions, including intergenic fusions, are variants and their biological functions and their response to ALK inhibitors remains unclear. Previously, we have discovered several new variant ALK fusions. Among them was the intergenic fusion LOC388942-ALK (LA). The patient responded but rapidly relapsed to crizotinib treatment.

Methods: To investigate the role of LA in the development and progression of NSCLC, the CRISPR-Cas9 gene editing has been applied to generate LA fusions in both NSCLC cell lines and primary lung organoids. Then these cells and organoids were transplanted into recipient mice. The tumorigenesis functions of LA were measured by cell proliferation and tumor growth in vitro and in vivo, respectively. Their response to ALK inhibitors were determined with these in vitro and in vivo models. RNA-seq was performed to investigate the molecular mechanism of LA in NSCLC.

Results: The LA fusion was successfully generated in NSCLC cell lines and primary lung organoids, verified by PCR and sanger sequencing. LA fusions led to increased levels of ALK proteins. Tumors with the LA fusion grew significantly faster than the control ones in mice. And they were resistant to ALK inhibitors. Transcriptomics analyses showed that LA significantly upregulated the EMT and TNF pathways.

Conclusions: Our study validated LA as a driver of NSCLC, which might be less responsive to ALK inhibitors. Thus, LA should be included for future NSCLC diagnosis and better treatments for these patients should be developed.

Keywords: NSCLC, Variant ALK fusions, Tumorigenesis

EP.02B.03 MALAT1 And NEAT1 Contribute to Adaptive Mutability in the Transition from Drug Tolerance to Drug Resistance in Lung Cancer

W.J.H. Davis[1,2], C. Drummond[1,2], G. Gimenez[1], E. Rodger[1,2], A. Chatterjee[1,2], G. Reid[1,2], [1]University of Otago, Dunedin/NZ ,[2]Maurice Wilkins Centre for Molecular Bio-Discovery, Auckland/NZ

Introduction: Responses to targeted therapies are initially dramatic in patients with lung adenocarcinomas that harbour actionable mutations in EGFR or KRAS, but relapse is almost inevitable. Drug tolerant persisters (DTPs) contribute to the emergence of acquired resistance via adaptive mutability and remain a difficult clinical challenge. Long non-coding RNAs (lncRNAs) are known to contribute to several characteristics of DTPs, however their contribution to drug tolerance is unknown. Here, we investigate the role of lncRNAs in the emergence of DTPs and how lncRNAs may contribute to adaptive mutability, a process that leads to the accumulation of DNA damage and a heightened rate of acquired resistance in DTPs.

Methods: EGFR-mutant PC-9 and KRASG12C-mutant H358 cells were treated with >IC90 concentrations of osimertinib or sotorasib respectively, for 3, 7 and 19 days to induce drug tolerance. Bulk RNA-sequencing was then performed to determine DTP phenotypic changes and to identify differentially expressed lncRNAs, with changes confirmed via RT-qPCR for coding and non-coding genes, and western blotting for protein coding genes. Antisense oligonucleotides (ASOs) were used to knock down MALAT1 and NEAT1 in the presence or absence of relevant targeted therapy, and the effects of these knockdowns on the DTP phenotype was determined by proliferation assays, bulk RNA-sequencing, RT-qPCR and western blotting. Plasmid-based reporters were used to measure the functional capacity of DNA repair mechanisms to investigate the contribution of these lncRNAs to adaptive mutability. Finally, resistance assays were used to measure the emergence of acquired resistance.

Results: DTPs from both PC-9 and H358 cells expressed increased levels of the stem cell factors OCT3/4 and NANOG as well as previously described markers of minimal residual disease in patients with lung cancers, such as AQP4, SFTPC and SFTPD compared to solvent controls. DNA damage repair pathways, such as DNA mismatch repair and homologous recombination were downregulated, while levels of error-prone polymerases were also increased in the DTPs from both cell lines. Several lncRNAs were differentially expressed in DTPs compared to solvent controls, including MALAT1, NEAT1, and UFC1. MALAT1 and NEAT1 are reported to be involved in stem cycle gene regulation as well as in drug resistance, and were selected for further investigation. Combining ASO-mediated knockdown of MALAT1 and NEAT1 with targeted therapeutics for 3 and 7 days in our models also partially reversed changes to DNA repair pathways, suggesting that these lncRNAs contribute to drug resistance by inducing adaptive mutability. In proliferation assays, MALAT1 knockdown reduced the number of drug-tolerant cells in both PC9 and H358 cell lines and resulted in lower rates of late emerging (> 2 weeks) adaptive drug resistance measured by resistance assays.

Conclusions: These results represent early links between lncRNAs, drug tolerance and drug resistance in lung adenocarcinomas. This work has identified the lncRNAs MALAT1 and NEAT1 as potentially important molecules implicated in the development of acquired drug resistance that emerges from drug tolerance. Further studies are ongoing to determine whether modulating MALAT1 represents a potential approach to augment therapy in patients with lung adenocarcinomas undergoing treatment with targeted therapeutics.

Introduction: Lung Squamous Cell Carcinoma (LUSC) is associated with significant morbidity and mortality. However, few studies have focused on programmed cell death-related genes (PCDRGs) in LUSC. Our aim was to investigate the prognostic significance of PCDRGs in LUSC using bioinformatics methods and construct a prognosis risk score model based on these genes. Additionally, our research sought to identify potential pharmaceutical inhibitors for effective alternative therapies and provided a novel theoretical basis for target and mechanism discovery in the clinical treatment of LUSC.

Methods: A predictive model named CDS was constructed by using TCGA, GSE37745, GSE157010, and GSE157009 datasets and combining with 10 different machine learning methods. To explore the correlation of PCDRGs with the tumor immune microenvironmen,Single-cell analysis was mainly employed.And RT-qPCR was used to validate the expression of PCDRGs. The top six drugs with favorable binding affinity to SLC39A8 was identified by virtual screening of 1615 FDA-approved drugs from the ZINC database via vina. Molecular interactions and binding conformations were visualized using PyMOL and MOE.

Results: The StepCox[forward] + RSF approach yielded the most effective prognostic model for PCDRGs. Patients in the low PCDRGs group exhibited improved prognosis, enhanced immune activity, immune infiltration, and tended toward an immunothermal phenotype with potential immunotherapy response. RT-qPCR confirmed abnormal expression of SLC39A8 RNAs in LUSC, with high expression correlating with poor prognosis. Additionally, small molecule inhibitors targeting SLC39A8 were identified through screening.

Conclusions: This study successfully developed a novel PCDRGs model for LUSC, and this model can be used as an important indicator for predicting the prognosis of LUSC patients and assessing their response to immunotherapy. Identifiing six active compounds with the potential to inhibit the expression of SLC39A8, which may play a role in the treatment and prevention of LUSC.

EP.02B.05 XBP1s-Related Super-Enhancers Suppresses Cuproptosis via Temporally Transcription Regulation in Lung Adenocarcinoma

Y. Gu, J. Wang, Jiangsu province hospital, Nanjing/CN

Introduction: The role of copper in tumor progression is thought to be a double-edged sword. Moderate levels of copper promote tumor progression and excess copper leads to a form of programmed cell death-cuproptosis. However, the relationship between Lung Adenocarcinoma (LUAD) and cuproptosis has not been studied.

Methods: Single-cell sequencing analysis and copper colorimetric assay identified higher pathological grade of LUAD simultaneous associated with higher copper accumulation and XBP1 expression. Then we utilized 4D-DIA proteomics to identify XBP1 promotes the degradation of LIPT1. CUT&Tag-seq and LC-MS/MS allowed us to discover that the intermediate regulatory molecules ISG15 and UBR4. Chromosome conformation capture (3C) experiment showed that XBP1s-related super-enhancers affect on the frequency of ISG15 promoter-enhancer interactions in different copper environments.

Results: Single-cell sequencing analysis and copper colorimetric assay identified higher pathological grade of LUAD simultaneous accompanied by higher copper accumulation and expression of XBP1. In addition, we confirmed that overexpression of the spliced form of XBP1 (XBP1s) negatively regulates the protein level of LIPT1 to inhibit copper ionophore induced LUAD cell death. In mouse xenograft models, co-administration of XBP1 inhibitors and copper ionophore significantly reduced tumor volume and growth rate. Additionally, XBP1s can undergo phase separation and form super-enhancers in the nucleus. This phenomenon was more intense in high copper environments and was closely related to the transcriptional regulation of XBP1s target genes. In a low copper environment, the XBP1s-related super-enhancers mainly promote the transcription of ISG15, and ISG15 interacts with LIPT1 to increase its stability. However, in a high copper environment, XBP1s reduces ISG15 transcription and increases UBR4 transcription. UBR4 can enhance the ubiquitination level of LIPT1 and ultimately leading to its degradation in the cytoplasm. Broadly, XBP1s-related super-enhancers selectively promote target gene transcription in a environment-dependent manner to protect cells from cuproptosis. On this basis, combination of copper ionophore and XBP1 inhibitors may provide a new insight into the early treatment of invasive LUAD.

Conclusions: Our study sheds light on the molecular mechanism by which XBP1s affect the cuproptosis pathway through the formation of super-enhancers in LUAD. In vivo experiment suggested the potential clinical value of the combined use of XBP1 inhibitors and copper ionophore.

EP.02B.06 Analysis on the Correlation Between RUNX3 Mislocalization and Epigenetic Parameters in Non-Small Cell Lung Cancer

W. Liu[1,2], C. Huang[1,3], Y. Shi[4,5], J. Lu[4], X. Chen[1,2,5], [1]Graduate School of Fujian Medical University, Fuzhou, Fujian Province/CN ,[2]Department of Thoracic Surgery, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, Fujian Province/CN ,[3]Laboratory of Immuno-Oncology, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, Fujian Province/CN ,[4]Department of Pathology, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, Fujian Province/CN ,[5]Interdisciplinary Institute of Medical Engineering of Fuzhou University, Fuzhou, Fujian Province/CN

Introduction: Our previous study demonstrated different manners of RUNX3 expression in NSCLC, i.e., negative, nuclear, cytoplastic and whole-cell RUNX3 localization, and RUNX3 non-nuclear expression or mislocalization in NSCLC was associated with postoperative metastasis. Current study was to investigate the possible underlying mechanism of RUNX3 non-nuclear expression or mislocalization in terms of epigenetic aspects.

Methods: 205 NSCLC and 5 normal lung tissue were built into tissue microarrays (TMA) and detected of epigenetic parameters like H3K27me3, H2AK119U1, EZH2, DNMT1/3b, TGF-β and c-myc. Western blot was used to evaluate the protein level of RUNX3, H3K27me3, DNMT1/3b and TGF-β in different expression patterns. Methylation level at RUNX3 promoter was assessed via pyrosequencing.

Results: Among NSCLC with negative, nuclear, cytoplastic and whole-cell RUNX3 expression, epigenetic markers like H3K27me3, DNMT1/3b, H2AK119U1, EZH2 and c-myc differed significantly (all P<0.05). Non-nuclear RUNX3 localization was correlated with low H3K27me3/EZH2/H2AK119U1/c-myc/DNMT3b expression (all P<0.05). Higher methylation level on CpG1 locus affected 4/2(nuclear/non-nuclear) distribution patterns (P<0.05). Higher methylation level on CpG1/2 resulted in low RUNX3 expression and higher probability of local relapse in postoperative patients (both P<0.05).

Conclusions: Conclusively, epigenetic parameters might partially result in RUNX3 mislocalization and RUNX3 promoter hypermethylation was closely correlated with local relapse in NSCLC.

EP.02B.07 HFE as a Novel Gene Associated with Primary Lung Cancer Risk:A Mendelian Randomization and Bioinformatics Study

X. Liu[1], X. Qiu[2], X. Li[2], Q. Cai[1], L. Lin[1], L. Huang[1], R. Zeng[3], J. Li[1], H. Liu[1], J. He[1], W. Liang[1], [1]The First Affiliated Hospital of Guangzhou Medical University, State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/CN ,[2]First Clinical School, Guangzhou Medical University, Guangzhou/CN ,[3]Nanshan School, Guangzhou Medical University, Guangzhou/CN

Introduction: Lung cancer ranks as the foremost cause of cancer-related mortality worldwide. Despite this, the association between serum iron levels and lung cancer risk remains ambiguous. This investigation aims to elucidate the potential causal link between serum iron status and primary lung cancer risk using Mendelian randomization techniques. Additionally, it seeks to delineate the involvement of the HFE gene in lung cancer etiology through bioinformatics analyses.

Methods: Leveraging genome-wide association study data from the UK Biobank, Mendelian randomization analysis was conducted, with lung cancer as the outcome variable and serum iron, ferritin, transferrin, and transferrin saturation as exposure variables. Statistical analysis utilized MR-base software and R packages, employing a fixed-effects IVW model to evaluate genetic causality, and MR-Egger and weighted median methods for robustness testing. Furthermore, a pivotal single nucleotide polymorphism (SNP, rs1800562) linked to the HFE gene was identified, exhibiting heightened expression in both lung adenocarcinoma and squamous cell carcinoma. The investigation encompassed the exploration of HFE's associations with other proteins and functional roles, employing techniques such as protein-protein interaction networks and enrichment analysis. Additionally, HFE expression in immune cells of non-small cell lung cancer (NSCLC) was analyzed using the immune cell single-cell database and The Tumor Immune Single Cell Hub 2 (TISCH2), alongside an exploration of the correlation between HFE and various phenotypes and drug targets.

Results: Elevated serum iron, ferritin, and transferrin saturation levels were correlated with a diminished risk of squamous cell lung cancer. Notably, a major SNP (rs1800562) pertaining to the HFE gene was identified through MR analysis, demonstrating heightened expression levels in both lung adenocarcinoma and squamous cell carcinoma. High HFE expression was associated with poorer disease-specific survival in lung cancer patients. Moreover, HFE exhibited negative correlations with various immune cell types and positive correlations with tumor-infiltrating lymphocytes (TILs) abundance in squamous cell lung cancer. Two potential interacting drugs with HFE were uncovered via drug target analysis. Gene set enrichment analysis and protein-protein interaction network analysis unveiled numerous potential biological functions and mechanisms of HFE in lung cancer.

Conclusions: This study furnishes evidence of a causal link between serum iron status and squamous cell lung cancer risk utilizing Mendelian randomization techniques. Moreover, it sheds light on the putative involvement of the HFE gene in lung cancer pathogenesis. HFE may modulate lung cancer onset and progression through its impact on immune cell infiltration and regulation of iron metabolism. These insights present novel molecular targets and biological mechanisms for lung cancer prevention and treatment. Further research is warranted to validate these findings and explore the clinical utility of HFE in lung cancer management.

EP.02B.08 Interrogating Sexual Dimorphism in Lung Cell Biology and Tumourigenesis for Cancer Treatment and Prevention in Never & Smokers

R. Joyce[1], Y. Chen[2], X. Dong[2], K. Sutherland[2], [1]Wehi & The University of Melbourne, Parkville/AU ,[2]WEHI, Parkville/AU

Introduction: The incidence of lung cancer in never-smokers (LCINS) is rising, and the majority of LCINS patients are female. Further, lung cancer in young people (under 54 years of age) is more common among females than males, and this increased incidence is unattributable to smoking. Although sex-based differences in LCINS incidence are evident, sexual dimorphism in lung cell biology and how it shapes lung tumourigenesis in non-smokers is largely unexplored. We interrogated published patient genomic datasets to determine if there are sex-based differences in the development of invasive mucinous lung adenocarcinoma (IMA), a subtype of lung cancer which predominantly develops in non-smoking, female people, at the transcriptional level.

Methods: Gene expression analysis of male and female IMA tumours and adjacent normal lung tissue was performed. Transcriptomic data derived from normal healthy lung cell subsets from male and female patients was also interrogated.

Results: Unique transcriptional programs are activated upon IMA development in female versus male patients.

Conclusions: These findings indicate that patient sex may shape the mechanisms underpinning IMA development at the molecular level, with implications for the design of targeted, preventative therapies for IMA and LCINS more broadly.

Keywords: Sex, IMA, transcriptomic

EP.02C TUMOR BIOLOGY - PRECLINICAL BIOLOGY - IMMUNE MODULATION

EP.02C.01 Investigating the Role of VISTA Immune Checkpoint in Human and Murine Mesothelioma Cell Lines

A. Sehgal, B.A. Jacobson, H. Zhang, R.A. Kratzke, M. Patel, K. Lan, J. Lan, J. Allred, University of Minnesota, Minneapolis/MN/USA

Introduction: V-domain Ig suppressor of T cell activation (VISTA) has emerged as a key immune checkpoint regulator with implications in tumor immunity. VISTA expression on T cells normally exerts inhibitory effects on T cell proliferation. The role of VISTA expression on tumors is less clear, though it has been shown to inhibit tumor specific T cell activity as well in some models. Mesothelioma (MM) cells highly express VISTA on the cell surface though to date its role in MM biology remains unclear.PURPOSE: In this study, we aimed to understand the role of VISTA in MM biology - both in terms of what signaling pathways regulate VISTA expression as well as the effects of VISTA silencing on MM cell biology. . We hypothesized that VISTA expression is regulated by MAPK and Akt signaling pathways that are constitutively active in MM cells and that inhibition of these signaling pathways could lead to translational strategies in combination with immune checkpoint blockade. In this study, we aimed to understand the role of VISTA in MM biology - both in terms of what signaling pathways regulate VISTA expression as well as the effects of VISTA silencing on MM cell biology. . We hypothesized that VISTA expression is regulated by MAPK and Akt signaling pathways that are constitutively active in MM cells and that inhibition of these signaling pathways could lead to translational strategies in combination with immune checkpoint blockade.

Methods: Western blot analysis and flow cytometry was used to assess VISTA expression in human (2373 and HAY) and murine (40L and AB12) mesothelioma cell lines. Additionally, siRNA transfection experiments were conducted in vitro to assess the effect of VISTA knockdown on key signaling pathways involved in cell proliferation. MEK inhibitor, trametinib was used to assess the effect of MAPK inhibition on VISTA expression. Human mesothelioma cells (2373) were treated with 50 μM trametinib, 500 μM trametinib, and DMSO as a control for 24 hours. Western blot analysis was then utilized to assess the impact of trametinib treatment on VISTA, phospho-ERK1/2, total ERK1/2, phospho-AKT, and total AKT levels.

Results: Our initial western blot analysis revealed the presence of VISTA expression in both human and murine mesothelioma cells, highlighting its relevance in this malignancy. Furthermore, siRNA transfection experiments demonstrated successful VISTA suppression in human and murine mesothelioma cell lines. In HAY cells, VISTA knockdown resulted in decreased ERK1/2 and AKT phosphorylation. These results suggest that VISTA signaling may impact upon downstream signaling pathways. Trametinib treatment of H2373 cells resulted in inhibition of ERK1/2 phosphorylation as expected, however, led to increased Akt phosphorylation and marked increase in VISTA expression.

Conclusions: These data would suggest that there is interaction between VISTA expression and ERK/Akt signaling pathways. The functional significance of these interactions need to be further elucidated. Inhibition of MEK/ERK signaling pathway leads to enhanced VISTA expression and thus in mesothelioma, MEK inhibition is not likely to have a VISTA-mediated immunotherapy effect.

Keywords: mesothelioma, VISTA, MEK

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.02C.02 Stearic Acid but Not Palmitic Acid Induces Immunomodulatory Changes that Initiate Pro-Neoplastic Processes in Lung Epithelium

M.N. Daavis[1], A. Roy[1], S. Weinberg[2], F. Weinberg[1], [1]University of Illinois at Chicago, Chicago/IL/USA ,[2]Northwestern University, Chicago/IL/USA

Introduction: Lung cancer (LC) detection and survival rates have steadily improved in part due to LC screening (LCS). However, a substantial number of patients need to be screened in order to detect one LC. Improving our understanding of the underlying biology of individuals who go on to develop LC is paramount.

Recent research indicates that changes in both the immune and metabolic microenvironments are critical factors for tumorigenesis. We recently demonstrated that in patients with resectable, early-stage LC, elevated levels of stearic acid (SA) and macrophage inflammatory protein 1β (MIP-1β/CCL4) were predictive of tumor-affected lung lobes. This suggests that SA might promote LC tumorigenesis via macrophage-dependent immunomodulation.

Palmitic acid (PA), the most abundant fatty acid (FA) in the human body, is structurally very similar to SA. Both PA and SA are saturated long-chain FAs, differing only in the number of carbons present. Both PA and SA are present in the lung microenvironment, with PA found at a higher concentration, and both are known to modulate innate immunity through macrophage activity. Based on our previous findings that SA is enriched in the serum of early stage LC patients, we hypothesize that SA, and not PA, is required for the immunometabolic changes that lead to the development of LC.

Methods: THP-1 monocytic cells were treated with PMA to induce differentiation into dedifferentiated macrophages. They were then stimulated with SA or PA. After 24hr both the THP-1 macrophages and the conditioned media (CM) were harvested. Expression levels of markers of macrophage differentiation were analyzed by quantitative PCR. The effect of the FA stimulated macrophage CM on cell proliferation was tested by real time IncuCyte live cell analysis using LC (H358, H2122) and immortalized non-cancerous lung epithelial (BEAS2B) cell lines. The LC and non-cancerous cell lines were also treated with SA and PA separately, and proliferation was measured by MTT assay. The effect of FA-stimulated macrophage CM on neoplastic transformation was studied using anchorage independent growth assays.

Results: THP-1 macrophages treated with SA demonstrated a pronounced upregulation of cellular markers, like Arg1 and CD206, which are specific for immunogenic macrophages, and the CM derived from these cells induced proliferation of BEAS2B cells. These effects were not observed in PA-stimulated macrophages or with the CM derived from them. Cell lines treated directly with either SA or PA did not demonstrate increased proliferation when assessed by MTT, indicating that the proliferation observed is macrophage-dependent.

Conclusions: SA promotes transformation of lung epithelial cells into a more proliferative precancerous or cancerous phenotype through an immunomodulatory pathway. However, PA does not demonstrate similar effects. Whether the observed effects are truly SA-specific or the result of FA enrichment will be the basis for future experiments. In the future, understanding the biology of FA-induced inflammation in LC may lead to the development of novel therapeutics which aim to attenuate pro-tumorigenic inflammation. Additionally, SA may be exploited as a potential biomarker of LC development, leading to novel LC detection assays and improved risk prediction modeling in high risk LCS individuals.

Keywords: tumor initiation, fatty acid, macrophage

EP.02D.01 Macrophage Migration Inhibitory Factor Promotes Invasion and Epithelial to Mesenchymal Transition in Lung Adenocarcinoma

R.R. Hudlikar, H. Wang, S.K. Gara, M.R. Zhang, D.S. Schrump, S.R. Carr, National Cancer Institute, Bethesda/MD/USA

Introduction: Interventions aimed at targeting components of the tumor microenvironment (TME) have shown promise for many solid tumors yet only marginally tested for in lung adenocarcinoma (LUAD). Earlier we identified macrophage migration inhibitory factor (MIF) as an important gene associated with recurrence free survival (RFS) in LUAD. However, limited knowledge exists regarding its mechanism of action in the TME suggesting the association of MIF with RFS. Herein we investigated the role of altered MIF expression on migration, invasion, and epithelial to mesenchymal transition (EMT) in LUAD.

Methods: Gene Expression Omnibus (GEO) transcriptomic datasets from European and North American patients with LUAD were analyzed for MIF expression and correlated with recurrence. MIF expression was studied in Tissue Microarray (TMA) using immunohistochemistry and digital analysis (HALO). Immunofluorescence and immunoblotting techniques were used to evaluate MIF expression in a panel of LUAD and immortalized normal respiratory epithelial lines. MIF downregulation was induced either using Ibudilast (MIF inhibitor) or stable lentiviral transfection (shRNA) in A549 or H1975 LUAD cells, which exhibit elevated endogenous MIF. Cellular proliferation, invasion, migration, colony formation, and expression of EMT markers were assessed to elucidate effects from MIF downregulation. Further effect of downregulation of MIF on cisplatin sensitivity was also evaluated.

Results: GEO analysis demonstrated an association between elevated MIF and poor RFS in patients with LUAD. Immunohistochemical and HALO analysis of TMAs confirmed elevated MIF in LUAD compared to normal lung tissues. Downregulation of MIF significantly reduced cell proliferation; decreasing expression of phosphorylated Erk. Downregulation of MIF decreased invasion and migration with concomitant decreasing c-Jun phosphorylation by reducing the levels of MMP-2 and 9 but not MMP-1 or 3. The shRNA mediated inhibition of MIF increased the expression of TIMP-1 and 2 by regulating the levels of MMP-2 and 9 (Fig 1) and decreased N-cadherin and vimentin via modulation of snail/slug pathway, potentially promoting EMT in LUAD cells. An increased sensitivity to cisplatin was also observed with downregulation of MIF.

Conclusions: Our study demonstrated MIF promotes invasion and migration in LUAD by upregulating MMP-2 and MMP-9 via the c-Jun/slug/N-cadherin axis along with increased cisplatin resistance, which can be attenuated with a pharmacological MIF inhibitor. This opens a novel target that can potentially be leveraged in the treatment of LUAD.

EP.02E TUMOR BIOLOGY - PRECLINICAL BIOLOGY - NOVEL MODELS/NOVEL TECHNOLOGIES
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.02E.01 Development of Patient-Derived and Xenograft-Derived Organoids for Lung Adenocarcinoma Study

W. Luo, M. Xu, D. Pu, N. Wong, C.S-H. Ng, The Chinese University of Hong Kong, Hong Kong/HK

Introduction: Lung adenocarcinoma (LUAD) presents a significant global health challenge, characterized by complex genetic aberrations within tumors. However, the inherent differences between primary tumors and many in vitro models have hampered advancements in elucidating LUAD pathogenesis. Directly generated from human tissues, the LUAD organoids preserve the genetic, transcriptomic, and phenotypic traits of originating patient tumor. Our research aims to develop advanced preclinical models for future LUAD studies.

Methods: Written consent was obtained from enrolled LUAD patients. Fresh lung and LUAD cells were isolated from nontumoral lung and LUAD tissues. After being embedded in Matrigel, the lung and LUAD organoids were cultured according to different mediums shown in Table 1. Tumor cells were injected into NSG mice for the generation of patient-derived xenografts (PDX). In parallel, xenograft cells were also isolated from PDX and cultured into xenograft-derived organoids. A schematic diagram of tissue culture was presented in Figure 1A. Pathohistological analysis and next-generation sequencing were performed on established organoids and matched patient tissues for characterization.

Table 1: Overview of culture medium components for lung and LUAD organoids

Results: Morphologically, lung organoids exhibited cystic structures with a single-layer compartment, whereas LUAD organoids manifested as densely packed spheroids with significantly thickened walls (Figure 1B). The lung organoids recapitulated the phenotype feature with the expression of alveolar type II cell markers (SFTPC and SFTPB) and alveolar type I cell marker (AQP5). LUAD organoids demonstrated distinct immunomarker expression profiles of TTF-1 and Napsin A. Whole-exome sequencing and transcriptome revealed genetic patterns and dominant mutational changes in organoids that are consistent with matched parental tissues.

Conclusions: Our lab has developed nontumoral lung and LUAD organoids directly from patients and PDX, whereby we provide robust experimental models for future studies. The comprehensive investigation into the phenotypic and genetic profiling of these organoids holds substantial promise for facilitating translational and individualized therapeutic strategies in the management of LUAD patients.

EP.02F.01 Berberine and Osimertinib Inhibit Progression of EGFR-TKI Primary and Acquired Resistant NSCLC Cells by a Multimodal Intervention

D. Wu[1], C. Ding[1], M. Liu[1], Z. Zhao[1], W. Zhao[1], P. Chen[1], C. Chen[1], X. Zhang[1], Y. Li[1], J. Chen[1], H. Liu[1], Z. Hu[1], [1]Tianjin Medical University General Hospital, Tianjin/CN

Introduction: Lung cancer is a prevalent malignancy in the world, leading to significant mortality rates. The emergence of acquired resistance to EGFR-TKIs poses a challenge in treating NSCLC patients effectively. Osimertinib (Osi), a third-generation EGFR-TKI, is commonly used but resistance development limits its long-term efficacy. Berberine (BBR), a natural compound, exhibits diverse anti-cancer properties. The aims of this study is to elucidate the inhibitory mechanism of combined Osi with BBR in treatment of NSCLC and evaluate the effectiveness of nano-drugs carrying these agents for treating Osi-resistant cells.

Methods: EGFR wild-type NSCLC cells (A549 and H460) and EGFR mutant NSCLC cells (H1975 OR and HCC827 OR) were utilized. The synergistic effects of Osi and BBR on NSCLC cells were assessed through colony formation, EdU staining, cell cycle, and apoptosis. Metastasis-related phenotypes were examined using wound healing, transwell, adhesion, and tube formation assays, along with cytoskeleton staining. Western Blot analysis was conducted to detect changes in proteins associated with cell cycle, apoptosis, and tumor metastasis. The synergistic effects of Osi and BBR were also investigated by xenograft models in nude mice and lung cancer organoids. Finally, liposomes encapsulating Osi and/or BBR, loaded with EGF as a targeting peptide and fluorescently labeled with FITC, were synthesized to create a new nano-drugs. The anticancer mechanism of nano-drugs was preliminarily explored through experiments.

Results: The combination of BBR and Osi synergistically inhibited the proliferation and metastasis of EGFR-TKI primary and acquired resistant cells and resulted in inhibited proliferation and colony formation, as well as decreased migration, invasion and adhesion ability of tumor cells. Meanwhile, formation of vascular-like structures of HUVEC and tumor cells was inhibited. Morphology of microtubules and microfilaments related to cytoskeleton was changed and apoptosis was increased after treatment with Osi combined BBR. Moreover, Osi and BBR combination inhibited the growth of NSCLC in nude mice and lung cancer organoids. Targeted nano-drugs carrying Osi and/or BBR selectively accumulated in NSCLC cells with high EGFR expression. Compared to nano-drugs carrying single agents, nano-drugs carrying Osi and BBR exhibited significant effect of inhibited proliferation and metastasis of tumor cells.

Conclusions: The combination of BBR and Osi synergistically inhibited the proliferation of EGFR-TKI primary and acquired resistant NSCLC cells, induced cell cycle arrest and apoptosis. The combination of two drugs inhibits tumor metastasis by inhibiting tumor migration, invasion, cell adhesion, decreasing tumor angiogenesis and changing the structure of microtubules and microfilaments. Targeted nano-drugs carrying Osi and/or BBR could selectively enriched in NSCLC cells with high EGFR expression and significantly inhibited the proliferation and metastasis of tumor cells in vitro and in vivo.

EP.02F.02 Individual and Combined Effects of Annonacin and 2-Deoxy-D-Glucose on Non-Small Cell Lung Cancer Cells

B.R. Bhattarai, C. Teets, A. Tope, Kentucky State University, Frankfort/KY/USA

Introduction: Non-Small Cell Lung Cancer (NSCLC) is the most common type of cancer, accounting for approximately 81% of all lung cancer cases, and remains a leading cause of cancer-related mortality worldwide. Despite advancements in cancer treatment, the five-year survival rate of NSCLC is low, warranting the urgent need for innovative and effective therapeutic approaches to treat it. The aberrant energy metabolism, which is a hallmark of cancer, including NSCLC, known as the Warburg effect, makes it a potential target for therapeutic interventions. Annonacin, a natural compound, has shown promise in targeting key metabolic pathways, inhibiting mitochondrial complex I, and exploiting the altered energy dynamics of cancer cells. In contrast, 2-Deoxy-D-Glucose (2DG) is a glucose analog, that has been widely studied for its ability to target the glycolytic pathway of energy metabolism. This investigation tests both glycolytic inhibitor and mitochondrial complex I inhibitor individually and in combination to target energy metabolism to inhibit A549 cell growth and explore their potential as novel antitumor agents and to treat NSCLC therapeutically.

Methods: The study was carried out in an in vitro model system using the A549 NSCLC cell line, where the NL20 Bronchial Epithelium cell line was used as a parallel control. Cells were treated with 0 μM, 2 μM, 4 μM, and 6 μM concentrations of Annonacin and 0 mM, 2.5 mM, 5 mM, and 10 mM concentrations of 2DG, both individually and in combination in triplicate experimental design with control. The MTT assay was employed to determine immediate cell viability and to assess the cytotoxic effects of applied treatments. The DNA damage induced by treatments was evaluated using a Comet Assay also called Single Cell Gel Electrophoresis. The oxidative stress in treated and control cells was determined through assays of superoxide dismutase and glutathione peroxidase. Furthermore, the long-term proliferative capacity of the cells post-treatment was examined using a colony-forming assay.

Results: Preliminary results indicate that both Annonacin and 2DG when used individually, exhibit a dose-dependent inhibitory effect on the viability of A549 cells. The combined application of 2DG and Annonacin showed a synergistic effect, resulting in a significant reduction in cell viability compared to individual applications. The Comet Assay revealed increased DNA damage in cells treated with the combination of Annonacin and 2DG, suggesting enhanced genotoxic stress. In addition, treated cells exhibited alterations in the activities of glutathione peroxidase and superoxide dismutase, indicating changes in the oxidative stress response. The colony-forming assay revealed a decrease in the long-term proliferative capacity of cells treated with the combination of Annonacin and 2DG.

Conclusions: The combination of Annonacin and 2DG has a synergistic effect on inhibiting the growth of A549 cells. The observed increase in DNA damage and alterations in the oxidative stress response further support the potential of this combined treatment as an effective therapeutic strategy for NSCLC. These findings need further investigation to elucidate the detailed underlying mechanisms and explore the in vivo and clinical applicability details for the combined administration of Annonacin and 2DG's use in NSCLC treatment.

EP.02F.03 Elucidating the Role of XRCC6BP1 In Mitochondrial Bioenergetics and Metabolism in Non-Small Cell Lung Cancer

M.P. Barr[1], A. Woods[2], G. Kirwan[2], A. Heeran[2], A. Kilgallon[2], A. Raju[2], S. Cuffe[3], S. Finn[1], [1]St James's Hospital & Trinity College Dublin, Dublin/IE ,[2]Trinity College Dublin, Dublin/IE ,[3]St James's Hospital, Dublin/IE

Introduction: X-Ray Repair Cross Complementing 6 Binding Protein 1 (XRCC6BP1) plays a key role in DNA double-stranded break (DSB) repair. Recent studies in our group identified XRCC6BP1 as a prognostic marker in patients with non-small cell lung cancer (NSCLC). The relationship between mitochondrial bioenergetics and DNA damage repair remains unclear. In this study, we explored the potential link between DNA damage repair, mitochondrial function and metabolism in NSCLC.

Methods: Stable transfected NSCLC cell lines (H460, A549, SKMES-1), representing large cell carcinoma, adenocarcinoma and squamous cell carcinoma histology, were generated using XRCC6BP1 shRNA and control lentivirus particles. The effect of XRCC6BP1 knockdown on the expression of 84 genes involved in mitochondrial biogenesis and function was assessed using human Mitochondria RT^2 Profiler PCR Arrays. These comprised of regulators and mediators of mitochondrial molecular transport, ions required for maintaining mitochondrial membrane polarization, ATP synthesis, in addition to intrinsic apoptosis pathway genes activated by intracellular damage signaling. Genes that were significantly upregulated or downregulated in response to XRCC6BP1 knockdown were validated by qPCR. Gene expression was also examined in an isogenic panel of matched parental and cisplatin resistant A549 and SKMES-1 NSCLC cells. Tumor cell apoptosis was assessed using Annexin V/propidium iodide staining by flow cytometry in the presence or absence of the DNA damaging agent, cisplatin (IC50). Cell metabolism and key parameters of mitochondrial function were examined using the SeahorseXF24 Cell Mito Stress Test kit in XRCC6BP1 shRNA and control shRNA lung cancer cells.

Results: Relative to control shRNA cells, 19 genes involved in mitochondrial function were significantly altered in XRCC6BP1 shRNA transfected A549 NSCLC cells compared to 5 genes in SKMES-1 cells. Two genes (AIP and UCP2) were upregulated in both cell lines while one gene (SLC25A12) was increased in A549 cells but decreased in SKMES-1 cells. Of interest, when data from similar arrays were assessed for H460 cells, UCP2 was found to be upregulated in all three lung cancer cell lines. Validation of these findings confirmed a significant increase ($p<0.001$) in UCP2 gene expression in XRCC6BP1 shRNA A549 cells relative to shRNA controls. Expression was also significantly increased ($p<0.01$) in cisplatin resistant A549 cells relative to their parental (sensitive) counterparts. Cisplatin induced significant apoptosis of XRCC6BP1 shRNA A549 and XRCC6BP1 shRNA SKMES-1 cells treated with cisplatin (IC50). These were comparable to levels of apoptosis observed in control cells. There were no significant differences between XRCC6BP1 shRNA A549 or XRCC6BP1 shRNA SKMES-1 cells relative to their control shRNA counterparts when baseline extracellular acidification rate, coupling efficiency, proton leak, non-mitochondrial oxygen consumption and spare respiratory capacity were examined. Basally, oxygen consumption rate (OCR) was significantly higher in A549 cells, while SKMES-1 cells had a significantly increased spare respiratory capacity ($p<0.01$) and diminished proton leak ($p<0.05$).

Conclusions: Our data show that UCP2 is upregulated in different NSCLC subtypes in response to XRCC6BP1 knockdown. Significant differences in the levels of proton leak and spare respiratory capacity between NSCLC cell lines highlights the different metabolic phenotypes that exist between adenocarcinoma and squamous cell lung cancers.

EP.02F.04 Development and Validation of an ADRB2-based Prognostic Model for Non-Small Cell Lung Cancer

T. Wang[1,2], S. Bu[1], X. Wang[1], H. Ge[1], C. Yang[1], X. Zheng[1], Y. Liu[3], X. Dong[2], [1]The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou/CN ,[2]The Warren Alpert Medical School of Brown University, Providence/RI/USA ,[3]The Affiliated Hospital of Nantong University, Nantong/CN

Introduction: ADRB2 (β2-adrenergic receptor) is upregulated in various malignant tumors, including non-small cell lung cancer (NSCLC), and associated with unfavorable disease advancement. Developing an ADRB2-based clinical score will facilitate the discovery of novel prognostic biomarkers and prospective targets for NSCLC.

Methods: Dysregulated genes associated with ADRB2 were identified by differential expression analysis of NSCLC from the TCGA database. Then, biological processes and signaling pathways involved in these genes were explored. An ADRB2-based clinical score model was constructed, and its relationship with immune checkpoint genes or immune cell infiltration was calculated by the CIBERSORT algorithm. Potential upstream regulatory mechanisms and therapeutic targets associated with the ADRB2-related genes were investigated using multi-omics data. A global network regulation model was developed.

Results: 5270 differentially expressed genes (DEGs) and 93 differentially expressed miRNAs (DemiRNAs) were identified as factors affected by ADRB2 in NSCLC. Dysregulated genes associated with ADRB2 were involved in the JAK-STAT signaling pathway and cytokine-cytokine receptor interactions, important for angiogenesis. High ADRB2 expression significantly positively correlated with immune checkpoint genes and infiltration of immune cells.

Conclusions: The ADRB2-based score clinical model has been develop, which predicts the prognosis of NSCLC patients and suggests possible therapeutic targets.

EP.02F.05 Lysosomal Calciumrelease via TRPML3 Enhances Drug Sensitivity of Gefitinib-resistance NSCLS Cells

S-h. Yang[1], M.s.K. Kim[2], M.s. Kim[2], [1]Wonkwang University Hospital, Iksan/KR ,[2]Wonkwang University, Iksan/KR

Introduction: Lysosomes have recently gained prominence as pivotal signaling hubs implicated in drug resistance within cancer cells. However, the precise role of Transient receptor potential mucolipin 3 (TRPML3), an endo-lysosomal calcium-permeable channel known to regulate lysosomal trafficking during endocytosis and autophagy, remains enigmatic in the context of cancer progression. This study aimed to elucidate the involvement of TRPML3 in modulating exosomal release triggered by lysosomal exocytosis during the development of gefitinib resistance in non-small cell lung cancer (NSCLC).

Methods: Exosomal counts and cell-cycle analysis were conducted by flow cytometry and western blot analysis. Ratiometric assays and enzymatic activity assessments were performed to investigate calcium signaling, lysosomal pH, and lysosomal exocytosis

Results: Our finding revealed that gefitinib-resistant NSCLC cells, HCC827/GR, exhibited significantly higher basal exosomal release and lysosomal exocytosis compared to gefitinib-sensitive NSCLC cells, HCC827. This difference was associated with an increased expression of TRPML3 in HCC827/GR cells. Furthermore, we observed a close correlation between the elevated exosomal release and lysosomal exocytosis and the upregulation of TRPML3 expression. Notably, the triggering of lysosomal calcium release through TRPML3 was facilitated by gefitinib-induced elevation of lysosomal pH. Our investigation demonstrated that deficiency of TRPML3 resulted in gefitinib-induced cell death, as indicated by the accumulation of Sub-G0 population, hindered cell proliferation, and facilitated poly (ADP-ribose) polymerase cleavage.

Conclusions: In summary, our data demonstrate the emerging role of TRPML3 as a molecular factor in anti-cancer drug resistance. By effectively sensing lysosomal pH acidification, TRPML3 orchestrates lysosomal calcium release, subsequently influencing lysosomal trafficking, exocytosis, and exosomal release. This study contributes to comprehending the defense mechanisms that developed by acquired drug resistance to tyrosine kinase inhibitor gefitinib in NSCLC cells.

EP.02F.06 Suppression of Chemotherapy Induced Antiviral Signaling by YAP/TAZ in Lung Cancer

S. Khavkine Binstock[1], K. Zou[1], Y.F. Wu[2], A. Kapus[1], K. Thu[1], [1]University of Toronto, Toronto/ON/CA ,[2]St. Michael's Hospital, Toronto/ON/CA

Introduction: Chemotherapy is widely used to treat lung cancer (LC) and initially induces tumour regression in most patients; however, chemoresistance inevitably develops. Thus, an improved understanding of the biology driving chemoresistance is needed to enhance chemotherapeutic efficacy in patients. YAP and TAZ are transcriptional regulators whose overactivation is well-documented to promote LC chemoresistance. Interestingly, some chemotherapies induce antiviral signaling in tumours, which contributes to their anti-cancer effects. Moreover, recent studies suggest that YAP/TAZ antagonize antiviral immunity by suppressing induction of type I interferons and interferon stimulated genes (ISG). Therefore, we hypothesize that YAP/TAZ-mediated suppression of antiviral signaling induced by chemotherapy represents a previously unrecognized mechanism of LC chemoresistance. Here, we investigated whether YAP/TAZ suppress chemotherapy-induced antiviral signaling in LC models as the first step in testing this hypothesis.

Methods: qPCR was used to assess gene expression of the type I interferon, IFNβ, in several lung adenocarcinoma (LUAD) cell lines with different levels of YAP/TAZ protein expression under basal conditions. LUAD lines with high (H1299, H2030) and low YAP/TAZ expression (H2122) were transfected with siRNA to knockdown YAP and/or TAZ, or a non-targeting control siRNA (siNTC). Cells were then treated with chemotherapies including cisplatin, doxorubicin and paclitaxel for 48 hours; or Poly(I:C) for 4 hours as a positive control for inducing antiviral signaling. qPCR was used to measure expression of IFNβ and the ISGs, OASL and CCL5 as readouts of antiviral signaling.

Results: Basal IFNβ expression was negatively correlated with YAP/TAZ expression in a panel of 7 LUAD cell lines, consistent with YAP/TAZ suppression of antiviral signaling. Poly(I:C) stimulation of H1299 cells (YAP/TAZ high) with YAP or TAZ knockdown led to a 2-3-fold increase in IFN-β expression, while combined YAP/TAZ depletion induced a 5-fold increase in IFN-β relative to cells transfected with siNTC. These results provide functional evidence that YAP/TAZ suppress antiviral signaling in LC cells. Similarly, chemotherapy treatment of H1299 cells with YAP or TAZ knockdown led to a 2-3 fold increase, and combined YAP/TAZ depletion induced a 4-6 fold increase in CCL5 and OASL relative to siNTC. Another YAP/TAZ high model, H2030, showed similar results with chemotherapy treatment. In contrast, H2122 cells with low basal YAP/TAZ expression showed little to no change in CCL5 and OASL expression upon chemotherapy treatment and little to no change in IFN-β expression with Poly(I:C) treatment when YAP and/or TAZ were depleted.

Conclusions: Our results suggest that YAP/TAZ suppression of chemotherapy induced antiviral signaling could contribute to chemoresistance. We plan to complement these knockdown experiments with YAP/TAZ overexpression and studies to determine whether YAP/TAZ-mediated suppression of antiviral signaling affects the sensitivity of LC models to chemotherapy. Our work illuminates a new putative mechanism for YAP/TAZ-mediated chemoresistance that could rationalize the use of YAP/TAZ inhibitors or drugs that augment antiviral signaling to enhance the efficacy of chemotherapy in LC.

Keywords: YAP/TAZ, Antiviral Signaling, Chemoresistance

EP.02F TUMOR BIOLOGY - PRECLINICAL BIOLOGY - TARGETED THERAPY/NOVEL THERAPY
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.02F.07 Targeting NRAS Increases Lung Adenocarcinoma Sensitivity to Paclitaxel Chemotherapy

Y. Liu[1,2], T. Mo[1], J. Feng[1], T. Wang[3], [1]The Affiliated Hospital of Nantong University, Nantong/CN ,[2]The Warren Alpert Medical School of Brown University, Providence/RI/USA ,[3]The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou/CN

Introduction: This project investigates the role of NRAS in the resistance of lung adenocarcinoma to paclitaxel. By combining transcriptome data analysis and in vitro experiments, it aims to propose a new strategy for improving the treatment outcomes of lung adenocarcinoma.

Methods: Initially, transcriptome data from The Cancer Genome Atlas (TCGA) and several other genomic databases were analyzed. We also investigated NRAS expression in various stages of LUAD to assess its correlation with disease progression. Subsequently, Gene Set Enrichment Analysis was utilized to identify genes and pathways associated with NRAS. Vitro experiments were also performed, which involved culturing various LUAD cell lines and using siRNA to knock down NRAS in these cell lines. Functional assays such as cell viability tests and scratch assays were then employed to confirm changes in drug sensitivity following NRAS knockdown.

Results: Our extensive analysis revealed a striking up-regulation of NRAS in LUAD tissues compared to normal lung tissues. This over-expression was more pronounced in advanced stages of LUAD. Importantly, higher levels of NRAS expression were correlated with poorer patient outcomes. Furthermore, patients with high NRAS expression exhibited decreased sensitivity to paclitaxel, indicating a potential mechanism of drug resistance. The GSEA highlighted significant enrichment of NRAS-related genes in pathways involved in the cell cycle, DNA damage response, and repair mechanisms. This suggests that NRAS may contribute to paclitaxel resistance through these pathways. In vitro experiments, LUAD cell lines with NRAS knockdown demonstrated markedly increased sensitivity to paclitaxel. This was evident in reduced cell proliferation and increased apoptosis rates upon treatment with the drug, compared to control cell lines.

Conclusions: Targeting NRAS, therefore, emerges as a promising therapeutic strategy. By inhibiting NRAS, it may be possible to enhance the efficacy of paclitaxel, thereby improving treatment outcomes for patients with LUAD.

Keywords: NRAS, Paclitaxel Chemotherapy, Sensitivity

EP.02G.01 Differentiation and Metabolic Phenotypes of Lung Squamous Cell Carcinoma Organoids are Modified by the Tumor Microenvironments

H. Ogawa[1,2], T. Koga[1], Y. Inoue[3], Y. Fujibayashi[1,2], R. Navab[3], Q. Li[3], N-A. Pham[3], N. Radulovich[3], N. Bernards[1], Y. Sata[1], S. Kitazawa[1], Y. Hiraishi[1], F. Yokote[1], T. Aoi[4], Y. Maniwa[2], M-S. Tsao[3], K. Yasufuku[1,5], [1]Toronto General Hospital, University Health Network, Toronto/ON/CA ,[2]Kobe University Hospital, Kobe/JP ,[3]Princess Margaret Cancer Center, University Health Network, Toronto/ON/CA ,[4]Graduate School of Medicine, Kobe University, Kobe/JP ,[5]Institute of Biomedical Engineering, University of Toronto,, Toronto/ON/CA

Introduction: Cancer organoids are recognized as a novel preclinical model retaining genetic and transcriptomic characteristics of the original tumors. In this study, we aimed to investigate the influence of the microenvironment on lung squamous cell carcinoma (SqCC) organoids.

Methods: We established a lung squamous cell carcinoma xenograft-derived organoid (XDO) model under organoid culture condition from a patient-derived xenograft (PDX) PHLC377 tumor. Lentivirus was used to transduce mCherry into XDO377 (referred to as XDO377mCh). We injected XDO377mCh subcutaneously and intratracheally into the lung of non-obese severe combined immunodeficient gamma (NSG) mice. We compared the pathology and gene expression profiles XDO377mCh-derived subcutaneous and lung tumors. Additionally, we established cancer organoids from both XDO377mCh-derived subcutaneous and lung tumors and compared their pathology and gene expression profiles with the parental XDO377mCh organoid (Figure).

Results: Pathological examination revealed a poorly differentiated non-keratinizing phenotype in the orthotopic lung tumors in mice, whereas the subcutaneous tumors and the parental tumor exhibited a moderately differentiated keratinizing SqCC. Immunohistochemistry showed stronger positivity for SqCC markers (P40, P63, SOX2) in the subcutaneous tumors compared to the lung tumors. RNA sequencing confirmed these findings, showing elevated expression of SqCC markers in the subcutaneous tumors compared to the lung tumors. GSEA hallmark analysis revealed significant upregulation of pathways related to “MTOR1 signaling”, “glycolysis”, and “hypoxia” in the subcutaneous tumors compared to the lung tumors. No significant differences in pathology or gene expression profiles were observed among the newly established cancer organoids derived from subcutaneous and lung tumors and the parental XDO377mCh.

Conclusions: Our findings suggest that the differentiation and metabolic status of lung squamous cell carcinoma are reversibly influenced by the tumor microenvironment. Cancer organoids can contribute to our understanding of the molecular mechanisms of tumor plasticity that is regulated by the microenvironment.

EP.03A.01 Lung Cancer: Artificial Intelligence, Synergetics, Complex System Analysis, Statistics and Simulation of Alive Supersystems.

O. Kshivets, Bagrationovsk Hospital, Bagrationovsk/RU

Introduction: 5-survival (5YS) and life span after radical surgery for non-small cell lung cancer (LC) patients (LCP) (T1-4N0-2M0) - alive supersysems was analyzed. The importance must be stressed of using complex system analysis, artificial intelligence (neural networks computing), simulation modeling and statistical methods in combination, because the different approaches yield complementary pieces of prognostic information.

Methods: We analyzed data of 782 consecutive LCP (age=57.6±8.3 years; tumor size=4.1±2.4 cm) radically operated and monitored in 1985-2024 (m=670, f=112; upper lobectomies=282, lower lobectomies=179, middle lobectomies=18, bilobectomies=46, pneumonectomies=257, mediastinal lymph node dissection=782; combined procedures with resection of trachea, carina, atrium, aorta, VCS, vena azygos, pericardium, liver, diaphragm, ribs, esophagus=198; only surgery-S=626, adjuvant chemoimmunoradiotherapy-AT=156: CAV/gemzar + cisplatin + thymalin/taktivin + radiotherapy 45-50Gy; T1=326, T2=258, T3=137, T4=61; N0=525, N1=133, N2=124, M0=782; G1=199, G2=248, G3=335; squamous=422, adenocarcinoma=310, large cell=50; early LC=218, invasive LC=564; right LC=420, left LC=362; central=294; peripheral=488. Variables selected for study were input levels of 45 blood parameters, sex, age, TNMG, cell type, tumor size. Regression modeling, clustering, SEPATH, Monte Carlo, bootstrap and neural networks computing were used to determine significant dependence.

Results: Overall life span (LS) was 2252.1±1742.5 days and cumulative 5-year survival (5YS) reached 73.2%, 10 years - 64.8%, 20 years - 42.5%. 513 LCP lived more than 5 years (LS=3124.6±1525.6 days), 148 LCP - more than 10 years (LS=5054.4±1504.1 days).199 LCP died because of LC (LS=562.7±374.5 days). 5YS of LCP after bi/lobectomies was significantly superior in comparison with LCP after pneumonectomies (78.1% vs.63.7%, P=0.00001 by log-rank test). AT significantly improved 5YS (66.3% vs. 34.8%) (P=0.00000 by log-rank test) only for LCP with N1-2. Cox modeling displayed that 5YS of LCP significantly depended on: phase transition (PT) early-invasive LC in terms of synergetics, PT N0—N12, cell ratio factors (ratio between cancer cells- CC and blood cells subpopulations), G1-3, histology, glucose, AT, blood cell circuit, prothrombin index, heparin tolerance, recalcification time (P=0.000-0.038). Neural networks, genetic algorithm selection and bootstrap simulation revealed relationships between 5YS and PT early-invasive LC (rank=1), PT N0—N12 (rank=2), thrombocytes/CC (3), erythrocytes/CC (4), eosinophils/CC (5), healthy cells/CC (6), lymphocytes/CC (7), segmented neutrophils/CC (8), stick neutrophils/CC (9), monocytes/CC (10); leucocytes/CC (11). Correct prediction of 5YS was 100% by neural networks computing (area under ROC curve=1.0; error=0.0).

Conclusions: 5YS of LCP after radical procedures significantly depended on: 1) PT early-invasive cancer; 2) PT N0--N12; 3) cell ratio factors; 4) blood cell circuit; 5) biochemical factors; 6) hemostasis system; 7) AT; 8) LC characteristics; 9) LC cell dynamics; 10) surgery type: lobectomy/pneumonectomy; 11) anthropometric data. Optimal diagnosis and treatment strategies for LC are: 1) screening and early detection of LC; 2) availability of experienced thoracic surgeons because of complexity of radical procedures; 3) aggressive en block surgery and adequate lymph node dissection for completeness; 4) precise prediction; 5) adjuvant chemoimmunoradiotherapy for LCP with unfavorable prognosis.

EP.03B.01 The Genomic Scarring Score as a Biomarker for the Use of PARP Inhibitors in Early-Stage Non-Small Cell Lung Cancer

K. Tsilingiri[1], A. Chalari[1], G. Christopoulou[2], A. Voutsina[3], I. Vatsellas[1], T. Loupis[1], D. Vrachnos[1], K. Potaris[4], I. Vamvakaris[5], G. Zachou[6], V. Georgoulias[6], P. Constantoulakis[2], A. Kotsakis[7], A. Klinakis[1], [1]BRFAA, Athens/GR ,[2]Genotypos S.A., Athens/GR ,[3]National Hellenic Research Foundation, Athens/GR ,[4]Department of Thoracic Surgery, "SOTIRIA" General Hospital, Athens/GR ,[5]Department of Pathology, "SOTIRIA" General Hospital, Athens/GR ,[6]Department of Medical Oncology, "Metropolitan General" Hospital, Athens/GR ,[7]Department of Medical Oncology, University General Hospital of Larisa, Larissa/GR

Introduction: Tumours with Homologous Recombination Deficiency (HRD) frequently arise due to germline or somatic BRCA1 or BRCA2 mutations and respond favourably to PARP inhibitors (PARPi). "Genomic scars" are the consequence of HRD and is measured using available diagnostic tools, which grade the tumours with a genomic scarring score (GSS). However, HRD may occur beyond the presence of genomic alterations in BRCA1, BRCA2 or any other homologous recombination repair (HRR) gene alteration. In this work, we sought to evaluate the GSS of operable non-small cell lung cancer (NSCLC) tumours and examine whether high GSS tumours can be successfully treated with PARPi independently of the presence of HRR gene mutations.

Methods: Using the available diagnostic panels (Amoy Dx®), we measured the GSS score and evaluated the HRR (germ line and somatic) gene alterations of 136 early-stage NSCLC tumours. HR deficiency was confirmed via staining for the formation of RAD51 foci. Patient-derived xenografts (PDX) were used to compare the response of HRD versus HRP (homologous recombination proficient) tumours to cisplatin or PARPi.

Results: High (>50) GSS was observed in 39 (28.5%) of the tumours and were considered to be HRD but only 13 (30%) of them harboured pathogenic/likely pathogenic (P/LP) germ line/somatic mutations; at the same time, 11 out of 97 patients (11.3%) with low GSS also carried P/LP HRR mutations, indicating that mutations in HR genes alone cannot explain the genomic instability phenotype in NSCLC. The incidence of pathogenic TP53 mutations was significantly higher in the HRD compared to HRP cohort (85% vs 50% respectively, p=0.001), while variant allele frequency of the TP53 mutations also showed a highly significant correlation (r=0.5648) with the GSS. Administration of PARPi significantly delayed tumour growth in high GSS but not in low GSS PDXs; moreover, the HR repair of cisplatin-induced double strand breaks, as evaluated by RAD51 foci formation, was also hampered in high GSS PDXs. Finally, there is a non-statistically significant trend for longer median DFS and OS for hGSS compared to lGSS patients, presumably because of the limited number of patients currently comprising the cohort and the incomplete patients' follow up

Conclusions: In this study, we present evidence that molecular traits compatible with HRD are evident in early-stage NSCLC. Preclinical data in PDXs indicate that these tumors might respond favourably to PARPi. Moreover, HRR gene mutations alone cannot account for all NSCLC cases that present a high GSS score, accompanied by reduced frequency, that would benefit from PARPi therapies. This study paves the way for the introduction to the clinic of PARPi in NSCLC for a subgroup of patients not necessarily defined by HRR gene mutations.

EP.03B.02 Association of Pre-Existing Conditions with Major Driver Mutations and Immune Contextures in Non-Small Cell Lung Cancer

P. Chen[1,2], J. Li[1,2], C. Li[1,2], X. Zheng[1,2], Y. Feng[1,2], W. Liang[1,2], J. He[1,2], [1]the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN ,[2]China State Key Laboratory of Respiratory Disease & National Clinical Research Centre for Respiratory Disease, Guangzhou/CN

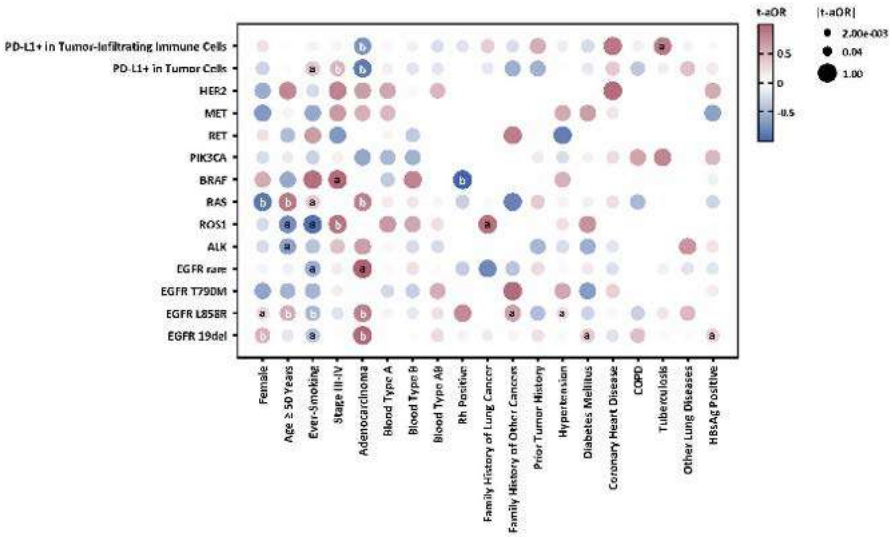
Introduction: The paradigm of therapies for non-small cell lung cancer (NSCLC) has evolved significantly with the advent of genetic profiling and the elucidation of immune landscapes, such as the expression of programmed cell death-ligand 1 (PD-L1). These factors contribute to the heterogeneous biological behaviors observed in NSCLC. Despite advancements, the influence of pre-existing conditions, including blood types, family history of cancers, and comorbid diseases, on the genetic and immunological landscape of NSCLC remains inadequately explored. This study aims to elucidate these correlations, thereby filling a gap in the current understanding.

Methods: A cross-sectional study was conducted at our institution, encompassing patients who underwent surgical resection for NSCLC from January 2014 to July 2018. Targeted next-generation sequencing (NGS) was deployed to detect somatic mutations in nine pivotal oncogenes, coupled with immunohistochemical staining to assess PD-L1 expression. Logistic regression analysis was utilized to examine the associations between pre-existing conditions and the occurrence of specific driver mutations or levels of PD-L1 expression.

Results: The cohort included 5,507 patients, all of whom underwent NGS, with 1,839 also evaluated for PD-L1 expression. Notable associations were identified: ROS1 mutations closely associated with a family history of lung cancer (OR: 5.356, 95%CI: 0.798-21.225, P = 0.035). EGFR L858R mutations were prevalent in patients with a family history of non-lung cancers (OR: 2.089, 95%CI: 1.029-4.135, P = 0.037) and hypertension (OR: 1.252, 95%CI: 1.001-1.562, P = 0.048). Pre-existing conditions such as diabetes (OR: 1.468, 95%CI: 1.042-2.047, P = 0.026) and hepatitis B surface antigen positivity (OR: 1.373, 95%CI: 1.012-1.847, P = 0.038) were correlated with EGFR exon 19 deletions. RhD negativity showed potential ties to BRAF mutations (OR: 0.009, 95%CI: 0.001-0.228, P = 0.001). A history of tuberculosis linked to increased PD-L1 expression in immune cells (OR: 3.597, 95%CI: 1.295-14.957, P = 0.034).

Conclusions: This comprehensive, large-scale study reveals significant associations between pre-existing conditions and specific genetic and immunological alterations in NSCLC. These findings underscore the importance of considering patients' medical histories when developing personalized treatment strategies, highlighting the potential for more tailored therapeutic approaches based on individual genetic and immunological profiles.

Keywords: non-small cell lung cancer (NSCLC), driver mutations, comorbid diseases



Notes:
-aOR Transformation: Displayed odds ratios (t-aOR) are log-transformed to correct skewness, followed by tan-transformation for distribution normalization, ensuring clear visualization.
-Color Coding: Red bubbles represent actual aORs > 1, indicating increased odds; Blue bubbles represent actual aORs < 1, indicating decreased odds.
-Significance Levels: (a) P = .002 to < .05; (b) P ≤ .002.

EP.03B.03 Whole Genome Analysis in Resected Adenocarcinoma and Squamous Cell Carcinoma of the Lungs

M. Ito, K. Suda, K. Sakai, S. Ohara, A. Hamada, M. Chiba, M. Shimoji, T. Takemoto, J. Soh, K. Nishio, T. Mitsudomi, Y. Tsutani, Kindai University, Osaka/JP

Introduction: A comprehensive genetic profile is essential for the development of therapeutic strategies for lung cancer. Genetic status is a predictor of response to targeted therapy and immune checkpoint inhibitors. There are limited data regarding the whole-genome profiles of lung adenocarcinoma and squamous cell carcinoma. Whole-genome sequencing can be used to detect features that are potentially therapeutically targetable or diagnostic markers.

Methods: A whole-genome analysis of resected primary lung cancer was performed. Genetic alterations (mutations including substitutions in intron, deletions, amplifications, and losses), homologous recombination deficiency, and tumor mutation burden (TMB) were evaluated. We evaluated the differences between adenocarcinoma and squamous cell carcinoma and their specific profiles. Clinicopathological backgrounds specific to the genetic features were also explored.

Results: Sixty-five adenocarcinoma and 34 squamous cell carcinoma cases were analyzed after cases with non-/minimally invasive, variant-type adenocarcinoma, or cases after preoperative treatment were excluded. In patients with adenocarcinoma, cases with an EGFR mutation harbored significantly lower TMB compared to EGFR wild-type cases (median: 1.59/Mb [range: 0.09-6.98; IQR: 1.1575-2.14] vs. median 3.84/Mb [range: 0-25.78; IQR: 1.03-8.92], p = 0.0289). Cases with a TP53 mutation harbored higher TMB (median: 7.5/Mb [range: 0.75-25.78; IQR: 2.615-11.5625] vs. median: 1.41/Mb [range: 0-10.64; IQR: 0.85-2.43]; p < 0.001). No significant differences in TMB were found with respect to T status, histological type, or PD-L1 expression in adenocarcinoma or squamous cell carcinoma cases. TP53 mutations were more frequent in patients with squamous cell carcinoma than those with adenocarcinoma (30.8% [20/65] vs. 76.5% [26/34]; p < 0.001). The number of cases with amplification and the number of amplified genes per case were significantly higher in patients with squamous cell carcinoma (incidence of cases with amplification: 37.5% [24/65] vs. 58.8% [20/34]; p = 0.0373; median number of amplified genes per case: 1.5 [range: 0-34; IQR: 0-3.75] vs. 0 [range: 0-6; IQR: 0-1]; p = 0.00428). Gene loss is significantly more frequent in patients with squamous cell carcinoma. (incidence of cases with gene loss: 12.3% [8/65] vs. 32.4% [11/34]; p = 0.0327; median number of lost genes per case: 0 [range: 0-6; IQR: 0-0] vs. 0 [range: 0-4; IQR: 0-1]; p = 0.00220).

Conclusions: TMB was significantly lower and higher in EGFR and TP53 mutant cases in patients with adenocarcinoma, respectively. Squamous cell carcinoma cases are characterized by a higher incidence of TP53 mutations, with a higher frequency and number of gene amplifications and losses compared to adenocarcinoma cases.

EP.03B.04 Clinicopathological Features of Lung Cancers with RICTOR Gene Amplification

M. Shono[1], K. Suda[1], K. Sakai[1], S. Ohara[1], M. Chiba[1], M. Ito[1], M. Shimoji[1], J. Soh[1], J. Yoshimoto[1], K. Nishio[1], T. Mitsudomi[1,2], Y. Tsutani[1], [1]Kindai University Faculty of Medicine, Osakasayama/JP ,[2]Izumi city general hospital, Izumi/JP

Introduction: The patients with lung cancer harboring amplification of the RICTOR (rapamycin-insensitive companion of mTOR) gene have been proposed as a subset of patients who may benefit from mTORC1/2 inhibitors (Cheng H, et al,. Cancer Discov 2015). However, only a few studies have been performed thereafter. Therefore, we aimed to determine the incidence and clinicopathologic features of lung cancer with RICTOR gene amplification.

Methods: We analyzed data from 142 lung cancer patients who received surgical resection between June 2022 and June 2023, and participated in a clinical study that performed next-generation sequencing (NGS) analysis of the tumors. The Fisher's Exact test and the Mann-Whitney U-test were used to analyze the correlations between the presence of the RICTOR gene amplification and categorical variables or continuous variables, respectively.

Results: Among 142 lung cancer patients, RICTOR gene amplification was detected in 15 patients (11%). The prevalence of the RICTOR gene amplification was highest in small cell lung cancer and large cell neuroendocrine carcinoma (LCNEC) (33%, 3/9 cases) followed by squamous cell carcinoma (11%, 4/35 cases), and lung adenocarcinoma (9%, 8/86 cases). None of 12 lung cancers of other histologies such as adenosquamous cell carcinoma harbored RICTOR amplification. Among 8 lung adenocarcinoma patients with RICTOR gene amplification, 3 had concurrent EGFR mutation (L858R, G719A, and exon 20 insertion) but none had KRAS mutation. In the analysis of clinical factors, all patients with RICTOR gene amplification but one were smokers. The presence of the RICTOR gene amplification was not associated with sex and age of the patients. TP53 mutation was numerically more frequent in patients with RICTOR gene amplification (60%) than those without (47%, p=0.42).

Conclusions: RICTOR gene amplification was present in 11% of lung cancer, and may be associated with smoking-related lung cancer with neuroendocrine features.

EP.03B.05 Construction and Validation of a Prognostic Model Using Loratadine-Related Genes in NSCLC Patient with Tumor Microenvironment.

X. Liu[1], L. Huang[1], F. Yao[2], R. Zeng[3], Q. Cai[1], L. Lin[1], H. Wang[1], Y. Feng[1], W. Liang[1], J. He[1], [1]the First Affiliated Hospital of Guangzhou Medical University, State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease,, Guangzhou/CN ,[2]Southern University of Science and Technology, Shenzhen/CN ,[3]Nanshan School, Guangzhou Medical University,, Guangzhou/CN

Introduction: This study aimed to investigate the association between loratadine use and lung cancer patients' survival and to develop a risk score formula for lung adenocarcinoma (LUAD) patients based on gene expression profiles and clinical features.

Methods: Utilizing the least absolute shrinkage and selection operator (LASSO) Cox regression, we developed a 5-gene prognostic signature related to loratadine's mechanism of action in LUAD, drawing from The Cancer Genome Atlas (TCGA) cohort and a Gene Expression Omnibus (GEO) dataset. We evaluated gene expression, immune infiltration, and animal experiments to confirm the functional significance of the identified risk genes in mice.

Results: A risk score formula of loratadine use was established incorporating five genes (ABCC2, NUPR1, KCNH2, ABCB1, NR0B2) to classify LUAD patients into high-risk and low-risk groups with different survival probabilities, confirmed by Kaplan-Meier curves and validated by time-dependent ROC analysis (AUCs for 1, 3, and 5 years: 0.677, 0.640, 0.644, respectively). Multivariate regression analysis identified pathological subtyping and the risk model as independent prognostic factors. Additionally, immune profiling revealed differential expression of immune cells and checkpoints between risk groups, with the low-risk group showing a favorable immune environment. In vivo experiments demonstrated the same conclusion. Finally, we conducted immunohistochemistry to validate the function of the risk genes. The results revealed significant differences in the expression of the KCNH2 and NR0B2 gene between the treatment group (receiving loratadine) and the control group (not receiving loratadine), which suggests that the use of loratadine may influence the survival of LUAD patients by affecting the expression of the KCNH2 and NR0B2 gene.

Conclusions: Our study introduces a loratadine-based risk score model for LUAD. The model, coupled with immune profiling, offers insights into the molecular and immunological landscape of LUAD, presenting implications for personalized medicine and targeted therapies.

Introduction: High prevalence of EGFR-mutant (EGFRm) lung cancer was found in the Asian population, especially in non-smoker. Preclinical data has demonstrated that inflammatory cytokines activated by PM2.5 affected the expansion of EGFRm clone in patients. Here, we explored the pathogenesis and the correlation between inflammatory markers and EGFRm NSCLC.

Methods: Resected NSCLC patients treated at Ramathibodi Hospital during 2016-2023 were enrolled. Tumor tissues and blood serum were retrieved from Ramathibodi tumor biobank. Del19 and L858R mutation were performed by real time-PCR in the cancerous tissue and digital PCR in the normal tissue of resected tumor in the same patient. NF-Kb and STAT3 protein signaling were measured by InstantOne ELISATM assays in both cancerous and normal tissue of resected tumor. Cytokines including of IL-1ß, IL-6, IL-8, IL-10, IL-12 and TNF-α were explored in baseline serum by flow cytometry (BD Cytometric Bead Array). Association factor between EGFR status and inflammatory cytokines determined by Logistic regression. P-value < 0.05 was defined as statistical significance.

Results: One-hundred and forty resected NSCLC patients were enrolled. The majority of NSCLC patients were female (65%), non-smokers (74%), stage 1 (64%), and treated with lobectomy (91%). The prevalence of EGFRm in cancerous tissue was 58% (Del19=30% and L858R=28%). Whereas, the normal tissue of resected tumor, EGFRm was found only 5% in EGFRm NSCLC. NF-Kb protein signaling was statistically higher in cancerous tissue compared to normal tissue [median OD=0.82 (IQR; 0.07-2.82) vs 0.32 (IQR; 0.05-2.48, P<0.001] (Figure 1). STAT3 protein signaling was also higher in cancerous tissue compared to normal tissue [median OD=0.32 (IQR; 0.10-1.58) vs 0.17 (IQR; 0.06-1.29, P<0.001]. Furthermore, STAT3 was significantly increased in EGFRm patients compared to EGFRwt patients in the cancerous tissue [median OD=0.36 (IQR; 0.234-0.592) vs 0.23 (IQR; 0.158-0.409), odds ratio=11.09 (95% CI; 2.17-56.58), P=0.004]. Serum TNF and IL-10, together with STAT3 in cancer cell were statistically significant higher in EGFRm compared to EGFRwt patients (P=0.003, 0.008, and <0.001, respectively). None of the cytokines was statistically different between EGFRm and EGFRwt patients in univariable analysis, only STAT3 in cancer cell, PD-L1 and smoking status were statistically significant difference by EGFR mutational status (P=0.004, 0.05, and 0.008). However, only STAT3 in cancer cells and non-smoker were associated with EGFRm NSCLC in multivariable analysis.

Conclusions: Inflammation could be pathway of both NSCLC and EGFRm lung cancer pathogenesis as we demonstrated in our pilot study. STAT3 is a potentially important inflammatory-predictive biomarkers. Larger cohort is needed.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.03C.02 The Potential of Fluoropyrimidine to be an Immunologically Optimal Partner of Immunotherapy for Thoracic Malignancies

H. Ogino[1], N.T. Nguyen[1], H. Kozai[1], A. Mitsuhashi[1], Y. Tsukazaki[1], Y. Yabuki[1], R. Ozaki[1], M. Hanibuchi[1,2], Y. Nishioka[1], [1]Graduate School of Biomedical Sciences, Tokushima University, Tokushima/JP ,[2]Graduate School of Biomedical Sciences, Tokushima University, Tokushima/JP

Introduction: Chemo-immunotherapy, a combination therapy of cytotoxic chemotherapy with immune checkpoint inhibitor (ICI), is a current standard regimen in the treatment of thoracic malignancies. Chemotherapy is known to induce not only direct cytotoxic effects on tumor cells but also immune modulating effects, such as stimulating immunogenic cell death (ICD) or depleting immune suppressive cells, such as myeloid derived suppressor cells (MDSCs). These effects are thought to be a rationale of combining chemotherapy with ICI. Either pemetrexed (PEM) or taxane plus platinum are the standard regimens in the combination with ICI for thoracic malignancies, however, it is still unknown that whether they are immunologically optimal partners. We then performed the immunological analyses to determine the optimal chemotherapy to be combined with ICI for thoracic malignancies.

Methods: We used four human NSCLC cell lines (PC9, A549, H226, and H2170) and one murine malignant mesothelioma cell line (AB1-HA). To evaluate the immune modulating effects of chemotherapeutic agents that are clinically administered for thoracic malignancies, we used 5-fluorouracil (5-FU), tegafur-gimeracil-oteracil potassium (S-1), PEM, paclitaxel (PTX), docetaxel (DTX), vinorelbine (VNR), gemcitabine (GEM), cisplatin (CDDP), and carboplatin (CBDCA). The induction of ICD in vitro was evaluated with cell-surface expression of calreticulin (CRT) and ATP secretion. The immunogenicity of ICD-induced tumor cells was evaluated with vaccination assay in mice. The number of tumor-infiltrating MDSCs was evaluated by flow cytometry and immunohistochemistry. The anti-tumor effects of several chemo-immunotherapies were evaluated with ABI-HA bearing mice.

Results: Among the several chemotherapeutic agents, 5-FU induced cell-surface expression of CRT on tumor cells tested more efficiently than others in vitro. 5-FU also enhanced the secretion of ATP from tumor cells. The efficiency of 5-FU in the induction of CRT was enhanced when combined with platinum. The vaccination with dying-AB1-HA cells treated with 5-FU, but neither PEM nor PTX, induced robust anti-tumor immune response in vivo. Furthermore, 5-FU and its oral formulation S-1, but not others, inhibited the accumulation of MDSCs in AB1-HA bearing mice through suppression of tumor-derived chemotactic factors for MDSCs, such as Bv8 and S100A8. Lastly, in comparison with PEM, administration of S-1 improved the synergistic anti-tumor efficacy of ICI in mice.

Conclusions: These results suggest that fluoropyrimidine can be an immunologically optimal partner of ICI through stimulating ICD of tumor cells and depleting MDSCs from tumor microenvironment for thoracic tumors.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.03C.03 Development of a Novel Immunotherapy for ICI Resistant KRAS-Mutantlung Cancer

T. Tenma[1], K. Nitanai[1], H. Yanada[1], C. Mori[1], R. Yoshida[1,2], Y. Minami[1], T. Nagato[3], S. Kitajima[4], T. Sasaki[1], [1]Department of Internal Medicine, Division of Respiratory Medicine and Neurology, Asahikawa Medical University, Asahikawa/JP ,[2]Institute of Biomedical Research, Yoshida Hospital, Asahikawa/JP ,[3]Department of Pathology, Asahikawa Medical University, Asahikawa/JP ,[4]Department of Cell Biology, Cancer Institute, Japanese Foundation for Cancer Research, Tokyo/JP

Introduction: Immune checkpoint inhibitors (ICIs) have proven to be effective in patients with advanced-stage lung cancer and have shown high efficacy in KRAS-mutant lung cancer. However, the efficacy of ICIs in KRAS-mutant lung cancer varies, and the presence of "co-mutations" is an important predictor of efficacy. Approximately 30% of KRAS lung cancer subtypes do not respond to ICIs, particularly KRAS-mutant lung cancers with co-mutations in LKB1 (KL lung cancer). This study aimed to present a novel treatment for ICI-resistant KRAS-mutant lung cancers.

Methods: We analyzed The Cancer Genome Atlas Program (TCGA) and the Cancer Cell Line Encyclopedia (CCLE) to investigate the association between co-mutations and our target molecule, protein X, in KRAS lung cancer. We validated its dual function as both a therapeutic target and a biomarker. The antitumor immune response was evaluated through in vitro immune cell co-culture experiments using KL lung cancer cell lines with forced expression of protein X. Furthermore, the effect of overexpressing protein X on tumor shrinkage was validated in vivo using a syngeneic tumor transplantation model. Additionally, immunohistochemistry (IHC) for LKB1 and protein X was performed on samples from 57 patients with KRAS lung cancer at Asahikawa Medical University Hospital to confirm the association between their expression levels.

Results: Co-culture experiments with immune cells showed that KRAS-mutant lung cancer cells overexpressing protein X showed enhanced immune response. Furthermore, when protein X-overexpressing KRAS-mutant lung cancer cell lines of syngeneic origin were generated and subcutaneously administered to immunocompetent mice, the tumor size decreased compared to that in the control group. Additionally, IHC results for LKB1 and protein X in KRAS lung cancer patient samples showed a correlation between the expression of these two molecules.

Conclusions: Protein X may serve as a novel therapeutic target for ICI-resistant KRAS-mutant lung cancers. Furthermore, induction of protein X expression could lead to novel immunotherapy approaches.

Keywords: non-small cell lung cancer, KRAS, Immune checkpoint inhibitors

EP.03D.01 Mechanistic Study of 5-Hydroxytryptamine-Mediated Promotion of Non-Small Cell Lung Cancer Metastasis by Regulation of RPL24

Y. Sun[1], D. Zang[1], J. Chen[1], M. Lin[1], [1]The Second Hospital of Dalian Medical University, DALIAN/CN

Introduction: Non-small cell lung cancer (NSCLC) is one of the most common and aggressive types of lung cancer. The gut microbiota can directly or indirectly influence host 5-HT levels. Previous experiments from our research group have shown that 5-HT can promote the migration and invasion of lung cancer cells.

Methods: In this study, we measured peripheral blood 5-HT levels in NSCLC patients with distant metastases (28 cases) and without distant metastases (20 cases) using ELISA kits. Simultaneously, we conducted metagenomic analysis of the gut microbiota in both groups of patients and correlated it with peripheral blood 5-HT levels. Next, we performed whole-genome sequencing of H1299 cells treated with 5-HT to identify differential genes. We assessed the impact of the differential molecule RPL24 on the migration and invasion ability of NSCLC cells through Western blotting, Transwell assays, and scratch assays. We predicted potential receptors of 5-HT using the GEPIA2 database. We measured the mRNA expression levels of 5-HT receptor genes in cells using qRT-PCR. We evaluated the effects of 5-HT and 5-HT receptor antagonists on the migration and invasion ability of NSCLC cells and on the EMT pathway using Transwell assays, Western blotting, and scratch assays.

Results: Peripheral blood 5-HT levels were significantly higher in NSCLC patients with distant metastases than in those without distant metastases. NSCLC patients with distant metastases had higher species richness and diversity of gut microbiota, and the abundance of the differential bacterium Clostridium difficile was positively correlated with peripheral blood 5-HT levels. Transient silencing of RPL24 promoted the migration and invasion of H1299 and A549 cells and facilitated EMT. The expression of the 5-HT receptor HT3A was higher in primary NSCLC tissues than in adjacent non-tumor tissues, and the mRNA expression of HTR3A in H1299 and A549 cells was higher than in lung epithelial cells. Partial reversal of the migratory and invasive ability of 5-HT was observed after treatment with 5-HT combined with ondansetron, indicating that HTR3A is the receptor mediating the role of 5-HT in regulating RPL24 to promote NSCLC migration and invasion.

Conclusions: NSCLC patients with distant metastases have higher peripheral blood 5-HT levels. These patients exhibit a unique gut microbiota profile, with the abundance of Clostridium difficile positively correlated with 5-HT levels. 5-HT downregulates RPL24 through the HT3A receptor, activates the EMT pathway, enhances the migration and invasion ability of NSCLC cells, and promotes NSCLC metastasis.

Keywords: Non-small cell lung cancer, 5-hydroxytryptamine, metastasis

EP.03D.02 HNRNPC-Regulated PA2G4 Promotes Proliferation and Metastasis of LUAD Cells

J-H. Chen[1], Y. Gai[2], Y. Long[2], [1]Guangzhou Twelfth people's Hospital, Guangzhou/CN ,[2]Guangzhou the Twelfth People's Hospital, Guangzhou/CN

Introduction: HNRNPC is a RNA-binding protein, which takes part in pre-mRNA processing. In our previous research, HNRNPC was identified to high-expressed in lung adenocarcinoma (LUAD) tissue with poor-prognosis. Moreover, HNRNPC has known as to extend PA2G4 mRNA and change its polyadenylate (PolyA) site. This research aims to explore the role and mechanism of HNRNPC/PA2G4 in LUAD.

Methods: Transcripts with different polyA site in PA2G4 mRNA 3'UTR are confirmed by 3'RACE-electrophoresis. The binding between HNRNPC protein and PA2G4 mRNA is confirmed by RNA pulldown, RNA binding protein immunoprecipitation (RIP) assays and luciferase reporter experiment. Gene expressions are detected by qRT-PCR experiment and western blotting. Transcription inhibitor Actinomycin D (ActD) is used to evaluate the RNA stabilization. Cell proliferation is evaluated by CCK8 assay and colony formation assay. Cell cycle is analyzed by flow cytometry assay. Cell migration and invasion are detected by Transwell assay

Results: PA2G4 mRNA has two transcripts with different PolyA sites, PA2G4-L and PA2G4-S. HNRNPC overexpression increases PA2G4-T level, while PA2G4-L level has no significant changes, which means that PA2G4-S is increased. Conversely, HNRNPC inhibition decreases PA2G4-T level and increases PA2G4-L level, which means that PA2G4-S is decreased. Moreover, HNRNPC overexpression promotes PA2G4 mRNA stabilization and HNRNPC inhibition have an adverse effect. The binding between HNRNPC protein and PA2G4 mRNA is further confirmed. After transfected with overexpression plasmids, PA2G4 mRNA and protein level are increased. ActD treatment shows that PA2G4-S is more stable than PA2G4-L. Furthermore, both PA2G4-L and PA2G4-S overexpression promotes LUAD cells proliferation and metastasis, but PA2G4-S overexpression has a better effect than PA2G4-L.

Conclusions: HNRNPC binds to PA2G4 mRNA, induces an advance PolyA site and shortened PA2G4 mRNA, which results in a stabilization of PA2G4 mRNA and promotes proliferation and metastasis of LUAD cells.

Keywords: LUAD, Proliferation, metastasis, HNRNPC, PA2G4

EP.03D.03 Genomic and Disease-specific Hallmarks of Extrachromosomal Circular DNAs in Lung Cancer and Its Potential Role in Cancer Progression

J. Kang[1], I-Q. Jiang[2], X-N. Hong[3], P. Han[4], J. Su[2], W-Z. Zhong[2], [1]Guangdong lung cancer institute, Guangzhou/CN ,[2]Guangdong Lung Cancer Institution, Guangzhou/CN ,[3]The Seventh Affiliated Hospital of Sun Yat-sen University, Shenzhen/CN ,[4]Qingdao-Europe Advanced Institute for Life Sciences, Qingdao/CN

Introduction: Extrachromosomal circular deoxyribonucleic acids (eccDNAs) carrying random genomic segments widely present in various cancers and participate in tumorigenesis and tumor progression, which are a newly discovered hallmark of cancer. However, their molecular functions and mechanisms in non-small cell lung cancer (NSCLC) are rarely known.

Methods: In this study, we comprehensively characterized and analyzed the circulome-associated genome heterogeneity in 34 NSCLC patients using Circle-Seq and RNA-Seq. 34 surgically NSCLC tissues, 34 matched normal adjacent tissues (NAT), and 23 matched recurrent cancer tissues (RCT) were used as study objects. All patients had complete prognostic information. qRT–PCR was used to verify the expression level of eccDNA.

Results: The eccDNA abundance in NSCLC tissues was aberrantly higher than that of NAT and that of RCT. The eccDNAs of NSCLC tissues and RCT are GC-rich. Analysis of the genomic distribution of eccDNAs shows that eccDNAs of NSCLC tissues and RCT are found on all chromosomes but enriched on chromosomes 7 and 19 with a high density of protein-coding genes, 5'Untranslated Regions and exon regions. Moreover, eccDNA with miRNA genes is highly enriched in NSCLC tissues and RCT. The eccDNA derived from CILP2 was upregulated in RCT and patients with eccDNAs derived from CILP2 was upregulated in RCT were associated with worse outcomes.

Conclusions: The cancerous eccDNAs could influence genome-wide gene expression and increased oncogene dosage of NSCLC. CILP2 promoting metastasis of NSCLC and CILP2 identified by eccDNA sequencing acts as an oncogene and might be a new biomarker for NSCLC diagnosis and prognosis evaluation.

EP.03D.04 SOX2 Inhibits Ferroptosis by Regulating FOXM1 Transcription Through Phase-Separation Recruitment of Coactivators

W. Zhang, J. Wang, Jiangsu Province Hospital and The First Affiliated Hospital of Nanjing Medical University, Nanjing/CN

Introduction: SOX2 is an oncogenic transcription factor that activates transcription by regulating promoter linkage. Intrinsic disordered regions (IDRs) in the transactivation domain of SOX2 are essential for the formation of phase separation droplets. Liquid-liquid phase separations (LLPS) are Intrinsic disordered regions (IDRs) of various proteins (including transcription factors, chromatin regulators, and RNA-binding proteins) that form dynamic liquid droplets or gel-like phase separation condensates through multivalent and weak interactions, thereby affecting organelle formation and countless biological processes. These include transcription, X chromosome inactivation, DNA damage, tumorigenesis, autophagy, etc. However, how SOX2 regulates transcription via phase separation to promote lung cancer progression remains unclear.

Methods: We analyzed the role of SOX2 in lung adenocarcinoma by bioinformatics. Then, we overexpressed or knocked down SOX2 in A549 and H1299 cell lines to detect ferroptosis-related indicators, proliferation, invasion and migration abilities. By analyzing the 317 amino acid sequence encoding SOX2, three major intrinsic disordered regions were identified. The ability of SOX2 to phase separation in cells was demonstrated by in vitro and in vivo droplet assay, fluorescence recovery after photobleaching (FRAP) assay and droplet fusion assay . The co-localization of SOX2 with transcriptional coactivators (P300, Med1, CDK9) and gene activation histone markers was verified by immunofluorescence. The binding sites were verified by luciferase reporter and Chip experiments. Stable cell lines with both overexpression and knockdown of SOX2 were successfully generated and confirmed in in vivo experiments.

Results: SOX2 promotes lung adenocarcinoma proliferation and inhibits ferroptosis. And has the ability of phase separation. It regulates transcription through phase separation recruitment coactivator to activate FOXM1 to initiate transcription and inhibit ferroptosis, thus affecting the progression of lung adenocarcinoma.

Conclusions: SOX2, through the IDR region of its trans-activation domain, undergoes phase separation, recruits coactivators and histone markers to regulate transcription to inhibit ferroptosis and promote lung adenocarcinoma progression. This provides new ideas and methods for the treatment of lung cancer.

EP.03E.01 Patient-Derived Organoids Can Predict Response to Chemotherapy and Targeted Therapy in Lung Cancer Patients

C. Wang[1], J. Ni[1], J. Zhu[1], B. Chen[1], X. Xu[2], B. Tian[3],[4], [1]Shanghai Pulmonary Hospital, Tongji University School of Medicin, Shanghai/CN ,[2]Institute of Radiation Medicine, Shanghai Medical College, Fudan University,, Shanghai/CN ,[3]Department of Orthopaedic Surgery, Zhongshan Hospital, Fudan University, Shanghai/CN ,[4]Cancer Center, Zhongshan Hospital, Fudan University, Shanghai/CN

Introduction: Lung cancer is a challenging disease with significant inter-individual heterogeneity, numerous options for clinical therapeutic agents, and a clear and unmet clinical need for biomarkers that predict responsiveness to cancer chemotherapy and targeted therapies. Here, we evaluated the ability of patient-derived organoids (PDOs) to predict the functional consequences of clinical drug response and tumor heterogeneity.

Methods: Lung cancer cells isolated from patients were cultured, after which pathohistologic validation, next-generation sequencing, and drug sensitivity testing were done to determine the sensitivity of each patient to specific drugs. We evaluated the utility of such testing, including: success rate in generating organoids, time to culture the organoids, reproducibility and heterogeneity of the drug testing, and correlation of the test results with clinical efficacy.

Results: We successfully generated and validated from 90% (54/60) of patients undergoing standard care. In this study, we generated 54 lung cancer organoids (LCO) from 60 patients, all derived from CT-guided lung puncture or bronchoscopic biopsy samples. These LCOs were cultured in a relatively short period of time and included four major histological subtypes of lung cancer and multiple mutation types that were consistent with parental tumor tissue.The in vitro drug sensitization correlated with the clinical outcome of the patients, both untreated and clinically treated. Importantly, PDOs display inter- and intrapatient drug response heterogeneity to chemotherapy and targeted drugs. The drug sensitization results correlated with the clinical outcome and progression free survival (PFS) of the patients.

Conclusions: Our research imply that PDOs can predict LC patients responses in the clinic and may represent a companion diagnostic tool in lung cancer treatment, complementing genetic testing and helping to develop personalized treatment strategies, and adding to our understanding of the heterogeneity of genetic and drug responses.

EP.03E.02 Elucidation of Trastuzumab-Deruxtecan Resistance Mechanisms using in Vivo Xenograft Model Reflecting Pharmacokinetics

S. Yano, Y. Murase, Y. Liu, S. Arai, T. Ueda, N. Terada, H. Koba, Y. Tambo, S. Nanjo, Kanazawa University, Kanazawa/JP

Introduction: Trastuzumab-deruxtecan (T-Dxd) is an antibody-drug conjugate, which has been approved for HER2-low expressing breast cancer, HER2-positive breast cancer, HER2-positive gastric cancer, and HER2 mutation-positive NSCLC, in many countries. T-Dxd is effective against these cancers, almost all patients experience relapse due to resistance. In vivo pharmacokinetics is an important factor which affects emergence of acquired resistance. Therefore, we used human HER2-positive-breast cancer, -gastric cancer, and -NSCLC cell lines to induce T-Dxd resistance in a xenograft model that can reflect in vivo pharmacokinetics, and investigated the resistance mechanism.

Methods: We inoculated gastric cancer cell line (N87) subcutaneously into immunodeficient mice, and treated the mice with T-Dxd (5 mg/kg) intravenously three times every 1 to 2 months when tumors regrew. Then, the enlarged tumor was recovered, and the resistant tumor cells (N87 T- Dxd AR) was established. For NSCLC and breast cancer, where central nervous system (CNS) metastasis is a clinical problem, we inoculated luciferase gene-introduced cancer cell lines (Calu-3, BT474) into leptomeningeal space of immune deficiency mice. We monitored tumor progression in CNS by luminescence after luciferin administration, and administered T-Dxd (5mg/kg) three times every 1 to 2 months when tumors regrew. Then, the enlarged tumors were collected, and resistant tumor cells (Calu-3 LMC T-Dxd AR, BT474 LMC T-Dxd AR) were established.

Results: Compared to the parental cells, all three resistant tumor cell lines were resistant to T-Dxd and Dxd, but sensitive to DTX and eribulin, in vitro. In addition, the three resistant tumor cell lines expressed HER2 at the same level as each parental cell line, and were sensitive to afatinib and lapatinib, which have HER2 kinase inhibitory activity. ABC-G2 (BCRP1) expression was increased in N87 T-Dxd AR cells compared to the parental cells. Furthermore, combined use of ABC-G2 inhibitors (Ko143 or KS176) restored T-Dxd sensitivity. On the other hand, ABC-G2 expression was not increased in Calu-3 LMC T-Dxd AR, and T-Dxd sensitivity was not restored even when ABC-G2 inhibitor was used in combination.

Conclusions: These results suggest that the mechanism of T-Dxd resistance differs depending on the cancer type. We are currently conducting studies to further elucidate the resistance mechanism of T-Dxd in order to develop treatments to overcome resistance.

EP.03E.03 Next Step for R1 Resection of Tracheal/Bronchial Malignant Tumor - Organoids Predict Adjuvant Therapy Response

R. Wang, L. Zhang, Y. Chen, C. Wang, J. Chen, J. Sun, S. Li, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Currently, there is no acknowledged guideline for adjuvant therapy in tracheal malignancies. This pilot prospective study with the goal of determining whether patient-derived organoids (PDOs) can model or predict postoperative outcomes for tracheal/bronchial cancers with positive resection margins (R1 resection).

Methods: Patients with R1 resection of tracheal/bronchial malignancy were enrolled to establish PDOs from surgical specimens. PDOs were verified by histological staining, of which interests were analyzed through drug and radiation sensitivity tests. Utilizing a comparative analysis in cellular viability pre- and post-exposure, alongside morphological observations via light field illumination, sensitivities were categorized into distinct tiers: highly sensitive (Grade A), moderately sensitive (Grade B), mildly sensitive (Grade C), or non-sensitive (Grade D). The most discerning therapeutic regimen was subsequently selected for implementation in patient's adjuvant treatment. The assessment of adjuvant treatment efficacy adhered to the RECIST version 1.1 criteria, thereby facilitating a comprehensive appraisal of the viability of PDO-based detection therapy sensitivity.

Results: 6 patients received surgeries, with distinct pathological types. PDOs cultures were successfully established, including nuclear protein testis carcinoma (NUT-C) (1/6), mucoepidermoid carcinoma (MEC) (2/6), adenoid cystic carcinoma (ACC) (2/6) and squamous cell carcinoma (SCC) (1/6). NUT-C showed high sensitivity to chemotherapy and SCC revealed mildly sensible to immunotherapy, while the others exhibited high sensitivity to radiotherapy. All patients received adjuvant therapies. Repeated computed tomography (CT) scans and surveillant bronchoscopy were performed for therapeutic evaluation. For the patients who underwent respective adjuvant treatment regimens, the median follow-up time was 4.5 months (ranging from 3 to 8 months), and neither lesion recurrences nor metastases, with a noticeable improvement in the quality of life compared to preoperative state.

Conclusions: Tracheal/Bronchial malignancy PDOs may be feasible for prediction of adjuvant therapeutic sensitivity and have clinical benefits to reduce the recurrence risk and improve prognosis for R1 resection cases. The prediction by PDOs will inform larger trials designed to further investigate the accuracy on the forecast of outcomes as well as strategies for airway cancers.

EP.03E.04 Establishment of a Cancer Orgnoid Model for Personalized Drug Selction

Y. He, Y. Chen, R. Zheng, Hangzhou Cancer Hospital, Hangzhou/CN

Introduction: Recently, the development of HER2 targeted therapy has improved the treatment efficacy on HER2 positive breast cancer, but the overall situation is still unsatisfying due to the complex pathology and tumorigenesis. So far, organoid model derived from BC patients has a good potential in becoming a promising in-vitro tool for personalized treatment and preclinical research. A breast cancer organoid model was established from the patient's tumor punch biopsy sample, which reproduced the morphological and molecular characteristics of the original tumor. Selecting drugs based on tumor organoid models can improve therapeutic efficacy.This study revealed that patient derived tumor organoid model could retain the tumor heterogeneity and contribute to the in-vitro drug testing for precision therapy.

Methods: Patients And Human SamplesFour puncture biopsies were obtained from a 51-year-old female patient with a breast tumor and collected with an 18G needle.The samples were used for organoid construction. Patient-derived Organoids ModelGenomic AnalysisBreast cancer tissue samples and cultured organoids were used to extract genomic DNA and perform whole-exome sequencing (WES) analysis,respectively. ImmunohistochemistryDrug ScreeningOrganoids were dissociated into single cells according to the passaging procedure described above. The collected cells were resuspended in appropriate amount of MasterAimTM Breast Cancer Organoid Complete Medium (AimingMed Hangzhou, China) with 5% Matrigel.After 48 hours, 6 concentrations of 5-fluorouracil, Pyrotinib, Pertuzumab, Docetaxel, Carboplatin, Trastuzumab, Paclitaxel, Epirubicin, Doxorubicin, Vinorelbine (Selleck) as well as DMSO controls were added in triplicates. After 4 days,The luminescence values were read on a multifunctional enzyme marker (Tecan).Clinical applicationSelect the clinical medication scheme according to the drug sensitivity results of Organoid

Results: A breast cancer organoid model was established from the patient's tumor punch biopsy sample, which reproduced the morphological and molecular characteristics of the original tumor. Drug sensitivity tested by organoids model suggested that the patient was not sensitive to the guideline recommended by first-line therapy, while combination of pyrotinib and 5-fluorouraeil showed highest tumor cell inhibition. After 2 cycles of combination of capecitabine and pyrotinib, the significant reduction of breast lumps and axillary lymph nodes were shown on ultrasound, with the decrease of tumor markers, and efficacy assessment of partial response (PR).

Conclusions: This study revealed that BCOs derived from advanced recurrent and TCbHP-resistant BC patient could retain the tumor heterogeneity and contribute to the in-vitro drug testing for precision therapy.

EP.03F.01 Modeling the Relationship of Clinical Safety Profile of EGFR Inhibitors with Wild-Type EGFR Inhibition in Cellular Model

J. Zhou, W. Deng, P. Jiang, Z. Zimmerman, V. Liptak, J.J. Cui, BlossomHill Therapeutics, Inc., San Diego/CA/USA

Introduction: EGFR inhibitors are established therapies for EGFR mutant NSCLC. Rash and diarrhea are well characterized adverse events (AE) associated with this class attributed to inhibition of wild-type (WT) EGFR. Systematic quantification of the relationship of nonclinical potency against WT EGFR with the reported clinical safety profile may help to better predict the potential clinical safety of novel drugs targeting this pathway. The study objective is to systematically evaluate the relationship between the reported rates and grades of rash and diarrhea across multiple clinical EGFR inhibitors with their inhibitory activity against WT EGFR.

Methods: Nonclinical inhibitory activities of EGFR inhibitors against WT EGFR were measured by deriving IC50 concentrations from cell proliferation assays in A431 cells carrying EGFR-WT gene amplification. The EGFR inhibitors include commercially available proxy compounds of gefitinib, afatinib, osimertinib, mobocertinib, sunvozertinib, zipalertinib, BLU-945, BDTX-1535, etc. Clinical safety data are obtained from drug labels or publications, including all grades AEs and Grades ≥3 rash and diarrhea. To assess correlations between A431 IC50 values and clinical data, Pearson correlation test was used. The relationship between AE rates and A431 IC50 data was modelled using linear regression model. With event count data and their sample sizes, a logistic regression model was also built. Its goodness-of-fit was assessed by the Hosmer and Lemeshow test.

Results: Highly statistically significant correlations of A431 cell IC50 values with All Grades rash (correlation coefficient r=-0.86, p=0.0027), with Grades ≥3 rash (r=-0.82, p=0.0067), with All Grades diarrhea (r=-0.84, p=0.0091), and with Grades ≥3 diarrhea (r=-0.82, p=0.012), respectively, were observed. Linear regression and logistic models adequately fit rash and diarrhea data, supported by the Hosmer and Lemeshow goodness-of-fit test results. The fitted regression line of clinical safety rates with 95% confidence limits against the A431 cell IC50 values together with the reported AE rates for rash and diarrhea are shown in the figure.

Conclusions: The relationship of clinical adverse event rates of rash and diarrhea with nonclinical inhibitory activity against WT EGFR in A431 cell proliferation assay is robustly described by regression modeling as determined by a systematic approach. The potency of inhibition of WT EGFR in a uniform nonclinical assay strongly correlated with overall rates and severity of rash and diarrhea observed in the clinical setting. These results may be useful in enhancing the understanding of the potential clinical safety profile of novel EGFR targeted therapies at the nonclinical development stage.

Keywords: EGFR inhibitor, cellular model, rash

EP.03F.02 Exploration of Acquired Resistance Mechanisms to the 4th-Generation EGFR-TKI in EGFR-Mutated Lung Cancer - An in Vitro Study

S. Fukuda, K. Suda, A. Hamada, H. Oiki, S. Ohara, M. Ito, J. Soh, T. Mitsudomi, Y. Tsutani, Kindai University Faculty of Medicine, Osaka-Sayama/JP

Introduction: In patients with lung cancer harboring activating EGFR mutation, the emergence of acquired resistance to EGFR tyrosine kinase inhibitors (TKIs) is almost inevitable even after a remarkable clinical response. Secondary mutations such as T790M or C797S are important mechanisms responsible for acquired resistance to the 1st / 2nd generation TKIs and 3rd generation TKIs, respectively. Novel EGFR-TKIs, the 4th generation EGFR-TKIs, are under early clinical development to overcome both the T790M and C797S mutations. However, even with these new drugs, it is anticipated that the cancer cells will develop resistance. In this study, we explored such acquired resistance mechanisms to the 4th generation TKI, BI-4020.

Methods: HCC4006, H1975, H3255, PC9, and HCC827 lung cancer cell lines, all of which harbor EGFR mutation, were exposed to increasing concentrations of BI-4020. After establishing cell lines that can grow in the presence of 2000 nM of BI-4020, the mechanisms for the resistance were explored by direct sequencing of the EGFR, copy number analysis of candidate genes, Western blotting, phospho-RTK array, and RNA sequencing.

Results: We successfully established acquired resistant cell lines from all cell lines used but H3255. None of the resistant cells harbor any secondary EGFR mutations. We found that HCC827 resistant to BI-4020 (HCC827BIR) had MET gene amplification (2.97 times) and that it was sensitive to a combination of capmatinib (MET-TKI) and BI-4020. On the other hand, HCC4006BIR and H1975BIR developed epithelial to mesenchymal transition as shown by reduced expression of E-cadherin, increased expression of vimentin, and morphological change. PC9BIR showed increased MET phosphorylation without MET copy number gain, however, capmatinib did not restore sensitivity to BI4020.

Conclusions: The on-target resistance through the secondary EGFR mutation was not detected. Instead, MET gene alterations and EMT known for the mechanisms to 1st - 3rd generation EGFR-TKIs, were recurrently observed.

Keywords: BI4020, lung cancer cell lines, acquired resistance mechanisms

EP.03F.03 Orally Bioavailable Cyclin A/B RxI Macrocycle has Antitumor Effect in SCLC & NSCLC Cell Line Derived (CDX) & Patient Derived Xenograft (PDX) Models

B. Levin, L-F. Liu, F. Hamkins-Indik, R. Odeh, C.E. Gleason, P.D. Garcia, D.J. Earp, M.C. Cox, E.W. Wang, Circle Pharma Inc, South San Francisco/CA/USA

Introduction: Currently, there is no approved therapy targeting Rb/E2F pathway deregulation, which occurs in the majority of small cell lung cancer (SCLC) tumors. Complexes between cyclins and cyclin-dependent kinases (Cdk) regulate the activity of RB1 and E2F to drive cell cycle progression. Key substrates and modulators of Cyclin/Cdk complexes bind to the cyclin hydrophobic patch (HP) through their conserved RxL motif. CID-078, an orally bioavailable, passively cell permeable, potent, and selective macrocycle binds the HP of cyclins A and B and blocks the interaction of E2F1 with cyclin A-Cdk2 and Myt1 with cyclin B-Cdk1. CID-078 has been shown to have potent and selective antiproliferative activity in multiple cancer cell lines, including tumor regression in SCLC xenografts and triple negative breast cancer (TNBC) PDX models with high E2F targets hallmark pathway. Here we show that elevated E2F targets and G2M checkpoint hallmark pathway scores and elevated levels of cyclin B1 and p-separase (S1126) are associated with response to cyclin A/B RxL inhibition in SCLC xenografts. These activities are consistent with the proposed mechanism of action for cyclin A/B RxL inhibition which leads to DNA damage, blocks progression at G2M, and leads to apoptotic tumor cell death.

Methods: CID-078 drug response was evaluated in 46 SCLC and 104 NSCLC cell lines. Hallmark pathway scores were calculated from RNAseq data by Gene Set Variation Analysis method using the MSigDB hallmark collection. Based on the significant association of high E2F hallmark pathway score, several CDX and PDX models were selected to evaluate response. NCI-H446 (SCLC CDX) was treated with CID-078 at 50 and 100 mg/kg BID and 25 and 100 mg/kg TID for 14 days. LUX083 (SCLC PDX), NCI-H23 (NSCLC CDX), NCI-H2106 (NSCLC CDX), and CTG-0860 (NSCLC PDX model with low E2F targets hallmark pathway score included as a negative control) were treated at 100 mg/kg BID and TID for 28 days. Post-CID-078 treatment and vehicle control samples from NCI-H446 were analyzed by multiplex IHC for protein level changes in E2F1, cyclin B1, mitotic specific marker p-separase, and DNA damage marker ATM.

Results: CID-078 induced antiproliferation activity in SCLC and NSCLC cell lines. Tumor models with high E2F and G2M hallmark pathways scores and/or elevated levels of cyclin B1 and gene expression levels for separase (ESPL1) showed tumor growth inhibition and/or regression at 100 mg/kg BID and TID (NCI-H446, LUX-083, NCI-H23, NCI-H2106). NCI-H446 tumor IHC analysis at day 6 post treatment showed an increase in p-separase and colocalization of p-separase and cyclin B1. CTG-0860, exhibited modest tumor growth inhibition, but no tumor regression.

Conclusions: As shown previously in TNBC PDX models, CID-078 treatment of SCLC and NSCLC models with high E2F hallmark pathway scores led to tumor regression. Interfering with RxL-mediated interactions between cyclins A and B with their substrates and modulators, including E2F1 and Myt1 by CID-078 may be a new treatment option for patients with SCLC, NSCLC, or TNBC. This hypothesis will be explored in the CID-078 first-in-human trial CID-AB1-24001 beginning later this year.

EP.03F.04 Treatment of Non-Small Cell Lung Carcinoma (NSCLC) Cells with Tumor Treating Fields (TTFields) And DNA-Dependent Protein Kinase (PK) Inhibitors

R. Engelman, D. Gerasimova, T. Borkum, S. Greenstein, E. Dor-On, Y. Barsheshet, A. Haber, M. Giladi, Y. Palti, Novocure Ltd, Haifa/IL

Introduction: Double-stranded breaks (DSBs) are considered the most deleterious form of DNA damage and can be repaired in cells through three main repair pathways: homologous recombination (HR), non-homologous end-joining (NHEJ), and microhomology-mediated end-joining (MMEJ). Tumor Treating Fields (TTFields) are non-invasive electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression. Recent research showed that TTFields downregulate expression of proteins from the Fanconi Anemia-BRCA pathway, thus lowering the cell's repair capacity via the HR pathway, leading to replication stress and DNA damage. Nedisertib and CC-115 are potent inhibitors of DNA-PK, a main protein mediating the repair of DSBs through the NHEJ pathway. CC-115 also inhibits mTOR, which regulates cell proliferation and survival. The current study examined the potential of the concomitant treatment of TTFields and DNA-PK inhibitors to impair DSBs repair and whether this effect can promote accumulation of DNA damage, triggering cancer cell death.

Methods: A549 and H1299 non-small cell lung carcinoma (NSCLC) cells were treated with TTFields (1 V/cm RMS, 150 kHz, 72 h), alone or with the addition of different concentrations of DNA-PK inhibitors (nedisertib or CC-115). Efficacy was measured by analyzing cell count, colony formation, and apoptosis induction. The overall effect was calculated by multiplying cell count with colony formation. To determine the type of TTFields-drug interaction, the expected additive effect was calculated from the effects of the individual treatments and compared to the actual measured value for treatments co-application (using the Bliss independence method). In addition, cell cycle distribution at different time points was performed for each treatment alone and for the concomitant treatments.

Results: Co-application of TTFields and nedisertib or CC-115 showed a synergistic interaction in A549 cells, which was somewhat higher for CC-115. In H1299 cells, the concomitant treatment of TTFields and nedisertib showed additive interaction and the concomitant treatment of TTFields and CC-115 showed synergistic interaction in cytotoxicity and an additive overall effect. The concomitant treatment of TTFields and nedisertib or CC-115 also resulted in G1 arrest of both cell lines.

Conclusions: Our results suggest a potential advantage for TTFields concomitant with DNA-PK inhibitors. The stronger interaction between TTFields and CC-115 compared to that with nedisertib seen in both cell lines, may possibly be attributed to the dual inhibitory effect of CC-115. In addition, the lower effect of both drugs in H1299 cells compared to A549 cells may be explained, at least in part, by the fact that H1299 cells have an amplification mutation in PRKDC, the catalytic subunit of DNA-PK. Future studies will test whether treatment with TTFields plus DNA-PK inhibitors may sensitize cancer cells to irradiation, a treatment modality that induces DSBs.

EP.03F.05 A Dose-Effect Relationship of a Novel Bronchoscopy Guided Endobronchial Radiofrequency Ablation for Peripheral Lung Tumors

W. Ji[1], J. Seo[2], C. Lee[2], M-K. Chon[3], W. Kim[4], C.G. Kang[5], J-H. Kim[3], [1]Asan Medical Center, Seoul/KR ,[2]Tau Medical, Yangsan/KR ,[3]Pusan National University Yangsan Hospital, Yangsan/KR ,[4]Mobility System Group, Korea Institute of Industrial Technology, Daegu/KR ,[5]Vasflex Co., LTD, Daegu/KR

Introduction: Bronchoscopy-guided radiofrequency ablation (RFA) represents a promising technique for treating peripheral lung tumors, and a predictive dose-effect relationship of RFA is crucial for its clinical application. Here, we present finding on the dose-effect relationship of our novel bronchoscopy-guided endobronchial RFA technique for peripheral tumors.

Methods: In this preclinical study, we employed a novel bronchoscopy-guided RFA procedure utilizing a specially designed balloon catheter (CAROL catheter) and an injectable bronchial electrode based on a medical grade liquid metal (E-GaIn) in porcine lungs. We evaluated the correlation between the volume of E-GaIn and the diameter of the ablation zone. Additionally, we utilized a pseudotumor model created by artificially injecting a mixture of beef meat and contrast dye to validate the efficacy of this novel bronchoscopy-guided RFA technique.

Results: Sixteen temperature-time controlled mode bronchoscopic RFA experiments were conducted, and we found a close correlation between the volume of E-GaIn and the size of the ablation zone (Table 1). This dose-effect relationship of RFA was well-established when the volume of E-GaIn was less than 0.5 ml (R2=0.63, Figure 1). However, achieving homogenous ablation with bronchial electrodes containing more than 0.5 ml of E-GaIn appeared unlikely. In the confirmatory pseudotumor model, all tumors (n=5, mean tumor volume 15,069.6 ± 9,624.3 mm3) were successfully ablated (mean ablation volume 165,441 ± 89,998.5 mm3) using this novel bronchoscopic RFA technique. The mean volume of infused E-GaIn was 0.58 ± 0.16 ml, and the mean ablation time was 464 ± 252.9 seconds.

Conclusions: Our study demonstrated that the novel concept of bronchoscopy-guided endobronchial RFA exhibited an excellent dose-effect relationship when the volume of medical-graded liquid metal was less than 0.5ml. These promising preclinical findings strongly advocate for the translation to human application.

EP.03G.01 Comparison of Tumor Immune Microenvironments Between Primary and Metastatic Sites in Non-Small Cell Lung Cancer

K. Sankar[1], J. Mercer[2], E. Jaeger[2], J. Godden[2], E. Williams[2], M. Thompson[2], S. Patel[3], K. Reckamp[1], F. Weinberg[4], [1]Cedars-Sinai Medical Center, Los Angeles/CA/USA ,[2]Tempus AI, Inc., Chicago/IL/USA ,[3]University of North Carolina in Chapel Hill, Chapel Hill/NC/USA ,[4]University of Illinois Chicago, Chicago/IL/USA

Introduction: The tumor immune microenvironment (TIME) plays a key role in tumor progression and response to immune checkpoint inhibitors (ICIs). Additional analysis of the TIME across sites of disease may help inform future clinical trial designs and identify unique processes to exploit through novel combinatorial approaches. Here, we investigated differences in the TIME of primary and common metastatic sites in patients with NSCLC.

Methods: We retrospectively analyzed de-identified next-generation sequencing data from unique patients with metastatic NSCLC (n=6,534) in the Tempus Database. Tumors from primary lung (n=3,823), liver (n=937), CNS, brain and meninges (n=1,035) and bone (n=739) were sequenced with the Tempus xT DNA (648-gene panel) and xR whole transcriptome RNA assays. Demographics, clinical characteristics, PD-L1 expression, tumor mutational burden (TMB), and proportions of B, T (CD4+, CD8+), NK cells and macrophages were compared across all 4 sites. Pairwise comparisons were performed using Pearson's Chi-squared, Kruskal-Wallis rank sum, and Dunn's tests, and the FDR method was used to correct for multiple comparisons.

Results: The cohort (median age at metastatic diagnosis=67, IQR 61-75, Male=50%) comprised a diverse population (White, 79%, Black/African American, 12%, Asian, 4.0%, Other, 5.8%). The immune biomarker composition varied in primary lung tumors as compared to metastatic sites. Liver, CNS, and bone sites had lower percentage of total immune cells, CD8+ T cells, CD4+ T cells and B cells, and higher percentage of macrophages as compared to primary lung tumors (Table 1) (q-values <0.001). PD-L1 positive status was lower in liver, CNS, and bone compared to lung (q<0.001, q<0.01, q<0.01 respectively). When compared to lung, TMB-H status was modestly higher in patients with CNS metastasis (q<0.001), while TMB-high status was unchanged in patients with liver or bone metastasis (q>0.05).

Conclusions: In this large, real world analysis of patients with metastatic NSCLC, we observed a less immunogenic TIME in liver, CNS, and bone sites of disease compared to primary lung tumors. Our findings are hypothesis generating and further research is warranted to understand how the immune composition of metastatic sites alters the efficacy of ICI in patients with NSCLC.

EP.03G.02 Molecular and Immune Landscape of Invasive Mucinous Adenocarcinoma (IMA) Of the Lung and Its Survival Outcome

S. Kim[1], H.S. Kim[1], W. Woo[1], L.I-Y. Chung[1], Y. Oh[2], A. Dugan[3], S. Fragkogianni[3], J. Godden[3], C. Chao[3], Y.K. Chae[1], [1]Northwestern University Feinberg School of Medicine, Chicago/IL/USA ,[2]John H. Stroger, Jr. Hospital of Cook County, Chicago/IL/USA ,[3]Tempus AI, Inc., Chicago/IL/USA

Introduction: IMA constitutes a rare subset of lung adenocarcinomas. Due to its low incidence, the IMA's biology and prognosis remain poorly understood. In this study, we analyzed the tumor microenvironment, gene expression, and clinical outcomes of IMA patients.

Methods: A retrospective cohort of de-identified records of patients with primary lung cancer were identified in the Tempus database and stratified into IMA or non-IMA. Clinical, biopsy, and molecular characteristics were assessed. Normalized RNA-seq data were used to test for differential gene expression (DGE). Real-world overall survival (OS) was compared by histological subgroup using Kaplan-Meier curves and Cox proportional hazards models using a prospective-like approach. Immune cell infiltration measures were estimated using the quanTIseq algorithm.

Results: The overall cohort consisted of 20,071 patients, with 699(3.5%) in IMA and 19,372(96.5%) in non-IMA. IMA demonstrated significantly lower tumor mutational and neoantigen burdens(3.1 vs. 4.2 mutations/Mb and 7 vs. 9 neoantigens/Mb; p<0.001) with fewer positive PD-L1 status(28% vs. 59%; p<0.001). The tumor microenvironment in IMA patients had higher infiltration of M2 macrophages, regulatory T cells, and NK cells(Table 1). DGE analysis highlighted significant upregulation in genes such as ERVW-1, REG4, TFF2, and TM4SF4 and significant downregulation in IL36RN, NAT8L, and LIN28B in IMA compared to non-IMA. Additionally, hundreds of additional genes were differentially expressed in IMA vs. non-IMA. OS for IMA patients was significantly worse compared to that of non-IMA(Fig 1, HR 1.46, [95% CI 1.07-2.01], p=0.018).

Conclusions: Our study demonstrates the unique pathological and molecular characteristics of IMA vs. non-IMA. IMA showed significantly worse overall survival compared to non-IMA. Our findings warrant further prospective investigation.

EP.03G.03 Tumor Treating Fields (TTFields) Induce Pro-Inflammatory Phenotype Skewing of Macrophages

T. Kan[1], Y. Barsheshet[1], B. Brant[1], T. Haj Khalil[1], T. Voloshin[1], A. Volodin[1], L. Koren[1], B. Koltun[1], A. Klein-Goldberg[1], E. Zemer-Tov[1], R. Paz[1], A. Haber[1], M. Giladi[1], U. Weinberg[1], Y. Palti[1], [1]Novocure Ltd, Haifa/IL

Introduction: Tumor Treating Fields (TTFields) are low intensity electric fields that disrupt cellular processes critical for cancer cell viability. Downstream to their antimitotic effect, TTFields have been shown in preclinical models to induce immunogenic cell death of cancer cells and elicit a systemic anti-cancer immune response. Co-application of TTFields with an immune checkpoint inhibitor (ICI) has recently demonstrated benefit in a phase 3 study in non-small cell lung carcinoma. The current research examined possible effects of TTFields on macrophage phenotype regulation.

Methods: Bone marrow-derived macrophages (BMDMs) were generated from the femurs and tibias of 5-8-week-old Balb\C mice. To induce M1 and M2 polarization, BMDMs were exposed to LPS+IFN-γ or IL-4, respectively. The polarized BMDMs were then treated for 24 h with 150 kHz TTFields, followed by flow cytometry examination of surface expression of the F4/80 macrophage biomarker. The treated macrophages were also tested for expression of the following activation markers: CD80, major histocompatibility complex class II (MHC II), inducible nitric oxide synthase (iNOS), CD206, and ARG-1. The supernatants of the treated cells were collected and analyzed for secretion levels of CXCL1 (KC), IL-18, IL-23, IL-12p70, IL6, TNF-γ, IL-12p40, TGγ1, CCL22 (MDC), IL-10, IL-6, G-CSF, CCL17 (TARC), and IL-1 γ using a multiplexed secretion assay. The lysates of treated cells were examined for RhoA activation using an appropriate kit and GEF-H1, c-Jun, and p65 phosphorylation levels by Western blot analysis.

Results: Following TTFields exposure BMDMs demonstrated elevated expression of CD80+ and MHC IIhigh pro-inflammatory M1 markers, and decreased expression of CD206 and ARG-1 M2 markers. The secretion pattern was pro-inflammatory, with increased levels of CXCL1, IL-18, IL-23, IL-12p70, TNF-γ, IL-12p40, CCL22, G-CSF, CCL17 and IL-1 γ. TTFields treatment induced activation of RhoA, and phosphorylation of GEF-H1, c-Jun and p65.

Conclusions: This study reveals a novel immunomodulatory role for TTFields, promoting in vitro pro-inflammatory macrophage polarization, possibly via transcriptional response driven by the GEF-H1/RhoA/ROCK pathway.

EP.03G.04 High SLFN11 Expression Predicts Response but is not Required to Confer Sensitivity to Lurbinectedin

A. Gupta, K. Vaidya, G. Brock, R. Humphreys, Jazz Pharmaceuticals, Inc., Palo Alto/CA/USA

Introduction: Lurbinectedin (Zepzelca®) received accelerated approval from the US FDA as monotherapy in June 2020 for the treatment of adults with metastatic small cell lung cancer (SCLC) with disease progression on or after platinum-based chemotherapy. Lurbinectedin binds to the GC-rich triplets in the promoters of protein-coding genes, blocks RNA polymerase II, and induces its degradation resulting in double-stranded DNA breaks and DNA damage that leads to cellular apoptosis. Schlafen 11 (SLFN11), a putative DNA/RNA helicase, irreversibly binds to DNA replication forks in response to stress and blocks replication. SLFN11 is an emerging predictive biomarker of response to therapeutics that elicit DNA damage including cisplatin, topoisomerase I/II, and poly(ADP-ribose) polymerase (PARP) inhibitors.

Methods: In vitro studies: Cytotoxicity assays were performed on cancer cell lines and patient-derived non-SCLC organoids. Lurbinectedin (100 nM-0.01 nM) was used and cell viability was determined by measuring intracellular ATP. SLFN11 expression was retrieved as RNAseq values from DepMap database. RNAseq value of >2 was assigned as SLFN11 high, and value of <2 was assigned as SLFN11 low. The significance of the difference in log10(IC50) between SLFN11 high and low lines was determined using the Mann-Whitney test. SLFN11 was knocked down (KD) using siRNA in 2 cervical (CA Ski and C-33 A) and 2 SCLC (NCI-H1048 and DMS79) cell lines. In vivo studies: Lurbinectedin response was evaluated in 3 SCLC xenograft models (NCI-H1048, NCI-H889, and NCI-H69) at doses of 0.06, 0.12, or 0.18 mg/kg IV Q3W. Tumor-bearing mice were randomly allocated to treatment and control groups (n=8) once tumors reached a volume of 100-150 mm3. Protein expression assays: SLFN11 protein was detected using Western blot (sc-374339) and quantified by image analysis. Immunohistochemistry was used to detect SLFN11 protein on xenograft tissues. The intensity of positive staining on tumor cells was scored at 4 levels: 0 (negative), 1+ (weak), 2+ (medium), and 3+ (strong). The percentages at each intensity were used to assign an H-Score (0-300).

Results: High SLFN11 models are 3-4-fold more sensitive to lurbinectedin compared with low SLFN11. SLFN11 RNA and protein show a strong correlation (r2=0.924). The in vivo efficacy shows the NCI-H1048 model is significantly more responsive with 90% tumor growth inhibition compared with 35% in NCI-H889 and NCI-H69 at 0.18 mg/kg dose (p-value=0.006). An H-score of 111.86 (NCI-H1048) and 0 (NCI-H889 and NCI-H69) was observed. Western blot confirmed ~95% protein loss in KD cells. SLFN11 KD did not affect lurbinectedin response in CA Ski, C-33 A, and NCI-H1048 cells. SLFN11 KD in DMS 79 cells had a modest 2-fold decrease in sensitivity to lurbinectedin.

Conclusions: Cell viability and in vivo studies confirm that high SLFN11 models are more sensitive to lurbinectedin. SLFN11 RNA and protein expression show strong correlation. Loss of SLFN11 does not affect sensitivity to lurbinectedin, suggesting it is a biomarker of response but not necessary for sensitivity. Some low SLFN11 models are sensitive to lurbinectedin, suggesting a role of other genes in determining drug response. Further proteomics and genomics work is needed to define additional response biomarkers.

Keywords: SLFN11, Lurbinectedin, biomarker

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.03H.01 Detection of PAX5 Gene Mutations in Patients with East Asian Non-Small Cell Lung Cancer Patients

Y. Zhu[1], C. Xu[2], W. Wang[3], W. Zhuang[4], M. Fang[3], G. Wang[5], Q. Wang[6], Y. Song[2], [1]Zhejiang Rongjun Hospital, Jiaxing/CN ,[2]Jinling Hospital, Nanjing University School of Medicine, Nanjing/CN ,[3]Zhejiang Cancer Hospital, Hangzhou/CN ,[4]Fujian Cancer Hospital, Fuzhou/CN ,[5]Xinqiao Hospital of Third Military Medical University, Hangzhou/CN ,[6]Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing/CN

Introduction: PAX5 is one of the most frequently mutated genes in B-cell acute lymphoblastic leukemia (B-ALL), and children with inherited preleukemic PAX5 mutations are at a higher risk of developing the disease. The aim of this study is to investigate mutations and prognosis of non-small cell lung cancer (NSCLC) harboring PAX5 mutations.

Methods: A total of 602 patients with non-small-cell lung cancer were recruited between July 2012 and December 2018. The status of PAX5 mutations and other genes were detected by next generation sequencing.

Results: PAX5 gene mutation rate was 0.83% (5/602) in non-small cell lung cancer, including T251I(1 patient), E113D(1 patient), H318L(1 patient), T386N(1 patient) and S134F(1 patient), and median overall survival (OS) for these patients was 22.0 months. Among them, all patients were PAX5 gene with co-occurring mutations. Briefly, patients with (n=2) or without (n=3) co-occurring ALK mutations had a median OS of 3.0 months and 24.0 months respectively (P=0.04); patients with (n=13) or without (n=1) co-occurring SMARCA4 mutations had a median OS of 15.5 months and 22.0 months respectively (P=0.64); patients with (n=2) or without (n=3) co occurring KEAP1 mutations had a median OS of 24.0 months and 5.0 months respectively (P=0.20); patients with (n=3) or without (n=2) co-occurring CREBBP mutations had a median OS of not up to now and 11.5 months respectively (P=0.30).

Conclusions: Althoght ALK, SMARCA4, KEAP1, CREBBP gene accompanied may have less correlation with PAX5 mutation in NSCLC patients, predict which patients may harbor PAX5 mutations, could have implications in triaging toward PAX5 variant identification for potential future targeted therapy. These data have implications for the identification of therapeutic target candidates.

EP.04A SCREENING AND EARLY DETECTION - IMPLEMENTATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.01 Lung Cancer Nurse Consultant-Led Pulmonary Nodule Assessment and Surveillance Clinic: Multidisciplinary Team Evaluation

V.N. Brunelli[1], S. Karipidis[2], A.C. Jones[3], D. Jeffery[2], J. Bianco[2], H. Marshall[4], K.M. Fong[4], D.C. Currow[1], [1]University of Wollongong, Wollongong/AU ,[2]Illawarra Shoalhaven Local Health District, Wollongong/AU ,[3]Illawarra Shoalhaven Local Health District and University of Wollongong, Wollongong/AU ,[4]University of Queensland Thoracic Research Centre and The Prince Charles Hospital, Brisbane/AU

Introduction: In July 2025, Australia will introduce a national Lung Cancer Screening Program. The assessment of pulmonary nodules and subsequent patient management are Program aspects anticipated to have major workforce implications.

This implementation project aimed to 1) demonstrate safe, advanced practice nursing relative to pulmonary nodule assessment, surveillance, and patient management, 2) promote the scope of the advanced practice nurse role in this service context, and 3) improve capacity in respiratory physicians to attend to high-risk cases in a timelier manner.

Methods: Early 2023, clinical redesign of a regional public out-patients respiratory medicine specialist service in New South Wales included: streamlined general practice referral pathways, nurse-led triage, rapid access pathway and pulmonary nodule assessment and surveillance for high-risk patients, consistency in diagnostic radiology reporting and, new standardised documentation. Two lung cancer nurse consultants were up-skilled via a mentor program in image review and reporting.

During April to July 2023, nurses evaluated incidentally found pulmonary nodules against evidence-based guidelines, provided recommendation for nodule management with governance review by a respiratory physician, and communicated the plan to patients and their primary care practitioner. The nurses assessed and managed up to 10 surveillance patients each at any one time, with each patient potentially requiring two to three images for review. The Evaluating the Nurse Practitioner Role: Multidisciplinary Team Questionnaire, a 22-item validated Likert scale (1=Strongly Disagree to 5=Strongly Agree) was adapted to elicit multidisciplinary team members' perceptions of the contribution and value of this nurse-led clinic to patients, the team and broader out-patients service (14 items), and perceptions of the abilities of the advanced practice role to deliver the clinic safely (8 items). Free text capability is also provided. Descriptive analyses generated sentiment scores reflecting the level of respondent's perceptions of a) the clinic and b) the advanced practice role. Qualitative content analysis helped to interpret some neutral and mildly negative sentiments.

Results: Eighteen respondents completed the questionnaire (August to September 2023). Of respondent's perceptions of the clinic, a sentiment score of 4.7 (out of a possible 5) suggests team members are very positive about the contribution and value of the clinic to patients, team functioning and service efficiency. This score was affected by mildly negative responses to item 1 ('I fully understand the Specialist Lung Cancer Nurse Pulmonary Nodule Surveillance Clinic'). Of respondent's perceptions of the advanced practice role to deliver the clinic, a sentiment score of 4.6 (out of a possible 5) indicates team members are highly confident in the lung cancer nurse consultant role to deliver the clinic service in a safe and appropriate manner. Informed by the content analysis, the 12-week pilot phase was considered too short, impacting time needed for team members to fully understand the scope of both the clinic and role in this important area of practice. This influenced neutral scoring, particularly across items centred on the advanced practice role.

Conclusions: This project highlights the critical importance of rigorous definition in the lung cancer nurse consultant role relative to Australia's imminent national Lung Cancer Screening Program.

EP.04A SCREENING AND EARLY DETECTION - IMPLEMENTATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.02 Automated Reading May Improve the Safety of Triennial Lung Cancer Screening Intervals for Low-Risk Subjects

R.E. Ledda[1], M. Balbi[1], F. Sabia[1], M. Ruggirello[1], R. Vigorito[1], G. Milanese[2], A. Marchianò[1], U. Pastorino[3], [1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, Milan/IT ,[2]Department of Medicine and Surgery (DiMeC), University Hospital of Parma, Parma, Italy, Parma/IT ,[3]Fondazione IRCCS Istituto Nazionale dei Tumori, Milano/IT

Introduction: Lung cancer (LC) screening with low dose computed tomography (LDCT) can reduce mortality in high-risk individuals, but the optimal screening interval has still to be defined. The BioMILD trial tested the feasibility and safety of triennial LDCT screening in subjects with a negative baseline LDCT, showing a limited risk of late diagnosis.

Methods: We re-assessed the diagnostic efficacy and safety of a prolonged LDCT interval by automated second reading of all negative baseline LDCTs, using an artificial intelligence (AI) software (Coreline AVIEW). Lung cancers detected before the scheduled triennial LDCT were analysed according to the AI LungRADS classification, to explore any avoidable risk of late diagnosis.

Results: Of the 3450 BioMILD participants with negative baseline LDCT, automated AI reading classified 423 (12.3%) as LungRADS 3 and 172 (5%) as LungRADS 4. A total of 3 LCs were detected in the re-classified subsets (0.5%), 2 in LungRADS 3 (at 25-31 months from baseline) and 1 in LungRADS 4 (at 28 months). The type and stage distribution (SCLC, stage III-IV) does not suggest a potential clinical benefit achievable by shorter LDCT intervals. Nonetheless, some of the LungRADS 4 subjects could have been more safely sent to 3-6 months and LungRADS 3 to annual or biennial LDCT, upon evaluation of the radiologist.

Conclusions: Automated AI reading can reduce the number of false negative baseline LDCTs and improve the selection of longer screening intervals, based on the individual LC risk. AI software represents a useful instrument in the hands of dedicated radiologists.

		AI Coreline			
	Total	LungRADS 1	LungRADS 2	LungRADS 3	LungRADS 4

EP.04A SCREENING AND EARLY DETECTION - IMPLEMENTATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.03 Quality Implementation of Lung Cancer Screening using the QUILSTM System: Baseline Data from Ten Programs in Kentucky

J. Studts[1], A.B. Mathew[1], T.W. Mullett[2], J.L. Alexander[3], A.R. Yates[3], J.R. Knight[4], [1]University of Colorado School of Medicine, Aurora/CO/USA ,[2]University of Kentucky College of Medicine, Lexington/KY/USA ,[3]University of Kentucky Markey Cancer Center, Lexington/KY/USA ,[4]University of Kentucky College of Public Health, Lexington/KY/USA

Introduction: Lung cancer screening (LCS) using low-dose computed tomography (LDCT) has emerged as an evidence-based approach to detect lung cancer early and reduce lung cancer mortality when conducted among individuals at high risk. Despite robust evidence supporting LCS implementation and a favorable insurance coverage climate due to established guidelines and recommendations, national LCS implementation has encountered a host of multilevel barriers, including incomplete LCS awareness among clinicians, limited engagement among eligible individuals, suboptimal adherence to the screening algorithm, and lack of integration into healthcare system operations. To address barriers and optimize LCS delivery, the Kentucky LEADS Collaborative developed a comprehensive system (QUILSTM System 1.0: Quality Implementation of Lung Cancer Screening) to evaluate LCS delivery, with a focus on supporting rural and low-resource LCS programs. The purpose of this study was to implement the QUILSTM System 1.0 in ten LCS programs to evaluate quality of LCS delivery in diverse settings.

Methods: A multidisciplinary development team created the QUILSTM Index 1.0, an evaluation system to assess quality LCS program operations across six domains: (1) Screening Eligibility, (2) Clinical Radiology Operations, (3) Interdisciplinary Team Operations, (4) Lung Cancer Prevention Efforts, (5) Patient Education, Counseling, and Support, and (6) Community Outreach. Each domain included multiple quality elements, creating 16 scored elements and a total score ranging from 0 to 75. The score was normalized to a range of 0 to 100% quality points. Ten LCS programs at academic, private, and rural community hospitals across Kentucky were evaluated using the QUILSTM Index 1.0. Three data sources contributed to calculating the QUILSTM Index 1.0, including: surveys and interviews conducted with LCS program navigators and medical directors and site-level LCS implementation data.

Results: Overall quality scores ranged from 55% to 87%, with an average score of 69% (SD=9%) across the ten sites evaluated. LCS Programs consistently received high scores on elements involving (1) Screening Eligibility Policy, (2) Screening Frequency & Duration Policy, (3) LDCT Performance, (4) Lung Nodule Identification, and (5) Provider Outreach with most programs receiving optimal scores. LCS Programs scored consistently low on several other elements, including (1) Team Review of Radiology Results, (2) Tobacco Treatment Interventions, (3) Tobacco Treatment Targets, and (4) Shared Decision Making.

Conclusions: Quality LCS implementation will be an essential component to achieving optimal individual and population health benefits promised by rigorous efficacy trials of LDCT. Across ten sites evaluated with the QUILSTM System 1.0, LCS programs performed well under the Screening Eligibility and Clinical Radiology Operations domains but demonstrated opportunities for improvement in the Interdisciplinary Team Operations and Lung Cancer Prevention Efforts domains. Despite the heterogeneity of sites, all ten LCS programs demonstrated areas for potential improvement. Next steps included delivering feedback to the sites using the QUILSTM Audit and Feedback process, and providing access to the QUILSTM Resource Portal and QUILSTM Coaching and Technical Assistance components to help LCS programs improve service quality. Longitudinal evaluations will also be conducted to assess change in service delivery and quality outcomes.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.04 Real-World Data of LDCT Lung Cancer Screening Implementation in a Public Healthcare System: Quebec Three 3-Year Experience

S. Martel[1], H. Lizotte[1], G. Boily[2], C. Riou[3], W. Dubuisson[3], N. Ezer[4], L. Moishe[5], N. Bouchard[6], P. Joubert[1], G. Albert[1], J. Taylor[4], L. Buré[7], V. Pen[8], A-B. Gorgos[5], S. Plante[1], R. Thériault[1], A-C. Guédon[2], J. Lanthier[2], J. Boulanger[2], E. Pagé[2], C. Truchon[2], C. Dufour[3], M-H. Guertin[9], S. Rodrigue[9], J. Massougbodji[9], [1]IUCPQ-UL, Quebec/QC/CA ,[2]INESSS, Quebec/QC/CA ,[3]MSSS, Quebec/QC/CA ,[4]CUSM, Montreal/QC/CA ,[5]CHUM, Montreal/QC/CA ,[6]CHUS, Sherbrooke/QC/CA ,[7]CISSS Montérégie-Centre, Longueil/QC/CA ,[8]CISSS Laval, Laval/QC/CA ,[9]INSPQ, Quebec/QC/CA

Introduction: Studies have shown that Low Dose Computed Tomography (LDCT) lung cancer screening decreases lung cancer mortality. However, only few jurisdictions worldwide with public healthcare system have implemented formal screening program. Cost is a concern but many other challenges might be obstacles to moving forward. Real-world data from experiences in this setting can provide some answers not available in randomized trials. Here, we present the three-year experience in Quebec, Canada.

Methods: Public LDCT lung cancer screening started in June 2021, implemented in a limited number of hospitals. The process involved an evaluation phase before a decision was made on whether to extend the program to the entire province. The objective was to enroll 3000 participants and analyze the data after two annual rounds of screening. A public communication campaign was launched at the outset but was not repeated thereafter. All referrals and self-referrals were centrally evaluated at the coordination center (IUCPQ) and LDCT scans were conducted at one of the designated hospitals nearest to the participant residence. Quebec decided to offer lung cancer screening to individuals aged 55 to 74 who were current or former smoker (with cessation ≤ 15 years), had a smoking history of 20 years or more, and a PLCOm2012norace score ≥ 2%. The Lung-RADS classification system was used. A standardized report template was used by all participant radiologists. All reports were forwarded to the coordinating center, which was responsible for communicating with participants and prescribing physicians and ensure proper follow-up. Smoking cessation interventions with the participants were also integrated.

Results: After 18 months, the coordination center received 8212 referrals, of which 4318 were deemed eligible and agreed to screening after a shared decision process. Among the first 3200 LDCT scans, 45% of participants were female (sex) and 71% were active smokers. The mean PLCO score was 5.2% (median 4.0%). The distribution of Lung-RADS 3 and 4 lesions met the target, with each comprising 7% of cases. Respectively, 94% and 83% of participants came back for their interval LDCT (Lung-RADS 3 and 4A) or annual screening (Lung-RADS 1 or 2). Potentially significant incidental findings were high at 25%, but included severe coronary calcifications (40%) and no chart research was performed to exclude those that were already known. Lung cancer detection rate in the first screening round was 1.6%, with 85% of cases being stage I or II cancers. Treatment modalities included surgery (±chemotherapy/immunotherapy) in 89%, and SBRT alone in 5%. Concerns regarding impact on resource utilization primarily centered around CT access in some centers, where wait times for screening LDCT increased overtime to a level requiring special interventions. To date, we had over 18000 referrals, with over 9000 of them deemed eligible for screening. Additional details of the three-year experience are available in the poster.

Conclusions: Structured LDCT lung cancer screening program in a public healthcare system is able to reach targeted early indicators according to previous randomized trials. Access to CT scans was a concern in our jurisdiction and needs to be specifically addressed.

EP.04A SCREENING AND EARLY DETECTION - IMPLEMENTATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.05 Lung Cancer Screening Outcomes in Aotearoa New Zealand

K. Parker[1], S. Crengle[2], K. Bartholomew[1], P. Sandiford[1], T. Oranga Pukahukahu Team[1], [1]Te Whatu Ora Health New Zealand, Auckland/NZ ,[2]University of Otago, Dunedin/NZ

Introduction: Lung cancer is the leading cause of cancer deaths for Māori and non-Māori. Māori LC mortality rates are over three times those of non-Māori. Lung cancer screening (LCS) using low dose CT (LDCT) reduces LC mortality by 20-26%. GP clinics were recruited to a clinical trial of invitation to LCS. Participating practices were censored from the invitation trial if they had not completed contacting their list of potentially eligible patients after 8 months and the eligible patient participants from these practices were then contacted and offered LCS. Secondary outcomes in this trial included results of participation at all parts of the screening pathway, nodule findings and incidental findings. These results are presented here.

Methods: GP clinics were recruited to a clinical trial of invitation to LCS. Potentially eligible participants (Maori, 55-74 years, not 'never smokers' in the PMS) in each practice were contacted and invited to participate in the trial. Consented participants underwent PLCOm2012 risk assessment (RA). Those with a risk assessment of ≥2% were offered shared decision making. If they chose to proceed with CT scan an appointment was arranged. Appropriate follow up was arranged according to the results of the CT scan. Information on incidental fundings was collected.

Results: Risk assessment was undertaken on 1013 people. The risk threshold of >= 2% was reached in 546 (54%) of people. After shared decision making 540 (92%) underwent a low dose CT scan. A further 115 received a CT scan under this pathway. Of the 504 completed CT scans: 63% have had no significant nodules (PC1); 24% required a 12 month follow up scan (PC2); 10% had 3 month follow up scan (PC3) and 2% were referred for immediate follow up. Incidental findings were observed in all scans. However, the findings were not usually associated with a beneficial intervention in 29%. Incidental findings that might need: non-urgent primary care intervention e.g. CVDRA, COPD management were seen in 47%; non-urgent secondary care referral in 21% of scans and urgent secondary care referral in 1% of scans.

Conclusions: Participation of Māori who were eligible for LCS was very high (92). This is much higher than Māori participation in current national cancer screening programmes. 47% of scans required subsequent follow up. All scans had incidental findings but most were not associated with a beneficial intervention or suggested conditions that, in this population, should already be managed in primary care e.g. COPD and cardiovascular disease risk assessment and management.

EP.04A.06 A Comprehensive Lung Cancer Screening Program: Ten Years in Review

A. Plank, L. Reagan, A. Dhamija, D. Albano, S. Reagan, M. Reiter, Stony Brook Medicine, Stony Brook/NY/USA

Introduction: Lung cancer remains the leading cause of cancer death worldwide. Lung cancer screening(LCS) provides opportunities for early detection, improved survival and tobacco cessation. The National Lung Screening Trial paved the way for accepted guidelines for LCS with updates after completion of the NELSON trial. Outcomes following implementation of LCS programs are not widely known. This investigation provides outcomes and lessons learned in the first decade of the LCS program at a large tertiary care cancer center. Disclosure of outcomes provides information to enhance success of subsequent programs.

Methods: The screening programs' REDCAP database was queried for the results. Demographics, CAT scan data, lung cancer diagnoses, adherence rates and tobacco cessation rates were computed.

Results: The screening center enrolled 2420 patients between 9/30/14 and 3/1/24 (130 patients were enrolled for tobacco cessation only with 2290 in LCS.

65%/35% Male/Female

49% Current Smokers

CT LungRAD distribution shown on Table 1

Adherence rates were 84% for first follow up CT scan

83(3.7%) lung cancer diagnoses

Cancer Cell Types: 52/83(63%) Adenocarcinoma 17/83(20%) Squamous Cell 5/83(6%) Small Cell 9/83(11%) Other

The distribution of stages in LCS compared to CDC are shown in Table 2.Self-reported quit rates were 29.5% within the first two years of screening.

Five year survival rates for patients diagnosed stage 1A/1B is 100%(n=26)

Conclusions: Lung Cancer Screening provides opportunity for early detection and increased survival rates. The distribution of stages among patients with lung cancer disclosed by CDC for the general population compared with those diagnosed in the screening program are shown in Table 2.LCS patient population had higher rates of early stages.In addition, LCS provides opportunities to engage in tobacco cessation counseling with increased quit rates compared to general population. Further investigation is warranted.

Keywords: screening, early detection, tobacco cessation

EP.04A SCREENING AND EARLY DETECTION - IMPLEMENTATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.07 A Framework and Toolkit to Support the Implementation of LDCT Screening with a Focus on Inclusion of Underserved Communities

J.T. Fathi[1,2], D.R. Baldwin[3], E. Medhurst[4], H. Wilcox[4], [1]GO[2] for Lung Cancer, Washington/DC/USA ,[2]University of Washington, Seattle/WA/USA ,[3]University of Nottingham, Nottingham/GB ,[4]The Health Policy Partnership, London/GB

Introduction: The Lung Cancer Policy Network, a global multi-stakeholder initiative of experts in lung cancer, has developed a framework and toolkit to aid the implementation of LDCT screening. The implementation framework spans six domains, consisting of key questions and metrics, aiming to support the implementation of high-quality screening for lung cancer globally. The implementation toolkit assists users in applying the implementation framework to a health system. Individuals at risk for lung cancer often suffer structural discrimination in health systems and public health programmes. To reduce health disparities and inequities, and improve screening uptake, strategies must leverage methods that address barriers to participation. Additional resources focused on increasing engagement with underserved communities have been developed to enhance the toolkit's usability, accessibility, and effectiveness. This expansion complements the Network's efforts to make improving the survival of lung cancer a global policy priority.

Methods: The toolkit was initially informed by a review of existing peer-reviewed and grey literature, interviews with nine experts across four continents, and insights from Lung Cancer Policy Network members. The expansion of the toolkit focuses on Domain 4 of the implementation framework: eligibility and recruitment. This was informed by Network member insights and literature research, including a focus on England and Aotearoa New Zealand.

Results: The first iteration of the implementation framework and online toolkit was published in March 2023. To date, the framework has been downloaded over 800 times and nearly 1,500 people have accessed the toolkit. The expansion to focus on underserved communities was launched in April 2024. To support the usability of the toolkit, the toolkit expansion includes a overview document showcasing the available resources, logically categorised by domain. Additional resources have also been developed to support the engagement and recruitment of traditionally underserved communities for lung cancer screening. This includes: • A template to identify traditionally underserved communities, understand their needs and design an inclusive lung cancer screening programme. • Two case studies of alternative approaches to increasing screening participation of traditionally underserved communities in different national contexts (England and Aotearoa New Zealand).

Conclusions: To our knowledge, this is the first framework to support the implementation of LDCT screening programmes globally. Application of the framework may inform implementation policies - facilitating high-quality, equitable and cost-effective screening. The toolkit development and expansion will support those designing and delivering LDCT lung cancer screening programmes by ensuring effective and equitable implementation to help address lung cancer inequalities.

EP.04A.08 Leveraging the Quebec Lung Cancer Screening Program to Create a Collaborative Biobanking Project for Research Purposes

S. Plante[1], S. Biardel[1], A. Mogas[2], M-C. Allard[1], S. Martel[1], H. Lizotte[1], R. Thériault[1], É. Turcotte[3], N. Bouchard[3], S. Rousseau[2], K. Boutet[4], L. Samy[5], N. Daaboul[6], N. Ezer[2], P. Després[1], V.S. Manem[1], Y. Bossé[1], P. Joubert[1], [1]Institut universitaire de cardiologie et de pneumologie de Québec-Université Laval, Quebec/QC/CA ,[2]McGill University Health Center, Montreal/QC/CA ,[3]CIUSSS de l'Estrie-CHUS, Sherbrooke/QC/CA ,[4]CISSS Côte-Nord, Sept-Iles/QC/CA ,[5]Hôpital Cité-de-la-santé, Laval/QC/CA ,[6]Centre Intégré de Cancérologie de la Montérégie, Greenfield Park/QC/CA

Introduction: In 2021, the Quebec ministry of health launched the Lung Cancer Screening Demonstration Project. In collaboration with several institutions, the Institut universitaire de cardiologie et de pneumologie de Québec-Laval University (IUCPQ-ULaval) was mandated to implement the program across the province of Quebec, Canada. With the support of the project's coordination center and the Quebec Respiratory Health Research Network (QRHN) Biobank network, we initiated a multicenter project for biobanking of clinical data, low-dose CT (LDCT) chest images and biological samples for research purposes. The objective of this initiative was to build a cohort of biological samples and data from a population at high risk of developing lung cancer and make these samples and data available to the scientific community for research projects on respiratory and non-respiratory diseases.

Methods: The collaboration with the QRHN Biobank provided valuable support, leveraging its established structures, procedures, and management framework across various locations in the province of Quebec. This partnership facilitated the implementation of the screening program in six hospitals, all of which agreed to participate in the project. Notably, nurses from the Lung Cancer Screening coordination center played a pivotal role by engaging eligible patients and inviting them to take part in the biobank.

Results: As of April 2024, 3,374 patients have signed the consent form, and 2,947 of them have also accepted to provide a blood sample. At the beginning of 2024, 718 patients have completed their 2-year follow-up with at least three LDCT scans. To date more than 6,271 LDCT scans have been completed and 22% of these exams show suspicious nodules with a Lung-RADS Score ≥ 3. 2,568 imaging studies are stored in the Biobank and the collection of data is in progress. After the last follow-up expected in 2026, more than 10,000 LDCT imaging studies will be banked for the entire cohort. Data and imaging studies are stored in centralized database and servers. Blood samples are stored and managed by IUCPQ-ULaval and McGill University Health Centre (MUHC) sites of the QRHN Biobank (2,752 and 195 blood samples respectively). Management frameworks for storage of data, images and biological samples were approved by local research ethic boards. A Data/Material Access Committee oversees the use of the Biobank.

Conclusions: This collaborative initiative aims to create a unique cohort of imaging, clinical data and biological samples in the context of a lung cancer screening program for research projects. Upon completion of the patient recruitment, scheduled for summer 2024, the data and samples will be available upon request. With the emergence of artificial intelligence-based applications in health research, and the advancement of blood-based biomarker development, this project holds the potential to uncover novel predictive and diagnostic biomarkers.

EP.04A.09 The Impetus, Formation and Initial Strategic Aims of the UCLCC Screening and Prevention Task Force

A. Prosper[1], D.T. Cooke[2], A. Ghasemiesfe[2], E.K. Tong[2], H. Leisy[2], J. Seibles[2], L. Rios[2], M. Chen[2], T. Yarbrough[2], M. Vella[3], B. Antonelli[3], Y. Gesthalter[3], H. Keshava[4], G. Sadigh[4], D.R. Strong[5], G. Cheng[5], J. Hudson[5], N. Patel[5], B.A. Glenn[1], D.M. Hamilton[1], R. Bastani[1], W. Hsu[1], Y. Lin[1], H.I. Tupper[1], D. Moghanaki[1], J.W. Goldman[1], A.L. Cummings[1], [1]University of California, Los Angeles, Los Angeles/CA/USA ,[2]University of California, Davis, Davis/CA/USA ,[3]University of California, San Francisco, San Francisco/CA/USA ,[4]University of California, Irvine, Irvine/CA/USA ,[5]University of California, San Diego, San Diego/CA/USA

Introduction: California has the second highest number of lung cancer cases and deaths in the US, but the lowest lung cancer screening (LCS) rate at 0.7% of eligible patients. The University of California (UC) system is unique among academic health systems in its reach across the most populous state with >8 million outpatient visits annually. In October 2021, clinical leaders from the 5 NCI-designated UC comprehensive cancer centers (UC-San Francisco, UC-Davis, UC-Los Angeles, UC-Irvine, UC-San Diego) developed a strategic plan, forming the UC Lung Cancer Consortium (UCLCC), and within its framework, a Lung Cancer Screening and Prevention Task Force (LSPTF) to improve screening rates within the UC system and the state. This work describes the formation, initial strategic aims, and accomplishments of the UCLCC LSPTF since inception.

Methods: Screening champions were identified at each UC campus by nomination of their peers, with two co-chairs elected for LSPTF oversight. To improve screening accessibility and prevalence, the LSPTF identified 3 strategic priorities: 1) to improve eligible patient identification, 2) to develop a digital resource to directly engage with eligible patients with smoking histories, and 3) to improve access for underserved communities. Participation in the LSPTF was opened to all interested UC health system employees, as well as members of the UCLCC's four other task forces in diagnostics, novel therapeutics, population health and policy, and tumor biology.

Results: The UCLCC LSPTF has facilitated coordination of lung cancer screening efforts and collaborative learning across UC campuses. To date, the UCLCC LSPTF includes 28 members. To address aim 1, a "standard work" approach to comprehensive LCS was agreed upon by the 5 sites, including stressing the importance of tobacco cessation strategies. Patient eligibility, primary care empanelment, and screening data were captured within the UC data warehouse as a prospective digital dashboard, allowing accurate and transparent tracking of LCS metrics across UC health systems. To address aims 2 and 3, a web-based shared decision-making LCS resource, ucscreenca.org, was created through a rapidly customizable modular platform, allowing UCLCC to reach individuals outside of the UC system. This resource was made publicly available November 2023 and includes screening eligibility assessment, personalized lung cancer screening navigation, and a screening center locator that is UC-agnostic. To support lung cancer awareness month, education and outreach events for patients and providers at each UC campus were coordinated through the UCLCC LSPTF in November 2023.

Conclusions: Through UCLCC LSPTF, the UC health system has developed statewide comprehensive screening metrics and a shared decision-making digital platform that has reached thousands of users. Formation of the UCLCC LSPTF has also inspired regional collaborations across the state between UC and community partners. Next steps in the UCLCC's 5-year plan include improving accurate capture of tobacco use data in the electronic medical record and assessment of the effect of lung cancer screening utilization dashboards on screening uptake and adherence in the UC system.

EP.04A SCREENING AND EARLY DETECTION - IMPLEMENTATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.10 Creating Safe Connections: Usability Testing of an Intervention Co-designed to Increase Equitable Access to Lung Cancer Screening

A. Sayani[1], A. Hussain[1], H. Freedman[2], B. Amenu[2], V. Ramasamy[2], T. Jeji[2], A. Pratt[3], E. Nicholson[4], A. Lofters[1], [1]Women's College Hospital, Toronto/ON/CA ,[2]Independent patient partner, Toronto/ON/CA ,[3]Independent patient partner, Vancouver/BC/CA ,[4]Canadian Partnership Against Cancer, Toronto/ON/CA

Introduction: Patients living with structural marginalization and at high risk of developing lung cancer (due to the social patterning of smoking addiction) report that clinical encounters which are stigmatizing and discriminatory are a major barrier to participation in lung cancer screening. Healthcare providers report a lack of skills and competencies to understand the underlying determinants of lung cancer risk and need training to deliver patient-centered care that is equity-promoting. To address this gap, we co-designed an educational intervention (an e-learning module) to increase equity at the point-of-access to lung cancer screening based on the Trauma and Violence Core Competency Framework, called Creating Safe Connections. Here we describe how we conducted usability testing of the intervention using a patient-centric and patient-partnered approach to maximise learning effectiveness prior to full scale implementation.

Methods: This is an interdisciplinary, patient-partnered, pragmatic, usability testing study. Team members included policymakers, healthcare providers, researchers and patient partners with lived/living experiences intersecting across elements of race, gender, disability, Indigeneity, immigration, poverty and homelessness. The objective of usability testing was to understand barriers and optimise learning effectiveness of the e-learning module. Participants were purposively recruited through snowball sampling from a pool of primary care providers, regional cancer strategic leads, educationists and patients. Data was collected from nine participants using a 5-points Likert scale survey and open-ended questionnaire to record: (i) the design of the interaction (questions related to the device used and navigation of content), and (ii) design of the instruction (presentation of content and learning impact).

Results: Data collection, analysis and modification of the e-learning intervention occurred in tandem and in line with user-centric design principles. 67% of participants accessed the intervention on a smartphone, and 33% used a laptop/desktop. All participants completed the entire module and 83% downloaded the accompanying notebook which contained reflective prompts and resources. 33% reported navigational challenges between segments of the module. 100% found the videos, case studies and learning prompts useful with all participants commenting on the exceptional quality and learning from the embedded videos. Overall, participants found the content useful for practice (67% strongly agree), the right mix of interactive versus non-interactive components (67% strongly agree and 33% agree), and would recommend it colleagues (100%), including institutional staff and healthcare leaders. Using an iterative approach learning effectiveness was enhanced by correcting navigational difficulties, linking to jurisdictionally relevant resources, adding more specific examples and language to the section on de-escalation of unsafe clinical encounters.

Conclusions: We describe an interdisciplinary and patient-centric approach to the usability testing of an intervention co-designed to increase equity in access to lung cancer screening. Through a systematic, iterative method we increased effectiveness of the learning module in preparation for national-level implementation. The e-learning module is now Continued Medical Education (CME) accredited and is freely available to any learner through the University of British Columbia, Canada learning platform.

EP.04A.11 Patients Reported Outcomes in Short- And Long-Term Lung Cancer Survivors Who Were Diagnosed via Chest Low-Dose CT Screening

Y. Peng[1,2], D.E. Midthun[3], D. Liu[1,4], J.A. Wampfler[3], Z. Liu[1,5], J.L. Ridgeway[3], K. Tan[1,5], C.M. Wheatley-Guy[1], R.P. Benzo[3], M.R. Buras[1], N.Y. Yu[6], V. Ernani[6], J. D'Cunha[6], K.L. Swanson[6], Z. Gu[1], A. Jatoi[3], A.L. Cheville[3], P. Yang[1], [1]Mayo Clinic, Scottsdale/AZ/USA ,[2]Fangshan Hospital, Beijing University of Chinese Medicine, Beijing/CN ,[3]Mayo Clinic, Rochester/MN/USA ,[4]West China Hospital, Sichuan University, Chengdu/CN ,[5]Beijing University of Chinese Medicine, Beijing/CN ,[6]Mayo Clinic, Phoenix/AZ/USA

Introduction: Low-dose computed tomography (LDCT) screening reduces mortality from lung cancer. Knowledge is limited regarding the effect of screening on long-term health and psychosocial-related quality of life (QoL). We investigated short and long-term QoL outcomes, comparing LDCT-screening detected to usual-care diagnosed lung cancer patients and to controls who screened negative for lung cancer.

Methods: In our 20-year prospective lung cancer cohort, we analyzed 4122 patients who answered Patient Reported Outcomes (PRO) questionnaires within three years of lung cancer diagnosis (short-term responders) and 1291 patients who answered five years after (long-term responders). From the cohort with PRO data, we identified and compared LDCT-screening detected (CT-screened, n[short]=350, n[long]=105) to the usual-care diagnosed (Usual, n[short]=2406, n[long]=654) lung cancer patients, and each patient group to Controls (n=480). QoL and social factors were scored on a 0 (worst)-10 (best) scale. A difference of 1.0 unit or more in median score was considered clinically meaningful.

Results: (all Ps<0.05) Among short-term responders, compared to the Usual, CT-screened patients were older (66 vs. 64), more females (54.6% vs. 47.9%), more stage I-II disease (72.2% vs. 37.3%) and treated by surgery only (56.0% vs. 25.3%); had a lower proportion of "Moderately-Markedly" reduced appetite (13.9% vs. 20.7%), lower proportion of "quite a lot" of difficulty in daily work or "could not do work" (22.1% vs. 30.9%), and better normal activity (8.6 vs. 7.4) and overall QoL (8.0 vs. 7.0). Among long-term responders, the two groups had similar differences in disease stage and treatment modality as in the short-term. Importantly, both groups in short- and long-term responders reported significant dyspnea (5.5-6.0) and fatigue (5.0 for all four groups). Compared to the Controls, short-term responders in CT-screened patients had similar mean age (66 vs. 67), more females (54.6% vs. 41.7%), longer quit-cigarette-smoking years (16.3 vs. 10.6) and higher proportion with a family history of lung cancer (16.0% vs. 0.6%). Although reporting the same overall QoL as Controls (8.0), in specific QoL and PRO domains, lung cancer patients had higher frequency of "Moderately-Markedly reduced" appetite (13.9 vs. 5.0%), lower social activity (7.0 vs. 8.0); were worse in fatigue (5.0 vs. 7.0), dyspnea (6.0 vs. 7.0), dry cough (8.0 vs. 9.0), physical well-being (7.0 vs. 8.0), mental well-being (8.0 vs. 9.0), emotional well-being (8.0 vs. 9.0); and had higher proportion of "quite a lot" of difficulty in daily work or "could not do work" (22.1% vs. 8.6%), and "often-very often" felt tired after work (43.1% vs. 27.9%). Similar results were observed in long-term responders except for the same social activity score (8.0) between patients and controls. All participants reported strong family/friends support (9.0-10.0), similar spiritual well-being (8.0-9.0), and financial (8.0-9.0) and legal concerns (9.0).

Conclusions: In short-term responders, both CT-screening-diagnosed lung cancer patients and non-cancer controls had better overall QoL and selected symptoms and social factors than the usual-care-diagnosed patients. Remarkably, dyspnea and fatigue were persistent symptom burden for lung cancer patients regardless of how they were diagnosed and how long since initial diagnosis, calling for targeted interventions.

Kisiel, MSN, FNP-BC[8], L. McCauley-Hixenbaugh, MBA[9], S. Phillips, DrPH[7], E. Plotkin, CMP-HC[8], M. Reid BSN, MSPH, PhD[4], A. Lile, MPH[8], [1]St Elizabeth Healthcare, Edgewood/KY/USA ,[2]University of Alabama at Birmingham, School of Health Professions, Birmingham/AL/USA ,[3]University of North Carolina, Center for Health Promotion and Disease Prevention, Chapel Hill/NC/USA ,[4]Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA ,[5]Cancer Support Community, Washington/DC/USA ,[6]LUNGevity, Chicago/IL/USA ,[7]Rhizome, LLC, Washington/DC/USA ,[8]Association of Cancer Care Centers, Rockville/MD/USA ,[9]West Virginia University Cancer Institute, Morgantown/WV/USA

Introduction: The Rural Appalachian Lung Cancer Screening Initiative is led by the Association of Cancer Care Centers (ACCC), the Appalachian Community Cancer Alliance, and patient advocacy partners. This multi-year initiative, recognized by the President's Cancer Moonshot, seeks to improve lung cancer screening rates by supporting health systems in the rural Appalachian region of the United States to develop and implement interventions through partnerships and technical assistance. Focusing on areas in Kentucky, West Virginia, and Virginia with significant barriers to screening, the initiative supports health systems in Pike County, Kentucky, and Buchanan County, Virginia.

Methods: Seven virtual interviews were conducted with individuals who live and work in the region. Interviews were conducted between September and October 2023 and gathered insights into community needs, strengths, and attitudes toward health, lung cancer, and lung cancer screening (LCS). Participants included multidisciplinary healthcare staff (n=9), public health professionals (n=4), community-based organization staff (n=2), and 1 politician, recruited through snowball sampling. Interviews were recorded, transcribed, and coded using thematic content analysis.

Results: Participants revealed community strengths like altruism, community closeness, diversity, and pride in their region's culture, history, and resilience. The region's isolation, natural beauty, and collaborative health organizations were noted assets. A holistic vision for a healthy community emerged, emphasizing access to education, diverse activities and support systems, health awareness, and addressing social determinants of health. Other aspects included effective primary prevention, resources, responsive community services, and opportunities for positive social connections. Trust between residents and healthcare providers was identified as an important aspect.Personal and perceived community trusted sources for health information included the Centers for Disease Control and Prevention (CDC), local health departments, media, primary care providers, and word of mouth. Motivators for seeking healthcare included family planning or urgent health issues. Barriers for seeking healthcare included transportation, cost, and fear. Lung cancer was perceived as a common problem, often detected late with significant impacts on patients and families, particularly in mining communities. Community barriers, motivators, and perceived solutions to accessing lung cancer screening are summarized in Table 1.

Conclusions: These findings highlight the importance of addressing structural barriers and enhancing awareness of lung cancer screening, particularly in higher-risk communities. Notably, the influence of media, family, and trusted community members offers a strategic avenue for health systems and public health professionals to leverage when tailoring interventions to reach and engage the community effectively.

Keywords: Appalachia, screening, lung cancer

Table 1.

Barriers	• Actual/perceived cost • Avoidance; doesn't want to receive bad news, other health needs or caregiving are higher priorities • Lack of knowledge, education, or awareness • No referral pathway • Primary care providers unaware or unaccepting of LCS • Smoking stigma and guilt; self-blame • Taking time off work • Transportation; long drive times
Motivators	• No cost to patient • Getting screened is beneficial to the family/more time with family if caught early • Ease and speed of scan • Recommendation by a healthcare provider • Seeing positive outcomes or experiences from others who have had screening or have lung cancer
Solutions	• Conduct more community outreach/marketing efforts • Provide free screening or increase awareness of screening coverage • Increase accessibility and convenience; offer more convenient locations • Combine with other screening activities/efforts • Provide transportation assistance • Leverage family members and social network to encourage screening • Create testimonials from similar people/trusted sources with messaging

EP.04A.13 Necessity for Early Detection and Screening Initiatives: Evidence from Indonesia

A.C. Putra, E. Syahruddin, S.L. Andarini, J. Zaini, E. Samoedro, Faculty of Medicine, Universitas Indonesia-National Respiratory Center Persahabatan Hospital, Jakarta/ID

Introduction: Late-stage diagnosis of respiratory diseases significantly hampers the effectiveness of treatment and patient prognosis. This study evaluates the prevalence of late-stage disease presentations at Rumah Sakit Persahabatan, Indonesia's national respiratory center, emphasizing the critical need for early detection and screening programs in the country.

Methods: A comprehensive retrospective review of patient records from 2018 to 2022 at Rumah Sakit Persahabatan was conducted. The analysis focused on assessing the frequency of complications at presentation, identifying the most common complications, and determining the proportion of early-stage disease diagnoses.

Results: An overwhelming 89.2% of patients were admitted with complications, indicative of advanced disease stages at the time of diagnosis. The primary complications identified were pleural effusion (33.4%), superior vena cava syndrome (SVCS) (21.9%), and cerebral metastasis (8.9%). Alarmingly, the data showed that only 0.1% of the diagnosed cases were in the early stages of the disease, underscoring a significant delay in detection and diagnosis.

Conclusions: The prevalence of late-stage presentations and the low detection rate of early-stage diseases reveal a substantial deficiency in the current diagnostic processes. This deficiency not only affects patient outcomes adversely but also places a heavier burden on healthcare resources. The establishment of structured screening and early detection programs is imperative to bridge this gap, facilitating timely intervention and potentially improving survival rates.

EP.04A.14 Community Outreach for Lung Cancer Awareness: Utilizing the 'Cancer Challenge' to Educate the Public

D.J. Donaldson[1], L. Abbott-McCloud[2], [1]LiveLung, High Point/NC/USA ,[2]LiveLung, Charlotte/NC/USA

Introduction: Lung cancer remains a leading cause of mortality worldwide, yet awareness of screening options remains alarmingly low. Our nonprofit organization has pioneered a community outreach initiative leveraging the Cancer Challenge tool to address this critical gap.

Methods: Through engagement at festivals and community gatherings, such as First Night Out and Hot Air Balloon Festivals, we have reached more than 2,000 individuals, providing vital information on lung cancer screening and the dangers of radon exposure. Central to our approach is the Cancer Challenge, a simple yet effective educational tool comprising sequentially-numbered quizzes designed to inform participants about screening guidelines. By offering incentives and utilizing an open-book format, we ensure active participation and facilitate learning among attendees. Moreover, our commitment to education extends beyond the event itself by providing duplicate copies of the quizzes on carbonless paper, allowing participants to share knowledge with others.

Results: Our outreach efforts have demonstrated significant impact, with more than 300 participants engaged at the Hot Air Balloon Festival alone and similar success at other events. Importantly, participants are educated about lung cancer screening guidelines and encouraged to correct misconceptions. Furthermore, our initiative has sparked interest in collaboration with primary care physicians to increase screening referrals. Moreover, our initiative stands at the intersection of community engagement and healthcare advocacy, epitomizing a synergistic approach to public health outreach. By harnessing the power of community events and leveraging educational tools, such as the Cancer Challenge, we have not only disseminated crucial information about lung cancer screening but also fostered a culture of proactive health awareness within local communities. The enthusiastic response from participants underscores the potential for grassroots efforts to effect meaningful change in healthcare. As we continue to refine and expand our outreach initiatives, we remain committed to forging collaborative partnerships with stakeholders across the healthcare landscape, paving the way for a more integrated approach to early detection.

Conclusions: Through our innovative approach, we have shown the efficacy of community outreach in raising awareness of lung cancer screening. By expanding our initiatives and fostering partnerships with healthcare professionals, we aim to increase screening, ultimately saving lives and reducing the burden of lung cancer. This community outreach initiative represents a promising strategy for disseminating vital information about early detection and risk reduction of lung cancer to the broader population. Further research is warranted to assess the long-term impact of such interventions and explore avenues for scalability and sustainability.

EP.04A.15 Recruitment Strategies in a Lung Cancer Screening Program for Asian Women with No Smoking History

W. Li, J. Bell, A. Chachoua, K-k. Wong, E. Shum, NYU Perlmutter Cancer Center, New York/NY/USA

Introduction: The Female Asian Nonsmoker Screening Study (FANSS) is a pilot study for Asian women with no smoking history to provide low-dose CT (LDCT) Chest scans for lung cancer (LC) screening annually for 3 years. Acknowledging potential challenges to recruit from a non-smoking population that is not typically targeted for LC screening and minority populations who have historically low enrollment rates to clinical trials, several factors including language barriers, participant availability and low awareness of LC in non-smoking populations were considered to support FANSS enrollment. Here we describe various recruitment strategies implemented to aid in study accrual.

Methods: Multimodal recruitment strategies were used. A dedicated phone line answered by receptionists able to speak English, several Chinese dialects and access to phone interpreters was established. Research staff are bilingual or utilized phone interpretation services in all participant interactions. Community outreach included informational flyers available in both English and Chinese that were sent to physicians serving primarily Asian communities and posted in pharmacies and storefronts in NYC Chinatown. A website was developed for interested individuals to submit their contact information. Our institutional EMR, Epic, incorporated DataCore in 3/2023 to aid in identifying potential study participants based on eligibility. A pool of participants with active MyChart accounts was created to search individual medical records with criteria “Asian,” “female,” “OK to contact for Research recruitment,” “age 40-74,” and excluded anyone with a smoking history and the term “Cancer” within the past 5 years. Participants from this pool were sent an IRB-approved recruitment message through MyChart from 3/2023-6/2023. Interested participants who responded directly through MyChart were contacted to verify and determine eligibility. All eligible participants who agreed to participate were consented either in-person or virtually by electronic consent to allow for scheduling flexibility.

Results: From 3/5/21 to 1/27/24, 1518 women inquired about FANSS through our website, dedicated phone line or MyChart messages. After determination of eligibility, 760 participants had an informed consent discussion either virtually or in-person. From 3/5/21 to 2/28/23, 356 participants expressed interest in the study, of which 247 participants underwent the consent process. From 3/1/23 to 1/27/24, 637 participants expressed interest excluding through MyChart, of which 423 participants underwent the consent process. Following the implementation of directed MyChart messaging during that same time period, 525 participants responded through the EMR, however 102 participants were not eligible due to inaccuracy in their charts (i.e. ethnicity or smoking history). Of those eligible, 90 participants were recruited to the study. MyChart recruitment led to an additional 21% (90/423) increase in study enrollment.

Conclusions: To increase recruitment to a LC screening program in participants without a smoking history, specific considerations tailored to engage minority populations are needed. Culturally appropriate outreach and program infrastructure including electronic consents were implemented. Incorporation of directed messaging through the EMR in the FANSS study also is a successful tool to further enhance recruitment to identify potential participants which may also be applied to improve uptake in both lung cancer screening for smoking populations and in recruitment to other clinical trials.

EP.04A.16 Cost-Effectiveness of Adaptive Schedules for Lung Cancer Screening: A Modeling Study

P. Cao[1], J. Jeon[2], R. Meza[3,4], [1]Purdue University, West Lafayette/IN/USA ,[2]University of Michigan, Ann Arbor/MI/USA ,[3]British Columbia Cancer Research Institute, Vancouver/BC/CA ,[4]School of Population and Public Health, University of British Columbia, Vancouver/BC/CA

Introduction: Current guidelines recommend annual low-dose computed tomography screening for lung cancer when the person meets the eligibility criteria based on age and smoking history. However, research suggests adaptive schedules, based on individual risk and screening results, offer comparable effectiveness with the potential for improved benefit-harm trade-offs. Given the projected increase in national cancer care costs and the substantial economic burden of lung cancer, it's crucial to assess the economic efficiency of adaptive schedules. Therefore, we conducted a cost-effectiveness analysis comparing adaptive schedules to regular (non-adaptive) screening strategies.

Methods: We extended the Lee and Zelen risk-threshold method to select screening schedules based on average or individualized lung cancer risks and life expectancy for the whole screen-eligible population, specific sub-groups (by sex or by pack year), or for each individual in the study population. We used the validated Two-Stage Clonal Expansion (TSCE) Model for lung cancer risk prediction and varied the annual TSCE risk threshold from 0.15% to 0.85%, with 0.05% increments. We adopted a healthcare sector perspective to assess the long-term cost-effectiveness of 240 adaptive schedules and three regular screening schedules (triennial, biennial, and annual) versus no screening. An established microsimulation model was used to project the costs and effectiveness of different screening schedules over a lifetime for individuals from the 1960 US birth cohort eligible under the 2021 USPSTF guidelines. Lifetime downstream costs (2023 dollars) and effects (life-years gained, quality-adjusted life-years gained [QALYs]) were discounted at 3%. Sensitivity analyses evaluated the impact of varying treatment and screening costs, health utilities, and screening disutilities.

Results: More than 80% of strategies considered in our study had incremental costs per QALY gained lower than $50,000 compared with no screening, with annual screening being the highest (Figure 1). Compared with efficient adaptive schedules, triennial and biennial screening were dominated, whereas annual screening had an Incremental Cost-Effectiveness Ratio (ICER) of $288,000 per QALY. Taking screening disutilities into account, annual screening was dominated. The most cost-effective scenario under the $100,000 willingness-to-pay (WTP) threshold was a schedule selected based on individual risks and adjusted for life expectancy, which had an ICER of ~$97,500/QALY.

Conclusions: Adaptive schedules were cost-effective based on a widely accepted US WTP threshold. Conversely, annual screening was over the WTP threshold and was dominated by adaptive schedules in some scenarios. Hence, in fixed-budget healthcare systems, adaptive schedules could provide better "value for the money" and should be considered.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04A.17 Screening for Lung Cancer in Indonesia: Are All the Variables Valid for Determining These Factors?

E. Syahruddin[1], N.N. Soeroso[2], H. Haryati[3], S. Ermayanti[4], U.A. Setiawan[5], A.R. Setijadi[6], S. Sukarti[7], L. Wulandari[8], I.A. Jasminarti[9], M.A. Hanif[10], S.M. Munir[11], [1]Faculty of Medicine Universitas Indonesia, Jakarta/ID ,[2]Faculty of Medicine Universitas Sumatera Utara, Medan/ID ,[3]Faculty of Medicine Universitas Lambung Mangkurat, Banjarmasin/ID ,[4]Faculty of Medicine Universitas Andalas, Padang/ID ,[5]Faculty of Medicine Universitas Brawijaya, Malang/ID ,[6]Faculty of Medicine Universitas Sebelas Maret, Surakarta/ID ,[7]Faculty of Medicine Universitas Lampung, Bandar Lampung/ID ,[8]Faculty of Medicine Universitas Airlangga, Surabaya/ID ,[9]Faculty of Medicine Universitas Udayana, Denpasar/ID ,[10]Dharmais Cancer Hospital, Jakarta/ID ,[11]Faculty of Medicine Universitas Riau, Pekanbaru/ID

Introduction: Lung cancer is a significant health problem in Indonesia that incurs high costs, but the prognosis is very poor due to the challenge of detecting early-stage lung cancer that is operable. To reduce the mortality rate, screening and early detection are essential. The healthcare system in Indonesia follows a referral-based model, so community health centers need tools that are suitable for the facilities. We have utilized a scoring form developed by IASTO (Indonesian Association for the Study of Thoracic Oncology) to assess the risk level of lung cancer. This study aims to screen for lung cancer in Indonesia and evaluate the validity of all variables in determining these factors.

Methods: This was a cross-sectional study conducted at 11 Pulmonology and Respiratory Departments in Indonesia. Clinical characteristics and data were collected from medical records of lung cancer patients at these departments nationwide between January 2023 and December 2023.

Results: A total of 920 subjects who met the criteria were analyzed in this study. Lung cancer was found at a median age of 58 (15 - 93) years old, with the majority of subjects being male (69.3%), diagnosed with adenocarcinoma (60.5%), active smokers (36.6%), ex-smokers (24.2%), and passive smokers (23.3%), and having no family history of cancer (86.8%). Risk factors for lung cancer based on scoring form were categorized as low (9.05%), intermediate (51.8%), and high (39.1%). High-risk patients were predominantly male (54.1%), older (46.3%), smokers (64.4%), and diagnosed with adenocarcinoma lung cancer, showing a different risk profile compared to patients with small cell carcinoma lung cancer, with a high risk of 59.5% and 72.4% for smokers. Patients with a family history of cancer had a risk of 82.1%. Patients without a history of lung cancer and those who were unsure had a moderate risk, at 53.2% and 50.5%, respectively. The majority of patients were exposed to carcinogens in the workplace, at 80.6%. Pollution in the home environment was a high-risk factor for 71.3% of patients. Patients with a history of COPD had a high risk of lung cancer (80%), while those with a history of tuberculosis had a risk of 69.2%.

Conclusions: This scoring assessment can be used as a tool for screening and early detection in Indonesia to follow the referral system from Community Health Centers to Hospitals that have facilities for definitive diagnostic procedures.

EP.04B.01 Evidence Based Communication on Lung Cancer Screening to Political Decision Makers

S.K. Schmidt[1], J.K. Keller[1], L. Rohwer[2], H. Wilcox[3], [1]Siemens Healthineers, Forchheim/DE ,[2], Gesellschaft für Internationale Zusammenarbeit GmbH (GIZ), Bonn/DE ,[3]Lung Cancer Policy Network, London/GB

Introduction: Lung cancer screening with low-dose computed tomography (LDCT) has been shown to provide a significant reduction on lung cancer mortality. Despite an extensive body of high-quality evidence with a significant number of randomized and non-randomized studies, today very few countries have national screening programs for lung cancer. This creates an implementation and impact gap between screening for lung cancer compared with other cancers. This is despite lower public health relevance of these cancers in terms of mortality and less extensive and compelling evidence for benefits of screening. As cancer screening programmes usually apply to large parts of the population (including health individuals), their financial impact can be greater than other healthcare decisions. In most countries, implementation and/or financing of national screening programmes are political decisions, or at least influenced by political decisions. These decisions are often made by people who are usually not experts in oncology, epidemiology or other relevant disciplines. To enable evidence-informed political decision making and make sure that scientific evidence is translated into political actions, scientific evidence has to be translated in a form that addresses the specific needs of this target group and can be taken up into decision-making. The Lung Cancer Policy Network, a global multidisciplinary alliance of experts in lung cancer, brings evidence-informed consensus policy recommendations to support policymakers to deliver commitments on priority issues in lung cancer, including LDCT screening.

Methods: Political decision processes were analysed for specific regions and decisions, e.g. the European Union's recommendation for cancer screening in the EU member states. Stakeholders in these decision processes were identified. Stakeholders' beliefs, concerns and any misunderstandings about lung cancer screening were identified during discussions. In addition, non-systematic literature searches identified studies that address the issues raised. Based on this, communication concepts for repeating concerns were developed and adjusted to the target group. These concepts were then distributed through various channels (e.g. websites, presentations, direct and indirect communication) to decision markers.

Results: Common concerns were false-positives, costs, exclusion or inclusion of specific target groups for lung screening, resulting unnecessary interventions and radiation dose from computed tomography. Strategies were developed to address these concerns, for example comparisons with other screening programs, cost-comparisons of lung cancer interventions (screening vs. late-stage treatments), positive examples from other, comparable countries or regions where screening is already implemented and results are available.

Conclusions: In order to lead to better political decision making, scientific evidence has to be translated and communicated in a way that addresses the specific background, previous experience, concerns and believes of political decision makers. If this is done, a successful communication of scientific evidence to decision makers can lead to better-informed decisions. The Lung Cancer Policy Network has developed extensive consensus-driven insights and recommendations to support political prioritisation of lung cancer and help improve outcomes from the disease.

EP.04B SCREENING AND EARLY DETECTION - NODULE IDENTIFICATION AND MANAGEMENT
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04B.02 Identification of Circulating MicroRNAs Associated with Lung Cancer Diagnosis and Progression

J. Samejima[1], Z. Li[2], C. He[2], T. Miyoshi[1], K. Tane[1], K. Aokage[1], M. Tsuboi[1], [1]National Cancer Center East, Kashiwa/JP ,[2]Mirxes, Research & Development, Singapore/SG

Introduction: This study aimed to identify circulating microRNAs (miRNAs) associated with lung cancer diagnosis and progression by comparing pre-surgery samples with post-surgery samples at different time points.

Methods: A total of 576 miRNAs were profiled using plasma samples collected from 50 lung cancer patients before surgery and at 3- and 6-month intervals post-surgery. Fold changes in miRNA expression were analyzed, and Pearson correlation coefficients were calculated to assess the consistency of changes over time. Differentially expressed (DE) miRNAs were identified by comparing pre-surgery samples with post-surgery samples. Statistical significance was determined using a p-value threshold of <0.05.

Results: The fold changes in miRNA expression at 6 months post-surgery were generally consistent with those at 3 months post-surgery (Pearson correlation coefficient = 0.76). Several DE miRNAs were identified, with 5 miRNAs significantly upregulated at 3 months post-surgery and 6 miRNAs significantly upregulated and 1 miRNA downregulated at 6 months post-surgery. Notably, miR-339-5p, miR-432-5p, and miR-335-3p showed consistent upregulation at both 3 and 6 months post-surgery, while their expression decreased at later stages based on pre-surgery data. Additionally, miR-629-3p exhibited significant downregulation at 6 months post-surgery, contrasting with its increased expression at later stages. These findings suggest that these miRNAs may play crucial roles in lung cancer progression and could serve as potential biomarkers for lung cancer diagnosis.

Conclusions: The identified miRNAs, particularly miR-339-5p, miR-432-5p, miR-335-3p, and miR-629-3p, show promising associations with lung cancer diagnosis and progression, highlighting their potential as biomarkers for clinical applications in lung cancer management. Further validation studies are warranted to confirm their utility and specificity in clinical settings.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04B.03 The Diagnostic Efficacy of Seven Lung Cancer Autoantibodies in Early Detection of Pulmonary Ground-Glass Nodules

H. Guo, Medical School of Chinese PLA, Beijing/CN

Introduction: The prognosis for lung cancer patients is significantly correlated with the stage of the disease at diagnosis. Most incidentally discovered pulmonary nodules are benign, but persistent ground-glass nodules (GGNs) carry a potential risk of malignancy. Our study aimed to investigate the diagnostic accuracy of seven autoantibodies in patients with malignant ground-glass nodules smaller than 3cm.

Methods: This study collected data from patients who visited several medical centers, including the PLA General Hospital, and three hospitals in other provinces of China between 2021 and 2023. The inclusion and exclusion criteria were set to clinical findings of pulmonary ground-glass nodule lesions with lung CT imaging data thickness ≤1mm. Based on radiological and histopathological examinations, 512 patients with malignant nodules were identified as the lung cancer group, while 188 patients with benign lung nodules and 130 healthy individuals were selected as the control group. All patients enrolled in the case group had ground-glass nodules less than 3mm. Fasting peripheral blood samples were collected in the morning from all participants. The serum levels of seven antibodies (P53, PGP9.5, SOX2, GAGE7, GBU4-5, MAGEA1, CAGE) were measured using the enzyme-linked immunosorbent assay (ELISA). The study analyzed the diagnostic efficacy of these seven autoantibodies, individually or in combination, for early malignant pulmonary nodules through receiver operating characteristic curve analysis.

Results: The serum levels of the seven autoantibodies in patients were significantly higher than those in the control group ($P < 0.01$). The sensitivity, specificity, and cut-off values for the differential diagnosis of the seven autoantibodies between the case and control groups are provided in Table 1. The combined diagnostic approach of the seven autoantibodies exhibited a sensitivity of 89.43%, specificity of 90.13%, and AUC of 0.9069, surpassing the performance of each autoantibody used individually. Furthermore, we applied XGBOOST for machine learning modeling of the seven autoantibodies, dividing the study population into a validation set and a test set at a 7:3 ratio. The model achieved commendable sensitivity and specificity in the validation set, with MAGEA1, P53, and PGP9.5 having significant feature weight proportions.

Conclusions: Our research assessed the diagnostic performance of seven autoantibodies in early-stage lung ground-glass nodules for benign-malignant distinction. It further established the cut-off values for these autoantibodies in differentiating GGNs, verifying the significance of detecting these autoantibodies in patients with early-stage lung ground-glass nodules. This provides a non-invasive and highly discriminative method for the evaluation of ground-glass nodules in high-risk patients.

Table 1. The sensitivity, specificity, and cut-off values for the differential diagnosis of the seve

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04B.04 Defining A Positive CT Screening for Lung Cancer Using Different Nodule Sizes: Implications from a Prospective Cohort Study in China

F. Wang, F. Tan, N. Li, N. Wu, J. He, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: Low-dose computed tomography (LDCT) effectively lowers lung cancer mortality but raises concerns about false positives. Limited data exist on size thresholds for positive results in Asian countries. Most studies and guidelines do not distinguish between solid and part-solid nodules, despite potential differences in malignancy rates and progression. This study utilizes the National Lung Cancer Screening (NLCS) cohort in China to determine threshold values for defining positive nodules in the baseline screening round, for solid, part-solid, and non-solid nodules, respectively.

Methods: From 2013 to 2018, 4160 participants with at least one positive nodule as defined by NLCS criteria (solid/part-solid noncalcified nodule [NCNs] ≥ 5 mm, non-solid NCNs ≥ 8 mm) were included. We assessed reductions in false positives and diagnosis delays using NLCS criteria and stricter nodule diameter thresholds. Additionally, we simulated a population aged 40-74 years based on the 2019 National Bureau of Statistics of China to estimate potential screening outcomes with various thresholds for the entire Chinese population.

Results: The NLCS baseline round had a 96.1% false positive rate. Compared to NLCS criteria, using an 8mm solid NCN threshold missed 7.35% of lung cancer cases but reduced false positives by 74.26%; a 6mm part-solid NCN threshold led to no delayed diagnoses and a 29.13% false positive reduction; a 10mm non-solid NCN threshold missed 12.00% of cases but cut false positives by 53.36%. Our proposed threshold, compared to Lung-RADS, NCCN, and I-ELCAP, resulted in the lowest rate of missed lung cancer diagnoses (6.02% vs. 20.30%, 19.55%, and 21.05% respectively) and the highest reduction in false positives (65.83% vs. 24.53%, 24.39%, and 41.89% respectively). Using these thresholds would have delayed diagnostic work-up for eight out of 136 cases, mainly adenocarcinomas (75%, 6/8) at stage I. All three missed cases in the non-solid nodules category were adenocarcinomas at Stage I. Implementing these thresholds nationwide in China would identify 4.4 million positive screens, detecting 83.2% (366 thousand) of lung cancer cases and preventing 58.2% (73,290) of lung cancer deaths. Compared to NLCS criteria, the proposed models would reduce false positives by 65.8%.

Conclusions: This study represents an initial step towards the development of evidence-based protocols for managing lung nodules in Asian countries, aiming to implement efficient lung cancer screenings that deliver the right care to the right individuals at the right time. Future studies should evaluate the appropriateness of 8mm, 6mm, and 10mm thresholds in prospective LDCT screening programs.

EP.04B SCREENING AND EARLY DETECTION - NODULE IDENTIFICATION AND MANAGEMENT
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04B.05 Discordance Between Nodule and Lung Cancer Location in Early Lung Cancer Detection Cohorts.

O. Ogbeide[1], W. Liao[1], M. Ray[2], J. Goss[1], A. Patel[1], T. Qureshi[1], O. Akinbobola[1], S. Peppers[1], A. Harris[1], A. Porter[1], K. Dortch[1], A. Saulsberry[1], C. Fehnel[1], M. Smeltzer[2], R. Osarogiagbon[1], [1]Thoracic Oncology Research Group, Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis, Tennessee, Memphis/TN/USA ,[2]University of Memphis, Memphis/TN/USA School of Public Health, University of Memphis, Memphis, Tennessee, Memphis/TN/USA

Introduction: Patients with lung nodules are at increased risk for lung cancer, but it is unclear how frequently lung cancer develops in the identified nodule or a different location. We examined concordance between nodule and lung cancer location in patients diagnosed with lung cancer after lung cancer screening (LCS) or management in lung nodule program (LNP).

Methods: Retrospective analysis of patients diagnosed with lung cancer in a community-based program after LCS with Lung RADS 2-4 at T0 or initial nodule-identifying scan in LNP, with reported nodule location, with nodules <30mm. Discordant cases had anatomic mismatch between nodule and cancer location. We compared demographic, risk factor and clinical characteristics between the discordant and the concordant groups in LCS and LNP cohorts.

Results: Of 1,280 eligible patients, 315(25%) had LCS; 965(75%) were in the LNP. In the LCS cohort, 202(64%) were concordant and 113 (36%) were discordant. In the LNP group, 721 (75%) were concordant and 244 (25%) were discordant. Concordance was significantly more likely in the LNP than LCS cohort (p = 0.0003). There was no significant difference in age, sex, race, ethnicity, insurance, and smoking status between the concordant or discordant LCS cohort, but discordant LNP cohort was more likely to be female, actively smoke, and have multiple nodules (Table). The dominant nodule was significantly smaller in discordant cases, and less likely to be located in the upper lobes. Although adenocarcinoma was the dominant histology in all cohorts, small cell lung cancer was almost twice as common in both discordant cohorts (p = 0.0432 in LCS) and (p = 0.0001 in LNP). The proportion of patients with stage IV was almost double (32% vs. 16%) in the discordant LNP group (p = 0.0005).

Conclusions: The dominant nodule not the source of lung cancer 25% or more of patients with a lung nodule, especially in higher risk patients, such as those eligible for LCS, and those who develop small cell lung cancer and LNP patients who develop stage IV disease. Digital imaging and artificial intelligence algorithms that focus exclusively on nodule characteristics may be limited by this fact.

Table 1. Characteristics of Concordant vs. Discordant Group in LCS and LNP Cohorts

EP.04B.06 High-Resolution CT with 1024-Matrix for AI-Assisted Diagnosis System in the Evaluation of Pulmonary Nodules

Q. Jiang[1], Y. Huang[2], H. Sun[1], Y. Xiao[1], [1]Changzheng Hospital, Shanghai/CN ,[2]Shukun Network Technology, Beijing/CN

Introduction: Accurate assessment and diagnosis of lung nodules based on computed tomography (CT) images is critical for clinical management. The rapid development of artificial intelligence (AI) has improved the detection and accuracy of lung nodules while reducing the viewing time of radiologists. This study aimed to explore the efficacy of 1024x1024 matrix and 512x512 matrix for an AI-assisted diagnostic system in the evaluation of lung nodules.

Methods: This retrospective study of 344 patients with chest CT from two hospitals between January 2020 to November 2023, during which CT images showing lung nodules of less than 30 mm were reconstructed with 2 different protocols: 512×512 matrix and 1024×1024 matrix. We analyzed both image quality and the detection of lung nodules by AI. Two chest radiologists subjectively rated the image quality using a 5-point Likert. For pulmonary nodule detection, we employed an AI-assisted diagnosis system, which automatically detected pulmonary nodules of different types (solid nodules, part-solid nodules, and nonsolid nodules).

Results: Among 344 patients with 4898 pulmonary nodules, the overall image subjective evaluation score for the 512 matrix was 3.63, and the score for the 1024 matrix was 4.18 ($p < 0.05$). Taking pulmonary nodules as a unit, the detection accuracy rate, precision, and recall of on 512 × 512 matrix and 1024 × 1024 matrix were 91.63% vs 98.32%, 95.68% vs 98.32%, and 95.59% vs 100% respectively. The classification accuracy of solid nodules, part-solid nodules and nonsolid nodules on 512 × 512 matrix and 1024 × 1024 matrix were 89.74% vs. 97.87%, 90.76% vs. 99.04%, and 90.33% vs. 99.36%, respectively.

Conclusions: The use of a 1024 × 1024 matrix improved image quality, increased the detail of the image and provided more accurate results for AI evaluation of lung nodules.

EP.04C.01 The Value of Ultrahigh Frequency Ultrasound in Localizing Small Pulmonary Ground Glass Opacity Intraoperatively: A Prospective Study

X. Gao, Y. Gao, C. Guo, Q. Zhu, S. Li, Peking Union Medical College Hospital, Beijing/CN

Introduction: Accurate localization of GGO in lung tissue intraoperatively, especially for small GGOs, remains challenging. Ultrahigh-frequency ultrasound (UHFUS), which allows for the visualization of micron-scale structures, is promising in addressing this issue.

Methods: The prospective observational study (NCT05994898) included patients with GGOs who underwent surgery between June 2023 and March 2024. Each GGO was sequentially detected and localized by palpation and UHFUS (22-38 MHz) in excised lung tissue intraoperatively. The UHFUS features were independently examined by two radiologists. The comparison of localization rate and time consumption were analyzed by the McNemar test and Wilcoxon test.

Results: A total of 36 patients (55 years ± 10; 9 men) with 58 GGOs were included, with 50 small (≤ 1 cm) nodules and 37 pure GGO nodules. For small nodules, UHFUS demonstrated a superior localization rate (48, 96.0% vs. 40, 80.0%, P = 0.02), especially for micro-nodules (≤ 5 mm) (15, 100% vs. 12, 80.0%) and pure GGOs (33, 94.3% vs. 25, 71.4%, P = 0.02), outperforming palpation. The localization time of UHFUS was markedly less than palpation (5 s, IQR: 5–8 s vs. 5 s, IQR: 5–15 s; P = 0.003) in small GGOs, and this difference was more pronounced in pure GGOs (5 s, IQR: 5–10 s vs. 12.5 s, IQR: 5–20 s; P = 0.004). On UHFUS, 83.3% of GGOs appeared as indistinct hypoechoic areas with posterior shadowing. UHFUS found three new GGOs intraoperatively and the agreement in diameter between UHFUS-pathology surpassed that observed with CT-pathology.

Conclusions: This in-human prospective trial demonstrated UHFUS is a real-time, non-invasive, and radiation-free strategy that is promising in localizing GGOs in excised lung tissue intraoperatively with the potential to enhance the efficiency of surgery, and capable of identifying new nodules. Further research exploring this novel localizing method of GGOs in intrathoracic situation is warranted.

EP.04C.02 Estimation of Numbers of Healthcare Providers Eligible for National Lung Cancer Screening in South Korea

C.K. Choi, N. Lee, Y. Kim, National Cancer Center, Goyang/KR

Introduction: Korea's current national lung cancer screening program is confined to specific criteria-meeting tertiary hospitals. However, amidst escalating screening rates and a potentially expanding target population, estimating the number of eligible screening institutions is crucial.

Methods: A survey was conducted from October to November 2023 among primary and secondary healthcare providers participating in the national breast cancer screening program in 2023, excluding oriental medicine hospitals. Of 2,919 surveyed institutions, 479 (16.4%) responded. Eligibility criteria for lung cancer screening participation included having a trained radiologist, possessing a 16-channel or higher computed tomography (CT) scanner, and engagement in the national smoking cessation support program. Data on CT scanner specifications were obtained from Health Insurance Review and Assessment Service, and the number of annual breast cancer screenings per provider and the address of healthcare providers were linked to data from the National Cancer Screening Information System. The probability of eligibility for participation in the national lung cancer screening program was estimated by stratifying characteristics (e.g., area and annual breast cancer screening numbers) of breast cancer screening institutions, extrapolating this to estimate the total number of eligible institutions.

Results: Respondent institutions showed higher rates of annual breast cancer screenings and a greater proportion of CT scanner with 16 or more channels compared to non-respondent (table 1). Among respondents, 24 primary and 33 secondary healthcare providers met the criteria for designation as national lung cancer screening institutions.

Characteristics of breast cancer screening institutes according to response

Conclusions: Expanding national lung cancer screening to primary and secondary healthcare providers could increase lung cancer screening capacity significantly. However, improving accessibility, especially in rural areas, presents challenges. Further evaluation, considering both distribution of screening subjects and institute, is necessary.

EP.04C.03 A Forgotten Group for Lung Cancer Screening: Lung Cancer in Patients with Aortic Aneurysms

R. Painter, A. Chau, T. Liang, A. Painter, M. Hegazi, C. Lee, N-K. Kabutey, A. Mahtabifard, H. Keshava, University of California, Irvine, Orange/CA/USA

Introduction: Smoking is the main risk factor of both lung cancer and aortic aneurysms with screening for both being based on smoking history. If found early, both lung cancer and aortic aneurysms can be intervened on preventing devastating consequences. However, there is minimal data about the incidence of lung cancer among patients with aortic aneurysms. Our study sought to identify the incidence of primary lung cancer in patients diagnosed with aortic aneurysms.

Methods: TriNetX, a global health research network comprised of 102 centers worldwide and 98 million patients, was queried for adults (age >18) with ICD codes consistent with primary lung cancer and aortic aneurysms from the United States. Demographic information was collected for all patients. Patients with lung cancer and aneurysms were compared to patients with only aneurysms or only lung cancer. These cohorts were propensity score matched for demographic and comorbidity variables. Outcomes were assessed with a multivariate regression and mortality was assessed with Kaplan-Meier Log-Rank Test.

Results: A total of 539,402 patients were diagnosed with thoracic or abdominal aortic aneurysms. Among those, 23,362 (4.3%) were found to also have lung cancer. Of patients with staging data, patients with both lung cancer and aortic aneurysms had a higher rate of Stage I cancer (32% vs 18%, $p<0.001$), and lower rate of Stage IV cancer (24% vs 32%, $p<0.001$), compared to patients with lung cancer alone. Repair of aneurysms occurred in 3.1% of patients with both lung cancer and aortic aneurysms with 2.4% having endovascular repair. Surgical resection of the lung cancer occurred in 6.1% of patients who had both, and 1.7% had both an aortic aneurysm repair and lung cancer surgery. Patients with both lung cancer and aortic aneurysms had higher mortality at five years (62.0% vs 55.7%, $p<0.001$) when compared to patients with only lung cancer.

Conclusions: Patients with aortic aneurysms are at risk of having lung cancer as smoking is the major risk factor of both. While screening guidelines may overlap specifically with a history of smoking, patients with aortic aneurysms represent an at-risk population who should be targeted for lung cancer screening. Practitioners should not hesitate to screen for lung cancer at the same time as aortic aneurysms.

EP.04C.04 Extended Inclusion Criteria for Lung Cancer Screening to Tabacco Related Diseases: Comparison of Preliminary Results in Two Prospective Cohorts

E. Armand[1], P. Habert[1], P-A. Thomas[1], X-B. D'Journo[1], C. Doddoli[1], A. Fourdrain[1], D. Trousse[1], G. Brioude[1], H. Dutau[1], I. Hamouda[1], L. Greillier[1], A. Mogenet[1], A. Todesco[1], J. Tronchetti[1], J-B. Lovato[1], J. Pluvy[1], O. Mercier[2], J. Issard[2], C. Caramella[2], P. Pradere[2], D. Boulate[1], [1]AP-HM, Marseille/FR ,[2]Hôpital Marie Lannelongue, Le Plessis Robinson/FR

Introduction: Criteria for lung cancer screening (LCS) eligibility are usually based on age, amount of tobacco consumption in pack-years or numbers of cigarettes smoked per day and duration; and active smoking or delay from quitting. These criteria may not be accurate and objectively quantifiable. Therefore, we hypothesized that history of smoking-related disease, which is an objective criteria, could be used as a selection criteria to identify participants at risk of lung cancer (LC) eligible to screening. In the PREVALUNG study (NCT 03976804), we previously reported 3.2% of lung cancer prevalence (14/434) including (10/14) 70% stage I or II LC at a first round of LCS among participants with LCS criteria enlarged to younger age (>45 years old), low tobacco consumption (minimal 1 cigarette per days for 10 years) and history of tobacco related diseases (atheromatous cardiovascular events). Our objective is to report our preliminary LC prevalence after a first LCS round in a new prospective cohort (PREVALUNG ETOILE, NCT 05649046) with inclusion criteria enlarged to other tobacco related diseases (COPD and history of cured tobacco related cancer) and to usual LCS criteria; and to compare these preliminary results to the PREVALUNG results.

Methods: PREVALUNG ETOILE inclusion criteria were age 45-75 years old and history of a tobacco related disease (atheroma, chronic bronchitis and tobacco-related cancer in remission > 5 years) and history of tobacco consumption for 10 years, or NLST (National Lung Screening Trial) and NELSON (Dutch-belgian lung cancer screening trial) trials; or North American recommendation criteria (age 50-80 years-old, pack-years of tobacco consumption, active or smoking cessation <15 years). Exclusion criteria are symptoms of LC, existing follow-up for pulmonary nodule, fibrosis, pulmonary hypertension, severe cardiac or respiratory failure and active pulmonary infectious disease. We measured LC prevalence after a first round of LCS including 5 months of follow-up, positive screening, rate of localized (stage I-II; 8th TNM classification) LC diagnosis and compared these proportions between PREVALUNG and PREVALUNG ETOILE cohorts using Chi-2 or Fisher's exact test when appropriate.

Results: Among 160 participants of PREVALUNG ETOILE, 127/160 (79.4%) had NELSON eligibility criteria and 84/160 (52.5%) had NLST eligibility criteria; 133 underwent a thoracic CT scan, 36 (22.5%) were positive or intermediate and were discussed in a multidisciplinary staff meeting. Five participants were indicated for one step diagnostic and curative minimally invasive thoracic surgery; while 24 were indicated for a follow-up scan at 3 to 6 months. We diagnosed 2 primary non-small cell LC (NSCLC, 1.5%) and 1 type B lymphoma (0.7%), representing 2/133 (1.5%) prevalent LC. Both primary LC were detected at stage I (100%). Two surgical procedures (one mid lobe resection and one left upper-lobe segmentectomy) were performed for hamartochondromas (1.5%). The prevalence of primary LC was not significant between PREVALUNG and PREVALUNG ETOILE participants (14/434 vs. 2/133, P=NS), stage I-II NSCLC were also similar (10/14 vs 2/2, p=NS).

Conclusions: Extended criteria for lung cancer screening to tobacco related diseases may provide relevant, safe and reproducible results.

EP.04C.05 Projected Impact of the Age of Initiation for Lung Cancer Screening on Health Outcomes and Healthcare Resources in Canada

Z. Sun[1], R. Meza[2], M. Diasparra[3], J.H.E. Yong[1], R. Garner[3], M.T. Warkentin[4], A. Coldman[2], [1]Canadian Partnership against Cancer, Toronto/ON/CA ,[2]BC Cancer Research Institute, Vancouver/BC/CA ,[3]Statistics Canada, Ottawa/ON/CA ,[4]University of Calgary, Calgary/AB/CA

Introduction: Screening with low-dose computed tomography (LDCT) has been shown to reduce lung cancer mortality, and it is now recommended in Canada for high-risk individuals aged 55-74 years. Some programs are considering starting screening at a younger age due to early and heavy smoking in certain groups. This study aimed to assess the impact of starting lung cancer screening at earlier ages on patient outcomes and healthcare resource use.

Methods: The analysis used OncoSim-Lung, a microsimulation model that simulates smoking and lung cancer histories in Canada. We simulated four scenarios in Canada: (i) no screening; and annual screening for individuals aged up to 74 years who have at least a 1.5% risk of getting lung cancer in the next 6 years at various start ages: (ii) 55 years, (iii) 50 years, and (iv) 45 years. We simulated a two-step intake process. First, individuals aged 45/50/55-74 years with 20+ years of smoking history were referred. Second, their LDCT eligibility was assessed using the Prostate, Lung, Colorectal, and Ovarian (PLCOm2012) risk model. Smoking cessation support was offered at both steps. Sensitivity analysis explored the effects of smoking cessation and a higher risk threshold (2% chance of getting lung cancer in 6 years).

Results: Starting lung cancer screening at 50 or younger requires few additional screening resources because few additional individuals meet the eligibility criteria. The impact is smaller at higher risk thresholds. However, starting earlier could save more lives by encouraging earlier smoking cessation, contingent on quit rates among those who are ineligible for screening but are still referred to smoking cessation intervention.

Conclusions: Starting lung cancer screening earlier for high-risk people could reduce lung cancer disparities without a significant strain on screening resources, but effective smoking cessation support is crucial for maximum benefit.

EP.04C.06 Investigation on the Incidence and Risk Factors of Lung Cancer Among Chinese Hospital Employees

Q. Liang, Z.h. Chen, W.z. Zhong, GuangDong Provincial People's Hospital, Guangzhou/CN

Introduction: With the increasing awareness of health check-ups among the population, there is a rising number of pulmonary nodules being detected and the population is younger. We aim to identify the true detection rate and incidence of pulmonary nodules in the population, as well as to discover the risk factors.

Methods: Hospital employees ≥40 years old who underwent low-dose computed tomography (CT) lung cancer screening from January 2019 to March 2024 were selected to record CT-imaging characteristics, pathology, staging, and questionnaires to investigate past history, smoking history, diet, mental health, etc. PM2.5 and radiation intake in radiation-related occupation received monitoring in hospital.

Results: The detection rate of suspicious pulmonary nodules was 9.84% (259/2633), and the incidence rate of lung cancer (including adenocarcinoma in situ) was 5.43%(143/2633). Morbidity among doctors, nurses, technicians, administers, and logistics was no difference (p = 0.945), but higher in women than in men (7.05% vs 3.73%,p<0.001). The median age of onset was between 45 and 50 years old, with the high-risk age being over 50 years old. The distribution characteristics and exposure factors of employees did not show significant differences from those of the general population(p=0.968), however, the incidence of lung cancer among hospital employees was higher than the general population(9.84% vs 0.041%). The relationship between lung cancer morbidity and PM2.5 was not clear (p = 0.543); and no lung cancer had been found in employees related ionizing radiation.

Conclusions: The high screening rate leads to high incidence of lung cancer, especially after COVID-19. However, with the increase in screening rates, the detection rate of lung cancer has decreased. Newly discovered lung nodules were all from new members who had never participated in lung cancer screening, and no new nodules appeared in the employees without suspicious nodules under following-up. A follow-up strategy for stable ground-glass nodules did not increase the incidence of lung cancer. Currently, small-sample analyses of lung cancer risk factors cannot identify direct causes or determine the exact incidence of lung cancer in the general population. However, increasing the lung CT screening rate helps to detect lung abnormalities earlier and determine whether intervention is needed.

EP.04C.07 A Novel NGS Assay Using cfDNA Methylation for Early Detection of Lung Cancer in a Screen-Eligible Population

G.A. Silvestri[1], P. Mazzone[2], [1]Medical University of South Carolina, Charleston/SC/USA ,[2]Cleveland Clinic, Cleveland/OH/USA

Introduction: Early detection of lung cancer reduces mortality, but adoption of lung cancer screening (LCS) is slow. A simple blood test could assist in identifying high risk patients and drive more eligible people to LDCT. Epigenetic changes are important drivers in cancer development. A set of novel methylation-based PCR markers successfully detected stage I NSCLC with 87% sensitivity [Mazzone et al. CHEST23 abstract #164]. We are now investigating the potential to improve performance by using NGS, since unlike PCR that focuses on specific methylation sites, NGS can cover all relevant sites in the genome. We used a novel approach utilizing tumor, normal lung, WBC, plasma samples from each patient in a discovery cohort and ultra deep next generation sequencing (up to 600x) to identify a set of highly informative candidate methylation markers that can be used for the detection of early lung cancer from plasma derived cfDNA. These candidate markers were combined to build a predictive assay. Here we present results from applying this assay to a large cohort of screen eligible patients.

Methods: Eight hundred patients meeting USPSTF LCS criteria for age (50-80y) and pack years (≥20) were prospectively enrolled. Those with a recent history of any cancer were excluded. Cases were pathologically confirmed, treatment naïve, primary invasive lung cancers (n=~200 with approximately 50% stage I). Controls were subjects with LungRADS 1 or 2 findings on their 1st or annual LDCT for LCS (n=~600). Whole blood was collected prior to any cancer treatment and processed into plasma. cfDNA was extracted from plasma, then exposed to methylation restriction specific digestion and then sequenced at a depth of 50x (Lung EpiCheck, Nucleix Inc, San Diego).

EP.04C.08 The Potential of Chest X-Ray Artificial Intelligence Detecting Missed Lung Cancer Diagnosis in a Community Based Cancer in Thailand

P. Upaisilsathaporn[1], S. Klawandee[2], P. Wanchaijiraboon[2], [1]Phrapokklao Hospital, Chantaburi/TH ,[2]Phrapokklao Cancer Center of Excellence, Chantaburi/TH

Introduction: This study aimed to investigate the benefit of artificial intelligence (AI) chest X-rays in detecting missed lung cancer diagnoses in community-based cancer centres where most of the chest X-ray interpretation is done by general practitioners.

Methods: We retrospectively reviewed the chest X-ray image database of newly diagnosed lung cancer patients from 1 January to 31 December 2022 at Phrapokklao Cancer Center of Excellence. A total of 197 patients were screened, the eligible 77 patients who obtained more than six months before lung cancer (LC) diagnosis. These images were evaluated by CXR Qure.AI software to identify abnormal nodules or perihilar thickening for more than six months before a definite diagnosis of lung cancer, defined as missed lung cancer (MLC) diagnoses. We assessed the median time of MLC diagnosis.

Results: Among the 77 patients analysed, fourteen patients (18.18%) were found to have MLC diagnoses. The mean duration of MLC diagnosis was 32.3 months with a 95% CI from 20.6 to 44.08 months, with a maximum of 101 months and a minimum of 8.2 months. Of 14 MLC patients, six patients (42.9%) were diagnosed with stage IV lung cancer, while three patients (21.1%) were diagnosed with stage III lung cancer.

Conclusions: This study's findings show the potential of AI technology to facilitate the detection of lung cancer from chest X-ray images.

Keywords: missed lung cancer diagnosis, artificial intelligence, chest x-ray

EP.04C.09 Liquid Biopsy Assay to Detect Low Levels of ctDNA in Early-Stage Lung Cancer Samples

M. Smith, M. Salmans, M. Wang, A. Carson, B-I. Lee, K. Cabrera, K. Fathe, M. Francis, B. Leatham, Genece Health, San Diego/CA/USA

Introduction: A fundamental challenge in technologies designed to analyze circulating tumor DNA (ctDNA) is the typically small fraction of cell-free DNA (cfDNA) in a blood sample that comes from tumor cells. This proportion of ctDNA is generally low in early-stage cancers, which are characterized by small, localized tumors, but increases as the cancer progresses and the tumors grow and metastasize. Therefore, the capability to reliably detect minimal quantities of ctDNA is crucial for technologies like liquid biopsies. These technologies are particularly focused on detecting cancers at an early stage, when the tumor size is small and the amount of ctDNA present in the bloodstream is minimal. Early detection is especially relevant in lung cancer, where American Cancer Society studies show that the 5-year survival rates plummet from 65% to 9% as the stage at diagnosis advances. Various approaches are being explored to increase the amounts of ctDNA available for analysis, including simply increasing the amount of blood required from the patient paired with ultra-deep targeted sequencing. A low-pass whole genome sequencing approach, in which global cancer-like patterns can be detected in minimal amounts of cfDNA, can provide a reliable indicator of tumor presence without requiring prohibitive amounts of input material. Here we demonstrate the ability of the Genece Health Lung Cancer Assay to leverage fragment and end-motif analysis of cfDNA to detect low levels of ctDNA from early-stage lung cancer samples, while only requiring minimal input material. With the cfDNA available from a single tube of blood from a patient, the Genece Health Lung Cancer Assay can detect all stages of cancer.

Methods: Plasma collected in Streck cfDNA BCT devices from 19 early-stage lung cancer samples (16 stage I samples & 3 stage II samples) were obtained from Discovery Life Sciences. Two plasma aliquots of each sample were extracted using the Apostle MiniMax High Efficiency cfDNA Isolation kit on the KingFisher instrument. Eluates were pooled, cfDNA was quantified using Agilent Tapestation, and then diluted in water to 2ng, 1ng, 0.5ng & 0.25ng, as possible, based on the measured cfDNA concentration. Additionally, each sample was tested neat (un-diluted). Samples with a low stock concentration were tested at 1.5ng or 1ng & lower depending on the starting concentration. Libraries were prepared and sequenced using low-pass whole genome sequencing. Sequenced reads were analyzed to generate fragment end-motif and size (FEMS) and associated cancer prediction scores using Genece Health's proprietary analysis pipeline and machine-learning algorithm.

Results: All early-stage lung cancer samples were detected neat, and subsequent dilution series of these early-stage samples established that an input of only 1ng cfDNA is required for utilization of the Genece Health Lung Assay.

Conclusions: Signal detection in these early-stage lung cancer samples, even after dilution, indicates that the Genece Health Lung Assay has a sufficiently low limit of detection to ensure highly sensitive performance in early-stage lung cancer samples with only a single tube of blood or less.

EP.04D.01 Claims-Based Yield Metric for Lung Cancer Screening

J. Reinstein[1], B. Pyenson[2], [1]Milliman, Atlanta/GA/USA ,[2]Milliman, New York/NY/USA

Introduction: Lung cancer is the leading cause of cancer mortality. While lung cancer screening (LCS) has demonstrated high potential reductions in mortality, few people eligible for LCS get screened. HEDIS/Star quality metrics for health plans, including metrics for the portion of eligible people obtaining colorectal, breast, and cervical cancer screenings, have promoted cancer screening, but no such metrics exist for lung cancer. Eligibility for other cancer screenings is largely based on age and sex, but eligibility for LCS is based on smoking history, which is difficult to obtain for all members. Efforts to obtain smoking history from electronic medical records for all plan members may be expensive and difficult to obtain and since the information is self-reported by patients, it is subject to reliability concerns. Therefore, we propose and test a metric based on the portion of incident lung cancers that occurred subsequent to screening.

Methods: The study population was sourced from the 100% Research Identifiable File for 2019-2020, with all Medicare covered claims for about 27 million lives of individuals enrolled in Medicare Advantage (MA) plans and from the Medicare Limited Data Set from 2019-2020, with claims for about 1.8 million lives of individuals enrolled in Medicare Fee-for-Service (FFS) with both Parts A and B. For non-institutionalized individuals between ages 52 and 77 who had coverage for a minimum of 12 months prior to the period, we identified incident lung cancers and the subset that received an LCS in the prior 6 months. The age limitations parallel but shorten LCS criteria of 50-80 to accommodate calendar year considerations.

Results: The yield rate is defined as the portion of incident lung cancers which were identified subsequent to an LCS. We calculated this yield for the entire population by age range and Medicare eligibility status, as well as for the five largest MA carriers. The yield rate was relatively consistent for all cohorts, at ~5%, although there were statistically significant differences among segments by age-sex and between FFS and MA.

Conclusions: A simple claims-based yield metric for LCS is practical and stable across payers. More research needs to be done to determine practical applications, such as minimum population sample sizes, feasible follow-up periods, and stability across time periods. Even with 100% screening of eligible people, not all lung cancers will be detected through screening, so research is needed to determine an ideal yield rate.

		MA Population			FFS Population		
Eligibility	Age	Incident LCs	Preceded by Screen	Yield (95% CI**)	Incident LCs	Preceded by Screen	Yield (95% CI**)
Aged non-dual	Total	22,240	1,160	5.2% (4.9%, 5.5%)	2,425	149	6.1% (5.2%, 7.2%)
Dual	Total	8,050	370	4.6% (4.1%, 5.1%)	547	45	8.2% (6.0%, 11.0%)
ESRD	Total	270	0	0% (0.0%, 1.4%)	33	0	0% (0.0%, 11.2%)
Total	52-54	270	0	0% (0.0%, 1.4%)	26	0	0% (0.0%, 14.2%)
Total	55-59 *	1,120	60	5.4% (4.1%, 6.9%)	300	21	7.0% (4.3%, 10.7%)
Total	60-64 *	2,540	140	5.5% (4.6%, 6.5%)			
Total	65-69	8,160	480	5.9% (5.4%, 6.4%)	804	72	9.0% (7.0%, 11.3%)
Total	70-75	11,460	590	5.1% (4.7%, 5.6%)	1,171	66	5.6% (4.4%, 7.2%)
Total	75-77	7,010	260	3.7% (3.3%, 4.2%)	704	35	5.0% (3.5%, 6.9%)
Total	Total	30,560	1,540	5.0% (4.8%, 5.3%)	3,005	194	6.5% (5.6%, 7.4%)
MA Plan A		7,460	410	5.5% (5.0%, 6.1%)	n/a	n/a	n/a
MA Plan B		5,790	270	4.7% (4.1%, 5.3%)	n/a	n/a	n/a
MA Plan C		2,860	150	5.2% (4.4%, 6.2%)	n/a	n/a	n/a
MA Plan D		1,490	80	5.4% (4.3%, 6.7%)	n/a	n/a	n/a
MA Plan E		750	50	6.7% (4.9%, 8.8%)	n/a	n/a	n/a

* These two bands are combined to meet privacy requirements.
** The 95% confidence interval of the yield rate is based on a Poisson approximation to the binomial distribution.

EP.04D.02 An Innovative Evidence-Based Laboratory Medicine (EBLM) Test to Help Doctors in the Assessment of Lung Cancer

S.J. Calleja, A. Roca, N. Benbouhia, C. Patiño, Kience Inc., Wilmington/DE/USA

Introduction: According to the World Health Organization (WHO), lung cancer is the leading cause of cancer-related deaths, claiming nearly 1.8 million lives each year, and of which primary risk factor remains tobacco smoking. It encompasses two main types: small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC), which represents most cases and comprises adenocarcinoma, squamous cell carcinoma (SCC), and large cell carcinoma. This malignancy is a health concern worldwide, presenting high incidence, mortality, and profound socioeconomic impact due to invasive and costly diagnostic procedures. Thus, we present Venient CDx Lung (Kience Inc., Wilmington, US) a novel non-invasive test that provides confirmatory diagnosis of lung cancer as a doctors' adjunct tool to suspicious image procedures findings, in order to reduce the number of unnecessary tissue biopsies that patients have to undergo.

Methods: The Venient CDx Lung test is a novel diagnostic algorithm designed to exclusively leverage serum and urine biomarkers. This innovative tool combines several independent public algorithms to provide comprehensive diagnostic insights, thus enabling the confirmation of lung cancer diagnosis. To evaluate the estimated accuracy of our new test, we conducted an extensive literature review to identify studies assessing the diagnostic accuracy of constituent algorithms, calculations, and combinations of analytes included within it, on the basis of a previous work by Dr. Rafael Molina et al. in 2016. In this study significant improvements in the diagnosis and classification of lung cancer were reported by combining the tumor markers CEA, CA 15.3, CYFRA 21-1, ProGRP, NSE, and SCC. We developed an upgraded version of this panel and created a refined algorithm that relies on the core set of our three machine learning algorithms: MBDAA, EBLMA and AIRA. We added the tumor marker CA-62 and a set of analytes into the test, to enable it not only confirm the presence of lung cancer but also to determine its type and subtype (SCLC or NSCLC, and within these, adenocarcinoma, SCC or neuroendocrine lung tumor). Additionally, liver and renal function indicators are integrated to enhance specificity. Thus, meeting the 1994 Barcelona criteria, proposed by the SEQC.

Results: With this refined algorithm we obtained a final sample size (n) of 4,296 individuals. With this sample size, we achieved a sensitivity of 0.93 and a specificity of 0.96. Subsequently, we conducted an approximation of the area under the receiver operating characteristic (AUROC) curve, as well as estimations for the positive predictive value (PPV) and the negative predictive value (NPV) based on these results, yielding values of 0.92, 0.95, and 0.93, respectively.

Conclusions: This data suggests that the innovative non-invasive blood and urine-based biomarker algorithm, Venient CDx Lung, holds promise in providing timely and accurate diagnosis of lung cancer, particularly among individuals aged 40 and above. Given the current epidemiological state of this malignancy, our findings underscore the significance of early detection. These results advocate for further exploration, prompting our intention to conduct a clinical study involving 10,000 participants to validate and enhance our findings and inform clinical practice.

Keywords: lung cancer confirmatory diagnostic, suspicious image findings, non-invasive

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04D.03 Shifting Stages: Implications of a Global Pandemic on Cancer Care and A Multipronged Approach to Early Diagnosis for Non-Small Cell Lung Cancer

R. Jindani, J.H. Rodriguez-Quintero, D. Da Costa, H. Kim, C. Shah, A. Sadoughi, M. Vimolratana, N.P. Chudgar, B.M. Stiles, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx/NY/USA

Introduction: Our institution has historically noted lower rates of patients diagnosed with early-stage lung cancer compared to peer institutions, which worsened during the COVID pandemic. In 2021, we established a dedicated early-stage thoracic oncology team, including thoracic surgeons and interventional pulmonologists. Strategic interventions aimed at expanding lung cancer screening, incidental lung nodule management, and patient navigation were implemented. We sought to determine whether these interventions affected the stage distribution for patients diagnosed with NSCLC.

Methods: We reviewed institutional data (1/1/18-12/14/23), identifying patients diagnosed with NSCLC to determine demographics and stage at diagnosis (8th edition AJCC classification). We compared two cohorts: pre-implementation between January 2018 and December 2020 and post-implementation from January 2021 to December 2023. Additionally, we analyzed changes in diagnosis patterns during the height of the COVID-19 pandemic in 2020. Chi-squared analyses were performed. Statistical significance was set at $p<0.05$.

Results: A total of 2,183 patients with a NSCLC diagnosis were identified. Many of these patients came through the newly established lung nodule clinic which manages screen-detected and incidental nodules. Referrals to the lung nodule clinic have steadily increased with over 300 referrals since inception in 2022. Concurrently, there was expansion of lung cancer screening, with an increase in completed tests from 764 in 2018 to 2099 in 2023. Among patients diagnosed with lung cancer, approximately half were women (N=1,124, 51.5%), 38.8% were Black (N=847), 32.3% were Hispanic (N=705), and 62.8% were insured by Medicare (N=1,370). Patients diagnosed as Stage I comprised just 26.7% in 2018, which decreased to only 21.1% in 2020. Since implementation of the early-stage initiatives, the proportion of stage I cases has risen steadily to 31.5% in 2023. Conversely, the proportion of patients diagnosed with stage IV NSCLC began at 41% in 2018, peaked at 51.2% during the COVID pandemic, and has decreased to 39.6% in 2023.

Conclusions: The COVID-19 pandemic prompted a shift in diagnosis patterns, emphasizing the imperative of contingency planning to uphold best practices in cancer care. Following implementation of a team focused on early diagnosis, a stage shift in lung cancer was identified with higher rates of patients diagnosed with stage I NSCLC. We attribute this to increased efforts in screening, incidental nodule management, and renewed focus on timelines of care. These efforts underscore the importance of multidisciplinary efforts to enhance early detection strategies. Further research is warranted to explore factors influencing trends and guide interventions in lung cancer diagnosis and management.

Keywords: early-stage NSCLC, lung cancer screening, multidisciplinary care

EP.04D.04 COVID-19 and Vaccines: A Decade of Insight from China Onpulmonary Nodules Detection and Progression

W. Ye[1], Y. Feng[2], W. Liang[2], J. He[3], [1,2,3]First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: The onset of the novel coronavirus (COVID-19) pandemic and the subsequent widespread deployment of vaccines to combat its spread have necessitated an in-depth investigation into their effects on various health aspects, including pulmonary conditions. Pulmonary nodules, which are often incidentally detected on low dose computed tomography (LDCT) scans, serve as potential early markers for lung cancer and other diseases. This study focuses on assessing the impact of COVID-19 infection and the administration of vaccines on the detection and progression rates of these nodules.

Methods: A comprehensive review of 691,412 LDCT scans from January 2013 to December 2023 was conducted. Seasonal adjustments were applied via the X-13ARIMA-SEATS algorithm to control for temporal variations. The study utilized a Regression Discontinuity Design (RDD) to evaluate shifts in nodule metrics adjacent to the December 2022 outbreak and subsequent vaccine distribution milestones. To explore pulmonary nodule detection variation, we classified LDCT scans into four groups based on nodule type: ground-glass only, solid only, both types, and nodules with unspecified characteristics.

Results: Chronologically, surrounding the December 2022 COVID-19 outbreak in China and adjacent to the tri-phasic vaccine dissemination, analysis revealed no significant breakpoints in nodule detection or proliferation rates within the clinical visit population (detection rate: p< 0.952,p<0.311,p<0.342,p<0.693; proliferation rate: p<0.513,p<0.464,p<0.793,p<0.467). Similarly, the health check population evidenced no marked discontinuities in detection or proliferation rates post-December 2022 (detection rate: p-value 0.97; proliferation rate: p-value 0.613). Examining nodule morphology from 2013 to 2023, ground-glass opacities showed a gradual uptrend in both detection and proliferation rates, whereas solid nodules' detection rate notably increased over the decade, inversely correlating with nodules of indeterminate characteristics.

Conclusions: The study concludes that COVID-19 infection and vaccination do not significantly impact the detection rate and progression of pulmonary nodules in LDCT scans. This suggests that the pathophysiological effects of COVID-19 and the immune response elicited by vaccination do not extend to altering the characteristics of pulmonary nodules detectable by LDCT. These findings provide valuable insights for clinicians and patients concerning lung health management during the pandemic. Despite the lack of association found in this study, the importance of vaccination against COVID-19 remains paramount in controlling the spread of the virus and protecting overall public health. Future research should aim to explore the long-term effects of COVID-19 infection and vaccination on pulmonary health and other organ systems to guide comprehensive disease management strategies.

EP.04D.05 Coronary Atherosclerosis as an Incidental Finding within the Lung Cancer Screening

E. Sostero[1], K. Chiffi[1], L. Jungblut[1], V. Englmaier[1], T. Frauenfelder[1], I. Opitz[1], S. Hillinger[1], [1]University Hospital Zurich, Zurich/CH

Introduction: Smoking has been associated with a high number of severe health risks such as cancer, chronic obstructive pulmonary disease, stroke and coronary heart disease. Smoking remains the foremost risk factor for lung cancer ranking as the first deadliest tumor. One option, which has been under investigation to mitigate lung-cancer related deaths, is early detection. Since 2019, a study evaluating the feasibility and efficacy of low-dose CT lung cancer screening (LCS) program in Switzerland is ongoing. Concurrently a retrospective analysis was conducted to evaluate the presence of coronary calcification (CAC), as an incidental finding, since smoking has been established as a major risk factor thereof as well.

Methods: Among the 215 participants in the LCS project, atherosclerosis was detected in the coronary artery of 121 individuals. To assess the severity of this condition, the SHEMESH score was utilized, which categorizes CAC in the four coronary arteries as follows: absent (0), mild (1) when less than one-third of the vessels exhibit calcification, moderate (2) when one-third to two-thirds of the artery is affected, and severe (3) when more than two-thirds of the artery is calcified. Two radiologists, gave to every participant a CAC score ranging from 0 to 12. Additionally, the results of the SHEMESH score were compared with age and pack year in a generalized linear mixed model.

Results: CAC was present in 56.1% of the participants. Among them, 31.1% (n = 67) had scores ranging from 1 to 3, 16.2% (n = 35) scored between 4 and 6, and 8.8% (n = 19) had scores between 7 and 12. Figure 1 displays the number of participants per each SHEMESH score. Age (p = 0.032, correlation coefficient = 0.098) and pack years (p = 0.011, correlation coefficient = 0.037) were found as significant predictors both demonstrating statistical significance.

Conclusions: We observed a high prevalence of atherosclerosis among LCS participants. There exists a high association between SHEMESH score and subjects' age and a lower correlation between SHEMESH score and pack years. This observation suggests that although cigarette smoke contributes to the risk of atherosclerosis, the disease may not strictly depend on the number of pack year. Furthermore, the possibility of CAC as an incidental finding as well as its consequences should be considered when setting up a Lung Cancer Screening program.

EP.04D.06 Observation of Peripheral Airways Using Ultra-Thin Fiberscope

T. Kinoshita[1], K. Oka[2], T. Ohtsuka[1], [1]Jikei University, Tokyo/JP, [2]Kansai Photon Science Institute, National Institutes forQuantum Science and Technology, Kyoto/JP

Introduction: The diagnosis of peripheral airway lesions generally relies on computed tomography scanning. Endoscopic observation of such lesions is rarely performed. Although new technologies have been introduced to improve the diagnostic performance of bronchoscopy for peripheral lesions, the yield of bronchoscopic biopsy for such lesions is comparatively low.

Methods: We have developed a 0.97 mm diameter ultra-thin optical fiberscope that can access the peripheral lung fields of human lungs. We used this fiberscope to successfully observe peripheral airway lesions in resected human lungs under negative pressure.

Results: In normal, non-smoker's lungs, the fiberscope was able to visualize individual alveoli beyond the respiratory bronchioles. In a case with a peripheral lung cancer, alveolar structures were destroyed and replaced with red tumors. In a lung specimen with interstitial pneumonia, extensive neovascularization was appreciated, with destruction of alveoli and thickening of the interstitium.

Conclusions: There have been no prior reports regarding the use of a fiberscope to observe human lung lesions at the alveolar level. Since this fiberscope can perform simultaneous observation and laser treatment, access to such peripheral lesions with this device also represents a novel opportunity for treatment.

EP.04E.01 Use of Routine Brain Imaging Surveillance after Definitive Treatment for Early-Stage Non-Small Cell Lung Cancer

N. Lin[1], J. Wu[2], S. Adams[2], S. Asch[2], A. Sox-Harris[2], S. Zeliadt[2], A. Leung[1], S. Han[1], L. Backhus[1], [1]Stanford University, Stanford/CA/USA ,[2]VA Palo Alto Health Care System, Palo Alto/CA/USA

Introduction: Prevalence of brain metastasis in early-stage non-small cell lung cancer (NSCLC) is low, and unnecessary imaging has potential to cause undue burden to patients and health system without survival benefit. Routine brain imaging for staging in early NSCLC occurs in 12-25% of patients in the US, yet estimates for its use in post-treatment surveillance is unreported. We sought to look at use of brain imaging after treatment of NSCLC, utilizing the Veterans Health Administration database to capture patterns and indications of imaging.

Methods: The primary outcome was receipt of brain imaging stratified by modality and indication (symptoms, surveillance, or follow-up for abnormal imaging). We included Veterans diagnosed with Stage I-III NSCLC between 2008-2016 who underwent definitive treatment and survived minimum 120 days corresponding to the first period of surveillance. We examined rates of imaging (CT or MRI) starting 120 days up to 5 years using claims data. A subset of patients underwent additional chart abstraction to obtain data regarding competing outcomes of second primary cancer, recurrence, or death. Multivariable analysis was used to examine predictors of asymptomatic brain imaging.

Results: Of the 20,532 patients; 43% (n=8,825) received brain imaging after treatment, the majority of which 61% (n=5,419) were CT scans and 39% (n=3,406) MRI. In the subset of 1,620 patients, 27% (n=432) received any brain imaging; however, 46% (n=738) of patients had documented recurrence or death making them ineligible for surveillance. After excluding these competing outcomes, 49% (n=432/882) received brain imaging, of which 7% (n=32) were completed for surveillance. Of these scans, a majority were CT (n=19, 59%) rather than MRI (n=13, 41%) and completed in the first year post treatment. Most surveillance brain imaging was done for Stage I patients (44% vs Stage II 28%, Stage III 25%). There were no predictors of receipt of surveillance on multivariable analysis and no difference in rates of detection on imaging done in the absence or presence of symptoms (4% vs 3.5%).

Conclusions: While only a small proportion patient received brain imaging surveillance, we found that most underwent CT rather than MRI and were done predominantly in Stage I patients with no measurable benefit of metastatic detection. Although a small proportion, inappropriate use of imaging surveillance adds to the burden of care for cancer patients and brings tremendous cost to the healthcare system. Continued work on dissemination of surveillance appropriateness criteria can decrease overutilization of resources without affecting patient care quality.

EP.04E.02 Quantification of Cerebrospinal Fluid Tumor DNA in Lung Cancer Patients with Suspected Leptomeningeal Carcinomatosis

S. Nanjo[1], T. Azad[2], M. Jin[2], S. Yano[1], A. Hui[2], S. Nagpal[2], M.H. Gephart[2], A. Alizadeh[2], M. Diehn[2], [1]Kanazawa University, Kanazawa/JP ,[2]Stanford University, Stanford/CA/USA

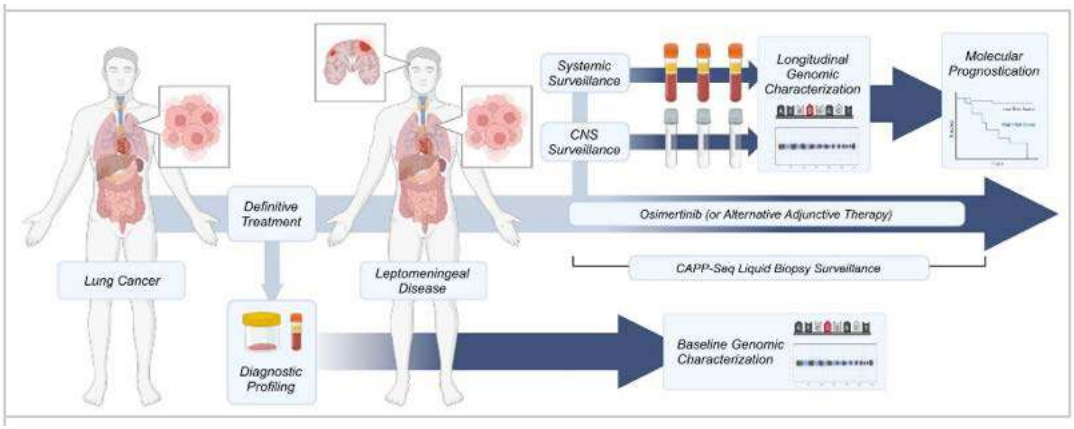
Introduction: The diagnosis and response assessment in leptomeningeal disease (LMD) relies upon cerebrospinal fluid (CSF) cytology, the clinical standard, as well as physical examination and magnetic resonance imaging (MRI) of the brain and spine. CSF cytology is highly specific for LMD but has a reported sensitivity of only 50-60%. Then, we aimed to develop a CSF-tDNA assay using CAPP-Seq, a targeted NGS-based method originally developed for the analysis of plasma ctDNA, for the diagnosis and monitoring of the central nervous system (CNS) metastasis in patients with lung cancer.

Methods: We applied CAPP-Seq using a lung cancer-specific sequencing panel to 81 CSF, blood, and tissue samples from 24 patients with advanced lung cancer who underwent lumbar puncture (LP) for suspected LMD. A subset of the cohort (N = 12) participated in a prospective osimertinib treatment trial for refractory LMD in which serial LPs were performed before and 3 weeks after initiating treatment.

Results: CSF-tDNA variant allele fractions (VAFs) were significantly higher than plasma circulating tumor DNA (ctDNA) VAFs (median CSF-tDNA, 32.7%; median plasma ctDNA, 1.8%; P <0.0001). Concentrations of tumor DNA in CSF and plasma were positively correlated (Spearman's ρ, 0.45; P = 0.03). For LMD diagnosis, cytology was 81.8% sensitive and CSF-tDNA was 91.7% sensitive. CSF-tDNA positivity was also strongly prognostic for overall survival (HR = 7.1; P = 0.02). Among patients with progression disease on targeted therapy, resistance mutations, such as EGFR T790M, were common in peripheral blood but were rare in time-matched CSF, indicating differences in resistance mechanisms based on anatomic compartment. Whereas, MET copy number gain was seen in the CSF-tDNA of 1/5 patients with CNS progression with osimertinib.In the osimertinib treated cohort, patients with CNS progression had increased CSF-tDNA VAFs at follow-up compared to pre-osimertinib CSF. While there was no significant association between pre-osimertinib CSF-tDNA VAFs and CNS progression, on-osimertinib CSF-tDNA VAF was strongly associated with CNS progression (HR = 6.2, P = 0.009).

Conclusions: We provide evidence supporting the utility of CSF-tDNA detection to diagnose LMD in lung cancer patients. Assessment of CSF-tDNA has the potential to measure molecular response of LMD to EGFR-TKI treatment at early treatment timepoints with implications for therapeutic decision making. The use of dynamic measurement of plasma ctDNA and CSF-tDNA status and profiling of co-occurring gene alterations provides support for prospectively testing novel strategies for personalized management of this devastating clinical entity

Keywords: CSF-tDNA, CNS metastasis, Osimertinib



EP.04E SCREENING AND EARLY DETECTION - STRATEGIES TO IMPROVE EARLY DETECTION

EP.04E.03 Enzymomics of Bodily Fluids Captures CD38-Orchestrated Immunometabolic Disorder for Early Detection of Immunotherapy Toxicity

S-C. Ma, W. Yang, Y. Wang, J. Tan, C. Cheng, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou/CN

Introduction: Enzymomics (omics of enzymes) resides in the core of catalytic processes and might exert immunometabolic effect on systemic diseases. As liquid biopsy allows for noninvasive monitoring of the systemic status, we asked whether liquid-based detection could capture the enzymomic disorder in immune-related adverse events (irAEs), a systemic autoimmune state secondary to immune checkpoint inhibition (ICI) treatment.

Methods: We generated pseudo-bulk profiles of enzyme-encoded genes from single-cell data of bronchoalveolar lavage fluids (BALFs) collected at baseline from 16 ICI-treated patients with non-small cell lung cancer (NSCLC). Differential analyses and gene set variation analyses of ICI-pneumonitis vs control BALFs were conducted at pseudo-bulk and single-cell resolutions. The discriminated capacity of the enzymomic biomarker for irAEs was tested in two external cohorts with different biopsy time points, one comprising 60 patients with pre-ICI blood biopsy and the other comprising 22 patients with post-ICI single-cell profiling of CD3+ T cells.

Results: Pseudo-bulk enzymomic profiles of BALFs revealed metabolic disorders in ICI-pneumonitis vs control, converging to an NAD-consuming enzyme CD38. The risk of ICI-pneumonitis was strikingly increased in patients with higher proportion of CD38+ immune cell in baseline BALFs compared with those with lower proportion. At the single-cell resolution, CD38 was upregulated in ICI-pneumonitis BALFs compared with control, particularly in T cells; mechanistically, CD38+ T cells exhibits a senescent-associated secretory phenotype (Figure 1). In external cohorts, pre-ICI blood-based CD38 expression could also predict higher risk of irAEs rather than durable clinical response derived from ICI; and the T cell-specific CD38 expression sticked to increase in ICI-colitis samples compared with those without ICI-colitis and non-ICI samples (Figure 2).

Conclusions: Liquid biopsy detecting CD38 on immune cells, especially T cells, within bodily fluids, including BALFs and blood, might enable early identification of patients at high risk of irAEs

Keywords: bodily fluids, enzymomics, immune-related adverse events

EP.04E.04 Machine Learning Classifier for Predicting the Radiation Pneumonia Grade in Non Small Cell Lung Cancer

J. Wu, Hangzhou Cancer Hospital, Hangzhou/CN

Introduction: Radiotherapy is one of the main treatments for lung cancer. Increasing the radiation dose can improve the local control rate and overall survival rate of the tumor, but at the same time it will increase the occurrence of radiation induced lung injury (RILI). Radiation pneumonia (RP) is the main dose-limiting RILT for lung cancer patients. RP not only affects the quality of life and prognosis of patients, but also increases the rate of readmission, which may even lead to death in severe cases. Therefore, early prediction of the incidence and grading of RP can provide decision-making basis for clinical precise treatment, optimize radiotherapy prescription and reduce the incidence of symptomatic RP. We aim to explore a machine learning classifier for early non-invasive prediction of RP grade in non-small cell lung cancer (NSCLC) patients.

Methods: We retrospectively collected 112 patients and they have been pathologically diagnosed as NSCLC. The CT images within 4 weeks before radiotherapy were collected, and the follow-up data of RP were collected within one year after radiotherapy. The RP was classified as 0~5 grades according to the RP grading standard established by Radiation Therapy Oncology Group (RTOG), and we defined the 0~2 levels as low-RP (n=69), and 3~5 levels as high-RP (n=43). All patients were randomly assigned to training group and testing group according to 7:3. The CT images were imported into 3D-slicer software to segment the regions of interest and extract 851 radiomics features. The radiomics features included first-order features, shape features, glcm, gldm, glrlm, glszm, ngtdm and wavelet transformed features. The intraclass correlation coeficient test, minimum redundancy maximum correlation, least absolute shrinkage and selection operator algorithms were used to select radiomics features. The machine learning classifiers including Logistic Regression, Naive Bayes, SVM, KNN, Random Forest, XGBoost, Gradient Boosting, AdaBoost were used to construct prediction model. ROC analysis was used to analyze the predictive efficacy of the model. The DCA curve was used to analyze the clinical value.

Results: In present study, the XGboost classifier showed the optimal predictive efficacy, the AUCs in the training and testing groups were 0.973 (95% CI [0.801 0.980]) and 0.814 (95% CI [0.800, 0.950]), respectively.

Conclusions: The radiomics features of CT may serve as the potential imaging biomarkers for prediction of RP grade, and the XGboost classifier may have the optimal predictive efficacy.

EP.04E.05 Prevalence and Characterization of MET Overexpression in Chinese NSCLC Patients: A Retrospective Real-World Analysis

L. Yang[1], J. Li[1], Y. Li[1], R. Lin[1], Y. Li[2], J. Chen[1], X. Lai[1], [1]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou/CN ,[2]The second Affiliated Hospital of Wenzhou Medical University, Wenzhou/CN

Introduction: Mesenchymal epithelial transition (MET) expression is discerned in 17-35% of non-small cell lung cancer (NSCLC) patients. The current knowledge of its impact on the treatment efficacy of MET-tyrosine kinase inhibitors (TKIs) remains constrained, despite MET being a promising therapeutic target. This study attempt to elucidate the characterization of MET overexpression within a hospital in China. This exploration holds potential significance for forthcoming investigations focusing on targeted MET therapy.

Methods: This retrospective real-world study analyzed non-small cell lung cancer (NSCLC) specimens from 1223 patients who underwent surgical resection or biopsy between June 2020 and August 2023 at the First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China. Specimens deemed suitable for MET immunohistochemistry (IHC) were included in the analysis. MET overexpression was assessed utilizing the anti-MET clone SP44 IHC assay from Roche Tissue Diagnostics, with a positive classification assigned if more than 50% of cells at 3+ intensity. Clinical data were retrieved from electronic health records. Associations among covariates were examined using the Spearman test, with significance set at p values < 0.05. Statistical calculations were conducted using R 4.3.1 software.

Results: Eighty seven patients were included. The detection rate of patients with MET positive (3+intensity) is 7%. MET overexpression patients was found more frequently in male (70.1%), adenocarcinoma (81.6%), IV stage (69.0%), concomitant hypertensin (39.1%). Regimens used were chemotherapy (2.3%), chemotherapy plus immune checkpoint inhibitors (11.5%). target therapy (40.2%). We also found that MET overexpression correlated with red blood cells decreased (correlation coefficient -0.3139, p=0.0036), and hemoglobin decreased (correlation coefficient-0.3805, p=0.0002). Due to the limited follow-up period, the Progression-Free Survival (PFS) in patients with MET overexpression was not reached.

Conclusions: We have successfully demonstrated a higher occurrence of MET overexpression in males, adenocarcinomas, and at stage IV in NSCLC patients. Additionally, our findings suggest a potential association between anemia and MET overexpression, which suggested that MET overexpression may cause anemia. Considering the increasing development and prevalence of MET overexpression, it emerges as a promising avenue for future research, potentially serving as a target for the characterization and treatment of NSCLC.

Keywords: MET overexpression, adenocarcinomas

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04E.06 The Prediction of Spread Through Air Spaces with Preoperative 18F-FDG PET/CT in Clinical Stage I Lung Cancer

G. Kocaman, C. Soydal, S. Dursun, Y. Kahya, S. Dizbay Sak, A. Kayı Cangır, Ankara University Faculty of Medicine, Ankara/TR

Introduction: Spread through air spaces (STAS) is associated with local recurrence, especially in limited resections such as segmentectomy or wedge resection. It is evaluated through histopathological examination postoperatively. Having information about STAS preoperatively can be influential in determining the type of resection.

The aim of this retrospective study was to investigate the utilization of preoperative F-18 fluorodeoxyglucose positron emission tomography/computed tomography (18F FDG-PET/CT) in predicting STAS in clinical stage I lung cancer.

Methods: The study included 205 patients (mean age: 62.61±8.5; 132 male, 73 female) with clinical Stage I lung cancer who underwent surgery between 2016 and 2024, had PET/CT imaging available at our institution, and did not receive neoadjuvant treatment. Maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) values were calculated from preoperative PET/CT images. Patients were grouped as STAS absent (STAS 0) and present (STAS 1). Differences between PET/CT parameters of STAS 0 and STAS 1 groups were compared using the Mann-Whitney U Test. Cut-off values to predict STAS status for PET/CT parameters were calculated with ROC analysis.

Results: Of the tumors, 168 (82.4%) were FDG avid, while the rest were not visible in preoperative imaging. Surgical procedures included lobectomy, wedge resection, segmentectomy, and pneumonectomy in 131, 45, 16, and 13 patients, respectively. Based on postsurgical histopathological examination, 126 lesions (61.5%) were negative for STAS, and 79 (38.5%) lesions were positive for STAS. The STAS positivity rate for FDG avid lesions was calculated as 69/168 (41%), and for non-FDG avid ones as 9/36 (25%) (p=0.07).

Significant differences were detected in SUVmax (8.2 [range 2.56-12.40] vs. 6.3 [range 0.62-9.78], p = 0.036) and SUVmean (4.9 [range 2.46-8.20] vs. 3.7 [range 0.51-7.60], p=0.018) according to the presence of STAS. However, this difference was not observed in MTV (4.67 [range 0.65-23.76] vs. 4.95 [0.63-20.07], p = 0.95) and TLG (8.73 [range 0.93-48.76] vs. 6.73 [0.70-53.66], p = 0.17).

In the ROC analysis, SUVmax and SUVmean showed the best diagnostic performance among PET parameters to predict STAS. SUVmax had an AUC value of 0.60 (95% CI 0.62-0.68) with a sensitivity of 79% and specificity of 41% at a cut-off of 3.47.

Conclusions: Preoperative 18F FDG-PET/CT findings might play a role in predicting STAS status. SUVmax and SUVmean appear to be more valuable indices than MTV and TLG in predicting the presence of STAS in clinical stage I lung cancer and for deciding the type of surgical resection.

EP.04E.07 Lung Cancer Patient Reported Experiences with Biomarker Testing

B. Schneider[1], D. Cronin[2], [1]MyHealthTeam, San Francisco/CA/USA ,[2]N/A, South Hamilton/MA/USA

Introduction: Research was undertaken to better understand awareness and experiences with biomarker testing among patients living with Non-Small Cell Lung Cancer (NSCLC). Additionally, research sort to understand potential health inequities in terms of access to biomarker testing.

Methods: In August 2023, an email invitation to an online survey was sent to US members of MyLungCancerTeam. In total, 82 members living with Non-Small Cell Lung Cancer completed the survey. All respondents were 21 or older and have been diagnosed with lung cancer.

Results: The majority of respondents had stage 3 or 4 lung cancer (53%) and 35% had been diagnosed within the last year. More than half (55%) have discussed biomarker testing with their doctor and 46% have had a biomarker test. Based on biomarker test results, 39% were put on an immunotherapy drug and 32% were put on a targeted therapy. For a small number (11%), results suggested they were not good candidates for immunotherapy. Five percent were able to apply for or enter a clinical trial based on results. The top reason for not getting a biomarker test is lack of familiarity with the test (38%). Other reasons for not getting tested included cancer being in remission (20%), the oncologist had already developed a treatment plan (18%) or did not feel the test was needed (8%). In total, 49% are or had been on an immunotherapy drug. The percent who were extremely satisfied with their treatment regimen was much higher if immunotherapy was part of that regimen (53% versus 29%). Results also identified health inequities regarding who underwent a biomarker test. For example, those who received the test were more likely to have at least an associate college degree (74% vs. 42%), earn $50K or more (56% vs. 40%), have private insurance (26% vs. 14%), live in a non-rural area (80% vs. 59%) and live in a non-Southern census region (70% vs. 61%).

Conclusions: Given the challenges in diagnosing lung cancer at an early stage, getting patients onto the most effective treatment regimen as early as possible is critical. Biomarker testing can help oncologists develop more targeted approaches to treating their patients. As such, eliminating disparities in regard to access to biomarker testing is paramount in ensuring health equity and the best possible outcomes regardless of who the patient is or where the patient lives.

EP.04E.08 Rapid in House Next Generation Sequencing and Impact on Treatment Decisions and Initiation in Advanced NSCLC

R.S. Kang, K.M. Bisson, A. Beharry, E. Goonaratne, B.S. Sheffield, P. Cheema, K. Perdrizet, William Osler Health System, Brampton/ON/CA

Introduction: Next-generation sequencing (NGS) in non-small cell lung cancer (NSCLC) has improved the detection of actionable genetic alterations and, subsequently, an increasing number of treatment options. Despite many Canadian laboratories offering NGS testing, there are many regions experiencing an average turnaround time for results of >2 weeks. The William Osler Health System (WOHS) has implemented rapid in-house NGS for patients with NSCLC and other cancers. This study examined turnaround times of in-house NGS to assess whether access to rapid NGS improved time to treatment decisions and access to targeted treatments in patients with advanced disease.

Methods: A retrospective chart review was done for patients diagnosed with NSCLC who underwent NGS from January 1, 2019, to December 31, 2022. Patient demographics, stage of cancer, NGS results, date of medical oncology consultation, treatments provided, and date of targeted therapy initiation were collected. Turnaround time (TAT) for in-house NGS results was defined as the procedure date to when the results were available in the electronic medical record for a physician to review. Two sample t-tests were performed using an alpha value of 0.05 to compare TAT means.

Results: During the inclusion period, 988 NSCLC patients had genomic sequencing performed at WOHS; 495 patients were diagnosed and treated at WOHS, and 493 were from external hospitals. Key demographics of patients diagnosed and treated at WOHS are summarized in Table 1. The mean TAT for all samples (N=988) was 14 days. TAT for WOHS patients shows a statistically shorter TAT (M=11 days) compared to non-WOHS patients (M=17 days) ($p<0.001$).

Table 1. Key WOHS patient demographic and baseline clinical characteristics.

When NGS results were available at the first medical oncology visit, treatment decisions were more likely to be made ($p<0.001$), a shorter wait time between medical oncology consultation and treatment decision ($p<0.001$) was observed and treatment was started faster (M=18 days) than patients without upfront NGS results (M=30 days) ($p>0.001$ not significant likely due to limited sample size). The targeted therapy prescription rate is demonstrated in Table 1. Targeted therapy was not prescribed for patients with targetable mutations where front-line targeted therapy was not available or indicated (e.g., KRAS G12C, ERBB2) or where systemic therapy was not indicated.

Conclusions: This community-based in-house NGS testing model can significantly decrease the TAT for NGS results for advanced NSCLC patients and ultimately improve the time-to-treatment decision and treatment initiation in the advanced setting. The impact this will have on patient outcomes, such as survival, is currently under investigation.

EP.04F SCREENING AND EARLY DETECTION - CLINICAL TRIALS IN PROGRESS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.04F.01 Challenges in Recruiting for a Randomized Controlled Intervention to Increase Lung Cancer Screening

L. Rios, D.T. Cooke, N. Hicks, S.L. Stewart, J.H. Dang, H. Leisy, S. MacDonald, C. Shulkin, R. Luna, J.E. Kohler, A. Elder, G. Salter, N. Singh, E.K. Tong, E.W. Chak, M. Chen, K. McHenry, UC Davis, Davis/CA/USA

Introduction: Lung cancer is the most fatal of all cancers, but of the four US Preventive Services Task Force (USPSTF) recommended cancer screenings, lung cancer screening (LCS) is the least utilized. Nationally, the median LCS rate is 5.0%, lower than that for any other screenable cancer. We are conducting a prospective, randomized clinical trial to test two interventions associated with increasing the completion of low-dose computerized tomography scans for LCS among eligible UC Davis ambulatory patients over usual care. In this preliminary report, we identify the ongoing challenges in recruiting eligible patients during the first 15 weeks of this clinical trial (ClinicalTrials.gov identifier: NCT06351085) involving 309 patients.

Methods: During Aim 1 we conducted key informant interviews with providers, patients who completed LCS, and age-eligible patients who smoked to qualitatively identify patient-centered factors that facilitate and impede participation in LCS. A Patient Advisory Board reviewed these findings and assisted in developing an educational video for patients that addressed perceived barriers and accentuated facilitators to screening. In Aim 2, we adhered to the USPSTF recommendations for LCS including shared decision-making for smoking cessation counseling. Primary care clinics designated a licensed vocational nurse as a Navigator to recruit patients for LCS on their behalf. These findings informed the randomization of two interventions: (a.) Navigator-guided intervention alone and (b.) Navigator-guided intervention plus a LCS awareness video linked to the electronic patient-physician portal to increase LCS compared to a usual care control clinic arm.

Results: The overwhelming proportion of existing electronic health records on patients' smoking histories were not current. Determining actual eligibility of patients ages 50-80 and who are current smokers or former smokers who quit within the past 15 years with > 20 pack-years needed to be done on a patient-by-patient basis. This typically required the Navigator to reach the patient by phone and going through a protocol to assess eligibility by age, smoking status, current cancer diagnosis, as well as recency of LCS if appropriate. Through this protocol, our initial findings indicate that [1] 6.5% (20/309) of patients have a current cancer diagnosis and are presumably in treatment and excluded from further recruitment to LCS; and [2] 80.0% (182/227) of those remaining patients contacted, were not eligible due to not meeting USPSTF recommendations. Sixty-two patients could not be contacted on the first attempt. After all of the other eligibility requirements were assessed, only 8.9% (22/247) of the reachable patients were determined to meet all of the LCS eligibility criteria. To date, among patients whose eligibility was verified, the two levels of Navigator-guided interventions resulted in a LCS rate of 41% (9 scheduled or screened/22 eligible).

Conclusions: These findings are very preliminary and caution should be exercised in extrapolating these results as this only represented the first 15 weeks of our ongoing intervention study. The role of the Navigator to thoroughly assess LCS eligibility beyond dependence of extant electronic patient records of smoking histories and other factors is essential.

EP.05A PULMONOLOGY AND STAGING - ENDOSCOPIC EVALUATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.05A.01 Efficacy and Safety of Midazolam with Fentanyl for Sedation During EBUS-TBNA: A Randomized, Double-Blind, Phase III Study

J. Yamada, D. Hazama, T. Fukui, A. Yatani, M. Okamoto, S. Fujimoto, R. Yoshimura, M. Takayasu, N. Takata, H. Sato, C. Mimura, K. Furukawa, N. Katsurada, M. Yamamoto, M. Tachihara, Kobe University Graduate School of Medicine, Hyogo/JP

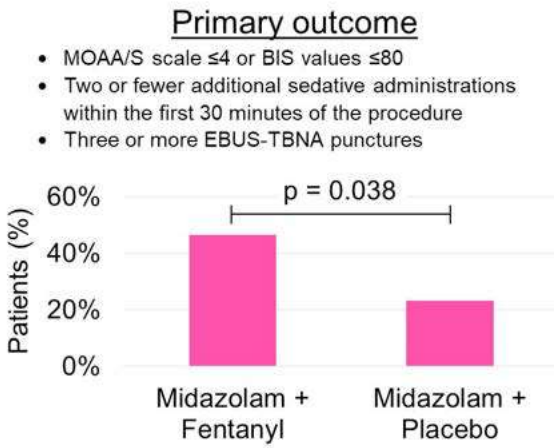
Introduction: Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) is the most commonly used technique for histologic sampling of mediastinal or hilar lymph nodes or masses. The CHEST guideline recommends moderate-deep sedation for EBUS-TBNA, and the British Thoracic Society guideline recommends midazolam or propofol in combination with opioids for flexible bronchoscopy. However, with few randomized trials, the optimal sedation regimen for EBUS-TBNA remains unknown. Here we evaluate the efficacy and safety of midazolam with fentanyl for sedation in EBUS-TBNA.

Methods: We conducted a single-center, randomized, and double-blind phase III study between December 2021 and October 2023. We compared the patients who received midazolam with fentanyl (fentanyl group) with the patients who received midazolam with placebo (placebo group) for sedation in EBUS-TBNA. We assessed the depth of the sedation in the procedure with the Modified Observer's Assessment of Alertness and Sedation (MOAA/S) scale and bispectral index (BIS) values. The primary endpoint was the rate of the patients achieving all of the following; 1) MOAA/S scale ≤4 or BIS values ≤80, 2) the number of additional sedative administrations ≤2 within the first 30 minutes of the procedure, 3) ≥3 times of punctures.

Results: We enrolled 84 patients (fentanyl group, 41; placebo group, 43). There were no significant differences in patient characteristics between the fentanyl and placebo groups. The primary endpoint was significantly better in the fentanyl group than in the placebo group (46.3% vs 23.3%; p = 0.038). A significantly lower rate of restlessness or agitation (MOAA/S scale 6) (16.3% vs 38.6%; p = 0.030), lower number of additional sedative administrations [median (range), 2 (1-4) vs 3 (1-4); p = 0.040], and higher rate of ≥3 punctures (87.8% vs 65.1%; p = 0.021) were observed in the fentanyl group than in the placebo group. There was no significant difference in complications such as unexpected deep sedation (MOAA/S scale 0 or 1) and hypopnea between the two groups. The operator visual analogue scale scores, where 0 is good and 100 is bad, for patient's cough [median (range), 30 (3-96) vs 68 (1-100); p = 0.011] and sedation [25 (0-96) vs 51 (0-100); p = 0.011] were significantly better in the fentanyl group.

Conclusions: The addition of fentanyl to midazolam for sedation in EBUS-TBNA not only provided better sedation but also increased the number of punctures without increasing complications. The combination of midazolam and fentanyl should be considered for sedation during EBUS-TBNA.

Keywords: Sedation, Midazolam with fentanyl, EBUS-TBNA



EP.05A PULMONOLOGY AND STAGING - ENDOSCOPIC EVALUATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.05A.02 Timing of PET-CT has no Significant Impact on Staging EBUS Results in Mediastinal Staging and Diagnosis of Lung Cancer

V. Dudzevicius, E. Idris, A. Abdeldayem, R. Mustafa, R. Sathyamurthy, G. Andrijevskiene, M. Burgess, R. Hartley, South Tees Hospitals NHS Foundation Trust, Middlesbrough/GB

Introduction: National Institute for Health and Care Excellence guidance on the diagnosis and management of lung cancer recommends positron emission tomography-computed tomography (PET-CT) scan followed by endobronchial ultrasound (EBUS) sampling in patients with suspected lung cancer who could potentially have treatment with curative intent. Studies have shown that PET CT as a sole test has relatively low sensitivity and specificity for lung cancer in areas with high prevalence of granulomatous diseases. But in combination with EBUS it helps to reduce radiotherapy field and performing PET CT first may help to reduce the need for repeat biopsy in those diagnosed with lung cancer. We compared staging EBUS results and mediastinal staging on PET-CT in patients with suspected lung cancer, depending on whether PET-CT scan performed first or after EBUS.

Methods: Staging EBUS performed in 59 patients referred with suspected lung cancer and hilar or mediastinal lyphadenopathy in a single centre between 2021-2023. Cases divided to EBUS group (EBUS performed prior to PET-CT) and PET-CT group (PET-CT performed prior to EBUS). Results of lymph nodes histology (or visual EBUS assessment, if nodes size were 6 mm or less) compared to fluorodeoxyglucose uptake on PET CT in relevant lymph nodes. Adequate sample with no malignant cells and low uptake, or presence of malignancy with moderate/high uptake considered as findings in agreement in both groups. Chi-squared test performed using MedCalc Software, Ostend, Belgium.

Results: 23 and 36 cases included in EBUS and PET-CT groups, respectively. Benign condition found in 3 (13.0%) vs 2 (5.6%), lung cancer - in 18 (78.3%) vs 32 (88.9%), lymphoma-in 2 (8.7%) vs 2 (5.6%) cases in EBUS and PET-CT groups, p=0.52. Mediastinal staging was in agreement in 16 (69.6%) EBUS vs 29 (80.6%) PET-CT group cases, p=0.34. EBUS downstaged the mediastinum in 1 (4.4%) vs 5 (13.9%), was positive in higher N station node in 2 (8.7%) vs 0 (0%) or confirmed benign condition in 3 (13.0%) vs 2 (5.6%) cases in EBUS and PET-CT groups, respectively, p=0.14. In benign condition - 1 (2.2%) vs 4 (28.6%), in lung cancer - 40 (88.9%) vs 10 (71.4%) and in lymphoma-in 4 (8.9%) vs 0 (0%) cases EBUS and PET-CT findings were in agreement or discordant, respectively, p<0.05. In lung cancer patients PET-CT also revealed EBUS inaccessible or metastatic disease in 4 (22.2%) and 6 (18.8%) in EBUS and PET-CT groups, p=0.44.

Conclusions: Staging EBUS has good diagnostic value and is useful method of mediastinal staging in patients with suspected lung cancer independently from PET-CT timing. EBUS and PET CT results discordance more often found in benign conditions. Performing PET-CT is required to evaluate for the nodes inaccessible by EBUS or for metastatic disease in patients with lung cancer.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.05A.03 The Accuracy of EBUS, EUS, EBUS Plus EUS, and Mediastinoscopy for Mediastinal Staging in NSCLC - A Systematic Review and Meta-Analysis

C. Baldotto[1], E. Mascarenhas[1], A. Gelatti[1], T. Vilas Boas Reis[1], M. Corassa[1], C.H. Andrade Teixeira[1], G. Castro Jr.[1], V. C. Cordeiro de Lima[1], [1]Brazilian Group of Thoracic Oncology, Porto Alegre/BR

Introduction: Lung Cancer, the leading cause of cancer-related deaths, demands accurate staging to optimize therapy and improve outcomes. This comprehensive systematic review presents the accuracy of EBUS, EUS, EBUS plus EUS, and mediastinoscopy for NSCLC staging.

Methods: Our review utilized the GRADE approach to systematically search for evidence on the accuracy of EBUS, EUS, combined EBUS and EUS, and mediastinoscopy for mediastinal staging of NSCLC. The research questions were framed in a PICO format based on the investigators' expertise and available literature. We searched MEDLINE/PubMed, EMBASE, Web of Science, Cochrane Library, and LILACS for each PICO question. Data from the original studies will be presented individually by the study in Tables 2x2 as measures of diagnostic test accuracy (true positives, false positives, true negatives, false negatives). The statistical analysis was performed according to the recommendations of the Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy using the "DTAplots", "mada", and "meta" packages in the R 4.2.1 software. Figure 1 describes the flow charts of study selection in the systematic review of each method.

Results: According to our analyses, EBUS plus EUS has the best diagnostic accuracy with an sROC of 0.99 (CI 95% 0.97-0.99). Also, the pooled sensitivity of EBUS plus EUS is higher than that of each method. The pooled sensitivity of EBUS and EUS is lower than that of both methods used together; however, it is reasonable to perform only one method when one is unavailable. Overall, the sROC of EBUS and EUS is close to that of EBUS plus EUS. In contrast, mediastinoscopy, despite its sROC of 0.99 (CI 95% 0.96-0.99), falls short in terms of pooled sensitivity compared to EBUS plus EUS. Its invasive nature, limited access to all LNs, and potential for significant complications are important drawbacks.

Conclusions: Mediastinoscopy has limitations in accessing some nodal stations, such as paratracheal and subcarinal. EBUS-TBNA plus EUS-FNA is recommended to assess mediastinal LN status accurately. The main EBUS plus EUS advantage is its high sensitivity, NPV, and even higher specificity, which is only comparable to mediastinoscopy. EBUS plus EUS is a minimally invasive technique that usually does not require general anesthesia. This method is generally a safe outpatient procedure. Nevertheless, EBUS plus EUS availability can be limited to tertiary care centers due to the requirement of specialists with dedicated training.

EP.05A PULMONOLOGY AND STAGING - ENDOSCOPIC EVALUATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.05A.04 Risk Factors for the Development of Pulmonary Infection after Bronchoscopy in Patients with Lung Cancer - A Centre in Greece

V. PAPAVASILEIOU[1], T. RAPTAKIS[1], S. LAMPADAKIS[1], I. VOULGARELI[1], A. PAPAVASILEIOU[2], A. KARAKATSANI[1], S. LOUKIDES[1], K. SYRIGOS[3], [1]UNIVERSITY GENERAL HOSPITAL "ATTIKON", ATHENS/GR ,[2]Qualities SA, ATHENS/GR ,[3]SOTIRIA GENERAL HOSPITAL, ATHENS/GR

Introduction: Flexible bronchoscopy and its new methods have revolutionized the era of the diagnosis, staging, and restaging of lung cancer. A rare late complication is post-bronchoscopy respiratory infection, which definition differs among studies. The incidence of this type of infection in lung cancer patients ranges from 3% to 6.3% according to published studies. In patients with lung cancer, this type of infection is critical not only due to treatment delays but also because it can lead to treatment cancellation and death.

Methods: We retrospectively studied 182 adult hospitalized patients with undiagnosed lung cancer who underwent bronchoscopy at "ATTIKON" University General Hospital from January 2022 to April 2023 for diagnosis and staging of the disease. The infection and non-infection groups were compared. Two groups were compared for age, sex, body mass index, smoking habit, Charlson Comorbidity Index, comorbidities, recent hospitalization for SARS-CoV-2 in the last month before undergoing diagnostic bronchoscopy, location of the primary cancer, histological type, stage of the disease, chest CT findings, duration of bronchoscopy, type of bronchoscopy procedure, endobronchoscopic finding of the endoscopy, laboratory testing of patients prior to undergoing bronchoscopy, prophylactic administration of antimicrobials before endoscopy.

Results: Pulmonary infection after the diagnostic bronchoscopy occurred in 7 patients (3.9%) and included pneumonia in 5 patients, parapneumonic effusion in 1 patient, and empyema in 1, too. Three of the four patients who developed pneumonia had been hospitalized for COVID-19 infection in the past month. The time from bronchoscopy to symptom onset averaged 5 days with a range (1 - 12 days). A pathogen was isolated in only one patient (14.3%) in sputum culture and blood culture and this pathogen was Acinetobacter baumannii. One died due to the pulmonary infection, and 4 had a delay in starting anticancer treatment of 20 days.

We identified as risk factors for post-bronchoscopy pulmonary infection the personal history of COPD (p=0.046), presence of emphysema in CT thorax (p=0.046), endobronchial lesions which causes stenosis ≥50% of the lumen (p=0.04), disease stage IV of NSCLC (p=0.03) and recent hospitalization for COVID-19 (p=0.04) using multivariate analysis.

Conclusions: We identified as risk factors of this complication the patient's recent hospitalization (in the last month) for COVID-19 infection (OR: 64.88, 95% CI: 8.39 - 501.65, p<0.001), individual history of COPD (OR: 8, 95% CI: 0.94 - 67.86, p=0.03), presence of emphysema on CT scan (OR: 8, 95% CI: 0. 94 - 67.86, p=0.03), the presence of an endobronchial lesion on bronchoscopy causing partial obstruction of ≥ 50% of the bronchus with further inability to advance the bronchoscope (OR: 9.6, 95% CI: 1.58 - 58.41, p<0.01), and stage IV in NSCLC.

There is a need to establish a homogeneous definition of complications and then conduct multicenter studies to identify risk factors.

EP.05A.05 Brazilian Single-Center Experience in the Staging of Thoracic Neoplasms Using Endosonographic Methods (EUS/EBUS)

J.V.C. Assef[1], A. Gonçalves e Silva[1], P.C.B. Boscardim[2], S. de Lazari[2], G.F. Gomes[2], J. Mendes de Souza[2], [1]Instituto do Câncer e Transplante de Curitiba, Curitiba/BR ,[2]Hospital Nossa Senhora das Graças, Curitiba/BR

Introduction: Lung cancer is one of the most frequently diagnosed solid tumors worldwide it is also the leading cancer-specific cause of death. Defining the best treatment strategy depends on accurate staging, which significantly impacts prognosis and patients' outcomes. Evaluating the mediastinum is a fundamental staging step. The non-invasive method EBUS/EUS has been increasingly used. Despite its availability in Brazil, few centers have reported their experience with the method. Even in supplementary healthcare, the cost and learning curve are barriers. At our hospital, we have an important thoracic oncology service, with an increasing number of patients undergoing EBUS/EUS. The aim of this study was to evaluate the performance of EBUS/EUS at this hospital, using sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy, and to compare this with existing data.

Methods: We conducted an observational, retrospective study by analyzing the medical records of patients who underwent mediastinal lymph node evaluation by endoscopic ultrasound (EBUS/EUS), from October 2021 to October 2023 at the Nossa Senhora das Graças Hospital in Curitiba (PR), Brazil. For the analysis of accuracy, sensitivity, specificity, PPV and NPV, only patients who underwent a surgical procedure (and thus had lymph node anatomopathological evaluation) were compared with EBUS/EUS data.

Results: During the period of the study, 160 patients underwent ultrasound evaluation of the mediastinum. The average age was 64 years (31-93), with 88 (55%) patients being male. The average number of lymph node chains examined was 4.78 (0-9) with an average of 2.6 (1-5) nodes biopsied per examination. Finally, 110 (68%) had anatomopathological results of the mediastinal lymph node evaluation (67% N0; 33% N2/N3). Out of the 110, 38 patients were referred for surgery. We found a specificity of 90.6% and a NPV of 93.5%, corresponding to a final accuracy of 86.8%, data that is in line with current literature.

Conclusions: The use of the non-invasive strategy EBUS/EUS, to assess the mediastinum has become a standard practice. Although it has been consolidated in the literature and common in large centers, there are still some challenges for its consolidation in Brazil. However, with our study data, we can demonstrate that the use of this method allows professionals to achieve good results, improving the accuracy staging and, by extension, the outcomes of our patients.

Table 2 – Results	
Sensitivity	66.7%
Specificity	**90.6%**
PPV	57.1%
NPV	**93.5%**
Accuracy	86.8%

*PPV: positive predictive value; NPV: negative predictive value

EP.05A PULMONOLOGY AND STAGING - ENDOSCOPIC EVALUATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.05A.06 Timing of Thoracentesis in Hospitalized Patients with Malignant Pleural Effusion: A Study of the US National Inpatient Sample

J.A. Elengickal[1], V. Varughese[1], M. Pavy[1], A. Sood[2], C. Cooper[1], [1]University of South Carolina Prisma Health, Columbia/SC/USA ,[2]North Shore University Hospital, Long Island/NY/USA

Introduction: Malignant pleural effusion is often the first presenting symptom in patients with cancer and signifies advanced disease with an associated high mortality. Thoracentesis is the treatment of choice in patients with limited life expectancy for symptomatic management of dyspnea or for patients who are not candidates for more invasive procedures such as drainage with pleural catheter, chemical pleurodesis. The aim of this study is to examine if timing of thoracentesis during hospitalization has an impact on patient outcomes in patients with malignant pleural effusions.

Methods: This is a retrospective cohort study using the 2020 National Institute Sample (NIS). Inclusion criteria were patients with diagnosed malignant pleural effusion, further stratified by diagnosis of primary lung cancer or metastatic lung lesions. Patient cases were matched with control based on demographic factors including age, gender, race, SES, and primary lung cancer or metastatic lung lesions. Primary intervention was thoracentesis and time to procedure during hospitalization. Primary outcomes included mortality and need for endotracheal intubation. Propensity score and nearest neighbor matching was used to assess causative relationship between late thoracocentesis (defined as thoracocentesis beyond day 3 of admission) and all cause mortality, after matching for age, sex, race, and SES. Similar analyses were done for causative association between time to thoracentesis and endotracheal intubation in both the groups.

Results: 30,289 patients were identified with malignant pleural effusion due to primary lung malignancy, of which 7,054 patients underwent thoracentesis during admission. 21,540 patients were identified with malignant pleural effusion due to metastatic lung lesions, of which 5,599 patients got thoracocentesis during admission. Thoracentesis after day 3 of hospitalization had a positive correlation for association with all cause mortality in malignant pleural effusions associated with primary lung lesions (OR:2.13, 95% CI: 1.42-3.20, $p<0.05$) and with metastatic lung lesions (OR: 1.73, 95% CI: 1.15-2.62, $p<0.05$). When done on day 1, 2, or 3 of hospitalization there were no statistically different rates of all cause mortality. While thoracentesis after 3 days of hospitalization was associated with significantly higher rates of endotracheal intubation in patients with primary lung lesions (OR: 1.50, 95% CI: 1.06-2.13, $p<0.005$), there was not a statistically significant difference in rates of intubation in patients with metastatic lung lesions (OR: 1.45, 95% CI: .99-2.11, $p=.052$).

Conclusions: This data demonstrates a correlation with late thoracentesis after day 3 of hospitalization and increased mortality in patients with a malignant pleural effusion. These results suggest thoracentesis should be considered earlier during hospitalizations of patients with malignant pleural effusions with primary lung cancers and metastatic lung lesions.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.05A.07 Feasibility and Safety of Nasal Access for EBUS-TBNA in the Korean Population: A Single Center Experiences

Y.j. Lee[1], H.W. Kim[1], Y. Kim[1], Y.J. Hong[1], J.H. Ha[1], [1]Incheon St. Mary's Hospital, Incheon/KR

Introduction: Endobronchial ultrasound (EBUS) is a reliable modality for accurately and safely diagnosing mediastinal lymph nodes and lung lesions. Despite previous studies establishing the feasibility of nasal route insertion, there remains a paucity of data on Asian populations. This study aimed to evaluate the feasibility and safety of EBUS-guided transbronchial needle aspiration (TBNA) using nasal access among the Korean population.

Methods: We conducted a retrospective analysis of patients who underwent an EBUS-TBNA at our institution from Mar 2015 to Mar 2024. Patients with mediastinal lymphadenopathy were included for various indications such as lung cancer staging, diagnosis of TB lymphadenitis, and lymphoma. An EBUS scope with 6.9 mm outer diameter (BF-UC260FW, Olympus, Tokyo) was utilized for all procedures. Initially, EBUS insertion was attempted via the nasal route in all subjects under conscious sedation. In cases where nasal insertion was failed through both nostrils, the oral route was used as an alternative. The primary outcome was to evaluate the success rate of nasal approach as a preferred alternative to oral insertion in the Korean population.

Results: Among the 1029 patients included in the study, the success rate of the nasal approach was 93.8% (95% CI: 92.1-95.2). There were no significant age differences between groups. Females under the age of sixty showed a relatively higher rate of failed nasal approaches. The midazolam level for conscious sedation was similar in both groups, but fewer analgesics were required for the nasal approach. Complications associated with the nasal route were primarily minimal epistaxis.

Conclusions: Nasal insertion has emerged as a preferred alternative for EBUS-TBNA, demonstrating relative safety and feasibility compared to oral route. Ongoing advancements in thinner, more flexible EBUS scope technology promise significant benefits for patients with narrower nasal passages or higher pain sensitivity.

Table 1. Descriptive characteristics between the nasal and oral access group; SD, standard deviation

	Nasal (N=963)	Oral (N=64)	*P* value
Age (years, mean±SD)	68.2±11.2	65.4±12.6	0.054
Sex			0.025
- Male	691 (71.8%)	37 (57.8%)	
- Female	272 (28.2%)	27 (42.2%)	
Procedure time (minutes)	22.3±7.7	24.4±9.4	0.091
Midazolam (mg, mean±SD)	2.5±0.8	2.8±1.1	0.094
Fentanyl (mcg, mean±SD)	53.5±12.0	58.6±14.2	0.007

Table 2. Association factors in nasal approach failures; OR, odds ratio; CI, confidence interval

	Nasal (No.)	Oral (No.)	Ratio	OR (95% CI)	*P* value
			Nasal access failure		
Male	691	37	5.08	1	
Female	272	27	9.03	1.77 (1.05-2.98)	0.032
Age (years)

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.05A.08 The Accuracy of Bronchoscopy and Transthoracic Needle Biopsy for Diagnosing Lung Cancer - A Systematic Review

E. Mascarenhas, C. Baldotto, A. GELATTI, T. VilasBoas Reis, M. Corassa, C.H. Andrade Teixeira, V. C. Cordeiro de Lima, G. Castro Jr., Grupo Brasileiro de Oncologia Torracia, Porto Alegre/BR

Introduction: The initial work-up of patients with lung cancer (LC), the leading cause of cancer-related deaths worldwide, includes accurate histologic diagnosis and staging, to inform a precise prognosis and to held in the treatment decision. This comprehensive systematic review perused the current clinical data about the accuracy of bronchoscopy and transthoracic needle biopsy (TTNB) for LC.

Methods: Our review was conducted by LC specialists and used the GRADE approach to systematically search for evidence on the accuracy of bronchoscopy and TTNB for LC diagnosis. The research questions were framed in a PICO format. We searched MEDLINE/PubMed, EMBASE, Web of Science, Cochrane Library, and LILACS for each PICO question.

Data from the original studies were presented individually by study in Tables 2x2 as measures of diagnostic test accuracy (true positives, false positives, true negatives, and false negatives). The statistical analysis was performed according to the recommendations of the Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy. It was performed using the "DTAplots", "mada" and "meta" packages in the R 4.2.1 software.

Results: We found a lack of primary studies assessing bronchoscopy's diagnostic accuracy in LC patients, making it impossible to conduct a meta-analysis with the available data. The diagnostic precision of bronchoscopy in detecting premalignant lesions is variable, emphasizing the need for additional non-invasive biopsy methods to improve its accuracy.

We conducted analyses to evaluate the diagnostic performance of TTNB for lung lesions. In our search, 20 studies conducted between 2000 and 2019 were included, with a sample size of 4606 patients. LC prevalence ranged from 59.02% to 95.18% across studies. Nineteen studies performed the CT-guided TTNB, and two performed the CT-FC-guided TTNB. The pooled sensitivity and specificity were 0.90 and 0.96, respectively. The LR+ was 30.6 (CI 95% 15.5-55.0), and the LR- was 0.09 (CI 95% 0.08-0.11). The DOR was 314.00 (CI 95% 143.0-603.0), and the sROC was 0.949 (CI 95% 0.906-0.973). Three distinct scenarios were simulated and characterized by varying pretest probabilities. When the pretest probability was 25%, the post-probability positive (PPP) and post-probability negative (PPN) were 91% and 3%, respectively. In the case of a pretest probability of 50%, the PPP and PPN were 97% and 9%, respectively. Lastly, when the pretest probability was 75%, the PPP and PPN were 99% and 23%, respectively.

Conclusions: Our analysis reinforces that CT-guided TTNB attains high diagnostic accuracy, especially for the diagnosis of peripheral lung nodules. In a 2019 meta-analysis, TTNB showed a pooled sensitivity of 97% and a pooled specificity of 100%. However, the false-negative incidence varies between 5% and 12%, maybe related to lesion sizes, inadequate needle gauge, and operator inexperience, which leads to sampling errors and inappropriate collection for analysis. Although TTNB presents good metrics for lung lesion diagnosis, it does not preclude the necessity of confirming the results by other diagnostic methods, including invasive procedures such as bronchoscopy.

EP.05A.09 The Accuracy of CT, 18FDG-PET/CT, and Mediastinoscopy for Staging in NSCLC - A Systematic Review and Meta-Analysis

V.C. Cordeiro de Lima, C.S. Baldotto, E. Mascarenhas, A. Gelatti, C. Mathias, L.H. Araújo Lima, M. Zukin, G.F. Prado, G. Castro Jr., Grupo Brasileiro de Oncologia Torácica (GBOT), Porto Alegre/BR

Introduction: Lung Cancer staging is a crucial step in determining prognosis and optimal therapy. This comprehensive and meticulous systematic review presents the accuracy of the most currently used methods for NSCLC staging: CT (computed tomography), 18FDG-PET/CT (PET/CT), and mediastinoscopy.

Methods: Our review was conducted by lung cancer specialists and used the GRADE approach to systematically search for evidence on the accuracy of CT, PET/CT, and mediastinoscopy for staging in NSCLC. Based on their expertise and available literature, the research questions were framed in a PICO format. We searched MEDLINE/PubMed, EMBASE, Web of Science, Cochrane Library, and LILACS for each PICO question. Data from the original studies were presented individually by the study in Tables 2x2 as measures of diagnostic test accuracy (true positives, false positives, true negatives, and false negatives). The statistical analysis was performed according to the recommendations of the Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy and using the "DTAplots", "mada", and "meta" packages in the R 4.2.1 software.

Results: According to our analyses, CT has limited accuracy for staging (sROC 0.73; CI 95% 0.67-0.75) and is susceptible to flaws (LR- 0.54; CI 95% 0.48-0.62). PET/CT diagnostic accuracy was sROC 0.87 (CI 95% 0.82-0.87). PET/CT is recommended for identifying suspected lymph nodes (LNs) to investigate the tumor extension and discard the presence of distant metastases. PET/CT has high rates of false positive and false negative results regarding mediastinal LN involvement (LR- 0.31; CI 0.95% 0.26 - 0.37), requiring confirmation by invasive methods. Compared with CT and PET/CT, mediastinoscopy has the best diagnostic accuracy method for mediastinal staging, with an sROC of 0.99 (CI 95% 0.96-0.99). The main advantage of mediastinoscopy is the direct visualization of nodes for sampling and dissection. On the other hand, mediastinoscopy is invasive, requires general anesthesia, cannot access all LNs, and can potentially cause significant complications. In addition, mediastinoscopy has a relatively high negative likelihood ratio (LR- 0.20; CI 95% 0.17-0.23), which can be attributed to the failure to dissect all LN stations.

Conclusions: CT scans are considered insufficient for accurately diagnosing and staging NSCLC in suspect LN and oligometastatic cases. PET/CT is useful in the initial evaluation to identify the sites of distant tumor involvement. However, PET/CT is insufficient for accurate mediastinal staging and identification of oligometastatic disease in NSCLC, scenarios in which confirmation by tissue biopsy is recommended. Mediastinoscopy is the preferred method for mediastinal staging in NSCLC, mainly in clinical settings where EBUS/ EUS are unavailable.

EP.05B.01 Characterization of Patients with Primary Lung Cancer who Attended a Pulmonology Clinic in Bogotá, Colombia

L.C. Silva Cala[1], L.C. Viola Muñoz[1], N.J. Proaños Jurado[2], D. Rivera[2], H. Vargas[1], [1]Fundación Neumológica Colombiana, Bogotá/CO ,[2]Universidad de la Sabana, Bogotá/CO

Introduction: Patients with primary lung cancer have seldom been described in Colombia, as is the opportunity of their access to diagnosis and treatment.

Methods: A cross sectional study was conducted to describe patients with non-lymphoid primary lung malignant neoplasms who attended at least one medical appointment with the thoracic oncology program at Fundación Neumológica Colombiana between January 2019 and August 2023. For those with epithelial neoplasms, often referred as Non-Small Cell Lung Cancer (NSCLC), genomic profiling was included.

Results: Of 163 patients with primary lung cancer identified, 88,3% were NSCLC, which included 67,5% adenocarcinomas and 17,8% squamous cell carcinomas. Another 11% were neuroendocrine neoplasms, which included 5,5% typical carcinoids, 1,2% atypical carcinoids and 3,7% small cell carcinomas. The clinical characteristics of these patients are summarized in table 1. The time elapsed between the clinical suspicion of lung cancer and the pathological confirmation, as well as between the diagnosis and the first oncologic treatment are described in figure 1. Patients with NSCLC were 59% female, 49% had no history of tobacco use, 37,5% had not been significantly exposed to tobacco, wood smoke, asbestos or silica, and 31% were diagnosed in stages 0-II. Information on EGFR status was available for 81 of 144 patients with NSCLC and 42% of these harbored EGFR mutations. Other driver genes were tested in fewer patients; however, altogether 52% of the NSCLC patients evaluated for at least one gene had a driver mutation (EGFR, ALK, RET, MET, ROS1 or BRAF V600).

Conclusions: Female sex, absence of a history of tobacco use, the presence of driver mutations and early stages were more frequent among patients with NSCLC at this center than previously reported in Colombia, although selection bias could have overestimated the prevalence of driver mutations. Time to diagnosis and treatment were longer than recommended by international standards.

EP.05B.02 Mucinous Adenocarcinoma of the Lung in a Brazilian Population: Clinical, Pathological, Molecular Features and Outcomes

C.A. Leite[1], F.M. da Costa[1], A.K. Medeiros[1], P.N. Aguiar Junior[2], A. del Gilglio[3], F.C. Maluf[1], M.A.F. Magalhães Filho[1], [1]Beneficencia Portuguesa de São Paulo, São Paulo/BR ,[2]Oncoclinicas, São Paulo/BR ,[3]Faculdade de Medicina do ABC, São Paulo/BR

Introduction: Invasive mucinous lung adenocarcinoma (IMA) is a rare subtype of adenocarcinoma with limited data available, especially in specific populations as Brazilian. This study describes the characteristics and outcomes of IMA patients treated at a Brazilian center, focusing on potential differences from other populations.

Methods: Retrospectively was analyzed data from 2,506 patients diagnosed with lung cancer between 2011 and 2023, identifying 106 with IMA. Demographic, clinical, pathological, molecular, and treatment data were collected.

Results: The median age at diagnosis was 65 years, with a female predominance. Most patients had a smoking history. Solitary pulmonary nodules were the most common presentation, unlike the reported multifocal pattern. KRAS mutations were the most frequent genetic alteration (60.6%). Surgery was preferred for resectable disease, while chemotherapy remained the mainstay for unresectable cases. Never-smokers had significantly better overall survival (OS). Solitary tumors were associated with better disease-free survival (DFS), immunotherapy did not improve OS when added to chemotherapy.

Conclusions: This study provides valuable data on IMA in a Brazilian population. While overall findings align with published data, some differences were observed, including potential prognostic factors. Further research is needed to confirm our findings.

EP.05B.03 Evaluating the Risk of Pneumonitis from G-CSF in Thoracic Cancer Patients with Pre-Existing ILD

A. Komatsu, T. Mimori, M. Kuriyama, S. Fujioka, T. Miyawaki, T. Shukuya, K. Takahashi, Juntendo University, Tokyo/JP

Introduction: In the chemotherapy of thoracic malignancies, granulocyte colony-stimulating factor (G-CSF) agents are sometimes used. There have been reports of pneumonitis associated with the use of G-CSF agents. It is cautioned to use these agents carefully in cases with pre-existing interstitial lung disease (ILD) due to the potential risk. However, the evidence supporting this caution is scant, and whether it actually poses a risk remains unclear.

Methods: We conducted a retrospective analysis of pneumonitis in patients treated with cytotoxic chemotherapy for thoracic malignancies. Data was collected from medical records to examine whether the use of G-CSF agents and the presence of pre-existing ILD findings influenced the development of pneumonitis after the initiation of chemotherapy.

Results: From September 2006 to January 2024, 1,029 patients were treated with chemotherapy for thoracic malignancies at our institution. The breakdown of diseases was as follows: 782 cases (76.0%) were non-small cell lung cancer, 171 cases (16.6%) were small cell lung cancer, and malignant mesothelioma and thymic carcinoma were both 23 cases (2.2%). Pre-existing ILD was found in 159 (15.5%) patients, of whom 79 (7.7%) had honeycomb lung findings. G-CSF agents were used in 437 (42.5%) patients. Pneumonitis following the initiation of chemotherapy was observed in 137 (13.3%) cases. The presence of pre-existing ILD was considered a risk factor for the development of pneumonitis (Odds ratio 1.75 [95% Confidence Interval 1.12-2.72]). However, the effect of G-CSF agent use was not statistically significant (Odds ratio 0.70 [95% Confidence Interval 0.48-1.01]). Furthermore, when assessing the risk of pneumonitis development due to G-CSF administration in cases with pre-existing ILD and those with honeycomb lung findings, no significant risk was identified in either scenario (Odds ratio 0.80 [95%CI 0.36-1.82], 0.57 [95%CI 0.16-1.98]).

Conclusions: The presence of pre-existing ILD in patients receiving G-CSF agents for thoracic malignancies may not influence the risk of developing pneumonitis during chemotherapy.

EP.05B.04 Correlation Between Radiologic Feature and Spread Through Air Space in Lung Solid Adenocarcinoma 30.0 mm or Less in Maximum Diameter

P. LI[1,2], Q. Sun[1,2], R. Yip[2], T. Holton[2], D. Yankelevitz[2], C. Henschke[2], [1]Harbin Medical University Cancer Hospital, Harbin/CN ,[2]Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: Tumor spread through air space (STAS) has been recognized as an important prognostic indicator for lung cancer patients. However, few studies have focused on radiologic features for predicting STAS for patients with small solid lung adenocarcinomas 30.0 mm or less in maximum diameter.

Methods: A retrospective study of 511 participants in the XXX with first primary clinical stage IA solid adenocarcinoma (ADC) 30.0 mm or less in maximum diameter who received surgical treatment. Patients with STAS-positive or STAS-negative were compared using a Wilcoxon rank-sum test and chi-squared or Fisher exact test. Significant predictors of STAS were identified using multivariable analyses.

Results: Of 511 patients with surgical resected solid ADCs 30.0 mm or less in maximum diameter (42% male, 58% female, median age 70 years [IQR: 64-77]), STAS was present in 63 (12.3%). Multivariable analyses showed that STAS was significantly associated with distance (mm) to the mediastinal pleura (OR=0.97; 95% CI, 0.96-0.99; P<.001), distance to the diaphragmatic pleura (OR=0.99; 95% CI, 0.99-1.00; P=.03), distal post-obstructive changes (OR=0.2; 95% CI, 0.05-0.5; P<.001) and vascular embedding (OR=2.2; 95% CI, 1.1-4.4; P=.02), after adjusting for age, sex and smoking. No significant relationship was found between preoperative CT-guided biopsy and presence of STAS.

Conclusions: Among solid ADCs 30.0 mm or less in maximum diameter, distance to the mediastinal pleura, distance to the diaphragmatic pleura, vascular embedding and distal post-obstructive changes were significant radiologic predictors of STAS. There was no evidence of significant relationship between pre-operative CT-guided biopsy and presence of STAS.

EP.05B.05 Integrative Prediction Model for Radiation Pneumonitis: Genetic and Clinical-Pathological Factors Utilizing Machine Learning

S.H. Choi[1], E. Kim[2], M.Y. Seol[1], Y. Chung[2], H.I. Yoon[1], [1]Department of Radiation Oncology, Yonsei Cancer Center, Heavy Ion Therapy Research Institute, Yonsei University College of Medicine, Seoul/KR ,[2]Department of Nuclear Engineering, Hanyang University, Seoul/KR

Introduction: Clinical and dosimetric parameters are linked to radiation pneumonitis (RP), while single nucleotide polymorphisms (SNPs) in TGF-β1 pathway genes are also associated with RP. However, research on the predictive value of SNPs for RP remains limited. In this study, we aimed to develop the most optimal model for RP prediction using machine learning (ML) methods. Additionally, we compared RP prediction models using clinical/dosimetric factors alone with those incorporating genomic factors.

Methods: A total of 59 patients with primary lung cancer undergoing thoracic radiotherapy between 2017 and 2019 were prospectively enrolled. We analyzed their pretreatment blood samples along with all clinicopathological/dosimetric variables and performed genotyping for 11 functional SNPs in the TGFβ pathway genes (TGF-β1, BMP2, and BMP4). Using Synthetic Minority Over-sampling Technique (SMOTE) and nested cross-validation (CV), we developed a ML-based prediction model for severe RP (grade ≥2). Feature selection was conducted using four methods (filtered-based, wrapper-based, embedded, and logistic regression), and performance evaluation involved three ML models: Extreme Gradient Boosting (XGBoost), Random Forest (RF), and Support Vector Machine (SVM), utilizing another round of Nested CV for both hyperparameter optimization and performance evaluation.

Results: With a median follow-up of 39.7 months, severe RP occurred in 20.3% of patients. In the logistic regression model, age (>66), smoking history, PTV volume (>300cc), and AG/GG genotype in BMP2 rs1979855 were identified as the most powerful factors for predicting severe RP. Additionally, incorporating SNP data for prediction alongside clinicopathological factors significantly improved the AUC compared to using clinicopathological factors alone (0.822 vs. 0.741, p = 0.029). The wrapper-based method selected the same feature set as the logistic regression method, showing the best performance across all ML models (the area under the curve (AUC): XGBoost 0.815, RF 0.805, SVM 0.712, respectively).[Figure: The predictive performance (AUC: mean ± standard deviation) of the different combinations of feature selection methods and machine learning models, as evaluated through repeated nested cross-validation with SMOTE]

Conclusions: We successfully developed an ML-based prediction model for severe RP, integrating clinicopathological and genetic factors. Age, smoking history, PTV volume, and BMP2 rs1979855 genotype emerged as significant predictors. Notably, incorporating SNP data significantly enhanced predictive performance compared to clinicopathological factors alone.

EP.06A.01 Computational Linguistic Analysis for the Isolation of Propitious miRNA Biomarkers in Lung Cancer

D. Ge[1], H. Nian[2], Z. Zhang[2], [1]Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai/CN ,[2]The Central Hospital of Xuhui District, Shanghai, Shanghai/CN

Introduction: In the realm of lung cancer research, microRNAs (miRNAs) are increasingly recognized as small, non-coding RNA entities that play a critical role in the disease's development. Individual studies have provided valuable insights into the mechanisms of miRNAs in lung cancer; however, their limited focus often restricts a comprehensive understanding of the full extent to which miRNAs contribute to the pathogenesis and treatment approaches of lung cancer.

Methods: In an effort to overcome the inherent biases of individual studies in lung cancer research, we employed computational linguistic analysis to elucidate the functions of microRNAs (miRNAs) in lung cancer and their potential as biological indicators. This involved tokenizing abstracts from academic publications and extracting key biomedical terms for thematic modeling. To categorize lung cancer, we utilized five machine learning models: Logistic Regression (LR), Naïve Bayes, Decision Curve Analysis (DCA), Random Forests, and Support Vector Machines (SVM). The significance of specific features was assessed to construct networks illustrating the interactions between miRNAs and lung cancer

Results: In our comprehensive analysis of microRNA (miRNA) studies related to lung cancer, we identified three distinct topics demonstrating specific tendencies among miRNAs in this context. Notably, Random Forests model emerged as a particularly promising tool for lung cancer prognosis, achieving an accuracy rate surpassing 60%. Crucially, miR-21 was identified as a key biomarker for lung cancer prognosis, targeting a broad spectrum of genes and signaling pathways involved in the disease.

Conclusions: Utilizing an integrative approach, we gained comprehensive insights into the relationship between microRNAs (miRNAs) and lung cancer, affirming the potential of miRNAs as biological indicators for this malignancy. This methodology offers a broad perspective on the interaction between miRNAs and lung cancer, underscoring their significance in the disease's context.

EP.06B.01 The Actual Status of Biomarker Testing and Prognosis in Postoperative Recurrent NSCLC: Subgroup Analyses of WJOG15421L (REVEAL)

T. Matsubara[1], T. Sakamoto[2], T. Takahama[3], T. Yokoyama[4], I. Yoshino[5], H. Akamatsu[6], M. Yamaguchi[7], S. Miura[8], T. Tokito[9], M. Tachihara[10], Y. Sato[11], T. Takenaka[12], K. Sugio[13], M. Mori[14], T. Takeuchi[15], M. Hiraoka[16], H. Kenmotsu[17], J. Fujimoto[18], M. Shimokawa[19], N. Yamamoto[6], K. Nakagawa[3], [1]Kitakyushu Municipal Medical Center, Kitakyushu/JP ,[2]Tottori University, Yonago/JP ,[3]Kindai University, HigashiOsaka/JP ,[4]Kurashiki Central Hospital, Kurashiki/JP ,[5]Chiba University Hospital, Chiba/JP ,[6]Wakayama Medical University, Wakayama/JP ,[7]NHO Kyushu Cancer Center, Fukuoka/JP ,[8]Niigata Cancer Center, Niigata/JP ,[9]Kurume University Hospital, Kurume/JP ,[10]Kobe University Graduate School of Medicine, Kobe/JP ,[11]Kobe City Medical Center General Hospital, Kobe/JP ,[12]Kyushu University Hospital, Fukuoka/JP ,[13]Oita University Hospital, Yufu/JP ,[14]Osaka Toneyama Medical Center, Toyonaka/JP ,[15]Xcoo, Inc., Tokyo/JP ,[16]Takeda Pharmaceutical Company Limited, Tokyo/JP ,[17]Shizuoka Cancer Center, Nagaizumi-cho/JP ,[18]Hiroshima University Hospital, Hiroshima/JP ,[19]Yamaguchi University, Ube/JP

Introduction: We previously reported the real-world status of biomarker testing and drug therapy in advanced or recurrent non-small cell lung cancer (NSCLC) (WJOG15421L). Although the problems in biomarker testing became apparent in clinical settings, there is no report to investigate biomarker testing focused on postoperative recurrent cases. Therefore, a subgroup analysis targeting postoperative recurrence cases was conducted in the WJOG15421L trial.

Methods: This retrospective multicenter study enrolled 1500 pts with advanced or recurrent NSCLC diagnosed between 1 July 2020 and 30 June 2021 from 29 centers. Of these, 229 postoperative recurrent pts were included in this subgroup analysis. The primary endpoint was the actual status of biomarker testing.

Results: The median age was 74.0 (range: 40-92) with 46.5% of pts diagnosed as stage I at primary surgery, and 67% was adenocarcinoma. The median time from primary surgery to recurrence (TTR) was 511 days, and 169 pts had distant metastasis. For the confirmation diagnosis of recurrence, approximately 23% underwent re-biopsy. The multiplex gene testing was performed in 100/229 pts (44%), and OncomineDxTT was performed in 78/229 pts (34%). The implementation rate of biomarker testing was as follows: EGFR 84%, ALK 77%, ROS1 68%, BRAF 55%, and MET 52%. The multiplex gene testing was performed more in patients with distant metastasis compared with local recurrence (47% vs 35%). There was no significant difference in the success rates of multiplex gene testing between resected archival specimens and recurrent specimens by re-biopsy. Additionally, although there was no difference in success rates during the time from surgery to sample submission, multivariate analysis revealed that when the interval between surgery and recurrence exceeded 3 years, multiplex gene testing was often not performed. Survival analysis, comparing 1192 pts with advanced stage in the REVEAL study, showed that postoperative recurrence pts had significantly better overall survival in both the overall population (HR=0.60 [95%CI: 0.47-0.76]) and the driver+ subgroup (HR=0.49 [95%CI: 0.28-0.86]), as compared to advanced pts.

Conclusions: Despite an ample quantity of specimens from surgical samples, the submission rate for multiplex gene testing in postoperative recurrence cases was only 44%. It was also revealed that multiplex gene testing was not often performed in pts with the interval until recurrence exceeded 3 years. Postoperative recurrence cases, even among the driver+ population, demonstrated a favorable prognosis compared to advanced cases. The widespread evaluation of driver mutations through multiplex testing is needed.

EP.06B PATHOLOGY AND BIOMARKERS - BIOMARKER
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06B.03 Performance of a Prognostic OTP, CD44, Ki-67 Biomarker Panel for Relapse in Paired Biopsies and Resections of Pulmonary Carcinoids

T. Van Weert[1], L. Moonen[1], L.M. Hillen[1], J. von der Thüsen[2], L. Lap[1], P. Group[3], R. Damhuis[4], A-M. Dingemans[2], J. Derks[1], E-J. Speel[1], [1]Maastricht University Medical Center, Maastricht/NL ,[2]Erasmus University Medical Center, Rotterdam/NL ,[3]Palga, Houten/NL ,[4]IKNL, Utrecht/NL

Introduction: Previously OTP, CD44 and Ki-67 were identified as prognostic biomarkers for pulmonary carcinoids (PCs). We aimed to examine prognostic biomarker performance in PC biopsies (Bx) compared to paired resection (Rx) specimens. A previous ENETS 2024 abstract with preliminary data has been amended using additional cases.

Methods: Patients with PC (stage I-III, 2003-2012) who underwent curative resection were selected from Dutch pathology archives. 119 paired Bx-Rx cases were collected, of which 89 cases were eligible for biomarker evaluation, including 11 recurrences. WHO 2021 classification revision was applied by a single pathologist. Atypical carcinoid (AC) histology was defined as the presence of 2-10 mitoses/2mm2 and/or necrosis. H-score was used for OTP and CD44 expression, whereas the Ki-67 proliferation index was scored by eyeball estimation with hot-spot scoring. Biopsy cases diagnosed as typical carcinoid (TC) and carcinoid NOS were grouped as one separate entity; non-AC. PCs were subdivided into low risk (OTP≥50; CD44≥30; Ki-67<5%) or high risk for recurrence (all others).

Results: WHO 2021 revision classified n=75/85 PC's from patients without recurrence as non-AC on Bx, whereas the IHC biomarker panel subdivided n=54/55 PC's as low-risk. On Rx, WHO classification revealed n=68/74 PC's from patients without recurrence as TC, while the IHC biomarker panel identified n=56/57 PC's as low-risk (Fig. 1). In Bx, stratification of recurrence-free survival based on WHO diagnosis (i.e non-AC vs. AC (p=0.389)) improved significantly when applying the IHC biomarker panel (i.e. low-risk vs. high-risk (p<0.001)). Spearman's correlation between Bx and Rx for markers OTP, CD44 and Ki-67 were 0.935 (p<0.001), 0.515 (p<0.001) and 0.247 (p=0.020), respectively.

Conclusions: Our data indicate that the OTP, CD44 and Ki-67 biomarker panel improves selection of patients with low-risk PCs and are applicable to Bx specimen, unlike the WHO classification. This may have clinical implications regarding the surgical treatment strategy. Validation with multiple pathologists is ongoing.

Introduction: Treating elderly patients presents challenges due to age-related declines, but recent recommendations advocate for age not being a sole determinant for adjuvant treatment decisions in non-small cell lung cancer (NSCLC) patients. Aging may alter expression levels of 5-fluorouracil (5-FU) biomarkers.

Methods: Expression changes with aging were explored using The Cancer Genome Atlas (TCGA) database. 5-FU-related biomarker expressions, including thymidylate synthase (TS), dihydropyrimidine dehydrogenase (DPD), orotate phosphoribosyltransferase, epidermal growth factor receptor (EGFR), and excision repair cross-complementation group-1 (ERCC1), were assessed in 89 NSCLCs elderly patients (≥ 75 years old) receiving adjuvant S-1, an oral fluoropyrimidine agent, therapy in a phase 2 trial named as the Setouchi Lung Cancer Group Study 1201 (SLCG1201).

Results: TCGA analysis (n=955) indicated decreased TS expression with aging, particularly in those aged 75 or older (Figure 1). In the SCLG1201 study, EGFR mutation patients (n=27) showed significantly higher DPD (p=0.0066) and EGFR (p<0.0001) expressions and lower TS (p=0.0125) and ERCC1 (p=0.0015) expressions. Low TS and high EGFR expressions correlated with favorable recurrence-free survival (RFS)(p=0.0365) and overall survival (OS)(p=0.0264) in univariate analysis (Figure 2). Multivariable analysis confirmed pathological stage as an independent prognostic factor for both RFS and OS (p=0.0052 and 0.0352, respectively).

Conclusions: Age-related decrease in TS expression supports the potential benefit of 5-FU-based therapy in elderly NSCLC patients. Low TS expression may predict better clinical outcomes in elderly NSCLC patients with adjuvant S-1 therapy, despite pathological stage being an independent prognostic factor. Further research is warranted to validate these clinical implications.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06B.05 Ultra-Stat Idylla EGFR Testing for Non-Small Cell Lung Carcinomas: Patient Selection and Impact on Clinical Outcomes

K.F. Fitzsimmons[1], C. Hughesman[2], M-F. D'Amours[2], D. Alex[2], D.N. Ionescu[2], B. Melosky[2], K. McNeil[2], C. Ho[2], S. Yip[2], J. Naso[3], [1]University of British Columbia, Vancouver/BC/CA ,[2]BC Cancer, Vancouver/BC/CA ,[3]Vancouver General Hospital, Vancouver/BC/CA

Introduction: Eligibility for EGFR targeted therapy for non-small cell lung cancer (NSCLC) is dependent on molecular testing results. Our institution recently began offering ultra-stat Idylla EGFR testing upon clinical request for NSCLC, which has the potential for faster turnaround time. However, this testing is limited to a single gene, such that negative or failed Idylla tests require subsequent next-generation panel sequencing. We aimed to (i) assess the demographics of patients selected for ultra-stat testing and how these demographics correlate with EGFR positivity rates, and (ii) assess the impact of ultra-stat testing on clinical outcomes.

Methods: Requests for ultra-stat Idylla EGFR testing between February 2nd, 2022 and February 26th, 2024 were identified from laboratory records, and clinical information on the ultra-stat tested patients was retrospectively compiled through an outcomes database and chart review. Associations were assessed using Fishers exact tests, and survival analysis was performed using Cox proportional hazards models.

Results: Sixty-eight NSCLC patients with ultra-stat Idylla EGFR test results were identified. Ultra-stat testing was most frequently requested by medical oncologists (42/68 cases, 62%) and respirologists (13/68 cases, 19%), with 21/68 patients (31%) admitted to hospital at the time of test request. The median laboratory turnaround time for ultra-stat testing was 1 day (range 0 to 7 days). Seven samples failed ultra-stat testing, and 44 of the remaining 61 (72%) were positive for EGFR mutations, much greater than the 19.7% EGFR positivity rate for panel-based sequencing at our institution between May 2021 and February 2024 (n=3,287). The detection of an EGFR mutation was significantly associated with Asian race (47/64 patients; P=0.0001) and had a near significant association with never smoking (54/68 patients; P=0.058). Thirty-eight (86%) of the EGFR mutation-positive patients were treated with EGFR-targeted therapy, initiated a median of 5 days (range 0 to 28 days) after ultra-stat results were reported. Patients who received targeted therapy after a positive Idylla result had significantly longer overall survival compared to other ultra-stat tested patients (P=0.017; HR 0.30, 95% CI 0.11-0.80; median follow time 161 days). Panel-based sequencing identified other targetable alterations in 9 out of 20 patients (45%) who had a negative or failed ultra-stat test. The median sequencing turnaround time was 10 days (range 7-29 days). Of the 24 ultra-stat tested patients with a failed/negative ultra-stat test, five (21%) died less than 14 days after receipt of the specimen for ultra-stat testing.

Conclusions: Rapid identification of EGFR mutations is possible through ultra-stat Idylla EGFR testing, allowing expedient targeted treatment initiation. The high EGFR-positivity rate among ultra-stat tested patients indicates effective identification of probable EGFR-positive cases by clinicians, with race being the most significant predictor of EGFR mutation. These findings will support the development of decision aids for selection of EGFR testing modality.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06B.06 A Meta-Analysis of Advanced Lung Index (ALI) in Advanced Lung Cancer Patients

K.H. Chan, S. Saroukhani, N. Song, S.H. Jafri, The University of Texas Health Science Center at Houston, Houston/TX/USA

Introduction: Systemic inflammation has been identified as an adverse prognostic factor in cancer development and progression. The advanced lung index (ALI) [body mass index (BMI) x albumin (ALB) / neutrophil-lymphocyte ratio (NLR)], has been demonstrated to be a prognostic indicator in several types of solid and hematological malignancies. However, the optimal cutoff values of ALI remain unclear.

Methods: We conducted a meta-analysis to evaluate the prognostic significance of pre-treatment ALI values, utilizing data extracted from 9 articles focused on advanced lung cancer. The primary endpoints were overall survival (OS) and progression-free survival (PFS). Pooled hazard ratios (HR) and corresponding 95% confidence intervals (95% CI) were computed using the random-effects model. In addition, we performed meta-regression analysis to assess the impact of ALI cutoff values across the studies.

Results: High pre-treatment ALI values above the cutoff were significantly linked to longer OS, both based on univariable HRs (HR = 1.94, 95% CI = 1.68-2.23) and multivariable HRs (HR = 1.57, 95% CI = 1.37-1.79) extracted from studies (Figure 1A and 1B). It's important to note that the analysis for PFS could not be conducted due to the limited number of studies reporting relevant HRs. The ALI cutoff values for distinguishing between high and low ALI groups in lung cancer patients ranged from 18 to 47. Our meta-regression analysis revealed that although marginally significant, the multivariable HRs for OS extracted from individual studies varied with ALI cutoff values ranging from 18 to 47 (P = 0.055). Specifically, higher ALI values (>40) were associated with better survival, while lower pretreatment ALI values (<20) were associated with worse survival.

Conclusions: This meta-analysis has affirmed that high pre-treatment ALI values are linked with longer survival in advanced lung cancer patients. However, the binary cutoffs of ALI values have shown variability across studies. Instead, the identification of a three-tier classification for pre-treatment ALI values (e.g., <20, 20-40, >40) is crucial for indicating varying prognoses in advanced lung cancer patients and could potentially be translated into clinical practice.

Keywords: advanced lung index (ALI), advanced lung cancer, prognostic markers

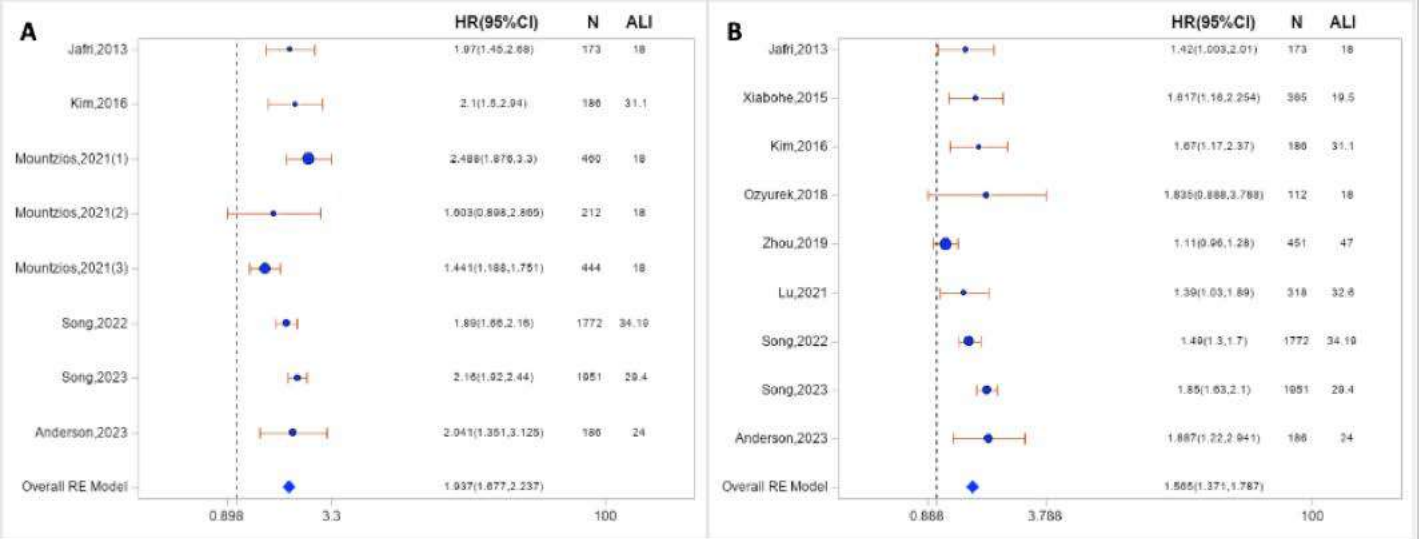

Figure 1 Forest plot illustrating prognostic significance of ALI value on overall survival from lung cancer based on univariable HRs (A) and multivariable HRs (B) reported in individual studies.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06B.07 CARE: Developing a Clinical Composite Score for mNSCLC and Co-Design Solutions to Bridge the Metropolitan vs Regional Gap

W. Faisal, D. Stout, E. Pitman, M. Tuohill, K. McCann, S. Dean, L. Bell, Grampians Health, Ballarat/AU

Introduction: Despite being the fifth most common cancer in Australia, NSCLC-related mortality remains the highest among all cancers with a five-year survival rate of approximately twenty percent.

Moreover, there is an absolute difference of six percent in five-year survival between patients from regional/rural areas, compared to metropolitan counterparts.

In addition to this geographical difference, the biology of wild-type mNSCLC is extremely varied (e.g. PD-L1, metabolic activity on FDG-PET, tumour differentiation) leading to significantly variable responses to treatment.

Developing clinical tools to identify patients upfront with worse tumour biology could aid prognostication and therefore may mitigate the need for over/under treatment.

Poorer clinical outcomes in regional patients compared to city patients also highlight the fact that treatment outcomes are not just dependent on tumour factors, but also dependent on patient- and health-service-related factors (e.g. distance to treating centre, delayed referral/diagnosis, guideline non-concordant treatment, lack of clinical trials etc).

Thus, through funding by the Thoracic Oncology Group of Australasia (TOGA), we aim to develop a Clinical Composite Score (CCS) encapsulating patient, tumour and health service factors that could help identify patients who are at risk of poorer outcomes, leading to reallocation of resources to develop and implement a co-design solution to address these issues at a system level.

Methods: To identify predictors of lung cancer outcomes across clinical, patient and health service factors, a retrospective analysis of hospital records will be conducted.

Measure patient and health service factors, including non-clinical independent variables, e.g. socio-economic index for area, distance from hospital, Aboriginal or Torres Strait Islander heritage, and clinical independent variables e.g. PDL1 score, TTF1 status.

Measure dependent variables e.g. timeliness to care, OS, PFS, adherence to guideline concordant treatment, as well as co-variates e.g. age, sex, smoking status, tumour differentiation, presence of visceral metastases, presence of central nervous system metastases, grade of tumour differentiation, mean SUV on FDG-PET scan.

A total sample of 293 participants will be required to reach a power of 0.95.

Variables which remain significant ($p<0.05$) after multivariate analysis will be used to create a composite score to predict lung cancer outcomes.

To describe clinical and non-clinical variables, means and standard deviations will be reported, t-tests and chi-square will be used to report differences between groups.

To explore the association between independent and dependent variables, univariate and multivariate regression models with significant variables in univariate analysis will be conducted.

Cox regression models will be used for analysis with timeliness to care, PFS and OS. Survival probabilities will be estimated using the Kaplan-Meier method and survival curves compared using the log-rank test.

All regression models will be adjusted for co-variates a priori.

Results: Awaiting results pending data collection.

Conclusions: The project aims are to develop a Clinical Composite Score for mNSCLC, incorporating tumour, patient, and health service factors, to identify patients at-risk of poorer outcome, in addition to co-designing a solution in the regional setting, addressing issues identified through the CCS, to propose system-level change.

A validation study for CCS in a larger, prospective, multi-centre study will also be proposed.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06B.08 Biomarker-Guided Treatment Selection in NSCLC: A Quality Improvement Initiative to Strengthen Multidisciplinary Care

B.P. Levy[1], T. Chavula[2], J. Storey[2], I. Dewald[2], J. Carter[2], C. Heggen[2], K. McKinnon[2], [1]John Hopkins University, Washington/DC/USA ,[2]PRIME Education LLC, New York/NY/USA

Introduction: Biomarker testing plays a central role in guiding treatment selection for advanced non-small cell lung cancer (NSCLC). The increasing number of biomarkers creates a high need for multidisciplinary coordination to ensure timely and comprehensive testing, appropriate interpretation of results, and evidence-based application to treatment decision-making.

Methods: In 2023, 58 health care providers (HCPs) at 4 US community oncology clinics completed surveys on barriers to molecular testing, multidisciplinary care coordination, and treatment selection in NSCLC. HCPs (n=30) then participated in audit/feedback (AF) sessions, featuring a mock tumor board, to review guidelines and clinical evidence and develop clinic-specific action plans to address identified gaps.

Results: HCPs reported ongoing challenges to integrating biomarker testing in routine practice, including prioritizing tests on limited tissue samples, deciding whether to begin treatment prior to receiving results, optimizing tissue collection, and inconclusive or failed tests. Although 76% reported that patients started systemic therapy ≤15 days following diagnosis, 31% reported testing turn-around times of 15-20 days. While most HCPs reported regular EGFR, PD-L1, BRAF, KRAS and ALK testing, testing was <50% for MET, ROS1, HER2, RET, and NTRK. Most HCPs (72%) were less than fully satisfied with the quality of communication between specialties in their practices. Frequency of communication varied: some teams reported that every case was discussed (24%) while others discussed only complex cases (24%) or only when an issue was raised (11%). About half (53%) participated in weekly multidisciplinary tumor boards. After the AF sessions, clinic-level action plans included improving integration of biomarker testing into standard clinical workflows, working as a multidisciplinary team to increase recognition of actionable biomarkers, improving patient monitoring protocols to manage adverse effects of newer therapies, and improving patient education on reasons for testing. On a follow-up survey, most clinical team members (86%-100%) agreed that program participation had led to improved communication and workflows, reduced time between diagnosis and test ordering, and increased use of guideline-concordant testing before treatment initiation.

Conclusions: NSCLC care teams recognize the value of guideline-concordant biomarker testing but continue to face practical challenges including lack of sufficient tissue, poor tissue quality, and long turn-around times. Integration of sustainable changes in clinical workflows and care coordination stemming from this QI initiative improved communication between specialties, leading to more timely and comprehensive testing.

EP.06B.09 The Role of Cytokines in Predicting the Efficacy of Immunotherapy in Advanced NSCLC Patient

W. Wang, Z. Li, Chongqing University Three Gorges Hospital, Chongqing/CN

Introduction: Immunotherapy checkpoint inhibitors (ICIs) have notably increased the 5-year survival rate for advanced non-small cell lung cancer (NSCLC) to up to 31.2%. However,it is important to note that not all patients benefit from this treatment,there's a lack of effective biomarkers for predicting ICIs' efficacy and adverse reactions. Studies suggest cytokines play a crucial role in tumor immune response and suppression,have been considered as potential biomarkers in clinical settings. In this study, our objective was to assess whether the levels of cytokines in the patient's blood sample are associated with tumor response and adverse reaction to ICIs as well as the survival of patients with advanced non-small cell lung cancer.

Methods: A total of 12 plasma cytokines were measured in advanced NSCLC patients(n=100) who underwent combined treatment using ICIs combination therapy every cycle treatment. Tumor assesment was conducted two cycles according to iRECIST standard in solid tumors. Patients are divided into stable disease group and progression disease group to compare the differences in cytokine levels between the two groups and the changes in cytokines before and after treatment.

Results: 20 patients have been enrolled currently, suggesting that the expression of IL10, $TNF\alpha$, and $IFN\gamma$ in the stable disease group (SD) were significantly lower than those in the progressive disease group (PD) ($p<0.05$) ,and the reductions of IL-17A, $TNF\text{-}\alpha$, IL-12P70, and $IFN\text{-}\gamma$ in patients after two or four cycles confers a better prognosis.

Conclusions: Our preliminary study suggests that cytokines can be served as indicators for predicting efficacy in non-small cell lung cancer patients undergoing ICIs with chemotherapy treatment. Subsequent studies with larger sample sizes are currently underway.

EP.06B.10 Clinical Feasibility of Multiplex Digital PCR for Major Mutation Detection in NSCLC Patients: The Droplex NSCLC Panel Test

K.A. Kim[1], J.H. Ko[2], H.J. Youn[2], Y-j. Choe[2], M.R. Kang[2], H.S. Shim[1], [1]Yonsei University, Seoul/KR ,[2]Gencurix Inc, Seoul/KR

Introduction: In recent years, the treatment landscape for non-small cell lung cancer (NSCLC) has evolved with the development of immune checkpoint inhibitors and targeted therapies aimed at various genes. Next-Generation Sequencing (NGS) technology is currently the gold standard for detecting variants in multiple genes simultaneously. However, NGS has limitations such as long turnaround time (TAT) and the need for substantial DNA or RNA extraction, along with expertise in performing advanced NGS. Therefore, we aimed to develop a Droplex NSCLC Panel Test Kit based on multiplex digital PCR, which may offer first-line multigene diagnostics due to its simple workflow, short TAT, low sample input amount, high sensitivity, high specificity, and lower costs compared to NGS. To date, a multigene mutation detection system using digital PCR has not been developed, and here, we validated the clinical effectiveness of the Droplex NSCLC Panel Test Kit. The Droplex NSCLC Panel Test Kit is designed to detect over 170 mutations commonly found in the target genes of major targeted therapies, including EGFR, ALK, ROS1, BRAF, MET, RET, KRAS, HER2, NTRK1, NTRK2, and NTRK3.

Methods: We retrospectively collected samples from patients diagnosed with NSCLC and having results of NGS and companion diagnostics. DNA and RNA were extracted from formalin-fixed paraffin-embedded tissue (FFPET). Subsequently, digital PCR was performed using the multiplex Droplex NSCLC Panel Test Kit with 20 ng of DNA and RNA simultaneously extracted from the patient's tissue samples. This was done through equivalence testing of 11 genes in FFPET of NSCLC patients, by comparing previous molecular testing results.

Results: Using FFPET samples from 35 NSCLC patients, a blinded NSCLC panel test was conducted. The results revealed EGFR mutations detected in 13 patients and cMET exon 14 skipping in 4 patients. Additionally, KRAS G12 mutations were found in 11 patients, while ROS1 fusion was detected in 3 patients, and HER2 mutation was found in 1 patient. No mutations were detected in 3 patients. The overall percent agreement for the detection of mutations using the Droplex NSCLC Panel Test and existing results was 91%. The three discordant samples were confirmed to contain mutations not currently covered by the kit's detection capabilities. Among these mismatches, two samples lack corresponding targeted agents at present.

Conclusions: The Droplex NSCLC Panel Test is an accurate and effective tool for detecting clinically relevant NSCLC mutations, as demonstrated by its high level of concordance with existing molecular results. It can serve as a first-line multiplex diagnostics due to its low DNA/RNA input requirement, lower cost, and minimal TAT. Additional studies with larger sample sizes are currently underway.

EP.06B.11 Construction of a Prognostic Model for Lung Adenocarcinoma Based on Disulfidptosis-related LncRNAs

M. Sun[1], M. Lin[2], [1]The Second Hospital of Dalian Medical University, Dalian/CN ,[2]Dalian Medical University, Dalian/CN

Introduction: Lung adenocarcinoma (LUAD) is the most common pathological type of lung cancer, with high incidence and poor prognosis. Disulfidptosis is a novel form of death induced by disulfide stress caused by excessive intracellular cystine accumulation under glucose starvation conditions. This study aims to investigate the significance of disulfidptosis-associated lncRNAs (DRlncRNAs) in the risk assessment and prognosis prediction of LUAD.

Methods: RNA-Seq data and clinical information of LUAD patients were obtained from The Cancer Genome Atlas (TCGA) database. Genes associated with differential expression of disulfidptosis were screened using Univariate Cox regression analysis. Subsequently, a prognostic model was constructed by LASSO-Cox regression analysis to classify patients into high-risk and low-risk groups. Time-dependent Receiver Operating Characteristic (ROC) curve, C-index curve, and Kaplan-Meier curve were plotted and compared to evaluate the predictive validity of the prognostic model. Functional Gene Set Enrichment Analysis (GSEA) and single-sample Gene Set Enrichment Analysis (ssGSEA) were used to explore the characteristics of enrichment pathways, immune-related functions and treatment response in high-risk and low-risk groups.

Results: A risk prognostic model was constructed consisting of 8 DRlncRNAs (ATXN1-AS1, AC018645.3, AC096733.2, AL049836.1, LINC01711, AF131215.5, AC027288.1, AL606489.1). Univariate and multifactorial COX analyses further revealed the model to be a prognostic factor independent of multiple clinicopathologic parameters.

Conclusions: The 8-lncRNA prognostic model we constructed can be used as a valid biomarker to predict the prognosis of LUAD patients.

Introduction: Personalized medicine plays a key role in clinical management of Non-Small Cell Lung Cancer (NSCLC) patients. A rapidly increasing number of predictive biomarkers have been yet approved by international societies to optimized therapeutical decisions for NSCLC patients. Several opening challenges drastically impacts on the reliability of molecular profiling in clinical practice including pre-analytical (sample management of scant diagnostic specimen), analytical (technical performance of diagnostic assays/platform) and post-analytical (data interpretation of complex molecular hallmarks) issues. In this heterogeneous scenario, harmonized procedures and comprehensive database integrating technical, molecular, and clinical records are essential to optimize clinical administration of NSCLC patients. Here, an audit of clinical and molecular records from n=1100 NSCLC patients collected among 80 referral Italian institutions (from January 2019 to December 2020) are retrieved from knowledge-based database (Biomarkers ATLAS, https://biomarkersatlas.com/).

Methods: By consulting Biomarkers ATLAS, we systematically collected molecular (technological approaches, KRAS, EGFR, BRAF, ROS1, ALK, RET, NTRK, MET molecular status) and clinical records (sex, age, histological type, smoker status, PD-L1 expression, therapy) from NSCLC patients administrated by two coordinator institutions (University of Turin and University of Naples). These data were structured in free of charge Biomarkers ATLAS repository and harmonized to be easily interpreted

Results: A list of clinical and molecular records were retrieved from n=1100 (n=552 mutated and n=548 wild type) NSCLC patients. Druggable molecular alterations were found n= 152 EGFR (13.8%), n=291 KRAS (26,5%), n=29 BRAF (2.6%) hot spot mutations, n= 46 ALK (4.2%), n=15 RET (1.4%), n=11 ROS1 (1.0%), and n=1 NTRK (0.1%) aberrant transcripts. Moreover n=3 MET exon 14 skipping (0.3%) positive cases were recorded. Molecular data were matched with five clinical variables

Conclusions: Biomarkers ATLAS, https://biomarkersatlas.com/) consists of an innovative, easily managing, and clinically informative diagnostic tool supporting healthcare figures by the integration of clinical and molecular data of real-world practice NSCLC patients

EP.06B.13 Prognostic Impact of Serum CA125 Level in Patients with cN0 Non-Small Cell Lung Cancer

Y. Yazaki, J. Ichinose, M. Kawahara, S. Yoshimine, A. Suzuki, Y. Matsuura, M. Nakao, S. Okumura, M. Mun, Cancer Institute Hospital of JFCR, Tokyo Ariake/JP

Introduction: This study aimed to investigate the prognostic significance of serum carbohydrate antigen 125 (CA125) level in patients undergoing resection for non-small cell lung cancer (NSCLC).

Methods: Patients who underwent macroscopically complete resection for cN0 NSCLC between 2005 and 2020 were included. The influence of preoperative serum CA125 level on overall survival (OS) and recurrence free survival (RFS) was evaluated by multivariable analyses using Cox proportional hazard models. The cut-off value of CA125 was set at 15 U/mL. The correlation of the elevation of CA125 with clinicopathological factors and recurrence patterns was analyzed. OS and RFS were estimated using the Kaplan-Meier method and compared using the log-rank test between the high CA125 group and the low CA125 group.

Results: After excluding 1158 patients (820 lacked preoperative serum CA125 data, 131 who underwent macroscopically incomplete resection, and 207 with clinical node-positive disease), a total of 2883 patients were included in this study. Among them, 720 (25%) had preoperative serum CA125 >15U/mL. Elevated CA125 was significantly correlated with male sex, smoking index, tumor size, non-adenocarcinoma histology and elevation of preoperative serum carcinoembryonic antigen. High CA125 group had more frequent nodal upstage (13.3% vs. 8.6%, p = 0.001), pleural invasion (23.3% vs. 13.1%, p <0.001), lymphatic invasion (24.7% vs. 18.1%, p <0.001), and venous invasion (36.1% vs. 25.5%, p <0.001). Long term prognosis was significantly poorer in patients with higher CA125 level than in patients with lower CA125 level (5-year OS, 78.3% vs. 91.0%, p <0.001; 5-year RFS, 69.7% vs. 84.0%, p <0.001). There was no significant difference between the two groups in the rate of positive pleural lavage cytology and in the frequency of first recurrence presenting with pleural dissemination or malignant pleural effusion. Preoperative CA125 level was significantly associated with poor OS (hazard ratio = 1.006, p <0.001) and poor RFS (hazard ratio = 1.005, p <0.001) in multivariable analyses.

Conclusions: Serum CA125 level is an independent prognostic factor in patients undergoing resection for cN0 NSCLC.

EP.06B.14 Differential Expression in Potential Therapeutic Target Protein by Treatment in Small Cell Lung Cancer with and without Transformation

S. Murata, H. Horinouchi, Y. Yatabe, J. Kashima, K. Masuda, Y. Shinno, Y. Okuma, T. Yoshida, Y. Goto, N. Yamamoto, S. Watanabe, Y. Matsumoto, K. Okuma, Y. Ohe, National Cancer Center Hospital, Tokyo/JP

Introduction: Small cell lung cancer (SCLC) is a disease with a poor prognosis. Besides combination strategy with immune checkpoint inhibitors (ICIs) and cytotoxic agents, antibody-drug conjugates (ADCs) and bispecific T-cell engagers (BiTE) are being developed. These drugs target tumor-associated surface protein. Transition of protein expression affected by treatment has not been fully investigated especially in the era of ICIs. The purpose of this study is to evaluate changes in protein expression in small cell lung cancer tissues before and after treatment.

Methods: This study included patients diagnosed with SCLC by surgery or biopsy and experienced re-biopsy after treatment, and patients initially diagnosed with non-small cell lung cancer and transformation to SCLC was diagnosed by re-biopsy at the National Cancer Center Hospital between 2014 and 2023. Tissues were obtained by surgery, bronchoscopy, or CT-guided biopsy with an interval of at least 100 days.

Results: Five resectable SCLC cases with paired surgical specimens and biopsy specimens at disease progression, and 18 cases with paired biopsy specimens at diagnosis and progression, were included. Of these, pathology specimens could be evaluated in a total of 15 cases: 5 for the former and 10 for the latter group. The median age of all patients was 68 years, 11 (73%) were male, 11 (73%) were smokers, 8 (53%) were in clinical stages I-IIIA, 1 (7%) in stages IIIB-IIIC, and 6 (40%) in stage IV. Among the latter 10 patients, 4 patients experienced SCLC transformation and 3 of them were treated by osimertinib. Progression free survival from first-line therapy was 362 days (264-NA) vs. 314 days (245-NA) and overall survival was 1466 days (567-NA) vs. 901 days (517-NA), respectively for non-transformed and transformed small cell carcinoma cases.

Conclusions: In this study, we plan to investigate clinicopathological features in paired specimens focusing on DLL3, ASCL1, NEUROD1, POU2F3, YAP1, and MDM2.

EP.06B.15 Targetable Genetic Alterations Associated with Non-Small Cell Lung Cancer Mortality

H. Tupper[1], L.C. Sakoda[2], M.Z. Yang[3], R. Liu[3], V. Sarovar[2], N. Alcasid[4], H. Dong[2], W.T. Dyer[2], J. Yang[2], A.R. Patel[5], S.K. Ashiku[5], J.B. Velotta[5], [1]UCLA, Los Angeles/CA/USA ,[2]Kaiser Permanente Northern California, Oakland/CA/USA ,[3]Kaiser Permanente San Francisco, San Francisco/CA/USA ,[4]University of California San Francisco East Bay, Oakland/CA/USA ,[5]Kaiser Permanente Oakland, Oakland/CA/USA

Introduction: Non-small cell lung cancer (NSCLC) biomarker testing recommendations have evolved rapidly with targeted therapy development: Biomarker testing was first recommended for advanced non-squamous cancer in 2011 and current guidelines recommend biomarker testing consideration for advanced NSCLC and stages IB-IIIA adenocarcinoma. Patients with targetable genetic alterations who received targeted therapy survive longer, but the prognostic value of targetable genetic alterations is unclear. This study retrospectively evaluates the overall mortality of NSCLC patients associated with the presence of targetable genetic alterations.

Methods: We evaluated patients aged 18-89 diagnosed with NSCLC from 2013-2020 in a large, integrated healthcare system serving a diverse population. We ascertained sociodemographic and cancer characteristics, receipt of valid biomarker testing within 6 months of diagnosis (IHC, FISH, PCR or NGS), test results, and overall mortality from institutional databases. We compared one- and three-year mortality after NSCLC diagnosis between patients with and without alterations in each targetable gene, after adjusting for age, sex, race/ethnicity, neighborhood deprivation index, smoking status, histologic subtype and cancer stage, using Cox regression analysis.

Results: Among 9834 NSCLC patients, 38.8% received biomarker testing, and most testing yielded valid results (77-92%). Among the 3256 patients with valid results, 54.9% were female, 36.2% were 75-89 years, 41.6% were non-White, 69.7% had a smoking history, 74.7% had stage IV cancer and 7.8% had squamous histology. EGFR was the most commonly tested gene. Genetic alteration prevalence was as follows: KRAS mutation or amplification 26.1% (410/1569); EGFR exon 18-21 mutation 25.5% (872/3421); MET mutation or amplification 5.5% (85/1540); ALK rearrangement 3.8% (113/2970); BRAF mutation or amplification 3.1% (78/1479); ERBB2 mutation or amplification 3.1% (45/1464); ROS1 rearrangement 2.1% (52/2511); RET rearrangement 1.1% (16/1459); NTRK rearrangement 0.3% (2/799). The adjusted hazard of death within one year after NSCLC diagnosis was lower for patients with EGFR or ALK alterations, but higher for patients with MET or ROS1 alterations (Table 1). The adjusted hazard of death within three years after NSCLC diagnosis was lower for patients with EGFR or ALK alterations, but higher for patients with ERBB2 alterations. There was no difference in one- or three-year mortality for patients with BRAF, KRAS, or RET alterations.

Conclusions: Biomarker testing and targeted therapy is transforming NSCLC management and outcomes. Although our data likely partially reflect the evolution of targeted therapy from 2013-2020, EGFR and ALK alterations may have a positive prognostic value, irrespective of treatment.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06B.16 Latin-American Non-Small Cell Lung Cancer Patient's Tumors Harbor Many Novels Potentially Actionable/driver Mutations.

E. Gonzalez[1], A. Blanco[1], G. Owen[2], M. Garrido[3], A. Corvalan[2], C. Ibañez[2], K. Marcelain[4], R. Armisen[1], [1]Universidad del Desarrollo, Santiago/CL ,[2]Pontificia Universidad Catolica de Chile, Santiago/CL ,[3]Universidad Mayor, Santiago/CL ,[4]Universidad de Chile, Santiago/CL

Introduction: Therapies that target activating EGFR, ALK, ROS1 and other mutations are first-line treatments in NSCLC patients. Latin-American patients are very poorly represented in clinical trials and in genomic databases, thus little is known about the prevalence of actionable mutations in this population. This study characterizes somatic mutations (SNVs and Indels) found in the DNA of eight NSCLC actionable genes (ALK, BRAF, EGFR, ERRB2, KRAS, MET, RET and ROS1) and describe a novel set of potentially actionable mutations, in 1890 NSCLC patients from Chile, Brazil and Peru.

Methods: DNA from NSCLC tumors, collected at the time of diagnosis in Chile, Brazil and Peru, were sequenced using a NGS panel (Oncomine Focus assay). After a stringiest quality control and variants filtering step, mutations (SNVs and Indels) were annotated using the Variant Effect Predictor, COSMIC, the Oncomine Variant Annotator (OVA), OncoKB, the Cancer Genome Interpreter and CancerVar to categorize somatic mutations.

Results: In the eight actionable genes a total of 1117 somatic DNA mutations were found. 46% (517/1117) of them corresponds to variants already described in COSMIC and/or OVA. 21% (239/1117) variants are present in OncoKB, including, as expected, well characterized and known driver actionable mutations. 44% (491/1117) are novel mutations, at the time databases were interrogated. Among those, 34% (167/491) are predicted passenger mutations by all the algorithms utilized and 66% (327/491) mutations are considered potentially driver mutations by one or more algorithms. Among these, 23% (74/327) are predicted high confidence novel driver variants by all algorithms. ALK (23%) and ROS1 (23%) account for most of these variants, followed by ERBB2 (14%), EGFR (11%), RET (11%), BRAF (8%), MET (7%) and KRAS (3%).

Conclusions: The analysis of many Latin America subjects revealed a significant number of clinically actionable but also novel somatic mutations in cancer genes highlighting the importance of including less-represented populations in clinical trials and molecular studies.

EP.06B.17 Detection of EGFR Mutations T790M and L858R for Therapeutic Guidance of NSCLC

M. Rana, S.M. Asil, C. Boutin, M.J. Kachwala, J. Espejo, A.A. Argun, Giner, Inc., Newton/MA/USA

Introduction: A common occurrence in most non-small cell lung cancer (NSCLC) patients that respond well to epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) therapy is that they eventually develop resistance to it. This resistance to EGFR-TKI therapies has been linked to the emergence of secondary EGFR mutations in exon 19, exon 20 (T790M), or exon 21 (L858R). Therefore, timely detection and characterization of EGFR mutations is critical for the prediction of response to EGFR-TKI, early identification of acquired resistance, and the subsequent implementation of personalized TKI therapy to ensure progression-free patient survival. Mutation monitoring in NSCLC patients is a significant challenge since tumor biopsy and surgery are invasive interventions that cannot be performed frequently and cannot account for tumor heterogeneity. As a result, up to 25% of patients fail to undergo proper EGFR assessment before receiving treatment.

Methods: To address these limitations in the current diagnostics and therapeutic guidance, Giner, Inc. has developed a highly specific assay that analyses circulating tumor DNA (ctDNA) in patient plasma to check for EGFR-based genomic alterations. The strong, established correlation between mutations detected in blood plasma ctDNA and mutations in tumor tissue makes liquid biopsy an ideal non-invasive alternative for the assessment of molecular aberrations and resistance to therapy. However, specific detection of ctDNA is extremely challenging since they exist at trace concentrations and are vastly outnumbered by other cell-free DNAs. Giner, Inc. has developed an integrated detection method for rapid, sensitive, and selective detection of single-base mutations in the EGFR genes T790M and L858R.

Results: Giner's PCR-enhanced ligation assay provides genomic DNA sensitivity down to 2 copies/μL (Figure 1) which corresponds to mutation allele frequency (MAF) levels of 0.01% (data not shown). This addresses the clinical sensitivity requirement and is 10 times more sensitive than the current standard digital droplet PCR (ddPCR) which has a limit of 0.1% for MAF.

Conclusions: Ongoing work aims to adapt the assay for multiplexed ctDNA detection, validate it with patient plasma samples, and integrate it into a prototype, thus achieving a significant milestone toward regulatory evaluation. Fully developed, this technology will facilitate the enactment of personalized therapy, improve treatment outcomes, and offer significant advantages over existing methods such as lower test cost, easier sample preparation, and faster sample-to-result turnaround.

EP.06B.18 Biomarker Landscape of Antibody-Drug Conjugates and Bispecific Antibodies in Clinical Trials for Lung Cancer

M.S. Kumar[1], C.D. Bhanushali[1], A.A. Khosla[2], S.S. Deshmukh[3], M.A. Modi[4], Y. Boumber[5], A.R. Naqash[6], V. Subbiah[7], A. Desai[5], [1]Saint Vincent Hospital, Worcester/MA/USA ,[2]William Beaumont University Hospital, Royal Oak/MI/USA ,[3]Dr. Shankarrao Chavan Government Medical College, Nanded/IN ,[4]Gujarat Cancer Society Medical College, Hospital, and Research Centre, Ahmedabad/IN ,[5]O'Neal Comprehensive Cancer Center, UAB Heersink School of Medicine, Birmingham/AL/USA ,[6]Stephenson Cancer Center, The University of Oklahoma, Oklahoma City/OK/USA ,[7]Sarah Cannon Research Institute, Nashville/TN/USA

Introduction: Despite the rapid advances in immunotherapy and targeted therapy, lung cancer remains the leading cause of cancer-related fatalities globally. The emergence of antibody-based therapeutics such as antibody-drug conjugates (ADCs) and bispecific antibodies (BsAbs) has sparked significant interest due to their promise in improving patient outcomes. While these therapies are designed to target tumor-associated antigens, there is a notable absence of biomarker-driven approaches in their development. We aim to explore the frequency and prevalence of biomarker-guided approaches in the ongoing clinical development of antibody-based therapies.

Methods: We surveyed clinical trials listed on clinicaltrials.gov for "non-small cell lung cancer" and "small cell lung cancer," specifically examining interventions involving "antibody-drug conjugates" or "bispecific" therapies. With a cutoff date of February 1st, 2024, the study focused solely on trials that were actively recruiting or not yet recruiting, excluding those that had been completed. For each trial, we gathered data on the phase of the trial, cancer stage, treatment line, drug target, linker-payload profiles (for ADCs), inclusion of, and method for target biomarker testing for patient selection. Utilizing descriptive statistics, we analyzed the collected information.

Results: Of the 95 clinical trials screened, 47 were included based on the specified criteria. Phase 1 trials comprised 34.04% (n=16) of the total, while combined Phase 1 or 2 trials represented 40.04% (n=19). Phase 2 trials accounted for 19.14% (n=9), and Phase 3 trials comprised 6.38% (n=3). The majority of trials targeted advanced stages of cancer, encompassing 95.7% (n=45), and predominantly investigated investigational therapies in second-line settings or beyond (85.1%, n=40). When considering drug categories, BsAbs took precedence, being the focus of 68.1% (n=32) of trials, while ADCs were involved in 31.9% (n=15) of trials. In terms of biomarker inclusion criteria, 44.7% (n=21) of trials incorporated this strategy, indicating a commitment to personalized medicine strategy, while 55.3% (n=26) did not. Among trials with biomarker selection, the majority utilized NGS-based genomic subsets (59.1%), while only 40.9% studied antigen expression through immunohistochemistry. The most common drug targets for BsAbs were EGFR x c-MET (28.1 %, n = 9 of 32) and PD-1 x CTLA-4 (9.4%, n = 3 of 32), whereas for ADCs, they were TROP2 (33.3%, n = 5 of 15) and HER2 (20%, n = 3 of 15). The payloads utilized most frequently among ADCs were monomethyl auristatin E (MMAE) (40%, n = 6), followed by topoisomerase 1 inhibitor payload (26.6%, n = 4).

Conclusions: Our study highlights the utilization of antibody-based therapies in lung cancer treatment, revealing a trend toward incorporating biomarker-guided approaches that are still evolving. Alongside retrospective biomarker exploratory analysis, future trials should prioritize the integration of prospective biomarker strategies for a more comprehensive understanding and implementation of personalized treatment approaches.

EP.06B PATHOLOGY AND BIOMARKERS - BIOMARKER
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06B.19 WNT/ß-Catenin Signalling Pathway in Non-Small Cell Lung Cancer: Study of Immuno-expression GSK-3ß, ß-Catenin, And CD44.

E. Kristiani, E. Syahruddin, A. Asmarinah, L. Rachmadi, M.F. Ham, J. Zaini, A. Kekalih, Universitas Indonesia, Jakarta/ID

Introduction: This study aimed to assess the role of the WNT/β-catenin signaling pathway in non-small cell lung cancer (NSCLC) and the association of GSK-3β, β-catenin, and CD44 with the clinicopathological profiles of NSCLC in the Indonesian population. GSK-3 β-β-catenin, and CD44 immuno-expression are expected to be markers for predicting response to platinum-based chemotherapy and have the potential to be target therapies in advanced-stage NSCLC patients.

Methods: This is an observational study. We retrospectively collected data on every patient diagnosed with advanced-stage (stage III-IV) adenocarcinoma (EGFR-wild type) and squamous cell carcinoma (SCC). Patients received platinum-based chemotherapy for three cycles between January 2018 and July 2023 from six hospitals in Indonesia. Patients with complete medical records and sufficient tissue samples were included. Subsequently, we stained the paraffin blocks with three immunohistochemistry antibodies. Positive GSK-β expression was identified in the cytoplasm, β-catenin in the nucleus, and CD44 in the membrane of the tumor cells. Immunohistochemistry staining was evaluated using an H-score by two pathologists who were blinded to the study. We analyzed the staining results along with clinicopathological factors, including RECIST status. RECIST statuses were classified as follows: Complete response, partial response, and stable disease were grouped into good outcomes, while progressive disease was categorized as a poor outcome.

Results: Out of 62 NSCLC patients, 53.2% were under 60 years old, 79% were male patients, 75.8% were at stage IV, 80.6% had an adenocarcinoma subtype, and 40.3% had progressive disease. There was a significant association between GSK-3β and clinicopathological factors. GSK-3β was expressed higher in subjects with male gender (p = 0.033), stage III (p = 0.031), and SCC subtype (p = 0.015). β-catenin and CD44 expression were higher in stage III. GSK-3 β expression was higher in subjects with a poor response, and β-catenin and CD44 expression were lower in subjects with a poor response, but this was not statistically significant.

Conclusions: The WNT/ β-catenin signalling pathway has a specific role in lung cancer. This study provides valuable insights for disease understanding in NSCLC.

EP.06B.20 Prognostic Impact of Nectin-like Molecule-5 (CD155) Expression in Non-Small Cell Lung Cancer

N. Hernandez-Pedro[1], X. Popa-Navarro[1], A. Avilés-Salas[1], M. Orozco-Morales[2], E. Caballé-Pérez[1], C. Castillo-Ruiz[1], J. Lucio-Lozada[1], P. Barrios-Bernal[1], J-M. Hernandez-Martinez[1], O. Arrieta[1], [1]Instituto Nacional de Cancerología, Mexico/MX ,[2]Instituto Nacional de Neurología y Neurocirugia, Mexico/MX

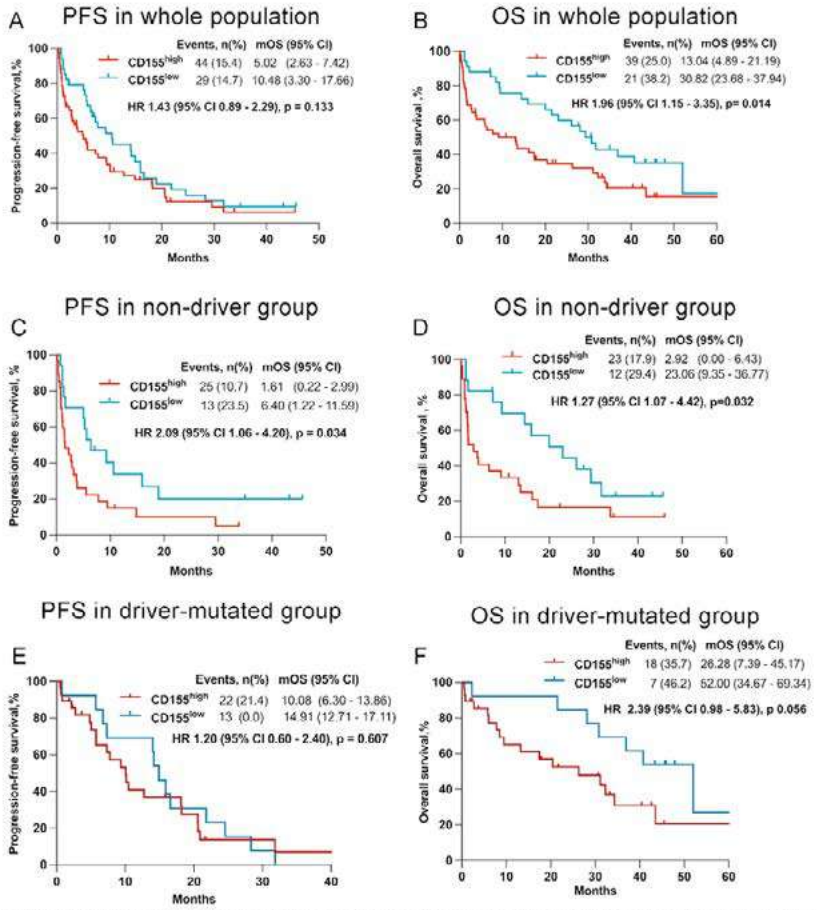
Introduction: CD155, a transmembrane protein which inhibits antitumor immune responses, has been shown to be a predictor of worse clinical outcomes in non-small-cell lung cancer (NSCLC). However, its association with the prognosis, clinical and genomic characteristics of Latin American patients remains unexplored. Thus, this study characterizes CD155 expression in NSCLC.

Methods: Tissue biopsies from 86 consecutive Latin American patients with locally advanced or metastatic NSCLC were assessed for CD155 protein expression, ALK rearrangements and EGFR mutations. Optimal cutoff values for CD155 expression were determined from receiver operating characteristic (ROC) curves according to the 2-year survival of patients with driver and non-driver mutations. Its association with clinicopathological features, median progression-free survival (mPFS), and median overall survival (mOS) was evaluated.

Results: The cutoff for high CD155 expression (CD155high) was 155 in the entire cohort and in patients without driver mutations, and 110 in patients with driver mutations. CD155 was detected in 84 patients (97.7%), more frequently (52.3%) and at higher levels (62.2%) in patients without driver mutations. EGFR L858R mutation was associated with lower CD155 expression than exon 19 deletion. CD155high patients had a significantly shorter mOS (13.0 vs 30.8 months; HR: 1.96 [95% CI, 1.15-3.35]; p=0.014). Among patients without driver mutations, CD155high was related to significantly shorter mPFS (1.61 vs 6.40 months; HR: 2.04 [95% CI, 1.03-4.02]; p = 0.034) and mOS (2.92 vs 23.06 months; HR: 2.17 [95% CI, 1.07-4.42]; p=0.032). In patients with driver mutations, CD155high was only borderline significant for shorter mOS (26.3 vs 52.0 months, HR: 2.39 [95% CI, 0.98-5.83];p=0.056).

Conclusions: CD155high is a predictor of worse survival outcomes in patients with advanced NSCLC, predominantly among those without onco-driver mutations. CD155 could be a potential biomarker and a molecular target in patients with poor responses to current therapies.

Keywords: nectin-like molecule-5, immune checkpoints, Non-Small Cell lung cancer



Prognostic significance of high CD155 expression on progression-free survival and overall survival of the whole cohort (A-B), group without driver mutations (C-D) and subset with driver mutations (E-F). CD155, Cluster of Differentiation 155. HR, hazard ratio. mOS, median overall survival. mPFS, median progression-free survival. CI, confidence interval. PFS was calculated from diagnosis to progression to first-line treatment. OS was determined by the period between diagnosis and death for any cause. Log-rank test was performed to determine statistical differences between Kaplan-Meyer curves as always as p values were less than 0.

EP.06C.01 KRAS Q61H Mutation Defines a Distinct Clinicopathological Entity of Lung Adenocarcinomas in East Asian Patients

K.A. Kim[1], M. Kim[2], C. Lee[1], H.S. Shim[1], [1]Severance Hospital, Yonsei University College of Medicine, Seoul/KR ,[2]Kyungpook National University Chilgok Hospital, School of Medicine, Daegu/KR

Introduction: KRAS mutations play an important role in the pathogenesis of lung adenocarcinoma, occurring in 20-35% of cases in the Western population. However, the incidence of KRAS mutations in East Asian patients is lower, and the clinicopathologic characteristics of KRAS-mutant lung adenocarcinoma have not been well studied.

Methods: Among a total of 1364 non-small cell lung cancer patients that underwent broad-panel targeted next-generation sequencing, the clinicopathologic and molecular characteristics of a total of 176 invasive lung adenocarcinomas (non-mucinous type n=122; mucinous type n=54) harboring oncogenic KRAS mutations were investigated.

Results: Patients harboring the KRAS Q61H mutation were identified in 10.2% (18/176) of cases. The presence of the Q61H mutation was significantly associated with worse overall survival in multivariate analysis compared to other variants (p=0.017). It was also associated with shorter progression-free survival in patients treated with first-line chemo-immunotherapy (p=0.007). KRAS Q61H mutations frequently co-occurred with STK11 mutations (p=0.023) and were associated with lower PD-L1 expression (p=0.003). Histologically, Q61H mutations were predominantly found in the non-mucinous subtype (p=0.037).

Conclusions: The KRAS Q61H mutation defines a distinct clinicopathological class of lung adenocarcinomas in East Asian patients, especially associated with worse prognosis.

Keywords: lung adenocarcinoma, KRAS Q61H, poor prognosis

EP.06C.02 Clinical Features and Survival Outcome of Lung Invasive Mucinous Adenocarcinoma: A Real-World Analysis of 387,197 Patients

Y.J. Heo[1], J. Kim[2], W. Woo[3], Y.K. Chae[3], [1]Northwestern Memorial Hospital, Chicago/IL/USA ,[2]Northwestern Memorial Hopital, Chicago/IL/USA ,[3]Northwestern Memorial Hopital, Illinois/IL/USA

Introduction: Pulmonary invasive mucinous adenocarcinoma (IMA) is known for its unique characteristics compared to non-IMA. In this study, we investigate clinical outcomes and prognostic factors from the Surveillance, Epidemiology, and End Results (SEER) database.

Methods: The clinical information of patients with IMA and non-IMA was extracted from SEER 17 registries from 2000 to 2020. The Kaplan-Meier was used to compare the differences in overall survival (OS). Univariate and multivariate Cox-proportional hazard regression analyses were further performed to investigate the independent prognostic factors for OS.

Results: A total of 387,197 patients diagnosed with IMA (4.0%, n=14,453) or non-IMA (96.0%, n=372,744) were included in the study. The IMA group demonstrated a higher rate in female group (p<0.001) and bilateral parenchymal involvement (p<0.001), while showing lower rate of nodal involvement (p<0.001) and distant metastasis (p<0.001). The IMA group presented a favorable a 5-year OS than non-IMA (31.7% vs 23.5%, p<0.001). In contrast, the distant SEER stage of IMA exhibited worse outcome (p<0.001, Figure.1). In multivariate Cox analysis for OS, both tumor types had similar risk factors such as age, sex, SEER stage, chemotherapy and radiation (Table 1). Notably, while both groups demonstrated a favorable outcome following chemotherapy, the effect was less in IMA than in non-IMA (HR: 0.782 [0.736-0.823] vs 0.571 [0.561-0.572], p<0.001).

Conclusions: Overall, IMA showed better clinical outcome compared to non-IMA from SEER database analysis. However, IMA with advanced stage exhibited opposite results. IMA seemed to derive less benefit from chemotherapy than non-IMA.

Introduction: Biological characteristics of each epidermal growth factor receptor (EGFR) mutational subtype is suggested to be different from one another. However, the correlation between EGFR mutational subtypes and histological predominance of lung adenocarcinoma using the recently-launched International Association for the Study of Lung Cancer (IASLC) grading system remains uncertain. This study aimed to clarify the clinicopathological characteristics of each EGFR subtype in surgically resected lung adenocarcinoma.

Methods: This is a retrospective multicentre study conducted by 21 institutions in Japan from January 2015 to December 2018. Among 4181 patients with lung adenocarcinoma, we enrolled 2248 patients who underwent complete anatomical radical resection and confirmed EGFR mutational status and histological predominant subtype. We collected clinicopathological characteristics including age, gender, smoking history, performance status (PS), presence of ground glass opacity (GGO), consolidation tumor ratio (CTR), predominant subtype, IASLC grade, pN status, ly, v, pl, spread through air spaces (STAS), pathological invasiveness and compared them between wild type vs. all EGFR mutations, L858R vs. 19del, common vs uncommon mutations, and 20ins vs. common mutations (L8585R or 19del).

Results: One-thousand-seventy-nine cases had EGFR mutation (48%). Among them, 518, 428, and 133 cases harbored L858R, 19del, uncommon EGFR mutations, respectively. In uncommon mutations, 20ins (n = 42, 4 %) was the most frequent, followed by G719X (n = 26, 2 %) and L861Q (n = 25, 2 %). Tumors harboring EGFR mutation had less pathological invasiveness ($p < 0.001$) including lymph node metastasis ($p = 0.004$.), ly ($p = 0.020$), v ($p < 0.001$), and pl ($p = 0.002$) than those harboring wild type. L858R mutations were more frequent in GGO, lepidic predominant, and IASLC grade 1 than 19del mutations. There were no clinicopathological differences between common and uncommon EGFR mutations except that ever smoker are more frequent in patients with uncommon mutations compared to common mutations. In comparisons of 20ins vs. L858R and 20ins vs 19del, no statistically significant differences were observed, however, tumors with 20ins were found to have worse PS than each common mutation.

Conclusions: Clinicopathological difference in each subtype of EGFR was revealed. Tumors with L858R had less pathological invasiveness and higher prevalence of IASLC grade 1 than those with 19del. No statistical difference were observed in pathological features between common mutations and uncommon mutations nor 20ins and each common mutation.

EP.06C.04 Impact of TP53/EGFR Mutations in Advanced-Stage NSCLC: LATAM Population

T. Runciman[1], g. Cruz-Rico[2], M. Galvez-Nino[3], C. Aliaga[1], C. Carracedo[1], O. Arrieta[2], [1]Clinica Aliada, Lima/PE ,[2]INCAM, Ciudad de Mexico/MX ,[3]INEN, Lima/PE

Introduction: NSCLC is one of the most frequent mortality cause worldwide. Nowadays its treatment it's strong correlated with driver mutation and the inmune environment. Despite well known driver mutations, not all patients achieve the same response when we expose them to the same treatment, this observation guide us to find other nondriver mutation that potentially could affect the response and have an impact in the overall survival finally. One of this mutation is TP53 who plays a crucial role in cell cycle and tumorigenesis, EGFR is a common mutation in Latam, its incidence could be as high as 40% depending of the region. However, there is a lack of information about the behavior of this alteration in our population. The aim of our study is to determined if the double mutation of tp53 and EGFR has an impact in our population.

Methods: The study retrospectively reviewed 462 Latin patients with advanced lung cancer from 2 oncological centers: Clinica Aliada (Peru), and Instituto Nacional de Cancerologia - INCA (Mexico) from January 2015 to December 2022. The exclusion criteria were as follows: loss to follow-up (n = 37), and absence of detailed NGS information (n = 33). Finally, a total of 356 patients with wild-type TP53 or mutant TP53 reported on NGS panels met the inclusion criteria in the present study and just 90 patients of those have EGFR mutation. The study was reviewed and approved by the Ethics Committee of each department.

Results: Patient characteristics 63.8% were female, median age was 58 (range 27-88), majority were smokers (53.9%). TP53 mutated in 62.9%, PD-L1 expression: 50.6% negative, 38% positive, 11.2% undetermined. EGFR: most frequent alteration was deletion 19 (52.2%), followed by L858R (21.1%) and insertion 20 (9%) Median number of co-mutations was 3 (range 1-12). 90% of the total patients received treatment, of those the response rate (RR) was 57.8%. The overall survival (OS) for the whole group was 38.5 moths (CI 95%) for the TP53 mutated was only 28.7 m vs 57.18 for the wild type group ($p < 0.005$). There was no difference accordance tu PD l1 expression. The PFS media for the whole group was 14.7 months (CI: 95%), we found no difference between the mutated (12.8m) and wild type group (17.2) ($p = 0.5$). No significant difference in PFS based on PD-L1 expression ($p = 0.5$).

Conclusions: TP53 was the most frequent mutation associate with EGFR in LATAM population. There is a significant impact in OS for those with TP53 but not in PFS.PD-L1 expression does not seem to be a significant predictor of survival or progression-free survival in this group.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06C.05 Impact of TP53 Mutation in Advanced NSCLC in LATAM

T. Runciman[1], C. Carracedo[1], O. Arrieta[2], G. Cruz-Rico[2], [1]Clinica Aliada, Lima/PE ,[2]INCAN, Ciudad de Mexico/MX

Introduction: A frequent mutation found in patients with lung cancer is TP53.Due to the diversity of molecular patterns in Latin American, it is important to determine if the presence of the TP53 mutation has any impact on the overall survival.

Methods: The study retrospectively reviewed 462 patients with advanced lung cancer from 2 oncological centers: Clinica Aliada (Peru), and INCAN (Mexico) from Jan 2015 to Dec 2022. 356 met the inclusion criteria. Statistical analyses were performed using Stata v.17.0. All tests were two-sided, and p-values less than 0.05 were considered statistically significant.

Results: The median follow-up was 5 y, 154 patients died during this period . A total of 149 patients (41.7%) carried TP53 mutations. Among this group, most of the patients were male (63.7 %).The majority had a driver mutation (81.3%). The majority have more than 4 molecular alterations detected beside TP53 (64.7% vs 35.3%, p<0.001).There were 214 patients where TMB could be evaluated, of these 88.8 % had an expression < or equal to 8Mb, having an expression of the TP53 mutation in 39.5% of the cases. In those with a TMB >8Mb, 70.8% had the TP53 mutation.According with PD-L1 and tp53 we did not find any difference.TP53 mutation was present in 149 patients (41.7%), the majority were missense mutations (93). The most frequent missense mutations were on exon 6 (n=29), followed by exon 4 and 8 . As for nonsense mutation, exon 5 was the most frequent (n=21). TP53 mutation was strongly related to the EGFR mutation, found in up to 69% of the total of this group.According to TP53 status, we found a median of 21.5 months for the group with mutant - TP53 and 46.5 months for the w-TP53 group (p<0.001) (Fig. 2A). The mortality HR of the TP53 mutation was 2.01 times the mortality HR of wild type (HR: 2.01; 95% CI: 1.44 - 2.81; p-value <0.001). Those who presented an increased number of mutations had worse OS: 0-1 vs 2-3 (HR: 2.02, CI 95% 1.27-3.2, P: 0.003) vs 4-11 (HR: 2.45, CI 95% 1.51- 3.97, P< 0.001). According to driver mutations, those with EGFR and KRAS had a worse OS if they had tp53 mutated. Since EGFR was the most frequent driver mutation, we also analyzed the OS in these patients finding a worse OS (20.5m vs NR) in patients with tp53 mutated, no difference was found according deletion exon 19 or other type of EGFR mutation. For the KRAS mutation, a detrimental of 9 months in OS was found (33.5 vs 24.5m). PFS For the tp53 wild-type, was 38 m vs NR in the mutant group.We did not find any difference according to tp53 mutational status and EGFR mutation, however, it was only 19 moths for those who have exon-19 deletion vs NR in other EGFR alterations.

Conclusions: TP53 mutant was associated with a worse prognostic in the general population but especially in EGFR mutation with a higher prevalence in contrast with other populations.

EP.06C.06 Outcome and Clinical Profile of Common and Uncommon EGFR Mutations in NSCLC: Retrospective Analysis from an Argentinean Cancer Center

F. Guerra[1], M. Bonet[1], A. Matteo[1], M. Altamirano[1], C. Gagliolo[1], M. Krasnapolski[1], M. Castro[1], [1]Instituto Ángel H. Roffo, University of Buenos Aires/AR

Introduction: The subtype of EGFR mutation is the strongest predictive biomarker to TKI response in patients with non-small cell lung cancer (NSCLC). The heterogeneity of these mutations and their association with different clinical and prognostic characteristics still remain an active area of research.

Methods: A retrospective analysis was conducted on patients with EGFR mutations, evaluating their clinical characteristics, specific EGFR mutations, and treatment outcome as an update of previous reported data from our population (JTO 2017, 12 S492, Abst P1.02-010).

Results: Between 2015 and 2023, we identified 484 metastatic NSCLC who had successful analysis for EGFR exons 18-21 mutations by PCR tests. A total of 91 patients (19%) had EGFR mutations. Exon 19 deletions and L858R mutation in exon 21 were detected in 51% (47/91) and 30% (27/91), respectively. Uncommon EGFR mutations were detected in 19% (17/90) of cases; exon 18 G719X was the most prevalent 14% (13/90), followed by Exon 20 INS (2%), L861Q (2%) and S7681 (1%). The median age of the whole group was 64 years (range: 34-85 years), with a female predominance (69%) in patients with common mutations and a male predominance (64%) in those with uncommon mutations. The median PFS to first line treatment was 11 months and 6.2 months for common and uncommon mutations respectively and OS was 28.4 months and 11.3 months, respectively. In multivariate analysis, male sex (HR = 2.35, 95% CI: 1.21-4.57, p = 0.01) and uncommon EGFR mutations (HR = 2.14, 95% CI: 0.97-4.73, p = 0.05) were associated with poor prognosis. Patients with uncommon EGFR mutations had a significantly higher prevalence of ever-smokers (88% vs. 24%, p = 0.001) and more synchronous central nervous system (CNS) metastases compared to those with common mutations (33% vs. 4.5%, p = 0.039).

Conclusions: Our population showed a positive correlation between smoking status and uncommon EGFR mutations in patients with NSCLC as previously described. The poorer survival observed in patients with uncommon mutations and higher incidence of synchronous CNS metastases underscores the need for and adequate diagnosis and personalized treatment strategies for this group

EP.06C.07 Impact of a Diagnostic Bronchoscopy Service with Embedded Reflex Molecular Testing within an Oncology Centre in Patients with Lung Cancer.

H. Charalambous[1], I. Stylianou[1], G. Karaoli[1], E. Papageorgiou[1], Z. Kordatou[1], E. Xenofontos[1], G. Fotopoulos[1], P. Gerasimou[2], P. Costeas[2], I. Kyprianou[2], P. Kara[3], E. Theophanous[3], G. Georgiou[3], I. Porfyridis[4], [1]Bank of Cyprus Oncology Centre, Nicosia/CY ,[2]Karaiskakio Foundation, Nicosia/CY ,[3]Nicosia General Hospital, Nicosia/CY ,[4]Bank of Cyprus Oncology Centre, Strovolos, Nicosia/CY

Introduction: Oncologists require PD-L1 and molecular testing results to initiate treatment for patients with metastatic NSCLC. In the diagnostic journey, delays are introduced following the initial biopsy, as often the histopathology Lab awaits instructions for PD-L1 and molecular testing, whilst further delays are due to the time that the pulmonary physician takes to refer to the oncologist, and the delay in the oncologist to see the patient and to request molecular testing. Often these delays result in a TurnAround Time (TAT) in excess of 4 weeks, where optimal practice should be within 2 weeks. Other issues relate to the quality of the paraffin embedded tissue to allow RNA sequencing. For these reasons, the Bronchiomics study, with a diagnostic bronchoscopy service was set up in a tertiary Oncology center aiming to speed up the diagnostic pathway for patients with suspected Lung Cancer.

Methods: At bronchoscopy a fresh tissue sample was sent directly to a molecular Laboratory (Karaiskakio Foundation) accompanied by blood for liquid biopsy, whilst another sample was sent for histology to the Nicosia General Hospital (NGH), with instructions to undertake PD-L1 testing and NGS on paraffin embedded tissue once a diagnosis of LC was made. The study was enacted at the end of October 2023, and 36 patients with suspected lung cancer were enrolled between October 2023 and March 2024.

Results: 29 males and 7 female patients, median age 67 years were enrolled. Lung adenocarcinoma was diagnosed in 10 patients, squamous in 8 patients, SCLC in 5 patients, other types of cancer in 4, whilst 9 samples showed no cancer. The median time from bronchoscopy to histology result was 6 days, to PD-L1 result 11 days, to liquid bx result 7.5 days for the fast assay and 13 days for the comprehensive liquid panel, to NGS result from fresh tissue 17 days and NGS result from paraffin embedded tissue 14 days. For consecutively referred patients to the Oncology center between September and October 2023, prior to the initiation of the Bronchiomics study, median time from bx/bscopy to histology result was 5 days, to PD-L1 result 28.5 days, to fast liquid biopsy result 17.5 days, to comprehensive liquid NGS result 25.5 days and to solid tissue NGS result 36.5 days.

Conclusions: The Bronchiomics study and initiation of reflex testing decreased the median time from bx/bscopy to receipt of molecular results significantly and brought the TAT close to 2 weeks.

EP.06C.08 Presentations and Outcomes of Pulmonary Carcinosarcoma: Results of Comparing Pulmonary Carcinosarcoma and Primary Lung Sarcoma

J-S. Cai, Peking University People's Hospital, Beijing/CN

Introduction: We investigated the presentation and survival outcomes of pulmonary carcinosarcoma (PCS) with the purpose of obtaining a clearer picture of this rare disease.

Methods: Eligible PCS and primary lung sarcoma (PLS) cases were extracted from the Surveillance, Epidemiology, and End Results (SEER) database. A least absolute shrinkage and selection operator (LASSO) penalized Cox regression model was performed to identify prognostic indicators. Kaplan-Meier method with a log-rank test was used to compare overall survival (OS). Competing risk analysis with a Fine-Gray's test was used to analyze cancer-specific survival (CSS). Propensity score matching (PSM) was used to minimize selection bias.

Results: 210 PCS cases and 260 PLS cases were included in this study. Regarding PCS, the incidence was 0.05%, and poorly differentiated/undifferentiated tumors accounted for a large proportion of the entire cohort (51.0%). In contrast to PLS, more PCS cases were older and involved with lymph node metastasis. Receiving surgery, receiving chemotherapy and non-metastasis status were identified as favorable prognostic factors of PCS patients' survivals. The survival curves displayed that the OS and CSS of PCS patients nearly overlapped with those of PLS patients both before and after PSM (all P > 0.05).

Conclusions: PCS was a rare and aggressive tumor. PCS patients could benefit from surgical resection and chemotherapy. In addition, the survival rate of this disease was comparable to that of PLS.

EP.06D.01 Prognostic Evaluation by Using ctDNA in Patients with EGFR Mutated Resectable Lung Cancer

Y. Murase, H. Koba, T. Ueda, S. Arai, N. Terada, Y. Tambo, S. Nanjo, S. Yano, Kanazawa University, Kanazawa/JP

Introduction: The detection of circulating Circulating tumor DNA (ctDNA) has been examined as a predictor of postoperative recurrence and survival in lung cancer patients.

Our research objective is investigating ctDNA detection and prognosis in EGFR mutated lung cancer.

Methods: We retrospectively examined patient background, EGFR mutation status, DFS, OS, and preoperative ctDNA in lung cancer patients who underwent surgery at Kanazawa University Hospital between January 2017 and May 2020, in whom preoperative chemotherapy was not administered. We extracted ctDNA from plasma (4ml) within 7 days before surgery using QIAamp Circulating Nucleic Acid Kid® (Qiagen). ctDNA from NSCLC patients with EGFR mutations (cobas EGFR Mutation Detection Kit) are analyzed by Digital Droplet PCR PrimePCR TM ddPCR TM Assay BIO-RAD.

Results: 285 patients were enrolled, and 93 patients were detected EGFR mutations in tissue. Plasma ctDNA was detected in 16 of 56 patients with tissue-confirmed L858R and in 7 of 32 patients with tissue-confirmed exon 19 deletions. 2-year DFS was 92.2% for ctDNA negative and 78.9% for ctDNA positive. In tissue EGFR mutated lung cancer patients, the patients who have ctDNA in plasma tested before surgery has shorter DFS compared with patients who without ctDNA in plasma.

Conclusions: In EGFR- mutated NSCLC, ctDNA positivity measured within a week before surgery correlated with shorter DFS and OS suggesting a good indication of adjuvant Osimertinib in this population.

EP.06D.02 Plasma-Derived Circulating Tumor DNA in Patients with Advanced EGFR-Positive Exon 20 NSCLC Treated With Osimertinib

F. Zwierenga, B. Muntinghe-Wagenaar, P. Rozendal, P. van der Leest, E. Schuuring, A.J. van der Wekken, University Medical Centre Groningen, Groningen/NL

Introduction: Plasma-derived circulating tumor DNA (ctDNA) is promising in monitoring responses and detecting resistance mechanisms in non-small cell lung cancer (NSCLC). NSCLC patients with EGFR exon 20 mutations (EGFRex20+) treated with high-dose Osimertinib (160 mg) showed modest anti-tumor activity (28% confirmed response rate) and acceptable toxicity. In this pilot study we aim to identify molecular response and resistance mechanisms using ctDNA collected during treatment.

Methods: Twenty-five EGFRex20+, p.(T790M) negative, NSCLC patients with WHO PS 0-2, received high-dose Osimertinib QD until progression or unacceptable toxicity. Cell free DNA collected at baseline, six weeks (T6), and progression was analyzed with the next generation sequencing (NGS) based Guardant360 CDx (73 gene panel). Molecular profiles of samples at progression were compared with matched pretreatment (baseline) samples to find resistance mechanisms to Osimertinib. A secondary objective is whether changes in ctDNA levels of the EGFRex20+ variant, at T6 and progression, compared to baseline, are associated with progression.

Results: Baseline ctDNA was analyzed in twenty patients. EGFRex20+ variant concordance between tumor biopsy NGS and ctDNA was found in 13/20 patients (65%). Fourteen patients underwent ctDNA profiling at all timepoints. All patients in this subset had either partial response (responder, n=6) or stable disease (non-responder, n=8) according to RECIST 1.1. No statistical correlation was found between changing ctDNA levels and overall response to osimertinib treatment in this subset. 9/14 patients showed an EGFRex20+ variant decrease six weeks post-therapy initiation, of which eight patients showed a decrease of tumor shrinkage at the same time (median shrinkage of target lesions -20%, IQR -36% to -11,5%). Eight patients showed an increase of the EGFRex20+ variant at disease progression (either growth of tumor [n = 5, median increase of target lesions 36%, IQR 27% to 155%] or overall deterioration/growth of non-target lesions [n = 3]). Two patients lacked the EGFRex20+ variant in ctDNA at baseline, but this variant was observed upon disease progression. Variants potentially associated with treatment resistance were identified in several genes at progression in 11/18 patients (61%): SNV (n=14), insertion (n=2) and gene-fusion (n=1). We found three variants that were previously related with resistance: TP53 (n=2) and EGFR p(C797S) (n=1).

Conclusions: This pilot study using a unique cohort of EGFRex20+ NSCLC patients treated with high dose Osimertinib highlights the complexity of variant dynamics during treatment and disease progression, suggesting a potential link between changed levels of variants detected at progression. Potential resistance mechanisms were shown in 11/18 patients using ctDNA.

EP.06D.03 Concurrent Liquid and Tissue Biopsy from Same Laboratory Increases On-Label Alteration Detection with Faster Turnaround Time

J. Tsai[1], G. Yalamanchili[2], G. Haynes[2], S. Gordon[2], L.E. Raez[3], [1]Guardant Health, Palo Alto/CA/USA ,[2]Guardant Health, Redwood City/CA/USA ,[3]Memorial Cancer Institute/Memorial Health Care System, Hollywood/FL/USA

Introduction: Next generation sequencing (NGS) is necessary to identify targetable alterations in advanced stage non-small cell lung cancer (NSCLC). Liquid biopsy via circulating tumor DNA (ctDNA) has demonstrated high concordance to tissue biopsy in newly diagnosed NSCLC with a marked decrease in turnaround time (TAT). Recent guideline language supports combination liquid and tissue testing in either the concurrent or reflex setting. As such, we examined concurrent liquid and tissue testing trends in patients with NSCLC.

Methods: We queried the Guardant Health database (4/2022-11/2023) for advanced lung cancer samples with an ordered liquid (Guardant360®) and tissue biopsy (Guardant360 TissueNext®) to create two cohorts: 1. "liquid and tissue" - both biopsies collected within 6 months of each other and reported (N=1,200), and 2. "tissue NC" - liquid biopsy reported, but tissue not completed (NC) (N=2,389). Frequencies of on-label alterations and reasons for tissue NC were analyzed. TAT was quantified as the difference between date of sample received and reported and analyzed with an unpaired t-test.

Results: The liquid and tissue cohort identified an on-label alteration in 24% of patients via liquid biopsy and in 33% of patients via tissue, with a concordance >96% in all on-label alterations. Both assays demonstrated fast turnaround time (TAT), but liquid biopsy had a median of 8 fewer days than tissue (6 vs. 14 days) ($p<0.0001$). In the tissue NC cohort, liquid biopsy identified an on-label alteration in 26% of patients, also with a median TAT of 6 days. Reasons for tissue biopsy NC were listed for 31% of patients. The most common reason for tissue NC was quality not sufficient or not meeting internal requirements (QNS) (25.2%). QNS rates largely reduced over time, i.e. <19% after June 2023. Yet, liquid biopsy detected on-label alterations in 21% of patients with tissue QNS samples. Additionally, 2.1% of tissue NC samples were cancelled at the request of the clinician/patient, and liquid biopsy detected an on-label alteration in 24% of such samples.

Conclusions: In this dataset, concurrent liquid and tissue biopsy identified an on-label alteration in ~1/4 of patients with high concordance. Liquid biopsy demonstrated faster TAT than tissue. These data support the updated guideline language and demonstrate that concurrent testing captures the greatest number of on-label alterations with faster time to results, which is especially important given risk of tissue QNS. Additionally, there are other alterations detected by these assays that provide prognostic information and opportunities to enroll patients in clinical trials that may expand actionability of test results.

EP.06D.04 Prognostic Value of Variant Allele Frequency in Circulating Tumor DNA for Survival Outcomes in Metastatic Non-Small Cell Lung Cancer

A. Peleg, R. Paredes de la Fuente, S. Lichtman, J. Gomez, D. Doroshow, F. Hirsch, R. Veluswamy, T. Marron, N. Rohs, C. Smith, C. Rolfo, Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: Through the analysis of plasma circulating tumor DNA (ctDNA), liquid biopsy has emerged as a non-invasive method of identifying tumor-derived somatic mutations, serving as an adjunct to tissue genotyping. Variant allele frequency (VAF) of ctDNA is a measure of the proportion of ctDNA molecules harboring specific tumor-derived mutations within a genetic locus. This study focuses on the prognostic potential of ctDNA VAF to predict survival outcomes in patients with metastatic non-small cell lung cancer (NSCLC). By examining the association between ctDNA VAF levels and patient survival, we aim to assess the utility of ctDNA VAF as a non-invasive prognostic biomarker in metastatic NSCLC.

Methods: Our retrospective study included patients at a single center who underwent liquid biopsies using the Guardant360 platform between January 2018 and March 2024. Eligible patients were those with confirmed non-small cell lung cancer (NSCLC) via tissue biopsy and metastatic disease identified on imaging. We collected demographic data, including age at diagnosis, race, ethnicity, smoking status, the presence of brain metastasis at diagnosis, and histologic sub-type. Analysis of ctDNA VAF was done utilizing Guardant360 liquid biopsy reports. Alterations with a VAF greater than 40% were excluded to omit potential germline mutations, focusing instead on somatic mutations. For each individual patient, we added the VAF of each somatic mutation to obtain the total VAF in that particular patient. Patients were then stratified into two separate groups based on total VAF levels, defined as either high (≥1%) or low (<1%) total VAF. Overall survival (OS) data were subsequently gathered. To assess survival outcomes, we employed Kaplan-Meier curves and Cox proportional hazards models, adjusting for relevant covariates.

Results: Our analysis included 293 patients, of whom 214 had a reported VAF, revealing 62 (28.9%) patients with a low VAF (mean VAF of 0.4%) and 152 (71.03%) with a high VAF (mean VAF of 16.5%). Demographic comparisons between the two groups showed no significant imbalance between either group. We observed a statistically significant difference in OS rates. Patients with a high VAF (n=74) exhibited a median OS of 5.16 months, whereas those with a low VAF (n=24) demonstrated a more favorable median OS of 10.25 months (p-value < 0.01). Adjusting for variables such as smoking history, brain metastasis presence, and cancer histology through the Cox proportional hazards model revealed a lower hazard ratio for death in patients with a low VAF (HR: 0.485, 95% CI: 0.289 to 0.814, p<0.01). A subsequent sub-analysis, which included only patients who received systemic therapy, immunotherapy, or targeted therapy, reaffirmed these findings, with median OS rates of 9.0 months for high VAF and 10.5 months for low VAF patients (p-value = 0.02).

Conclusions: Our study demonstrates an association between high VAF level in ctDNA and shorter OS among patients with metastatic NSCLC. Our findings highlight the potential role for utilizing ctDNA VAF as a prognostic biomarker. Further studies are needed to assess the benefit of integrating analysis of ctDNA VAF into clinical practice to better predict patient outcomes and tailor treatment plans.

EP.06D PATHOLOGY AND BIOMARKERS - CTDNA
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06D.05 The Prognostic Role of the Dynamic Changes in the Plasma ctDNA Levels in Advanced NSCLC after IO Initiation: A Meta-Analysis

G. Koronakis[1], N. Syrigos[1], M.S. Kamaratou[1], A. Koronaki[1], D. Grapsa[1], K. Thomopoulou[2], K. Syrigos[1], [1]National and Kapodistrian University of Athens, Athens/GR ,[2]HYGEIA hospital, Athens/GR

Introduction: Studying the dynamic changes in ctDNA concentrations via liquid biopsy in the peripheral blood of patients with advanced NSCLC receiving immunotherapy constitutes a new and highly promising biomarker. Unfortunately, the primary research in that field is plagued by methodological variability, thus limiting its capability of producing solid conclusions. The current study stands as a systematic review and meta-analysis of the present-day literature, aspiring to elucidate the prognostic importance of the longitudinal kinetics of the ctDNA concentration in the peripheral blood of patients with advanced NSCLC shortly after immunotherapy initiation.

Methods: A systematic review of the current literature (written in English) was performed via certified and international databases (PUBMED, Scopus, Web of Science, Cochrane Library, ClinicalTrials.gov) until September 2023. The Hazard Ratio (HR) from articles (approved based on pre-specified criteria) was recorded and used to assess the correlation between the reduction in ctDNA concentration with median disease-free survival (mDFS) and the median overall survival (mOS, primary endpoint) and the median disease-free survival (mDFS, secondary endpoint) in patients with advanced NSCLC receiving immunotherapy.

Results: 17 studies with 1437 patients were selected. Reduced concentration of ctDNA three to twelve weeks after immunotherapy initiation was positively correlated with a statistically significant improvement in the median OS [Hedges q = 0,32, OR = 1.79 - 95% CI (1.39 - 2.26), p < 0.001] and the median DFS [Hedges q = 0,26, OR = 1.60 - 95% CI (1.24 - 2.10), p < 0.001]. Further statistical analysis, performed in the patients' subgroup that completely eradicated ctDNA levels from peripheral blood, showcased a similar statistically significant benefit in the mOS [Hedges q = 0.26, OR = 1.60 - 95% CI (1.04 - 2.43), p = 0.03], and a (non-statistically significant) benefit in the mDFS [Hedges q = 0,31, OR = 1.76 - 95% CI (1.27 - 3.97), p = 0,17]. Absence of consensus regarding the precise cut-off values for properly defining the ctDNA concentration reduction (complete vs. partial reduction, different accepted percentage changes in the case of partial reduction) was noted.

Conclusions: The longitudinal study of ctDNA concentration in the peripheral blood of patients with advanced NSCLC receiving immunotherapy can provide valuable prognostic information. However, conducting prospective multicentre studies with strict methodological planning and joint consensus on any possible grey areas is required for this biomarker to become a clinical reality.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06E.01 Preexisting CD153+CD4+ T Cells Cause Lung Specific Toxicity via Type 3 Immunity without Kidnapping Efficacy in Immunotherapy

Z-X. Rong[1], S-C. Ma[1], Z-P. Xu[1], Y-C. Ruan[1], X-T. Cai[1], W. Wei[2], Z-Y. Dong[2], [1]Southern Medical University, Guangzhou/CN ,[2]Nanfang Hospital, Southern Medical University, Guangzhou/CN

Introduction: Temporal and spatial unpredictability, and ligature with efficacy represent two puzzles about immune-related adverse events (irAEs) of immune checkpoint blockade (ICB) in cancers. Immunotherapy-related pneumonitis (IRP) often causes cessation of ICB and even death. However, the understanding of IRP is still in its infancy.

Methods: Single-cell RNA sequencing (scRNA-seq) was employed to profile 6 samples of paired PBMC at baseline and grade 2-3 IRP from three patients. Candidate genes were identified, followed by validation with a pan-organ irAEs cohort and an IRP cohort. Analysis of real-world pharmacovigilance big data, TCGA, flow cytometry, and Genotype-Tissue Expression Project (GTE-x) were performed to investigate the roles of candidate genes in IRP. Biological functions of candidate phenotype were determined by pathways enrichment. Three independent ICB cohorts were applied to evaluate the effect of candidate genes on ICB efficacy.

Results: Conjoint scRNA-seq analysis of our own and two external cohorts identified CD153 as a predictor of IRP, whose expression was exclusively on CD4+ T cells. Pre-existing CD153+CD4+ T cells forecast toxicity after ICB specifically in lungs, rather than in other organs. Integrative analysis of pharmacovigilance big data with TCGA, and GTE-x also revealed a significantly positive relationship between IRP and CD153, with the same observed on CD30, ligand of CD153. Furthermore, flow cytometry of in vitro stimulated primary splenocytes confirmed up-regulated CD30 levels upon immune activation. Further scRNA-seq analysis of CD4+ T cells identified a proinflammatory subpopulation expressing high levels of CD153 and canonical markers of type 3 immunity, which mainly shaped autoinflammatory disorders. Levels of CD153 or CD30 did not interfere with ICB efficacy in three independent ICB cohorts.

Conclusions: Preexisting CD153+CD4+ T cells might be a bonafide predictor of ICB toxicity specifically in lungs, while blockade of CD153 or type 3 immunity might be a feasible intervention uncoupling ICB toxicity and efficacy.

EP.06E.02 Integrated Analysis of Prognosis and Immune Characterization of COMMD3 In Lung Squamous Cell Carcinoma

J. Wu, Hangzhou Cancer Hospital, Hangzhou/CN

Introduction: The copper metabolism MURR1 domain protein (COMMD) has been known to play roles in tumorigenesis, progression and metastasis in tumor cells. However, the characters of COMMD3 in lung squamous cell carcinoma (LUSC) are still unclear.

Methods: The transcription level of COMMD3 was analyzed using TCGA database, and the value of COMMD3 in distinguishing LUSC from healthy people was analyzed via ROC analysis. Human Protein Atlas database was used to display the immunohistochemistry results of COMMD3. The prognostic value of COMMD3 was analyzed using Kaplan-Meier (KM) analysis. Via R software 'rms' package, the nomogram was developed to predict the 1, 3, 5-year progression free interval (PFI) and disease specific survival (DSS). Limma package in R software was used to analyze the COMMD3 expression-correlated differentially expressed genes (DEGs). The Gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analysis were performed via ClusterProfiler package. The relationship between COMMD3 and immune infiltration was analyzed via GSVA package.

Results: The COMMD3 was found to be significantly upregulated in LUSC than that in normal lung tissues, and the AUC was 0.731 for distinguishing LUSC from healthy people. The high level of COMMD3 was significantly associated with better prognosis including PFI and DSS. Nomograms were developed to predict PFI and DSS in LUSC patients. In addition,the 207 DEGs including 161 up-regulated genes and 46 down-regulated genes were found, and the first five up-regulated genes (AMER2, SOX1-OT, PNMA5, ADGRG7, DEFA5) and down-regulated genes (TKTL1, AC105177.1, SPANXB1, TGM6, GPHB5) were displayed. The COMMD3 expression was correlated with immune cells infiltration, Tcm cells were the most negatively correlated with COMMD3 (r=-0.221, p<0.001) and T helper cells were the most positively correlated with COMMD3 (r=0.228, p<0.001).

Conclusions: COMMD3 may have important roles in immune infiltration and may serve as a prognostic biomarker in LUSC patients.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06E.03 Body Composition and Inflammation Index-Based Nomograms to Assess the Outcomes of Patients with NSCLC Receiving Chemoimmunotherapy

Q. Fang, S. Yang, J. Yu, W. Li, F. Wu, S. Ren, J. Shi, F. Zhou, Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University Medical School Cancer Institute, Tongji University School of Medicine, Shanghai/CN

Introduction: It has been debatable about impact of body composition on the outcome of chemo-immunotherapy in advanced non-small cell lung cancer(NSCLC). This study sought to explore the predictive value of pretreatment CT-derived body composition indices, inflammatory indices and nutritional indices evaluated by peripheral blood in patients with advanced NSCLC treated with chemo-immunotherapy, so as to identify vulnerable patients for improving outcomes for these patients.

Methods: Patients with NSCLC receiving chemo-immunotherapy between March 2017 and March 2019 were included in this retrospective analysis. Nomograms were created using LASSO Cox regression. The concordance index (C-index), calibration plots, decision curve analysis (DCA)were used to evaluate the nomograms' performance.

Results: According to LASSO regression, systemic immune-inflammation index (SII), platelet to lymphocyte ratio (PLR), prognostic nutrition index (PNI), visceral Adipose Index (VAI), total Adipose Index (TAI), skeletal muscle density (SMD) were screened out as interfering factors for PFS, while SII, VAI, SMD, sarcobesity were significantly associated with OS. The C-index for the nomograms of PFS and OS were 0.668 and 0.753, respectively. The calibration curves indicated excellent agreement between the predicted and actual survival outcomes of 6- and 9-month PFS and 12- and 18-month OS. Patients with sarcobesity had worse OS (20.233m,95%CI 15.221-25.246) compared to non-sarcobesity patients (36.833m, 95%CI 10.392-63.275, P < 0.001), while the difference was not reflected in patients classified according to sarcopenia. Subsequent analysis revealed that patients with high SII, high VAI and low SMD had worst PFS and OS than patients with low SII,low VAI and high SMD (PFS:HR 6.012,95% CI 2.681-13.484, P<0.001; OS:HR 16.903,95% CI 5.314-53.763, P<0.001).

Conclusions: Increased sarcobesity index was risk factor for survival outcomes, while sarcopenia was not. A comprehensive analysis of body composition (visceral adipose index:VAI and skeletal muscle index: SMD) and inflammation index (SII)may contribute to prognostic stratification of patients with advance NSCLC receiving chemo-immunotherapy as first-line.

EP.06E.04 Insight Into the Significance of CD8+ Tumor-Infiltrating Lymphocytes in Lung Adenocarcinoma

K. Shiomi, M.I. Ichinoe, S. Hayashi, D. Sonoda, Y. Kondo, S. Tamagawa, Y. Sugiyama, S. Mitushashi, M. Naito, M. Mikubo, M. Shirasawa, Y. Nakahara, T. Sato, K. Naoki, Y. Murakumo, Y. Satoh, Kitasato University School of Medicine, Sagamihara-shi/JP

Introduction: Although there are great expectations regarding the use of tumor-infiltrating lymphocytes (TILs) to predict effects of immunotherapies and prognosis, knowledge about TILs remains insufficient for clinical application. In this study, we focused on CD8+ T cells, which are the most promising candidate biomarker among TILs, and investigated the clinical significance of CD8+TILs in lung adenocarcinoma (LAC) with a more objective method using a digital pathology scoring software program.

Methods: Among patients who underwent surgical resection of LAC in 2011-2017, those with pathological stage IB-III were immunohistochemically studied to evaluate CD8+TILs in the tumor stroma. The impact of CD8+TILs on relapse-free survival was analyzed with Kaplan-Meier survival analysis and multivariate analysis using a Cox proportional hazards model/Fine-Gray model. Furthermore, we examined the association between the number of CD8+TILs in the tumor stroma and the efficacy of immune checkpoint inhibitors (ICIs) in patients who received ICIs at the time of postoperative recurrence using swimmer plot.

Results: The multivariate analysis showed that large and intermediate numbers, but not small numbers, of CD8+TILs in the tumor stroma may be related to a more favorable prognosis (large vs. small: HR, 0.66; 95% CI, 0.36-1.20, P=0.17; intermediate vs. small: HR, 0.70; 95% CI, 0.39-1.23, P=0.21). However, an exploratory study showed that even among groups with intermediate to large number group of CD8+TILs, there is population with poor prognosis. The swimmer plots showed that the larger number of CD8+TILs in the tumor stroma tended to be associated with the better progression-free survival (PFS) and overall survival (OS).

Conclusions: Our study provided partial but important information on the significance of CD8+TILs in LAC. To use CD8+TILs as biomarkers, in addition to the number of CD8+TILs, it seemed necessary to assess the functional status of CD8+TILs. Therefore, we need to identify the molecules indicating dysfunctional CD8+ T cells and to establish a simplified pathological detection method of them.

EP.06E.05 Is Diffusion-Weighted Imaging Able to Indicate Pathological Response in NSCLC after Neo-Adjuvant Immuno-Chemotherapy?

D. Kifjak[1], H. Prosch[1], M. Hochmair[2], G. Langs[1], S. Pochepnia[1], A. Korajac[1], B.H. Heidinger[1], R-I. Milos[1], M. Hacker[1], L. Beer[1], [1]Medical University of Vienna, Vienna/AT ,[2]Klinik Floridsdorf, Vienna/AT

Introduction: About one third of non-small cell lung cancer (NSCLC) patients show an excellent histopathological response to neo-adjuvant immuno-chemotherapy leading to better prognosis. Nonetheless, this leaves two third non-complete responders raising the need for reliable markers to predict treatment response. Preliminary studies using advanced multiparametric MRI parameters were effective in predicting histopathological response. These parameters, however, are not included in routine MRI protocols. Therefore, the aim of our study was to evaluate whether standard care MRI using diffusion-weighted imaging (DWI) can discriminate between complete pathological response (cPR) and non-cPR.

Methods: This study is part of a large prospective single-center study which enrolled 14 (5 male, 9 female) operable NSCLC patients who received three cycles of neo-adjuvant immuno-chemotherapy. Images were obtained with a 3 T MR scanner including a DWI sequence within six weeks prior to surgery. Tumor lesions >1 cm were included in the analysis. Three independent readers defined regions of interest on the apparent diffusion coefficient (ADC) map. The histological results were retrieved from patients' records. Patients were assigned to either cPR or non-CPR groups. The median of measured ADC values was recorded and the differences between cPR and non-cPR groups were evaluated using an unpaired T-test.

Results: Six patients had a cPR and eight patients a non-cPR, respectively. Both, minimal and average ADC values did not show any statistically significant differences between cPR and non-cPR (median_min: 628.5 (IQR 307.5), median_ave: 1174 (IQR 507.5) and (median_min: 546.5 (IQR 263), median_ave: 1126 (IQR 352)), p= 0.796; p= 0.393 (Figure 1). The tumor size was not significantly different between the two groups (median: 29mm (IQR 20) vs. 37mm (IQR 24)), p=0,415.

Conclusions: The preliminary results of our pilot study indicate that ADC does not discriminate between cPR and non-cPR in operable NSCLC after neo-adjuvant immuno-chemotherapy.

EP.06E.06 Elucidating the Interplay Between Oncogenic Fusions and the Tumor Immune Microenvironment in Lung Adenocarcinoma

X. Chen, B. Wang, J. Zhang, Foshan Hospital of Traditional Chinese Medicine, Foshan/CN

Introduction: In non-small cell lung cancer, particularly in lung adenocarcinoma, fusion mutations of driver genes were associated with a higher degree of malignancy. The patients with fusion mutations tended to be more prevalent in later stages of tumor development, correlating with a higher rate of lymph node metastasis, vascular invasion, or an increased likelihood of brain metastases. Although targeted therapy was the preferred treatment for lung cancer driven by fusion mutations, with ALK rearrangements showing less benefit from PD-1/PD-L1 inhibitors, an open stance was maintained towards immunotherapy for other fusion-driven mutations (such as ROS1, RET, NTRK, etc.). Therefore, research into the immune microenvironment of tumors driven by fusion mutations warranted further exploration.

Methods: Tumor samples from lung adenocarcinoma patients with oncogenic fusions (N = 21) and non-targetable mutations (N = 21) were analyzed. The formalin-fixed, paraffin-embedded slides, they were stained using the Opal multiplex immunohistochemistry (mIHC) Detection Kit (Akoya), targeting 11 markers in two seven-color panels. Tumor and stromal areas were identified by cytokeratin (CK) and DAPI staining. Results, showing immune cell percentages of total cells, provided insights into cell subpopulation distributions in tumor and stroma.

Results: In patients with oncogenic fusions, ALK rearrangements constituted 47.62% (n=10), RET rearrangements accounted for 19.05% (n=4), and NRG1 rearrangements made up 14.28% (n=3). The remaining fusions, including ROS1, FGFR1, FGFR3, and BRAF, each represented a single case. In the population with oncogenic fusions, there were no statistically significant differences in the distributions of all 13 immune cell subpopulations within tumor and stromal areas. This consistency was maintained even when specifically examining the ALK rearranged subgroup, with no significant differences found between the areas. However, in the population with non-targetable mutations, the proportions of CD68+/CD163- macrophages, PD-1+ cells, and CD20+ cells were significantly lower in the tumor areas compared to the stromal areas (p=0.018, p=0.021, and p=0.00014, respectively). Comparing the immune microenvironments of the oncogenic fusion population to those with non-targetable mutations, an interesting finding was that CD56 dim NK cells were more abundant in the tumor areas of the oncogenic fusion group (p=0.0035). Furthermore, FoxP3+ cells were more concentrated in both tumor and stroma areas in the oncogenic fusion group (p=0.0059 and p=0.033, respectively).

Conclusions: In patients harboring oncogenic fusions, the immune cell landscape exhibits uniformity across both tumor and stromal regions, particularly in those with ALK rearrangements. This stands in stark contrast to patients with non-targetable mutations, where specific immune cells are notably less abundant within tumor environments. Significantly, the oncogenic fusion cohort demonstrates an increased presence of CD56 dim NK cells and FoxP3+ cells, indicating unique immunological profiles distinct from those observed in non-targetable mutations.

EP.06E.07 Geospatial and Molecular Characterization of Tumor Immune Cell Infiltration in NSCLC

T. Faith, A. Hulbert, R. Nguyen, M. Pasquinelli, F. Weinberg, University of Illinois College of Medicine at Chicago, Chicago/IL/USA

Introduction: Non-small cell lung cancer (NSCLC) is the leading cause of cancer mortality worldwide. Molecular testing has identified an increasing number of NSCLC associated genes, but their exact roles are not well understood. Examining tumor immune cell infiltration as a function of altered RNA expression and a patients' residential address can help characterize both the tumor-immune interface and environmental effects that may contribute to genetic changes and treatment response in NSCLC. We hypothesize that tumor immune infiltration in NSCLC is related to altered RNA expression secondary to residential environmental factors.

Methods: RNA sequencing was performed by TEMPUS labs on patients with NSCLC at a single academic institution (UI Health) and residential zip codes were collected on all patients and used to explore the relationship between tumor immune infiltration and altered RNA expression.

Results: 144 NSCLC FFPE tumor samples were studied. We found that a number of genes were highly associated with increased tumor immune cell infiltration (figure 1). Additionally, we found that tumor immune cell infiltration patterns differed depending on a patient's geospatial region (zip code).

Conclusions: Our study suggests altered RNA expression likely impacts tumor immune infiltration in NSCLC or vice versa. Initial findings warrant further investigation into the specific genes and environmental factors contributing to altered immune landscapes within NSCLC tumors and their potential relationship to treatment efficacy. Future studies are needed to elucidate the complex interplay between genetics, environment, and immune response in NSCLC progression and treatment outcomes.

EP.06E.08 Clinical Significance of JPH4 and Correlation with the Immune Microenvironment of Lung Adenocarcinoma

L. Tang[1], J. Feng[2], T. Wang[3], Y. Liu[2], [1]Affiliated Hospital of Nantong University, Nantong/CN ,[2]Affiliated Hospital of Nantong University/Brown University Rhode Island Hospital, Nantong/CN ,[3]Henan Cancer Hospital, Henan/CN

Introduction: To investigate the expression of JPH4 in lung adenocarcinoma, its correlation with clinicopathologic features and its potential prognostic significance, as well as its regulation of the tumor microenvironment.

Methods: Based on TIMER and GEPIA databases, we analyzed the differences in JPH4 expression in lung adenocarcinoma and paracarcinoma tissues, which were validated by immunohistochemistry (IHC), Western blot, and RT-qPCR. Differences in overall survival between high and low JPH4 expression groups and correlation with clinical information were analyzed using TCGA database. Cox proportional risk regression analysis showed independent prognostic significance of JPH4. GSEA enrichment analysis of JPH4 was performed to explore its potential biological functions and mechanisms. The role of JPH4 in regulating the immune microenvironment of lung adenocarcinoma was also explored based on the TIMER database and immune infiltration algorithms such as ssGSEA and ESTIMATE. The relationship between JPH4 and common immune checkpoints was also analyzed.

Results: TIMER and GEPIA databases showed that the expression of JPH4 was significantly lower in lung adenocarcinoma, and IHC, Western blotting and RT-qPCR experiments confirmed that the expression of JPH4 in lung adenocarcinoma tissues was also significantly lower than that in Para cancerous lung tissues. Based on public databases and clinical samples, survival analysis showed that high expression of JPH4 was associated with favorable prognosis of lung adenocarcinoma; secondly, there were significant differences in the expression of JPH4 in different clinical stages, and the higher the T and stage, the more downregulated the expression of JPH4 was. Cox multifactorial analysis showed that JPH4 could be used as an independent favorable prognostic factor for lung adenocarcinoma (HR=0.634, P=0.03). JPH4 mRNA expression was significantly positively correlated with the degree of immune cell infiltration, and deletion of JPH4 copy number at the arm level decreased the degree of immune cell infiltration. JPH4 was also significantly positively correlated with immune checkpoints.

Conclusions: JPH4 was significantly downregulated and associated with poor prognosis in lung adenocarcinoma. The mRNA level of JPH4 affected the microenvironmental homeostasis of lung adenocarcinoma and mediated an increase in the level of anti-tumor immune cell infiltration, such as CD8+ T cells, which inhibited the development of lung adenocarcinoma. It suggests that JPH4 is an independent prognostic protective factor and is associated with anti-tumor immunity in lung adenocarcinoma and can be used as a prognostic marker.

EP.06E.09 Spatial Multiomics Analysis Reveals AT2 Cells Inhibit B Cells of TLS in Pre-invasive Lung Adenocarcinoma after Neoadjuvant Immunotherapy

W. Wang, S. Cheng, K. Chen, H. Li, Peking University People's Hospital, Beijing/CN

Introduction: The incidence of multiple primary lung cancers (MPLCs) is increasing gradually, especially multiple subsolid nodules (SSNs). In addition to surgery, other treatments such as immunotherapy combined with chemotherapy are not effective for multiple SSNs, and the mechanism is unknown. Here, we conducted spatial multi-omics analysis to explore molecular characteristics that influence immunotherapy efficacy.

Methods: We performed whole exome sequencing, transcriptome sequencing, and imaging mass cytometry (IMC) testing for all resected lesions of a 61-year-old MPLC patient. There were four pulmonary lesions, among which the primary nodule (PT) was solid, and the rest were SSNs. After neoadjuvant immunotherapy, PT and right lower paratracheal lymph nodes (R4LN) had reached pathologic complete response (pCR); however, SSNs including two minimally invasive adenocarcinoma (MIA) and one atypical adenomatous hyperplasia (AAH), were unresponsive and remained stable in size.

Results: HE staining revealed the presence of multiple tertiary lymphoid structures (TLSs) in all nodules, implying that therapeutic response also occurred within the SSNs. Genomics and transcriptomics showed that SSNs harbored more copy number alterations and significantly involved in cell-substrate adhesion pathway, indicating genomic instability and immune evasion related to worse immune response. Multiplexed IMC for functional metaclusters displayed there was no significant difference in CD20-labeled TLS among different responding lesions, while AT2 cells were significantly enriched in SSNs. Further analysis of the spatial cell neighborhood (CNs) showed nonresponding SSNs hold higher AT2 positive niche (CN2) and responding nodules enriched AT2 negative CN (CN8), suggesting AT2 cells play a key immunosuppressive role by interacting with surrounding cells. Analysis inside and outside TLS found that mature B cells in TLSs and AT2 cells outside TLSs had accordant spatial distribution, which further proved that inhibitory effect of AT2 on B cells in TLSs resulting in poor immunotherapy effect. Our previous single-cell sequencing results reconfirmed that AT2 interacts more strongly with B cells in nonresponding nodules and exerts immunosuppressive effects via MIF ligands. In addition, other therapeutic clusters and interactions were also revealed, such as memory T cells appear to play a positive role in immune efficacy.

Conclusions: We provide a new insight into the immunosuppressive function of AT2 cells on B cells within TLS in the case of poor immune response of SSN lesions, bringing new targets for multiple SSNs treatment.

Keywords: Multiple primary lung cancers, Tertiary lymphoid structures, Cellular interaction

EP.06F.01 Survival Benefits of NGS in Advanced Lung Adenocarcinoma Vary by Populations and Timing of Examination

P-H. Lee, Y-H. Huang, K-H. Hsu, T-Y. Yang, J-S. Tseng, Taichung Veterans General Hospital, Taichung/TW

Introduction: Despite the widespread application of next-generation sequencing (NGS) in advanced lung adenocarcinoma, its impact on survival and the most suitable timing for the examination remains uncertain. Our study aimed to analyze the impact of mutation-targeted treatment following NGS examination on survival, considering different populations and various timing of examination.

Methods: This retrospective hospital-based cohort study screened advanced lung adenocarcinoma patients who underwent tissue or liquid NGS testing between December 2018 and January 2024. Patients were followed up until death or the end of the study (29 Feb 2024). We categorized these patients into four groups according to the timing of NGS examination: Group 1: treatment-naïve, upfront NGS; Group 2: Treatment-naïve, exclusionary EGFR/ALK/ROS1; Group 3: post-treatment, no known EGFR/ALK/ROS1; Group 4: known driver mutation and post-tyrosine kinase inhibitor treatment.

Results: A total of 528 patients who underwent NGS examination were screened. After exclusion 104 patients (not of advanced lung cancer, and histology indicating non-lung adenocarcinoma), 424 patients with advanced lung adenocarcinoma (tissue biopsy 211 and liquid biopsy 213) were included. There were 128, 126, 90, and 80 patients in Group 1, 2, 3, and 4, respectively. In Group 1, 2, 3, and 4, targetable mutations were identified in 76.6%, 49.2%, 41.1%, and 33.3% of the patients, respectively ($P < 0.001$). Mutation-targeted treatments were applied in 68.0%, 15.1%, 27.8%, and 22.5% of the patients, respectively ($P < 0.001$). In each group, the top two most frequently detected targetable mutations were: Group 1 (EGFR 54.7%, ALK 6.3%); Group 2 (METex14 skipping or METamp 13.5%, HER2 mutation 13.5%); Group 3 (EGFR 21.1%, HER2 mutation 7.8%); Group 4 (EGFR T790M 13.6%, MET amplification 11.1%). Patients receiving mutation-targeted treatments exhibited significantly longer overall survival (OS), with a median of 59.9 months, compared to those not receiving such treatments, who had a median survival of 43.1 months (aHR 0.54 [95% CI 0.37-0.79], $P = 0.001$). However, the survival benefits varied between the four groups, with the profoundest benefit among the treatment naïve upfront NGS population (Group 1, not reached [NR] vs. 40.4 months, $P = 0.028$). The median OS for patients with mutation-targeted treatments was also significantly longer among Group 2 patients (19.2 vs. 12.4 months, $P = 0.049$). The median post-NGS survival for patients receiving mutation-targeted treatments were numerically longer than those without treatments in Group 3 (49.9 vs. 38.1 months, $P = 0.684$) and Group 4 (NR vs. 19.3 months, $P = 0.377$).

Conclusions: Our research shows that the proportion and types of targetable mutations identified through NGS testing as well as the survival benefits vary among different populations and timing of examination. However, regardless of when the examination takes place, individuals who are identified with targetable mutations and undergo mutation-targeted treatments tend to experience longer survival compared to those who do not undergo such treatment.

EP.06F.02 Enhancing Clinical Utility: Oncomine Dx Target Test Augments Biomarker Detection in Advanced Non-Small-Cell Lung Cancer

T-J. Kim, C.K. Park, J.U. Lim, T.J. An, H.K. Yoon, The Catholic University of Korea, Seoul/KR

Introduction: Despite considerable progress in targeted therapies for advanced non-small-cell lung cancer (NSCLC), there remains controversy surrounding the integration and utilty of single gene tests alongside next-generation sequencing (NGS) within clinical diagnostic platforms for identifying critical biomarkers. This controversy arises primarily from tissue limitations and reimbursement challenges.

Methods: In this study, we investigated the impact of integrating the upfront Oncomine Dx Target Test (ODxTT) and single gene tests (SGTs) into routine clinical practice by analyzing data before and after implementation. Our analysis compared the performance of ODxTT alongside concurrent SGTs in cohort 1 (n = 458) over a three-year period. We juxtaposed this evaluation with SGTs exclusively conducted during the same timeframe in cohort 2 (n = 1850) and against cohort 3 (n = 1968), which exclusively underwent SGTs before the integration of ODxTT over the identical period. Notably, all cohorts underwent single gene tests targeting EGFR, ALK, and ROS1 mutations.

Results: The ODxTT demonstrated a success rate of 98.7% (452/458), while single gene tests in both cohort 2 and cohort 3 achieved a success rate of 99.7%. Among the cases analyzed with ODxTT, 51.5% (233 out of 452) revealed clinically significant biomarkers. Notably, ODxTT detected clinically significant genes not identified by simultaneous SGTs, including RET fusion (1.3%), BRAF V600E (1.7%), MET exon 14 skipping (1.1%), as well as KRAS G12C (2.8%), PIK3CA (2.4%), ERBB2 (0.4%), FGFR3 (0.2%), NRAS (0.4%), and MAP2K1 (0.4%). Both EGFR and ROS1 were evaluated by ODxTT and SGT. The incidence of EGFR exon 20 insertion (0.9%) tended to be higher, while ROS1 (4.8%) was significantly more frequently detected in ODxTT compared to SGT. However, the rates of EGFR T790M and rare EGFR variants did not exhibit significant differences between ODxTT and SGT.

Conclusions: The integration of ODxTT alongside single gene tests provides significant additional information without compromising the performance of single gene tests. With ODxTT's high success rate, this integration expands the scope of comprehensive therapeutic strategies for advanced lung cancer.

EP.06F.03 Analysis of Copy Number Variations of MET, EGFR and ERBB2 Genes in a Lung Cancer Patient Series: Comparison of FISH with NGS

S. Buglioni, C. Ercolani, A. Di Benedetto, I. Terrenato, A. Palange, G. Americi, P. Visca, E. Pescarmona, G. Minuti, L. Landi, F. Cappuzzo, IRCCS, Regina Elena National Cancer Institute, ROMA/IT

Introduction: Amplification of MET, EGFR and ERBB2 genes plays an important role in the development of non-small-cell lung cancer (NSCLC), which can also mediate primary and secondary resistance to EGFR tyrosine kinase inhibitors. Fluorescence in situ hybridization (FISH) is the standard method for detecting gene amplification and Next Generation Sequencing (NGS)-based molecular profiling of advanced NSCLC patients is strongly recommended by scientific agencies including the European Society for Medical Oncology (ESMO). Meanwhile, the role of NGS in identifiyng amplification remains uncertain. The aim of this study was to validate and compare Copy Number Variations (CNVs) of MET, EGFR and ERBB2 genes detected by a NGS 50 genes panel with those obtained by a FISH assay.

Methods: Thirthy-four patients diagnosed with advanced NSCLC were included. FISH and NGS were conducted. In this study MET, EGFR and ERBB2 were classified as positive by FISH (FISH positive) when Gene Copy Number (GCN) was >5, regardless of chromosome signals. A chromosomal copy number >4 was considered polysomy. MET, EGFR and ERBB2 were classified as positive by NGS when CNV was ≥4. The Oncomine Precison Assay gene panel and the Genexus integrated sequencer (Thermo Fisher Scientific) were used for NGS analysis.

Results: Thirteen of 34 patients (38%) were FISH MET positive: 11 (85%) had polysomy and 2 (15%) were dysomic. Twenty-one FISH negative cases were all dysomic. NGS accurately identified the MET gene status in all dysomic cases, while 82% of patients in the polysomic FISH scenario had a CNV <4 by NGS analysis. Thirty-eight percent of cases were FISH EGFR positive: 31% had polysomy and 69% were dysomic. Notably 67% of discordant cases between FISH and NGS fell into the polysomic FISH setting, as observed for the MET gene. Regarding ERBB2 gene, 26% of cases were FISH positive. We observed that, unlike the MET and EGFR genes, only a few cases were polysomic (15%) and all showed a FISH GCN >5 and a NGS CNV <4. The row agreement between FISH and NGS for MET, EGFR and ERBB2 genes was: 74%, 79% and 78% respectively.

Conclusions: In the dysomic context, the two methods agree in detecting both normal and alterated gene copy number cases. Since polysomy cannot be detected by NGS using a 50 genes diagnostic panel, observed discrepancies are confined to the polysomic setting. It is important to point out that, unlike conventional gene amplification assessment, which considers positivity by ratio (GCN/chromosome CN), we only evaluated positivity by GCN, which is why the high percentage of positive FISH cases reported in this study. Finally, FISH remains the gold standard for differentiating polysomy from normal copy number and amplification.

EP.06F.04 The Characteristics of Plasma Sample NGS Analysis in the Detection of Lung Cancer Driver Genes

K. Uchibori[1], L. Siew-Kee[2], R. Ebina-Shibuya[3], E. Miyauchi[3], M. Hanibuchi[4], Y. Nishioka[4], Y. Tambo[5], S. Yano[5], J. Sugisaka[6], Y. Kawashima[6], T. Shoji[7], J. Sakakibara-Konishi[7], M. Nishio[1], Y. Nakamura[8], [1]The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo/JP ,[2]Cancer Precision Medicine Center, Japanese Foundation for Cancer Research, Tokyo/JP ,[3]Tohoku University Graduate School of Medicine, Sendai/JP ,[4]Graduate School of Biomedical Sciences, Tokushima University, Tokushima/JP ,[5]Faculty of Medicine, Institute of Medical Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa/JP ,[6]Sendai Kousei Hospital, Sendai/JP ,[7]Hokkaido University, Sapporo/JP ,[8]National Institute of Biomedical Innovation, Health and Nutrition, Osaka/JP

Introduction: The detection of driver mutations is critically important in the treatment of non-small cell lung cancer (NSCLC), with tissue specimens being usually used for this purpose. However, the use of plasma specimens is rapidly gaining popularity. The advantages of NGS analysis using plasma samples include the low invasiveness and convenience of sample collection, as well as a shorter turn around time. Nonetheless, it remains unclear to what extent plasma samples can substitute tissue specimens. We investigated the characteristics of plasma sample NGS analysis in clinical practice through a multicenter institutional study.

Methods: A prospective observational study was conducted at six facilities in Japan, enrolling cases suspected of advanced lung cancer planned for pathological diagnosis and driver gene screening. Clinical presentation, presence of driver mutations, their detection methods, and PD-L1 status were extracted from electronic medical records. At the time of diagnostic procedure, 14 ml of blood was collected for RNA and DNA extraction from plasma and subsequent NGS analysis using the Genexus system and Oncomine Precision Assay, all performed automatically.

Results: From June 2022 to September 2023, 303 cases were registered, with 261 cases diagnosed as NSCLC. The median age was 71 years (range 26-90), with 164 males and 97 females. Performance status (PS) 0/1/2/3/4: 81/149/21/5/4, never smoker/current or former: 69/162, cStage I/II/III/IVA/IVB/recurrence/unknown: 15/7/52/66/108/13/1, Adenocarcinoma/Squamous/NSCLC: 183/54/24. Driver mutations were present/absent/unknown in 116/134/11 cases, with/without tissue specimen multiplex driver gene testing in 214/47 cases (table). EGFR and ALK mutations were detected in 13 and 3 cases, respectively, without multiplex testing. PD-L1 <1%/1-49%/≥50%/Unknown: 69/76/72/44. For cases excluding post-surgical recurrence, the median time from specimen collection to confirmation of genetic aberration was 20 days (range 5-744). NGS analysis of plasma samples was available in 226 cases, with the identical driver mutations detected in 60 cases as in tissue specimens. The agreement was less frequent for fusions than mutations (55.9% vs 34.8%). In 7 cases, driver gene were detected only in plasma samples. The median time from plasma sample collection to result was 8 days (range 2-26).

Conclusions: Detection of driver genes through NGS analysis of plasma samples was possible in approximately half (51.7%) of the cases compared to tissue samples, but results were obtained more quickly. Only a few driver mutations were detected exclusively in plasma samples.

EP.06F.05 External Quality Assessment Results of Third-party NGS Laboratories in China for the Detection of Rare Mutations in Lung Cancer

Q. Yao[1], X. Zhou[1], L. Zhang[2], W. Fang[2], J. Ma[3], Q. Ye[4], C. Wu[5], Y. Hou[6], L. Dong[7], D. Su[8], Y. Tang[9], Z. Wang[10], H. Meng[11], [1]Fudan University Shanghai Cancer Center, Shanghai/CN ,[2]Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou/CN ,[3]The Affiliated Cancer Hospital of Zhengzhou University and Henan Cancer Hospital, Zhengzhou/CN ,[4]The First Affiliated Hospital of University of Science and Technology of China (USTC), University of Science and Technology of China, Hefei/CN ,[5]Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai/CN ,[6]Zhongshan Hospital, Fudan University, Shanghai/CN ,[7]Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai/CN ,[8]Cancer Research Institute, Zhejiang Cancer Hospital, Hangzhou/CN ,[9]West China Hospital, Sichuan University, Chengdu/CN ,[10]Beijing Hospital, National Center of Gerontology, Beijing/CN ,[11]Harbin Medical University Cancer Hospital, Harbin/CN

Introduction: Rare mutations in lung cancer are defined as mutations with an incidence of less than 5%, and multiple variant forms have been identified. With the progress of drug development, the reliable detection of rare mutations has attracted more and more attention from clinical practice. For third-party laboratories with NGS platforms, their ability to detect rare mutations in lung cancer needs to be tested.

Methods: Ten standards were prepared from cell lines, including variants with drugs approved or in the late development stage such as EGFR 20 insertion, MET 14 skipping, MET amplification, HER2 mutation, RET fusion, and BRAF mutation, and titrated to 5% mutation frequency to mimic tissue samples (5 samples) and 1% mutation frequency to mimic plasma samples (5 samples). The genotype of each standard was verified by ddPCR and NGS, respectively. The registration is freely open to all third-party laboratories with NGS platforms. Standards were distributed to laboratories that signed the informed consent and were required to be tested using NGS methods to report functional variants of EGFR, MET, HER2, RET, and BRAF. The results of each laboratory were evaluated and scored based on variant calling and interpretation. Laboratories were considered to pass the assessment if all variants were reported accurately in all mimic samples.

Results: A total of 30 third-party laboratories participated in this evaluation, of which 29 reported valid results. Regarding the variant calling, the pass rate of mimic tissue samples was 72.4% (21/29), and that of mimic plasma samples was 65.5% (19/29). For various targets, participants had the highest error rate for detection of MET amplification (tissue 5/29 including 1 false positive, plasma 6/29), followed by MET 14 skipping (tissue 2/29, plasma 4/29, all errors occurred in the mutation: c.2888-35_2888-17del), and relatively lower error rates for RET fusion (tissue 1/29, plasma 2/29) and BRAF mutation (tissue 1/29, plasma 1/29); both EGFR and HER2 mutations were accurately identified. Regarding variant interpretation, the percentage of laboratories with no error in mimic tissue samples was 55.2% (16/29) and that of mimic plasma samples was 51.7% (15/29). Participants had the highest error rate for the interpretation of MET amplification (11/29), followed by BRAF mutations (5/29), EGFR 20 insertion (3/29), MET 14 skipping (2/19), HER2 mutations (2/29), and RET fusions (1/29). Overall, the number of laboratories that reported no error in both variant calling and interpretation was 13 in mimic tissue samples and 11 in mimic plasma samples.

Conclusions: Overall, about 70% of participants passed the assessment for the detection of rare mutations in lung cancer. Results showed that more calling errors were found in variant types of amplification and fusion, and mimic plasma samples than mimic tissue samples. In addition, only about 50% of participants received a perfect score on variants interpretation, suggesting laboratories should pay more attention to the update of the interpretation database. In conclusion, third-party NGS laboratories must participate in quality assessment regularly.

EP.06F.06 Concurrent DNA and RNA NGS Testing to Characterize Rare Fusions in Advanced NSCLC Patients

J.L. Feliciano[1], L. Gai[2], Z. Rivers[2], A.J. Hockenberry[2], H. Nimeiri[2], K.A. Beauchamp[2], R. Ben-Shachar[2], J. Guinney[2], J. Patel[3], [1]Johns Hopkins University School of Medicine, Baltimore/MD/USA ,[2]Tempus AI, Inc., Chicago/IL/USA ,[3]Northwestern University Feinberg School of Medicine, Chicago/IL/USA

Introduction: Therapy directed at molecular actionable variants improves survival in patients with advanced NSCLC and is standard of care. Although there is familiarity with common fusion targets such as ALK, ROS1, and RET, there is growing evidence that emerging rare fusion targets in advanced NSCLC are likely promising targets for matched therapies that also may lead to improved outcomes. Here we report the prevalence of rare BRAF, NRG1, and EGFR fusions, and their co-occurrence with other NCCN recommended actionable NSCLC targets, using concurrent DNA-RNA NGS testing in a real-world patient cohort.

Methods: Deidentified records were extracted from the Tempus multimodal database, consisting of 5,546 advanced (Stage IIIB-IV) patients with a primary diagnosis of adenocarcinoma NSCLC who underwent solid-tumor testing with both DNA-seq and RNA-seq (Tempus xT and xR assays, respectively). Concurrent RNA-NGS and DNA-NGS pipelines were run separately and manually reviewed as part of the Tempus clinical workflow. Fusion partners with the highest read support are reported. NCCN-recommended testing for targeted variants analyzed included ALK, RET, ROS1, and NTRK1/2/3 fusions, MET exon 14 skipping variants, EGFR pathogenic single nucleotide variants (SNVs)/indels (e.g., exon 19 deletions), BRAF V600E, and KRAS G12C.

Results: The overall prevalence of rare fusions in our cohort was 0.6% (n=32): 0.3% (n=18) BRAF, 0.2% (n=9) NRG1, and 0.1% (n=5) EGFR. Fifty percent (n=16) of the rare fusions were detected solely by RNA-seq—including 66.7% (n=12) of BRAF, 22.2% (n=2) of NRG1, and 40% (n=2) of EGFR. Of the 32 NSCLC patients with rare fusions detected, 31% (n=10) harbored an NCCN NSCLC guideline-recommended co-variant. This frequency varied by fusion type: 50% (9/18) of BRAF, 11% (1/9) of NRG1, and 0% of EGFR. All patients with a BRAF fusion and NCCN-recommended co-variant (n=9) had EGFR exon 19 deletions [n=9]; two of these patients had additional T790M variants. Seven out of 8 patients with co-occurrence of BRAF fusions and EGFR SNV/indels, with concomitant treatment information, were treated with EGFR-targeted therapy prior to sequencing, implicating the clonal emergence of BRAF fusions as a possible resistance mechanism to anti-EGFR therapy.

Conclusions: Concurrent DNA-RNA NGS improved the detection rate of emerging rare fusion variants in advanced NSCLC patients compared to DNA-NGS, doubling the number of rare fusions detected and eligible patients that may benefit from targeted therapy. Importantly, co-occurrence of rare fusions and EGFR classical activating mutations in patients pre-treated with anti-EGFR therapy suggests a potential resistance mechanism and consideration of upfront, dual mutation, targeted treatment to improve outcomes. Further clinical studies are needed to validate the best treatment options for these patients with rare fusions.

EP.06F.07 Comparison Between EGFR PCR Alone and NGS with Gene Fusion PCR for Detecting Oncogenic Driver Alteration in Thai NSCLC Patients

L. Thamlikitkul[1], B. Ngamvirojcharoen[1], N. Poungvarin[1], [1]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok/TH

Introduction: Targeted therapies have significantly improved the prognosis for NSCLC patients with oncogenic driver alterations. Thus, molecular testing results are essential to determining the systemic treatment option. EGFR mutation is the most common altered oncogene among Thai NSCLC patients. This mutation can be detected using PCR and NGS. While EGFR PCR offers faster turnaround time (TAT) and lower costs, it does not identify other less common actionable alterations. Conversely, NGS provides comprehensive mutation detection at the expense of longer TAT and higher costs. Since EGFR TKI is the only targeted therapy reimbursable for all Thai patients, EGFR PCR alone is the most commonly used test for NSCLC patients in Thailand. Here, we evaluated the concordance of EGFR test results between PCR and NGS and analyzed their TAT. Moreover, we examined the benefit of concurrent NGS and gene fusion-panel PCR to detect other actionable alterations.

Methods: We conducted a retrospective analysis of 155 NSCLC patients who were treated at Siriraj Hospital and Siriraj Piyamaharajkarun Hospital in Bangkok, Thailand, from November 2021 to August 2023 and had concurrent EGFR PCR, gene fusion-panel PCR, and targeted NGS results. Tumor tissue was tested using cobas EGFR mutation test v2, Idylla GeneFusion assay, and QIAact Lung DNA UMI Panel or QIAact AIT UMI Panel (sequenced with Qiagen GeneRead NGS system) or QIAseq targeted DNA-AIT panel (sequenced with MiSeq), respectively. Data were analyzed using SPSS Version 29.0.2.0.

Results: EGFR PCR detected EGFR mutation in 53.5% (83/155) of cases (Table). All EGFR PCR-positive cases were also detected by NGS, although one case with exon 19 deletion was identified as L747P by NGS. Among EGFR PCR-negative cases, NGS detected uncommon EGFR mutations (L861R/L833F, A750FS, G779F) in 3 cases. Cohen's kappa coefficient for EGFR mutation detection between PCR and NGS was 0.96 [95%CI 0.917 to 1.005]. NGS and gene fusion-panel PCR recognized an additional 37/155 cases (23.9%) harboring other oncogenic driver alterations (Table). Median (SD) TAT for EGFR PCR, gene fusion-panel PCR, and targeted NGS were 7.1 (3.8), 7.1 (3.8), and 19.0 (4.7) days, respectively.

Conclusions: Sensitizing EGFR mutation was found in 49.7% of NSCLC patients in Thailand. EGFR test results were highly concordant between PCR and NGS. However, NGS had a 12-day longer TAT compared to EGFR PCR. Gene fusion-panel PCR and NGS identified an additional 11.6% of patients harboring actionable alterations who may benefit from FDA-approved targeted therapies.

EP.06F.08 Cancer Evolution Analysis for Lung Carcinomas with Multiple Driver Mutations

K. Seto, K. Masago, H. Iwashimizu, O. Noritake, T. Matsui, N. Sakakura, Aichi Cancer Center Hospital, Nagoya/JP

Introduction: Driver gene mutations in non-small cell lung cancer (NSCLC) are generally considered to be mutually exclusive. However, rare cases have been reported in which multiple driver mutations within the same tumor or multiple tumors within the same individual harbor different driver mutations.

Methods: In this study, we report on NSCLC cases in which multiple driver mutations were detected in the same individual and discuss their clinical significance and implications for treatment using RNA sequencing for cancer evolution analysis.

Results: Case 1. 77-year-old male, suspected N1 lung adenocarcinoma, planned neoadjuvant therapy. However, surgery and adjuvant therapy using EGFR TKI were planned because the biopsied specimen harbored the EGFR L858R mutation. Left upper lobectomy was performed, and postoperative pathology was T3N0M0 adenocarcinoma and showed EGFR L858R+KRAS G12C. Adjuvant therapy with CDDP+VNR was performed after surgery. Case 2. 59-year-old female, 8mm ground-glass opacity in the right middle lobe, suspected early-stage lung cancer, and the tumor was resected. Pathological diagnosis was adenocarcinoma, pT1aN0M0, pStageIA1, with EGFR Exon19del + KRAS G12C in the same tumor. Case 3. 72-year-old male, cT1N1M0 squamous cell carcinoma. Neoadjuvant therapy was performed. However, the tumor was unresectable due to PD. EGFR G810S mutation + G857W mutation + KRAS G12C mutation were detected in a biopsied specimen from the tumor. Case 4. 64-year-old female, multiple adenocarcinomas, pT1cN0M0, pStage IA3, underwent right upper lobectomy. EGFR Exon19 del mutation + MET Exon14del mutation was detected in different tumors in the same individual.

Conclusions: Genetic mutations in lung cancer have traditionally been considered mutually exclusive. However, owing to the recent increased use of multiplex testing using next-generation sequencing (NGS), lung cancer cases with multiple driver mutations in the same individual have been reported. In this study, we reviewed NSCLC cases positive for multiple driver gene mutations based on NGS testing and discussed the mechanisms of driver mutations on cancer development and progression. We reported a cancer evolution analysis of four lung cancer cases with multiple driver mutations.

EP.06F.09 Epidemiological Profile of Patients with Non-Small Cell Lung Cancer Treated at Oncologia D' or Bahia from January 2018 to December 2022.

M.D. Loula[1], M.I.d.S. Cesar[2], C.S.d.R. Baldotto[3], E. Mascarenhas[4], [1]Hospital São Rafael, Salvador/BR ,[2]Escola Bahiana de Medicina e Saúde Pública, Salvador/BR ,[3]Oncologia D´or, Rio de Janeiro/BR ,[4]Oncologia D´or, Salvador/BR

Introduction: Lung cancer is one of the most prevalent tumors in the world and responsible for the highest mortality among neoplasms. Its epidemiological and anatomopathological profile has been changing over the years and with the advancement of precision medicine, the treatment of non-small cell lung cancer is no longer based solely on chemotherapy and has become more individualized and with based on specific molecular changes and programmed death ligand-1 (PDL-1) status. The presence of driver mutations varies according to different geographic regions and patient profiles, therefore, it is extremely important to define the epidemiological and molecular profile of patients treated in our region.

Methods: After approval by the local ethics committee, a retrospective, cross-sectional, descriptive study was carried out, collecting data from medical records of patients diagnosed with non-small cell lung cancer undergoing treatment in at least one of the units of the Oncologia D´or Bahia from January/2018 to December/2022.

Results: The medical records of 422 patients were analyzed and 160 patients were included in the study. The patients were mostly women (56.25%), smokers (55%) and with an median age on the diagnostic of 67,5 years. The most common histology was non-squamous (81.25%), followed by squamous cell carcinoma (15.6%). Around 50% of the patients were diagnosed in EC IV and most patients did not have an indication for curative thoracic surgery at the time of diagnosis (59.3%). Regarding molecular characteristics, 15% of patients had PDL1 between 1-49%, 10% had high PDL1 expression (≥50%) and 17.5% of patients were PDL1 negative. The most common driver mutations found in the studied population were EGFR (23%), followed by ALK (3.75%), MET (3.1%), KRAS G12C (2.5%), ROS-1 (2.5%) , HER-2 (1.25%) and RET (0.62%). Statistical analysis is being carried out to evaluate the correlation between age, smoking, site of metastases and the presence or absence of PDL1 expression and driver mutations.

Conclusions: The data found in this work is similar to other Brazilian studies on the epidemiological profile of patients with non-small cell lung câncer.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06G.01 Prognostic Significance of Purinergic Receptor- and Ectonucleotidase- Expression in NSCLC Tumor Cells and Stroma

S. Prozmann, K. Kurowski, F. Kind, B. Passlick, P. Bronsert, S. Schmid, University Medical Center Freiburg, Freiburg im Breisgau/DE

Introduction: Purines are not merely a source of energy but have the ability to act as extracellular signal molecules and activators of immune cells. Therefore, the purinergic system regulates the antineoplastic immune response and plays an important role in the development and progression of solid tumors. The purinergic system is controlled by two key players: purinergic receptors and ectonucleotidases. This study investigates how their expression in the tumor cells and the tumor microenvironment interferes with the tumor biology and prognosis.

Methods: In this retrospective cohort study, we analyzed tumor tissue samples of 142 patients diagnosed with NSCLC. Tissue microarrays were created and stained immunohistochemically to detect the expression of the purinergic receptors and ectonucleotidases. A histochemical H-score was used to divide the tissue into high and low expressing phenotypes in tumor cells and stroma. These phenotypes were then correlated with the clinical and pathological data. The purpose of this study was to determine whether the expression of the purinergic receptors P2X4/P2X7 and the ectonucleotidases CD39/CD73 correlates with the overall (OS) and progression-free survival (PFS). As a secondary endpoint it was analyzed how different expression patterns influence clinical parameters like tumor size, pack years, metastasis or SUVmax.

Results: Higher levels of the purinergic receptor P2X4 in the tumor cells correlated with a prolonged PFS (p=0.036; HR 2.11 [1.05-4.22]). Similarly, an overexpression of CD39 on the malignant cells is a favorable prognostic factor (PFS p=0.007; HR 1.89 [1.19-2.99]; OS p=0.009; HR 2.08 [1.2-3.61]). On the contrary, a lower expression of CD73 in the tumor is associated with an extended PFS (p=0.004; HR 0.43 [0.24-0.77]) and OS (p=0.035; HR 0.55 [0.32-0.96]). In the stroma cells, higher levels of both CD39 (p=0.008; HR 2.2 [1.23-3.94]) and CD73 (CD73 p=0.03; HR 3.58 [1.13-11.4]) correlate significantly with a longer PFS. An association between an overexpression of CD39 and a smaller tumor size (p=0.016), a lower SUVmax(p=0.035) and a reduced tendency to metastasize (p=0.006) and relapse (p=0.003) could be observed.

Conclusions: This study demonstrates a correlation of the purinergic system with the tumor biology and survival in NSCLC. Notably, ectonucleotidases can be identified as factors with a high prognostic and biological impact. From a pathophysiological point of view, an overexpression of CD39 and low CD73 levels lead to higher concentrations of purinergic metabolites and activate the antineoplastic immune response. This mechanism explains the observed impact on PFS and OS of the respective expression patterns.

Keywords: NSCLC, purinergic system, immunotherapy

EP.06G.02 Profiling the Metastatic Potential of Non-Small Cell Lung Cancer Patients Based on TP53 Classification

J. Lu[1], Y. Lou[2], R. Zhong[2], J. Sun[2], H. Zhong[2], B. Han[2], [1]Shanghai Chest Hospital, Shanghai Jiaotong University School of Medicine, Shanghai/CN ,[2]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN

Introduction: Non-small cell lung cancer (NSCLC) is known for its high metastatic potential, yet the precise genetic profile metastatic potential remains elusive. In this study, our aim was to characterize the molecular features contributing to metastatic potential, focusing on TP53 classification.

Methods: In the present study, 2736 treatment-naïve patients diagnosed with stage I to stage IV NSCLC were enrolled. Tissue samples from targeted lesions underwent processing using next-generation sequencing (NGS) technology. The NGS platform utilized was a commercially available gene panel comprising 68 cancer-related genes (Burning Rock Biotech, Guangzhou, China). We performed an analysis to assess the association between TP53 mutation frequency and histopathological types to characterize potential molecular features. Additionally, we investigated the disparities between TP53 (-) and TP53 (+) patients. Finally, we initiated the development of a TP53-based classification system for metastatic features.

Results: In this cohort, 48% of patients were diagnosed with invasive LUAD, 11% with LUAD, 9% with LUSC, and the remaining patients were diagnosed with other pathological subtypes, including microinvasive LUAD (7%), LUAD in situ (6%), and LUAD + LUSC (3%). Among patients diagnosed with LUAD in situ, microinvasive LUAD, and invasive mucous LUAD, the percentages of TP53 (+) patients were 1%, 6%, and 13%, respectively, defining them as the TP53 (Low) cohort. For those diagnosed with acinar invasive LUAD, invasive LUAD, and LUAD, the percentages of TP53 (+) patients were 30%, 32%, and 55%, respectively, defining them as the TP53 (Medium) cohort. Patients diagnosed with poorly differentiated LUAD, metastatic LUAD, and LUAD + LUSC had percentages of TP53 (+) patients at 68%, 70%, and 74%, respectively, defining them as the TP53 (High) cohort. Finally, patients diagnosed with non-keratinized LUSC, keratinized LUSC, and LUSC had percentages of TP53 (+) patients at 78%, 89%, and 95%, respectively, defining them as the LUSC cohort. These findings suggest that pathological subtypes with high malignancy harbor a higher frequency of TP53 mutation. Further analysis indicates that specific TP53 co-mutations, such as RB1+ATM, KRAS+STK11, EGFR+KRAS, contribute to increased metastatic potential in LUAD, while specific TP53 co-mutations, such as PIK3CA+CDKN2A, FGFR1+FGF4, contribute to increased metastatic potential in LUSC.

Conclusions: Collectively, this study suggests that differences in driver gene patterns potentially play a crucial role in increasing metastatic potential. The acquisition of tumor metastatic potential may be closely associated with these co-mutations, particularly in TP53 (+) patients.

EP.06G.03 Newly WHO Reporting System for Lung Cytopathology: Reproducibility Test of the Diagnosis

Y. Minami[1], A. Takenaka[2], K. Hiroshima[3], A. Yoshizawa[4], R. Haba[5], K. Kawahara[6], Y. Shibuki[7], S. Miyake[8], H. Kakinuma[9], Y. Satoh[10], [1]National Hospital Organization Ibarakihigashi National Hospital The Center of Chest Diseases and Severe Motor & Intellectual Disabilities, Tokai-mura/JP ,[2]National Hospital Organization Osaka National Hospital, Osaka/JP ,[3]Tokyo Women's Medical University, Yachiyo/JP ,[4]Nara Medical University, Nara/JP ,[5]Kagawa university hospital, Miki-cho/JP ,[6]Kobe university graduate school of mediine, Kobe/JP ,[7]National Cancer Center Hospital, Tokyo/JP ,[8]Tokyo medical university hospital, Tokyo/JP ,[9]Kumamoto University Hospital, Kumamoto/JP ,[10]Kitasato university school of medicine, Sagamihara/JP

Introduction: Diagnosis of lung cancer and management of patients requires histological or cytopathological diagnosis. In particular, cytopathological specimens of lung cancer may be collected even when tissue cannot be obtained, and can be used for cytopathological and genetic diagnosis. However, until now, there has been no universal cytopathological category classification for lung cancer. Therefore, the Japanese Lung Cancer Society (JLCS) and the Japanese Society of Clinical Cytology (JSCC) jointly proposed four cytopathological categories: "negative for malignancy," "atypical cells," "suspicious for malignancy," and "malignancy. The WHO Reporting System for Lung Cytopathology in 2022 added "Insufficient/Inadequate/Non-diagnostic" to these four categories and proposed the following five categories: "Insufficient/Inadequate/non-diagnostic", "benign", "atypical ", "suspicious for malignancy," and "malignant". In order to disseminate this classification widely, we evaluated the reproducibility of the category through tutorial, and investigated the issues and problems with the category.

Methods: Forty-two cases were selected from the case that had been collected for previous studies to create this classification, and a diagnostic and tutorial system was created and reviewed through web-based first diagnosis, tutorial, and second diagnosis. Participants were recruited through the website of JLCC and by e-mail. One 100x and one 400x photograph centered on the lesion to be diagnosed in each case was shown. The questions were: 4 choices for the category under the new criteria (benign, atypical, suspicious for malignancy, malignant), 7 choices for the presumed pathological diagnosis (benign tumor, inflammatory change, adenocarcinoma, squamous cell carcinoma, small cell carcinoma, large cell neuroendocrine carcinoma, other), and 4 choices for the first and second decision bases (cell cluster, cytoplasm, nuclei, other). The results were analyzed and compared between first and second diagnosis by t-test using calculating the average number/rate of correct or incorrect answers for 42 cases per participant and for 105 participants per case in both diagnoses. χ-square test was used to identify cases with diagnostic difficulties and cases with high tutorial effect, and to explore the problems.

Results: There were 105 participants with the average number of correct answers by category being 16 (16/42: 38.1%) for the first diagnosis and 20.3 (20.3/42: 48.3%) for the second diagnosis, with a significant increasing ($p < 0.001$). The analysis was divided into seven presumed pathological diagnosis, 105 participants had average number and rate of correct answers of 20.3 (20.3/42:48.3%) in the first diagnosis and 25.1 (25.1/42:59.8%) in the second diagnosis, significantly increasing with $p < 0.001$. The average number/rate of correct answers per case for the 42 cases was 40.2 (40.2/105:38%) in the first diagnosis and 51.5 (51.5/105:49%) in the second diagnosis, which increased significantly ($p=0.0147$). Four cases that were difficult to match even after tutorial and 3 cases that were highly effective in tutorial were presented. The most important basis for diagnosis was nuclear findings in both diagnoses.

Conclusions: It is necessary to educate and disseminate appropriate diagnostic criteria so that this report form can be used accurately. In particular, it is necessary to devise ways to have patients with ambiguous findings, those with poor characteristic morphology correctly diagnosed with cancer.

EP.06G.04 Clinicopathological Differences between EGFR Mutated and EGFR Wild-Type Lung Adenocarcinoma with Papillary Predominant Pattern

E. Goto, T. Taki, K. Nomura, T. Miyoshi, K. Tane, J. Samejima, K. Aokage, M. Nagamine, M. Kojima, S. Sakashita, N. Sakamoto, M. Tsuboi, G. Ishii, National Cancer Center Hospital East Japan, Kashiwa-City/JP

Introduction: We aimed to reveal the clinicopathological differences between epidermal growth factor receptor (EGFR)-mutated and wild-type (WT) lung adenocarcinoma (LUAD) focusing on the predominant subtype.

Methods: This study included 352 with EGFR mutation and 370 with WT patients in consecutive stage I LUAD classified by the predominant subtype, and their clinicopathological characteristics and prognosis were analyzed. Using the Cancer Genome Atlas Program (TCGA) cohort, we analyzed differences in gene expression between EGFR mutation and WT groups. Furthermore, we performed immunohistochemical evaluations for 46 with EGFR mutation and 47 with WT patients in consecutive stage I papillary predominant adenocarcinoma (PPA).

Results: Compared to the PPA with WT [n = 115], those with EGFR mutation [n = 99] exhibited smaller invasive size ($p = 0.03$) and less frequent vessel invasion ($p < 0.01$). However, PPA with EGFR mutation showed significantly worse 5-ys recurrence-free survival (RFS) rates compared to those with WT (70.6% versus 83.3%, $p = 0.03$). Contrarily, no significant differences were observed in other predominant subtypes. In the TCGA cohort, PPA with EGFR mutation tended to show higher expression of galectin-3, which is associated with tumor metastasis and resistance to anoikis, compared to those with WT ($p = 0.06$). Immunohistochemical evaluation revealed that galectin-3 expression was significantly higher in PPA with EGFR mutation than in those with WT ($p < 0.01$).

Conclusions: The prognosis for PPA with EGFR mutation proved to be less favorable compared to that with WT, which might be due to a higher expression level of galectin-3.

EP.06G.05 Molecular Characteristics of Pulmonary Lymphoepithelioma-Like Carcinoma in the Chinese Population

W. Yu, L-z. Kong, K. Li, Shanghai Fourth People's Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Pulmonary lymphoepithelioma-like carcinoma (PLELC) is a rare and distinct subtype of non-small cell lung cancer often with better clinical outcomes than other subtypes. It usually affects young, non-smoking, Asian populations and is associated with Epstein-Barr virus (EBV) infection. The molecular characteristics of PLELC are relatively vague due to its rarity, which may limit the treatment of this rare malignancy.

Methods: We retrospectively studied the Next-generation sequencing (NGS) data (733-gene panel) of tumor tissue specimens from 26 PLELC patients over the past 3 years. All samples were obtained by surgical resection or aspiration biopsy. Microsatellite instability and EBV infection were also detected by NGS.

Results: In 26 PLELC patients performed NGS, the median age was 48.5 years and 69.2% were female. Genomic analysis revealed that 61.5% (16/26) of the patients exhibited gene alterations with no typical driver mutations, predominantly in the form of copy number variations (CNVs, 9/26) and single nucleotide variations (SNVs, 9/26). There was no statistical difference in age between patients with and without gene alterations (median: 48.5 vs 52.5 years,p=0.672, Mann-Whitney U test). Among the genes with copy number gains, the 11q13 amplicon (CCND1/ FGF19/ FGF4/ FGF3) showed the highest frequency (11.5%, 3/26), along with KRAS (11.5%, 3/26) and CCND2 (11.5%, 3/26). SNVs were identified in TP53, CYLD, CBFB, NRAS, AXIN1, PIK3CA, BMPR1A, NFKBIA in 34.6% (9/26) of PLELC patients, in addition to an ATM insertion. No gene arrangement variation was detected. One PLELC patient presented solely with a germline pathogenic deletion mutation in BAP1 which predisposed to various cancers, without any coinciding somatic gene alterations, indicating a possible genetic risk. There were no patients with microsatellite instability (MSI) and 22 patients were found to be positive for EBV.

Conclusions: The study demonstrates a notable frequency of copy number variations at 11q13, KRAS, and CCND2 in PLELC. Exploring the molecular features of PLELC enhances our comprehension of its underlying biology, thereby advancing the diagnosis and precise management of this uncommon malignancy.

EP.06G.06 Molecular Profiling of Separate Primary Non Small Cell Lung Cancers

G. Dutcher, University Hospitals Seidman Cancer Center, Cleveland/OH/USA

Introduction: Reflex NGS testing for all NSCLC tumors is standard at our institution. Tumors with same histological diagnosis and different molecular profiles may be considered separate primary lung cancers.

Methods: Retrospective review of NSCLC cases at our institution with more than one tumor molecular profile report. The molecular profile is an in-house NGS assay detecting DNA and RNA alterations in over 60 genes including known driver mutations (EGFR, ALK fusion, KRAS, MET amplification) and other genes relevant to solid tumors (TP53).

Results: Fifty-five (55) paired specimens with separate molecular profile reports were identified (total of 110 specimens). Adenocarcinoma was the most common histologic diagnosis. Squamous histology was present in 14 pairs, and 5 pairs had discordant histology. At least one alteration in TP53 was detected in 73% of specimens (40/55) and represented the most common alteration. In 15 cases, the TP53 mutations were at different loci. In 18 cases, only one of the paired samples carried a TP53 mutation. KRAS was the next most common alteration, mostly discordant between pairs. 7/55 paired samples had KRAS mutation at the same gene but different loci. Only 4% (2/55) of the pairs had the same KRAS alteration, and also had discordant TP53 alterations.

Conclusions: Molecular profiling with NGS should be performed on multifocal tumors. Most tumors have different molecular profiles despite same histology, suggesting separate primary lung cancers with distinct clonal evolution.

Keywords: molecular profile, NSCLC

EP.06G.08 Clinicopathologic and Molecular Features of SWI/SNF-Deficient Thoracic Tumors

K. Chang[1], J. Feng[1], T. Wang[2], Y. Liu[1], s. lu[3], [1]Affiliated Hospital of Nantong University/Brown University Rhode Island Hospital, Nantong/CN ,[2]Henan Cancer Hospital, Henan/CN ,[3]Brown University Rhode Island Hospital, PROVIDENCE/RI/USA

Introduction: Recently identified subtype known as SWI/SNF (Switch/Sucrose Non-Fermenting) defective tumors has emerged. SMARCA2 and SMARCA4 are two catalytic subunits essential for the function of the SWI/SNF complex. Particularly, inactivating mutations in the SMARCA4 gene result in a loss of expression of the catalytic subunit BRG1 and establish a critical link to tumorigenesis.

Methods: Immunohistochemical, second-generation sequencing technology, and statistical methods were applied to analyze the clinicopathological, and genomic features and prognosis of SWI/SNF-deficient thoracic tumors.

Results: Using the expression of keratin and SMARCA2 as classification criteria, we classified the cases into SMARCA4-deficient non-small cell lung cancers and thoracic SMARCA4-deficient undifferentiated tumors. A minority (15/37) exhibited the common morphological features of highly moderately differentiated adenocarcinomas, which was the same as the 12 cases of isolated deletion tumors in the SMARCA2 gene, and the majority of cases (22/37) exhibited poorly differentiated or undifferentiated morphology. In addition, 10 cases were classified as " thoracic SMARCA4-deficient undifferentiated tumor with rhabdomyosarcoma-like tumor cells, with a few exhibiting epithelioid cell histomorphology. By X-tile, we analyzed the IRS and prognostic correlation of SMARCA4 in 485 cases, with an optimal cutoff value of 5 (P=0.00011). In our study, those with SMARCA4-deficient non-small cell lung cancers demonstrated a better prognosis compared to those with thoracic SMARCA4-deficient undifferentiated tumors (P=0.0219). Furthermore, patients exhibiting moderately to highly differentiated morphology showed improved prognoses (p = 0.0004), as did those who received immunotherapy (p = 0.036. In contrast to SMARCA4-deficient tumors, only one patient of the 12 SMARCA2-deficient tumors with preserved SMARCA4 expression received chemotherapy but had a good prognosis.

Conclusions: SMARCA4 could be a new predictor of lung tumor prognosis.

Keywords: SMARCA4, Thoracic Tumor, SWI/SNF-deficient

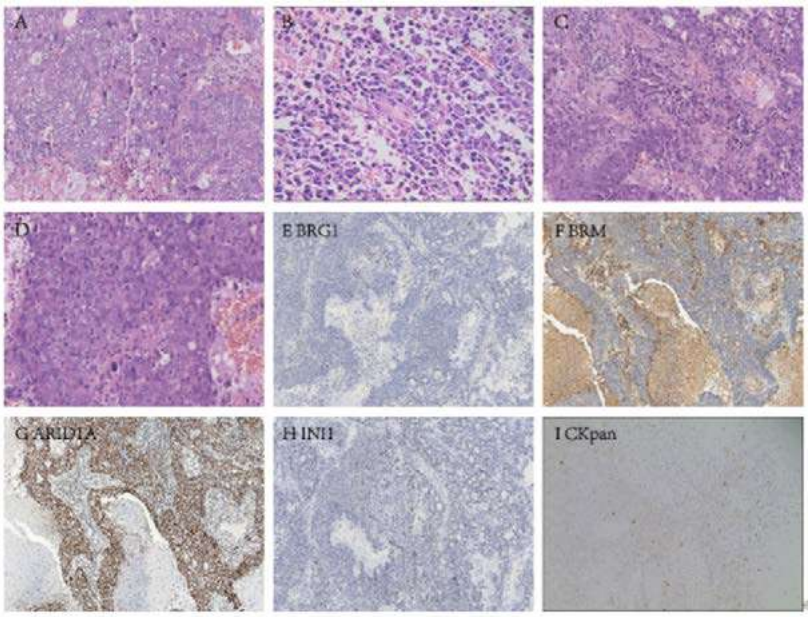

FIGURE 2. Histologic and immunohistologic features of SD-TSTs. The tumor cells were solid or glandular in arrangement, with epithelioid cells, large size, abundant cytoplasm, eosinophilic, and obvious nucleoli. (A) The tumor cells were rhabdoid in shape and some of them were polygonal. (B) Lymphocytic infiltration is seen in the interstitium of the tumor. (C) The nuclei of tumor cells are obvious, with loss of adhesion and pathological nuclear division images easily seen. (D) SMARCA4 expression was negative in tumor cells and positive in the nuclei of the stromal lymphocytes. (E) SD-TSTs showed negative expression of SMARCA2 in the nuclei of tumor cells. (F) Most of the tumor cells were positive for BAF250A in the nucleus. (G) Most of the tumor cells were positive for SMARCB1 in the nucleus. (H) Negative expression or diminished expression of pan-CK. (I)

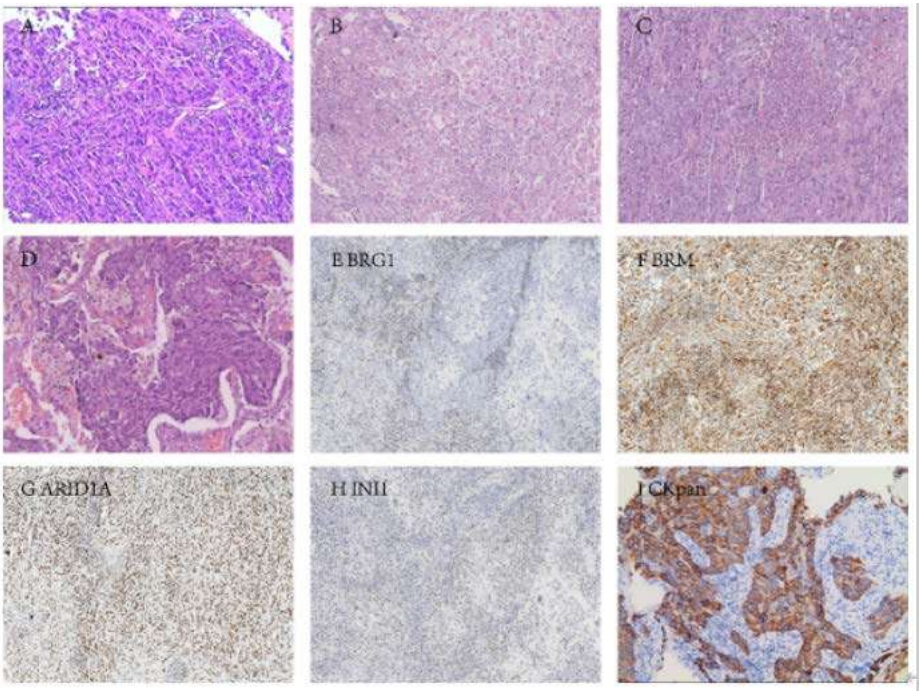

FIGURE 1. Histologic and immunohistologic features of SD-NSCC. The tumor cells were solid and glandular in arrangement, with epithelioid morphology, large cell volume, abundant cytoplasm, and eosinophilic. (A) Classic rhabdoid cells. (B) A large number of lymphocytic infiltrates were seen in the interstitium. (C) Focal clear cytoplasm and vesicular chromatin, pathologic mitosis is easily seen. (D) SMARCA4 expression was negative in tumor cells and positive in the nuclei of the stromal lymphocytes. (E) SD-NSCC tumor cells were positive for SMARCA2 in the nucleus. (F)) Positive for BAF250A in the nucleus of tumor cells. (G) Positive for SMARCB1 in the nucleus of tumor cells. (H) Diffused positive expression for pan-CK (I)

EP.06G.09 Harnessing Real-World Data for Translational Research in Lung Cancer: MD Anderson Thoracic GEMINI Program

J.J. Zhang, H. Tran, L. Hong, H. Li, K. Qin, W. Rinsurongkawong, N. Vokes, X. Le, F. Skoulidis, T. Cascone, S. Hubert, J. Wu, J.J. Lee, L. Byers, D. Gibbons, A. Vaporciyan, J. Heymach, MD Anderson Cancer Center, Houston/TX/USA

Introduction: Lung cancer continues to be the foremost cause of cancer-related fatalities worldwide, with nearly 2 million lives lost each year. The majority of lung cancer patients receive standard-of-care (SOC) treatments. The treatment experiences of these patients including their diagnostic tasting, treatment-related side effects, tumor responses and overall survival, hold valuable information that can inform lung cancer therapy and shape future clinical trials. Unfortunately, this invaluable data is not consistently captured. To maximize the knowledge gained from each lung cancer patient treated at MD Anderson Cancer Center (MDACC), we have initiated the Thoracic GEnomic Marker-guided Therapy INItiative (GEMINI) program.

Methods: Following completion of consent procedures, we systematically gather comprehensive molecular, clinical, and demographic information (>850 data points per patient) from lung cancer patients seeking oncological care at MDACC. These data are meticulously curated by data specialists with specialized training in thoracic oncology. Additionally, optional peripheral blood samples are collected, and any remaining tumor specimens following clinical diagnosis and molecular profiling are carefully stored. During SOC biopsies, additional tissue samples are collected when deemed safe, for patient-derived xenograft models, primary cell lines or banked for translational research projects. Collaborating with information technology experts and data scientists, we are developing a user-friendly electronic medical record (EMR) interface to facilitate accurate and efficient review of molecular biomarkers. Furthermore, we are establishing a pipeline utilizing natural language processing (NLP) techniques, which will transform biomarker data from various sources into structured data.

Results: From 01/28/2014 to 04/04/2024, GEMINI database currently houses comprehensive clinical and molecular data from 12,981 lung cancer patients with prospective collection of 7,673 blood samples and 846 tumor tissues in addition to the remaining diagnostic specimens. Serving as a research platform across MD Anderson and other collaborating institutions, GEMINI has facilitated 120 projects, resulting in 115 impactful publications and 250 meeting abstracts. For instance, GEMIMI has served as the essential platform for a series of studies on Kras co-mutations and the impact of radiomics features on the benefit from immunotherapy in lung cancer patients. Importantly, many of these studies have served as critical rationale for numerous clinical trials that have led to the change of SOC. Additionally, leveraging artificial intelligence, we are implementing a continuous learning system that integrates both molecular biomarkers and clinical data, thereby enhancing the research process, improving data precision, and enabling comprehensive data analysis.

Conclusions: The MDACC Thoracic GEMINI program is a prospective initiative designed to systematically gather, archive, and analyze clinical, molecular, and demographic data from lung cancer patients. Databases like GEMINI serve as invaluable reservoirs of information for lung cancer investigations, contributing to enhanced patient outcomes and propelling advancements in personalized oncology therapy.

EP.06G.10 Comprehensive Analysis of the Clinicopathological Features, Targetable Profle, and Prognosis of Mucinous Adenocarcinoma of the Lung

D. Ueda[1,2], A. Kamigaichi[2], N. Tsubokawa[2], T. Mimae[2], Y. Miyata[2], N. Tatsumoto[1], M. Okada[2], [1]Miyoshi central hospital, Miyoshi-shi, Hiroshima/JP ,[2]Hiroshima university hospital, Hiroshima/JP

Introduction: The clinicopathological or genetic features related to the prognosis of mucinous adenocarcinoma are unknown because of its rarity. The clinicopathological or targetable features were investigated for better management of patients with mucinous adenocarcinoma of the lung.

Methods: We comprehensively evaluated the clinicopathological and genetic features of 60 completely resected mucinous lung adenocarcinomas. Targetable genetic variants were explored using nCounter and polymerase chain reaction, PD-L1 and TTF-1 expression were evaluated using immunohistochemistry. We analyzed the prognostic impact using the Kaplan-Meier method and log-rank test.

Results: Of the 60 enrolled patients, 13 (21.7%) had adenocarcinoma in situ/minimally invasive adenocarcinoma, and 47(78.3%) had invasive mucinous adenocarcinoma (IMA). Fifteen patients (25%) showed a pneumonic appearance on computed tomography (CT). CD74-NRG1 fusion, EGFR mutations, and BRAF mutation were detected in three (5%), four (6.7%), and one (1.7%) patient(s), respectively. KRAS mutations were detected in 31 patients (51.7%). Two patients (3.5%) showed immunoreactivity for PD-L1. No in situ or minimally invasive cases recurred. IMA patients with pneumonic appearance had signifcantly worse recurrence-free survival (RFS) and overall survival (OS) ($p<0.001$). Furthermore, IMA patients harboring KRAS mutations had worse RFS ($p=0.211$). Multivariate analysis revealed that radiological pneumonic appearance was signifcantly associated with lower RFS ($p<0.003$) and OS ($p=0.012$). KRAS mutations served as an unfavorable status for RFS ($p=0.043$).

Conclusions: Mucinous adenocarcinoma had a low frequency of targetable genetic variants and PD-L1 immunoreactivity; however, KRAS mutations were frequent. Pneumonic appearance on CT imaging and KRAS mutations were clinicopathological features associated with a worse prognosis.

Keywords: lung cancer, mucinous adenocarcinoma, KRAS mutation

EP.06G PATHOLOGY AND BIOMARKERS - PATHOLOGY
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.06G.11 Effects of Gut Microbiota and Metabolites on Peritoneal Metastasis of Non-Small Cell Lung Cancer

Y-W. Luo[1], C-G. Liu[1], J. Chen[1], M. Lin[1], [1]The Second Hospital of Dalian Medical University, Dalian, China, Dalian/CN

Introduction: Peritoneal metastasis (PM) is a rare metastasis of non-small cell lung cancer (NCLC), and patients with PM have a poor prognosis. Previous studies have shown that gut microbiota and its metabolites are closely related to lung cancer. At present, the relationship between gut microbiota and its metabolites and PM of NCLC still needs further investigation.

Methods: The study included 17 newly diagnosed NCLC patients and collected their baseline stool samples prior to treatment. Patients were divided into N group and PeM group according to the presence or absence of PM at diagnosis. Metagenomic sequencing and metabolomics detection were performed on fecal samples from the two groups to compare the differences in gut microbiota and metabolites between the two groups, analyze related metabolic pathways, and search for potential biomarkers.

Results: Among the enrolled NCLC patients, 5 patients had PM and 12 patients had no PM. The analysis found that there were significant differences in gut microbiota and metabolites between the two groups. Compared with patients in the group N, the abundance of Dialister, Dialister_succinatiphilus and Lachnospira in the PeM group increased, while the abundance of Parabacteroides_ distasonis and Morganellaceae decreased. In PeM group, metabolites such as 3beta,7alpha-Dihydroxy-5-cholestenoates were up-regulated, while metabolites such as Bilirubin glucuronide and Harderoporphyrin were down-regulated. By using the Kyoto Encyclopedia of Genes and Genomes (KEGG) database to enrich the differential metabolites, it is found that the pathway related to lipid metabolism has the most significant difference, including primary bile acid biosynthesis, biosynthesis of unsaturated fatty acids, fatty acid biosynthesis, fatty acid degradation, etc.

Conclusions: This study shows that there are statistical differences in the gut microbiota and metabolites of NCLC patients with or without PM, which may provide new ideas for the prediction, diagnosis, treatment and prognosis assessment of NCLC patients with PM.

EP.06G.12 The Fibrosis Around the Pulmonary Artery Is Associated with Difficulty in Dissection During Surgery after Systemic Therapy

M. Kawahara[1], J. Ichinose[1], H. Ninomiya[2], Y. Yazaki[1], S. Yoshimine[1], A. Suzuki[1], Y. Matsuura[1], M. Nakao[1], S. Okumura[1], M. Mun[1], [1]Cancer Institute Hospital of Japanese Foundation for Cancer Research, Ariake, Koto-ku, Tokyo/JP ,[2]Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo/JP

Introduction: The number of surgeries after systemic therapy for lung cancer is increasing. The difficulty of dissection of the Pulmonary Artery (PA) is a serious problem. Large vessels and airways in the tumor bed have been reported to develop therapy-related proliferative fibrosis in the surrounding area after systemic treatment. We investigated the correlation between fibrosis around the PA and difficulty in dissection.

Methods: Six patients who underwent anatomical lung resection after systemic therapy for lung cancer were included. The pathologist (H. N.) identified the proximal part of the PA adjacent to the tumor or metastatic lymph nodes in the resected specimen and assessed using hematoxylin and eosin staining and Elastica van Gieson staining. The thickness of the fibrous layer around the PA was measured and its ratio to the thickness of the media was calculated. The association between perivascular fibrotic change and difficulty in dissecting the sheath of the PA during surgery was analyzed.

Results: Of the six patients, two underwent surgery after neoadjuvant therapy (one bilobectomy after pembrolizumab plus chemotherapy and one lobectomy with nivolumab plus chemotherapy) and four underwent surgery as salvage surgery after systemic therapy (three lobectomies after targeted therapy for ALK rearrangement and one lobectomy after targeted therapy for EGFR mutation). The operation time was 214 ± 70 min and the blood loss was 120 ± 130 mL. Complete resection was obtained in all cases. In one case, we could not dissect the PA from the surrounding parenchyma, and we dissected them together using a stapling device. There was no mortality. Pathological CR was observed in two cases after treatment using immune checkpoint inhibitors. Perivascular fibrous layer around the PA was observed in all cases, and its thickness varied between cases. The ratio of the thickness of the fibrous layer to the media was significantly higher in the four cases in which the pulmonary artery sheath was difficult to dissect than in the other two cases. (2.85 ± 1.19 vs. 0.81 ± 0.04, p = 0.042). We did not find a constant association between the type of systemic treatment and the thickness of the fibrous layer.

Conclusions: The fibrosis around the PA was associated with difficulty in dissection during anatomical lung resection after preoperative systemic treatment. Further research is needed to determine whether the fibrosis arised in the tumor bed and whether radiological findings can predict a thickening of the fibrous layer.

EP.06G.13 TP53 Somatic Mutation and its Association with Clinicopathological Parameters and Long-Term Clinical Outcome in Non-Squamous NSCLC Patients

J.P.C. Apolinário, C.C. Avelar, L.L.d.S. Campos, E.M. de Lima, P.H.C. Diniz, Rede Mater Dei de Saúde, Belo Horizonte/BR

Introduction: Remarkable advances in molecular profiling of non-small cell lung carcinoma (NSCLC), a leading cause of global cancer-related mortality, have led to improvements in long-term clinical outcomes. However, a better comprehension of resistance mechanisms in this heterogeneous disease may add benefit to daily practice. Beyond its well-recognized role in carcinogenesis, p53 alterations emerge as an important resistance mechanism and may guide treatment decisions. In this cohort, we aimed to investigate the prevalence of TP53 somatic mutations among non-squamous (ns) NSCLC patients and their association with clinical features and relevant long-term clinical outcomes.

Methods: We retrospectively collected clinicopathological data from advanced nsNSCLC patients whose full molecular panel, including TP53 mutation, was ordered by an assistant oncologist in a Brazilian referral private center between January 2021 and January 2024. Those harboring STK11 and KEAP-1, recognized as resistance mutations, were excluded. Treatment decisions were made according to local practice. The Cox Regression Model assessed their independent association with long-term outcomes, such as progression-free survival (PFS) and overall survival (OS). Shapiro-Wilk tested normality, with significance assumed at $p < 0.05$.

Results: In this cohort, 39 patients were included. The median age at diagnosis was 64.1 years (SD ±11.95), and adenocarcinoma was the predominant histologic subtype (98.0%). CNS (38.0%) and bones (46.0%) were common metastasis sites. Molecular analyses revealed PD-L1 positivity in 56.4%, TMB < 10 in 74.3%, EGFR mutation in 28.2%, ALK translocation in 7.6%, and somatic TP53 mutations in 64.1% of cases. Co-existing TP53 and RAS mutations were found in 15% of patients. Among patients with targetable mutations (n=12), only 41.6% received the recommended treatment upfront, while 58.3% had their treatment transitioned. Considering the entire cohort, PFS was 13.2 months, and OS was 16.3 months. After adjustment for clinicopathological variables, radiotherapy directed to the primary tumor increased the risk of disease progression by 5.6 times (p=0.01). Unusual site metastases and TMB ≥10 were associated with poor OS (3.1 times, p = 0.04, and 6.89 times, p = 0.01, respectively). Regarding molecular parameters, TP53 somatic mutation seemed to be associated with poor OS (OR 1.8), in univariate analysis, among patients with targetable molecular alteration. However, none of the studied molecular variables were independently associated with relevant clinical outcomes in the multivariate model.

Conclusions: This study assessed the nsNSCLC molecular complexity and its possible role in resistance mechanisms. Somatic TP53 mutations were prevalent among this population and may be associated with poor clinical outcomes, but unequivocal evidence could not be demonstrated. Our findings point towards an association between this mutation and poor clinical responses to tyrosine-kinase inhibitors, but not for immunotherapy, suggesting a possible role in resistance mechanisms. However, further investigation is necessary.

EP.06G.14 Discovery of Immune-Related Long Noncoding RNA Signatures in Lung Adenocarcinoma

D. Hu, UCLA, Los Angeles/CA/USA

Introduction: Lung adenocarcinoma (LUAD) represents a significant category of lung and bronchus cancers, categorized under non-small cell lung cancer. Unlike squamous cell lung cancer, LUAD is predominantly observed in younger women, individuals with a history of smoking, and within Asian demographics. It mainly originates from the epithelium of the bronchial mucosa, with a smaller proportion stemming from the mucous glands of the larger bronchi. This study focuses on identifying and assessing immune-related long non-coding RNAs (lncRNAs) as potential prognostic biomarkers in LUAD.

Methods: We downloaded lncRNA expression profiles for LUAD from The Cancer Genome Atlas (TCGA) and immune-related genes from the Immunology Database and Analysis Portal (ImmPort). Pearson correlation analysis was conducted to reveal immune-associated lncRNAs. The TCGA LUAD patient cohort was randomly segregated into training and testing groups. Within the training group, both univariate and multivariate Cox regression analyses identified significant immune-related lncRNAs, subsequently verified through Cox regression, principal component analysis (PCA), and receiver operating characteristic (ROC) analysis in the testing group.

Results: Seven immune-related signature lncRNAs with prognostic significance in LUAD were identified. Both univariate and multivariate Cox regression analyses indicated the risk score derived from our seven-lncRNA model as a significant survival indicator, compared to other clinical-pathological factors (age, gender, stage, N, T). Kaplan-Meier survival analysis showed significantly enhanced overall survival in the low-risk group versus the high-risk group across both training and testing cohorts. ROC analysis revealed the AUCs for 5-year overall survival within the range of 0.81-0.89 for training, testing, and the combined cohorts. PCA further evidenced significant divergence in immune status between the high-risk and low-risk groups.

Conclusions: We established a prognostic model in LUAD based on seven immune-related signature lncRNAs. This model may have clinical significance and could contribute to the advancement of tailored immunotherapy approaches for LUAD.

EP.06G.15 Rapid Immunohistochemistry of Microsatellite Instability Using Non-Contact Alternating Current Electric Field Mixing

K. Imai, H. Nanjo, Y. Wakamatsu, S. Takashima, T. Matsuo, S. Kuriyama, H. Suzuki, R. Demura, H. Iwai, S. Shibano, Y. Minamiya, Akita University Graduate School of Medicine, Akita/JP

Introduction: Tumors caused by failure of the DNA mismatch repair system generally show microsatellite instability (MSI). High-frequency MSI cancers have been shown to be more susceptible to Immuno-Oncology therapies. The aim of this study was to evaluate the clinical reliability of a new rapid immunohistochemistry (IHC) technique for assessing the molecular status intraoperatively, through detection of tumoral deficient mismatch repair protein (dMMR; MLH1, MSH2, MSH6, and PMS2) expression.

Methods: The rapid IHC method uses non-contact alternating current (AC) mixing to achieve more rapid/stable staining within a minimum of 13 min during surgery (Figures 1 and 2). Three deficient mismatch repair (dMMR)-IHC patients (with Lynch syndrome, 16 formalin-fixed paraffin-embedded (FFPE) samples) and 6 dMMR-IHC deficient patients (6 FFPE samples) in our group hospitals were deemed eligible for establishing MSI-IHC protocol. Of 25 patients obtained the MSI result by MSI Analysis System as companion diagnostics between January 2021 and February 2024, the accuracy of the dMMR diagnoses from frozen sections/FFPE of thoracic/pulmonary tumors are compared between the conventional and rapid AC mixing IHC.

Results: The Rapid-IHC protocol was established with primary antibody 10min / secondary antibody 5min (HRP labeled) using AC mixing for all 4 dMMR antibodies. The concordance of MSI-IHCs staining between the conventional and rapid IHC was achieved 100%. dMMR-High FS/FFPE samples (including a patient with pulmonary sarcoma) were wholly matched.

Conclusions: Rapid MSI-IHC with AC mixing could potentially serve as a clinical tool for intraoperative determination of tumor molecular status. AC mixing technology will contribute to improving pathological diagnostic capability through the development of original/innovative rapid IHC.

EP.06G.16 Pleural Fluid EGFR Mutation Testing in 10 Patients with Advanced Lung Adenocarcinoma with Pleural Effusion

Y. Kim, Y.J. Lee, J.H. Ha, Y.J. Hong, Incheon St. Mary's hospital, Incheon/KR

Introduction: Many studies have documented the utility of malignant pleural effusion (MPE) for detecting EGFR mutations. Reports suggest that MPE supernatant samples could serve as a viable alternative liquid biopsy specimen. These samples contain a higher concentration of tumor-derived DNA compared to plasma samples and are easier to obtain from patients with advanced lung cancer who have MPE.

Methods: From June 2023 to March 2024, we collected pleural fluid to detect EGFR mutations from 11 patients who were suspected to have MPE at Incheon St. Mary's hospital. Among these, we retrospectively reviewed the EGFR positivity, types of mutations, level of circulating free DNA (cfDNA) in pleural fluid, serum, and tissue samples from 10 patients who were diagnosed as lung cancer with MPE.

Results: EGFR mutation tests were performed on the pleural fluid of a total of 11 patients, among whom 10 were diagnosed with lung cancer and 1 was diagnosed with pleural metastasis from colon adenocarcinoma. Among a total of 10 patients with lung cancer and MPE, 2 patients were negative for EGFR mutations in all three specimens-tissue, serum, and fluid. Four patients were positive in all three specimen types. Two patients had positive results in both tissue and pleural fluid, one patient was positive in tissue and serum only, and in one case, the patient was in the terminal stage, and EGFR mutation test could not be performed. Among the four patients who were positive for EGFR mutations in all three types of samples, 2 were found to have the Exon 19 deletion mutation, and 2 had the L858R mutation. In all these 4 patients, cfDNA levels in pleural fluid were found to be higher than those in serum. Notably, among those with the L858R mutation, one patient, who was diagnosed with progression disease due to newly developed MPE, tested negative for the T790M mutation in serum but positive for T790M in the pleural fluid EGFR mutation test.

Conclusions: Testing for EGFR mutations in MPE is efficient and reliable due to the accessibility of samples, quality of specimen considering higher concentration of tumor derived DNA, and it is especially useful for identifying resistance mutations such as T790M in patients with MPE progression disease. It holds promise for guiding treatment decisions in advanced lung cancer. There is anticipation for future work to increase the sample size or conduct prospective studies on this subject.

EP.06G.17 A Clinical Conundrum: Lung Cancer in the Breast

J.A. Nakata[1], I. Whittall[2], M. Russo[3], J. Friedberg[1,4], S. Su[1,4], [1]Fox Chase Cancer Center, Philadelphia/PA/USA ,[2]Thomas Jefferson University School of Medicine, Philadelphia/PA/USA ,[3]Temple University, Philadelphia/PA/USA ,[4]Temple University Health Systems, Philadelphia/PA/USA

Introduction: Most patients with lung cancer present with advanced disease. Rarely, lung cancer can metastasize to the breast and be confounded with primary breast carcinoma. To date, only case reports or small series have been published on this topic. Our study provides the largest comprehensive review of the current literature to highlight common key clinical and histopathologic features in this unique patient population.

Methods: A search using the PubMed database for studies published from 1962 to 2024 was performed using the following keywords: "lung cancer", "non-small cell lung cancer", "lung adenocarcinoma", "lung squamous cell", "small cell lung cancer", "lung neuroendocrine", "metastasis to breast", "metastasize to breast", "breast", "metastasize". A secondary search using the references of relevant studies was performed for additional articles. The inclusion criteria consisted of studies of lung cancer with breast metastasis. Articles were excluded for any of the following criteria: 1) lung cancer with breast metastasis was not described, 2) abstracts without full texts were available, 3) insufficient clinical data reported, 4) non-original cases, 5) study was not published in a peer-reviewed journal, or 6) study was written in a non-English language.

Results: Our literature search produced 3268 unique articles. 359 full manuscripts were reviewed based on inclusion and exclusion criteria. 84 manuscripts were included comprising 146 total patients. A summary of patient demographics, clinical disease characteristics, tumor immunohistochemistry and biomarker profile, disease management, and clinical outcomes is described in Table 1. Adenocarcinoma was the predominant cancer type in the breast. 57/114 (50%) of patients had metachronous metastatic breast disease with an average identification time of 24 months from diagnosis of lung primary. The most common site of additional metastatic disease was bone in 32/75 patients (42.7%). Biomarker analysis was consistent with lung adenocarcinoma in most patients; however, markers typically associated with non-lung sites, namely breast and gastrointestinal origin, were positive in a minority of patients. 26/103 (25.2%) were initially managed as primary breast cancer with 24/26 patients undergoing breast resection. Excisional thoracic surgery was performed in 11/49 (22.4%) of patients, which included lobectomy, pneumonectomy, segmentectomy, and decortication. The overall mortality was 58.9%, with an average follow-up of 14.9 months.

Conclusions: Patients with lung cancer that have breast metastasis may be at high risk for misdiagnosis and inappropriate treatments including unnecessary surgery. Our study demonstrates that careful clinical consideration and thorough histopathologic evaluation is critical for accurate management and optimal prognosis for metastatic lung cancer.

EP.06G.18 Lung Cancer with Pleural Dissemination is Potentially a Non-Shedding Tumor

H. Hong[1], J-T. Zhang[1], Y. Zhang[2], M. Song[2], X. Gao[3], H-J. Li[1], S-R. Cui[4], S. Dong[1], Y-L. Wu[1], W-Z. Zhong[1], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN ,[2]Geneplus-Beijing Institute, Beijing/CN ,[3]State Key Laboratory of Microbial Resources, Institute of Microbiology, Chinese Academy of Science, Beijing/CN ,[4]Operational Research, Department of Industrial Engineering and Operations Research, Fu Foundation School of Engineering and Applied Science, New York/NY/USA

Introduction: Non-small cell lung cancer (NSCLC) with pleural dissemination (M1a) includes a subset of patients demonstrate an indolent biology and may benefit from surgical resection of the primary tumor. In this study, we aims to evaluate the prognostic value of circulating tumor DNA (ctDNA) in M1a patients after surgery.

Methods: In this study, we analyzed 12 preoperative and 80 postoperative blood sample from 29 M1a patients with serial ctDNA detection. Additionally, 25 preoperative and 151 postoperative serum carcinoembryonic antigen (CEA) results were collected for comparasion. The primary endpoint was progression-free survival (PFS).

Results: The overall ctDNA detection rate for M1a disease was 26.1% (24/92). As of 31 December, 2022, 17 patients had disease progression with a median PFS of 14.3 months, among whom three had detectable longitudinal ctDNA before progression. The sensitivity of longitudinal ctDNA was 17.6%. In contrast, six patients had an elevated CEA trend within 3 months after surgery and before progression. The sensitivity of the elevated CEA level trend after surgery was 35.3%. Patients with longitudinal undetectable and detectable ctDNA demonstrated with a similar PFS; by contrast, patients with a decreasing CEA trend within 3 months after surgery was associated with an improved PFS (HR 0.24, 95% CI: 0.06-0.99, P=0.007).

Conclusions: Overall, our findings indicate that M1a NSCLC may represent a "non-shedding" tumor. In M1a patients, ctDNA detection demonstrated a limited prognostic value, while serum CEA in these cases may perform as a more cost-effective biomarker for predicting disease progression.

EP.06G.19 Characterization of Metabolomic Landscape in Underrepresented Patients with Lung Cancer

J.J. Pothen, A. Hulbert, A. Mallisetty, M.M. Pasquinelli, R.H. Nguyen, F. Weinberg, University of Illinois Chicago, Chicago/IL/USA

Introduction: Despite the high incidence of lung cancer, little is known about how differences in patient populations (e.g. geographic location and race) correlate with differences in metabolic pathways in lung malignancies. Understanding which pathways are enriched can provide further insight into how these demographic factors affect the malignancy's behavior, and ultimately lead to personalized, more effective therapies.

Methods: As part of an exploratory study, we collected plasma from 42 patients with confirmed lung cancer, and from 60 patients without a lung cancer diagnosis. Metabolomic profiling was performed using ultra-high performance liquid chromatography - mass spectrometry. Untargeted metabolomics analysis was performed using MetaboAnalyst 5.0 software to uncover patterns in individual metabolite expression. We used orthogonal partial least squares discriminant analysis to demonstrate significant differences in metabolite expression in malignant vs non-malignant (control) lung samples. We then sorted all metabolites by their Variable Importance in Projection (VIP) scores to determine which metabolites contribute most to the model, and therefore which have the greatest statistical difference between malignant and non-malignant samples.

Results: We found significant differences in metabolite enrichment between patients with lung cancer and those without cancer (Figure 1). Additionally, we found that specific amino acids such as cystine and amino acids important in arginine synthesis were decreased in patients with lung cancer compared to non-cancer patients (Figure 2).

Conclusions: Our metabolomic analysis demonstrates significant differences in metabolite expression and their associated pathways between lung cancer and non-lung cancer samples. Interestingly, we find decreased levels of certain amino acids, traditionally found to be in higher levels in cancer patients, in our patients with lung cancer. Further analysis will involve characterizing the anthropometric factors that may account for these differences. Additionally, we plan to focus on aggregating geospatial data to further identify neighborhood-level differences in metabolite enrichment in underrepresented patients with lung cancer.

Keywords: metabolomics, lung cancer, underrepresented

IIS-FJD, Madrid/ES ,[23]Hospital Universitario de Fuenlabrada, Madrid/ES

Introduction: Squamous cell lung carcinoma (SQCLC) is a disease usually related to tobacco history, which may rarely be present in never smokers. There is little evidence about the clinical and molecular characteristics of this subgroup of patients, as well as their outcomes in terms of survival, with the majority of studies developed in Asian population.

Methods: our study aimed to retrospectively describe the epidemiological, clinical and molecular characteristics, as well as survival outcomes, of a Spanish cohort of non-smoking patients diagnosed with advanced SQCLC included in the Thoracic Tumor Registry (TTR) of the Spanish Lung Cancer Group, between February 2001 and December 2023. Differential characteristics between the non-smoker and the current/previous-smoker groups were analyzed.

Results: A total of 2351 patients with advanced SQCLC were included in our study, of which, 100 were never-smokers. The median age was similar between both groups (69.7 vs 67.8 years), with a higher percentage of women in the non-smoking group (63% vs 12.1%, P 0.001), as well as patients with history of cancer (26% vs 17.1% p = 0.017). No differences were found regarding occupational exposures. Performance status and symptoms at diagnoses were similar, but, subcutaneous, extrathoracic lymph nodes and central nervous system metastases were more frequent in non-smokers (4% vs 1.3%; p=0.02; 22% vs 12.7%; p=0.007; 16% vs 9.9% p=0.05, respectively). Molecular analyses were performed more frequently in the non-smoking group (82% vs 63%), including PDL1, but not all driver genes were analyzed in each patient. No molecular differences were found between both groups (table 1). There were no differences in the type of treatment received, nor in the number of patients who received any local treatment. With a median follow-up of 38.4 months, no differences were found in the progression free survival (5.7 vs 5.5 months, p = 0.85) or in the overall survival (10.9 vs 9.1 months, p = 0.64) between both groups.

Conclusions: Our study is one of the largest series of SQCLC in never-smokers in the European population. It is a rare entity, which is more frequent in women and in patients with history of cancer. There were no differences in terms of survival between never-smokers and current/previous-smokers. Our study could not find molecular differences between both groups, probably due to the heterogeneity in the genes tested and techniques applied across the TTR. However, further research is needed in the molecular aspects to better characterize this unusual disease.

EP.07A.01 Association Between Surgical Approach < Surgical Outcome in Lung Cancer Patients Undergoing Segmentectomy

S. Shiono[1], J. Suzuki[1], H. Watanabe[1], M. Endo[2], [1]Yamagata University, Yamagata/JP,[2]Yamagata Prefectural Central Hospital, Yamagata/JP

Introduction: Although segmentectomy tends to have a better overall survival for early stage lung cancers based on the results of randomized clinical trials, local recurrence rate following segmentectomy is higher than that following lobectomy. To perform a safe segmentectomy and reduce the local recurrence rate, an understanding of the 3-dimensional anatomy is essential. Segmentectomy performed through a thoracotomy (8-12 cm in length), the so-called hybrid approach, provides direct vision intraoperatively and is safe. Video-assisted thoracic surgery (VATS) provides a 2-dimensional view without direct vision. The purpose of this study was to compare short-term surgical outcomes and survival among patients who underwent segmentectomy for lung cancer using a hybrid approach compared to VATS.

Methods: This was a retrospective study using a prospectively collected database from two institutions. Patients with clinical T1N0M0-stage IA with the following characteristics underwent segmentectomy: patient request, poor performance status, and impaired respiratory function and/or severe co-morbidities. In one institution the hybrid approach was performed via an 8-cm thoracotomy, while VATS without direct vision was performed at the other institution. From June 2016 to December 2021, a total of 250 patients underwent segmentectomy for lung cancer. We evaluated 250 patients who underwent segmentectomy using the hybrid approach or VATS and compared the perioperative surgical outcomes and overall survival. Additionally, propensity score matching was performed to balance patient characteristics between the groups.

Results: Ninety-seven hybrid approaches and 153 VATSs were performed. The background of patients was similar in the groups, but the proportion of complex segmentectomies was higher in VATS (52.6% vs. 73.9%; P<0.001). The intraoperative and acute postoperative surgical outcomes in the hybrid approach and VATS, respectively, were as follows: median operative time, 146 and 167 min (P=0.006); median blood loss, 4 and 49 g (P<0.001); number of dissected lymph nodes, 4 and 2 (P=0.046); incidence of grade ≥2 postoperative complications, 18.6% and 13.2% (P=0.252); median duration of chest tube drainage, 2 and 1 d (P=0.008); median postoperative hospital stay, 4 and 4 d (P=0.832); and readmission within 30 d after discharge, 5.2% and 1.3% (P=0.113). There was 1 death within 30 d after surgery using VATS. The 5-year overall survival with the hybrid approach and VATS was 91.7% and 92.6%, respectively (P=0.408). After propensity score matching, the hybrid approach had a shorter operative time and less blood loss than VATS. The 5-year overall survival was 92.2% and 90.6%, for the hybrid approach and VATS, respectively (P=0.792).

Conclusions: The hybrid approach was associated with shorter operative times, less blood loss, and more dissected lymph nodes than VATS. There were no significant differences in perioperative surgical outcomes. Although the number of complex segmentectomies was higher in VATS than in the hybrid approach, the hybrid approach had superior intraoperative outcomes and similar survival compared to VATS.

EP.07A.02 Staple Formation by Endostapler and Bronchial Wall Thickness in Pulmonary Lobectomy: Prospective Observational Study

M. Nakao[1], S. Tamagawa[1], Y. Horikoshi,[2], A. Suzuki[1], J. Ichinose[1], Y. Matsuura[1], S. Okumura[1], M. Mun[1], [1]Cancer Institute Hospital, Japanese Foundation for Cancer Research, Toyko/JP,[2]Johnson & Johnson K.K. Medical Company, Tokyo/JP

Introduction: We conducted a single-center, prospective observational study to evaluate staple formation according to cartridge type of endostapler and bronchial wall thickness, and the rate of postoperative complications in patients undergoing pulmonary lobectomy.

Methods: Eighty patients who were planned for lower lobectomy were enrolled (Figure 1). The bronchus was divided using endostapler (ECHELON FLEX™ Powered Plus Stapler). The cartridge (Gold, Green, or Black) was selected at the surgeon's discretion. After measuring the thickness of the bronchial stumps, the bronchial tissue was proteolysed and all staple formation was scored from 1 to 3 points, focusing on staple ends return, with 3 representing an approximately perfect B-shaped closure, 2 representing both staple ends slightly returning but not forming a B-shape, and 1 representing one or both staple ends not returning.

Results: Gold, Green and Black cartridges were used in 26, 49 and 5 patients respectively. Green/Black was used more frequently than Gold in patients with thicker bronchial stumps (p = 0.001). The mean staple formation score tended to be higher in patients used Green/Black than Gold (p = 0.087). The proportion of score 2 or higher was equivalent (p = 0.766). The proportion of score 3 was higher for patients used Green/Black than Gold (p < 0.001). Bronchial stump thickness was significantly correlated with gender (p < 0.001) and height (p = 0.001). In men, and women over 160 cm in height, the mean score of staple formation tended to be higher for patients used Green/Black cartridge than that used Gold cartridge (p = 0.068) (Figure 2). No postoperative bronchopleural fistula was observed.

Conclusions: Although each cartridge performed well ensuring tissue apposition and good clinical outcomes, the Green or Black cartridges appeared to be more appropriate for the lower bronchus, especially in men, and women over 160 cm in height.

EP.07A.03 Influence of Preoperative Percutaneous Transthoracic Lung Biopsy on Recurrence and Mortality after Surgery for Lung Cancer

E.J. Hwang, Seoul National University Hospital, Seoul/KR

Introduction: Percutaneous transthoracic lung biopsy (PTLB) is a representative procedure for lung cancer diagnosis. There has been controversy regarding the association between preoperative PTLB and long-term risk of recurrence or mortality in surgically treated lung cancer patients.

Methods: A public database from the Korea Central Cancer Registry was analyzed. The database comprised information regarding the diagnosis, stage, treatment, and outcomes of patients diagnosed with lung cancer in 51 institutions in South Korea. From the database, data from patients who underwent curative-intent surgery were included for the analysis, while patients with multiple primary lung cancers and patients who received neoadjuvant treatment were excluded. Restricted mean survival time (RMST) analyses were conducted to investigate the association between the conduction of preoperative PTLB and recurrence-free survival (RFS), lung cancer-specific survival, or overall survival (OS) after surgery. Age, sex, histologic classification, pathologic stage, type of surgery, and adjuvant treatment were considered confounding factors.

Results: Among 3,182 patients (1,975 men, mean age 64 years), 1,257 (39.5%) underwent preoperative PTLB. Patients who underwent preoperative PTLB exhibited significantly shorter RFS (P<.001; survival probability at 3-year after surgery, 76.4% vs. 84.2%), lung cancer-specific survival (P<.001; survival at 7-year after surgery, 69.1% vs. 78.7%), and OS (P<.001; survival at 7-year after surgery, 63.2% vs. 72.1%). After adjustment for potential confounding factors, conduction of preoperative PTLB was an independent factor for reduced RFS (RMST at 3-year after surgery, 964 vs. 992; P=.005), lung cancer-specific survival (RMST at 7-year after surgery, 2154 vs. 2215; P=.040), and OS (RMST at 7-year after surgery, 2083 vs. 2136; P=.045).

Conclusions: Preoperative PTLB was an independent factor for reduced RFS, lung cancer-specific survival, and OS in patients undergoing curative-intent surgery for lung cancer. Judicious decisions would be required for the conduction of preoperative PTLB in patients under suspicion of resectable lung cancer.

EP.07A.04 Risk Factor Analysis and Predictive Model for Air Leakage after Thoracoscopic Lung Wedge Resection

Y. Huang[1], M. Chen[1], B. Zheng[1], C. Chen[1], [1]Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: The rate of postoperative complications is low due to the wedge resection procedure does not involve the major structures. However, postoperative air leak is still common. There are no large-scale studies in this area. This study aimed to identify risk factors for air leakage (AL) after thoracoscopic lung wedge resection and to develop a predictive model to screen suitable patients for tube lessness.

Methods: Patients undergoing thoracoscopic pulmonary wedge resection at Fujian Medical University Union Hospital between January 2015 and December 2020 were included in this study. Univariate and multivariate logistic regression analyses were used to identify independent risk factors and establish the corresponding models. Concurrent data from two other centers were also collected as a validation set for external validation.

Results: A total of 2503 patients who met the selection criteria were enrolled. The overall incidence of AL was 11.34% (284/2503). The development data set included 2006 cases; columnar plots were drawn based on the results of the multifactorial logistic regression analysis. The final model included age>70, FEV1%<80%, nodule size, benignity/malignancy, and pleural adhesions(none, focal, diffuse). In the development data set, the C-index was 0.829. There were 497 cases in the external validation set, at this, the C-index was 0.833.

Conclusions: The prediction model of AL was performed well, and may be clinical useful to assessed AL and identify patients who can benefit from a tubeless strategy.

EP.07A.05 Evolution of Use of Sublobar Resection in a US Population-Based Cohort Before and after Two Randomized Controlled Trials

O. Akinbobola[1], S. Ely[2], M.A. Ray[3], C. Fehnel[1], A. Saulsberry[1], K. Dortch[1], A. Minhas[4], T. Ng[5], J. Zhao[5], M.P. Smeltzer[3], R.U. Osarogiagbon,
[1]Baptist Cancer Center, Memphis/TN/USA,[2]George Washington University, Washington/DC/USA,[3]University of Memphis, Memphis/TN/USA,[4]Methodist University Hospital, Memphis/TN/USA,[5]Baptist Memorial Hospital, Memphis/TN/USA

Introduction: We evaluated sublobar resection practices for early-stage non-small cell lung cancer (NSCLC) in a population-based cohort after two pivotal randomized controlled trials, JCOG 0802 and CALGB 140503, established similar outcomes to lobar resection.

Methods: We retrospectively analyzed patients with stage IA from 2009 to 2023 in the Mid-South Quality of Surgical Resection cohort, which includes 14 hospitals in Arkansas, Mississippi, and Tennessee regions and categorized eligible and ineligible patients based on the selection criteria from the JCOG 0802 and CALGB 140503 trials to ensure a representative comparison (Figure 1. CONSORT diagram). We assessed resection trends overall; and 2009 to 2019 (pre-) versus 2020 to 2023 (post-publication of JCOG 0802, the first published RCT), using the Cochran-Mantel-Haenszel test and logistic regression, including an interaction term for periodic impact analysis.

Results: Of 3,030 patients, 61% met trial eligibility; 6.5% underwent segmentectomy, 10.3% wedge resections. Sublobar resection use increased overall (Figure 2a) and among eligible patients (Figure 2b) (p<.0001 for both). Changes among ineligible patients remained insignificant (p=0.2609). Wedge and segmentectomy rates decreased gradually from 2009 to 2019, but then increased after 2019, more so in segmentectomy (Figure 2). Pre-JCOG 0802, patients were 50.8% less likely to have sublobar resections (OR=0.492, 95% CI: 0.338-0.718, p=0.0002) and the period-eligibility interaction was significant with 42.5% higher odds of undergoing sublobar resection post-JCOG 0802 (OR=1.425, 95% CI: 1.425-1244, p<.0001).

Conclusions: The utilization of sublobar resection for early-stage NSCLC has increased post-JCOG 0802 and CALGB 140503, especially segmentectomy. The increase has mostly been in appropriately selected patients. Use of sublobar resection among ineligible patients has not yet diminished, suggesting opportunity for improvement.

Keywords: Resection, NSCLC, Early Stage

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07A.06 Usefullness and Appropriate Indication of Intraoperative CT-Guided Marking Using O-Arm Based on Cancellation Rate

Y. Hirai[1], T. Nakaya[2], H. Iguchi[2], A. Fusamoto[2], Y. Yata[2], Y. Nishimura[2], [1]Wakayama Medical University, Wakayama/JP,[2]Wakayama Mediacl University, Wakayama/JP

Introduction: Improvements in imaging technology and lung cancer screening have led to an increased detection rate of small pulmonary tumors that include ground glass nodules (GGNs). These GGNs and small nodules are often difficult to find if they cannot be recognized from the lung surface. It is difficult to accurately predict preoperatively whether small nodules in the peripheral lung fields can be detected intraoperatively. We had percutaneous preoperative CT-guided marking with dye from 2007 to 2016, but discontinued it due to reports of air embolization. Since 2017, we have been performing intraoperative CT-guided marking using O-arms, and we would like to discuss the indications for marking based on the cancellation rate as well as the usefulness of the method.

Methods: Of the 3021 respiratory surgery cases from May 2017 to May 2023, 2007-2016 were considered the early period group and 2017-2023 the late period group. There were no significant differences in gender, age, tumor diameter, or solid component diameter between the groups.

Results: In the early group, 18 of 1447 patients (1.2%) underwent marking. In the late group, marking was planned in 75 of 1574 patients (4.8%), 17 were cancelled intraoperatively, and marking was performed in 58 patients (3.7%). In all cancelled cases, lesions could be detected intraoperatively. The number of markings was significantly higher in the late group (1 in the early group and 2.8 in the late group, $p<0.01$). 3.2 CT sessions were performed in the early group and 1.3 in the late group, significantly lower in the late group ($p<0.01$). The operation time for partial resection was significantly longer in the late group (102 minutes) than in the early group (75 minutes) ($p<0.01$), but there was no difference in the operation time for segmentectomy and lobectomy. Bleeding was 10 ml in the early group and 11 ml in the late group, with no difference. In the early group, 1 of 18 patients had to convert to open chest surgery due to lack of intraoperative dye confirmation, but in the late group, all patients were successfully marked. In the early group, pneumothorax occurred in 4 cases, which were immediately treated by surgery. In the late group, there were no complications caused by marking.

Conclusions: Compared to previous methods, the intraoperative marking method using O-arm was considered superior in terms of marking accuracy and complications. The intraoperative cancellation rate was 22%, and it was possible to determine intraoperatively that marking was unnecessary in 1/4 of the cases. On the other hand, the ability to easily cancel the marking increased the safety of lesion retrieval and allowed the surgeon to select the most appropriate indication for the lesion.

EP.07A.07 Comparison of Inpatient Opioid Use and Pain Control Following Thoracoscopic Segmentectomy Versus Lobectomy for Non-Small Cell Lung Cancer

X. Wei[1], R. Xiang[2], H. Yu[2], Q. Shi[1], W. Dai[1], Q. Li[1], [1]Sichuan Cancer Hospital & Institute, Chengdu/CN,[2]Chongqing Medical University, Chongqing/CN

Introduction: Video-assisted thoracoscopic surgery (VATS) segmentectomy and lobectomy are common surgical approaches for non-small cell lung cancer (NSCLC). However, their impact on in-hospital opioid use and pain management remains uncertain. This study aims to compare postoperative opioid use and pain control between the two procedures.

Methods: Patients were extracted from the ongoing CN-PRO-Lung 3 longitudinal cohort study. Retrospective analysis included NSCLC patients underwent VATS segmentectomy or lobectomy from April 2021 to November 2022. Propensity score matching (PSM) matched patients 1:1 based on sex, age, BMI, smoking status, Charlson Comorbidity Index (CCI), and TNM staging. Data on opioid usage and postoperative symptoms (assessed by the PSA-Lung scale) were collected. Mixed effects model compared symptom scores on postoperative days 1 to 5.

Results: We found that during surgery, patients undergoing segmentectomy received a lower total dose of opioid medications compared to those undergoing lobectomy (86.55 [67.5-112.5] vs. 100 [77.55-126.9] mg, p < 0.0001). Postoperatively, patients in the segmentectomy group continued to have lower rates of opioid medication usage (55.67% vs. 71.18%, p < 0.0001) and lower total doses compared to the lobectomy group (24 [0-48] mg vs. 36.92 [0-74] mg, p < 0.0001). Finally, regardless of patient-controlled analgesia (PCA) use, patients in the segmentectomy group still received lower total doses of opioids postoperatively compared to those in the lobectomy group (210 [180-230] vs. 216 [180-248.46], p < 0.0001). However, there were no differences between segmentectomy and lobectomy patients in the symptoms of pain, cough, fatigue, disturbed sleep, drowsiness and distress on postoperative days 1-5 (all p > 0.05).

Conclusions: Segmentectomy results in reduced intraoperative and postoperative opioid usage without exacerbating postoperative symptoms. It offers a more economical and effective opioid usage profile compared to lobectomy for suitable NSCLC patients, while maintaining effective postoperative symptom control.

EP.07A.08 Modified Periareolar Incision for Uniportal Segmentectomy

Z. Yang, B. Zheng, Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: The periareolar approach is rarely used in previous reports of thoracoscopic surgery, and most of them directly destroy the breast into the thorax. Here, we modified this surgical approach by establishing a subcutaneous tunnel to avoid injury to the breastthat has certain advantages over conventional uniportal incision.

Methods: Fourteen patients were enrolled for segmentectomy. We avoided damaging the mammary gland into the thoracic cavity by creating a subcutaneous tunnel between the skin and the mammary gland that separated from the periphery of the areola outward to the fourth intercostal space of the anterior axillary line. A plastic wound protector was used to hold open the incision and stabilize its position. The incision was enlarged by fingers with the paraffin oil. In this way we have completed the Modified Periareolar incision. All the segmentectomy procedures were completed and specimens ware removed through the incision. The incision was sutured and the recovery effect was followed up.

Results: Among the 14 patients, the mean length of stay after surgery was 2.93 ± 1.03, and the postoperative pain score using VAS was 2.14 ± 1.40 and 1.57 ± 1.16 on the first and third day after surgery, respectively. In terms of short-term postoperative complications, 9 patients had no complications, 2 had pleural effusion, 1 had subcutaneous emphysema, and 1 had both pleural effusion and subcutaneous emphysema. Changes in nipple sensitivity were assessed on a five-point scale (1 is no effect and 5 is great effect), yielding a score of 2.29 ± 0.83. Patient scars were assessed using POSAS, with scores of 1.57 ± 0.76 and 1.71 ± 0.82 for observer and patient evaluations, respectively.

Conclusions: The periareolar approach has rarely been used in previous reports of thoracoscopic surgery. However, no article has reported the use of a periareolar approach in segmental resection. Most of the reported patients are male, but the demand for cosmetic effect in women is always higher than that in men. Previous studies have suggested that women have more developed breasts, so periareolar incisions are not suitable for women. However, our method of establishing a subcutaneous tunnel could maintains the integrity of the breast, so it can also be better applied to female patients, which is the innovation of our study.Our observations suggest that this approach has some benefit. Firstly, due to the elasticity of the chest skin, the retractor can bypass the mammary gland and create a good surgical field. Secondly, due to the pigmentation of the areola, the incision is more concealed and the aesthetic result is better. Third, according to the feedback of patients, the postoperative pain was mild and did not affect life. However, there are some technical difficulties with the incision we designed. Surgeons need time to adjust to new surgical methods. The establishment of the subcutaneous tunnel requires the surgeon to have a good anatomical basis. The occurrence of medium and long term complications needs to be further investigated.

EP.07A.09 A New Method to Detect Air Leaks in Video-assisted Thoracoscopic Surgery Using Indocyanine Green Inhalation Under Near-infrared Fluorescence

H. Xu[1], Z. Wang[2], F. Yang[2], Y. Li[2], J. Zhou[2], [1]Peking University People's Hospital, Beijing/CN,[2]Peking University People's Hospital, Beijing/CN

Introduction: Postoperative air leaks are the most common complications after lung surgery, with an incidence of 8%-26%. The key principle in preventing postoperative air leaks is to accurately and comprehensively identify and repair the sites of air leakage during surgery. Currently, the gold standard method for identifying air leak sites in thoracoscopic surgery is the submersion sealing test. However, this method seriously affects the surgical field and may lead to the omission of air leak sites, and this method cannot continuously visualize air leak sites during repair. This case series aimed to demonstrate the feasibility of indocyanine green (ICG) inhalation for the detection of air leak sites.

Methods: We enrolled patients who underwent thoracoscopic lung surgery at our hospital between September 2023 and December 2023. After lung resection, indocyanine green (ICG, 3.75 mg/ml) was inhaled via a mesh nebulizer. The suspected air leak sites were then detected under near-infrared fluorescence. Subsequently, the submersion sealing test was used to validate the air leak sites identified through fluorescence. The detection efficiency of these two methods was evaluated.

Results: This case series included 5 patients. Intraoperatively, a total of 20 fluorescent air leak sites were identified under near-infrared fluorescence, among which 2 patients had extensive adhesion between the visceral pleura and parietal pleura, with 8 and 6 fluorescent air leak sites, respectively. After verification via the submersion sealing test, 17 (85%) fluorescent air leak sites were confirmed to be true air leak sites. The average time for detecting air leak sites under near-infrared fluorescence was 15.8 seconds, and fluorescence imaging could persist until the end of surgery. None of the patients experienced complications related to ICG inhalation. Two patients experienced postoperative air leak and were successfully treated by conservative treatment.

Conclusions: Intraoperative ICG inhalation provides a convenient, simple, and effective method for detecting air leak sites during thoracoscopic lung surgery. This method does not affect the surgical field and allows for continuous visualization of air leak sites. We demonstrated that ICG inhalation is a novel method for detecting air leak sites with great potential for clinical application.

Keywords: Intraoperative air leak detection, Indocyanine green inhalation, Near-infrared fluorescence

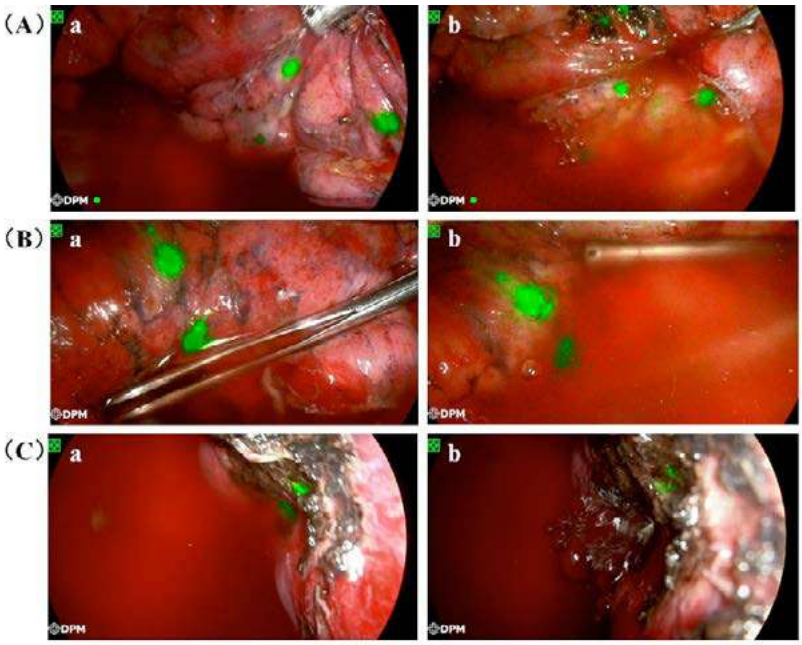

Figure 1. The fluorescence imaging of air leak sites. Subfigures a and b in each figure represent the detection results of air leak sites using near-infrared fluorescence and the submersion sealing test, respectively. In Figure (A), all three fluorescent imaging sites are all true air leak sites. In Figure (B), only the upper fluorescent imaging site is a true air leak site, while the lower fluorescent imaging site shows no bubbles in the submersion sealing test. In Figure (C), the fluorescent imaging site is a true air leak site, with a large number of bubbles generated in the submersion sealing test.

EP.07A.10 Concordance Between Lymph Node Station Examination Reported on a Checklist and the Final Pathology Report after Curative Lung Cancer Resection

M. Ray[1], S. Ely[2], O. Akinbobola[3], C. Fehnel[3], A. Saulsberry[3], K. Dortch[3], M. Smeltzer[1], R. Osarogiagbon[3], [1]University of Memphis, Memphis/TN/USA,[2]George Washington University, Washington D.C./WA/USA,[3]Baptist Cancer Center, Memphis/TN/USA

Introduction: Checklists improve communication between clinical teams. We previously reported discordance between lymphadenectomy claims in surgeons' notes and the final pathology report. We examined the concordance between station-specific lymph node examination reported by surgery teams on a checklist and the final pathology report.

Methods: We examined curative-intent lung cancer resections in the Mid-South Quality of Surgical Resection cohort from 2009-2022, a population-based dataset involving implementation of a lymph node collection kit. The kit included a checklist requiring surgery teams to indicate whether or not they examined lymph nodes from specific stations (2R, 4R, 7, 8, 9, 10R for right-sided and 2L, 4L, 5, 6, 7, 8, 9 and 10L for left-sided resections). We examined frequency of nodal evaluation indicated by checklist and pathology report, further assessed with a kappa statistic, and the reasons attributed for non-examination of lymph nodes.

Results: Of 1875 resections with the kit, 1097 (59%) were right-sided; 778 (41%) left-sided. The checklist was used in 97% of right-sided, and 96% of left-sided resections. For right-sided resections, checklists indicated stations 7 (86%) and 10R (85%) were sampled most, stations 2R (32%) and 9 (17%) were sampled the least (Figure 1). Station 10R had the highest discordance rate with the pathology report (29 patients, 3% of 1097) while station 8 had the highest significant kappa statistic of 0.86 (Table 1.). The most common reason across stations for checklist non-examination was "no lymph nodes identified". In left-sided resections, stations 5 (80%), 9 (80%) and 10L (82%) were sampled the most, and 4L (39%), 6 (24%), and 8 (26%) the sampled the least. Stations 7 and 10 again had the highest rates of discordance, while station 4l had the greatest significant kappa statistic. Absence of identifiable lymph nodes was the most common reason attributed for non-examination. The reasons for lack of sampling across other stations were similar in that the overwhelming reasons were not nodes were identified or no reason was provided (blank or not specified).

Conclusions: Stations 2r, 4l and 8 had the largest kappa statistics while stations 7 and 10 had the greatest rates of discordance, while having the most prevalent sampling. The absence of nodes was the most common reason who not sampling a station, or the node was sampled during mediastinoscopy

EP.07A.11 AI Models for Intraoperative Diagnosis Based on Surgical Resection Images in Stage IA LUAD: A Prospective, Multicentric Study

H. Zhou[1], L. Yao[1], I. Cai[2], Q. Li[1], H. Lin[3], L. Huang[4], L. Yao[5], [1]Department of Thoracic Surgery, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN,[2]the School of Computer Science and Technology, Harbin Institute of Technology, Shenzhen, [518055], China., Shenzhen/CN,[3]The First School of Clinical Medicine, Guangdong MedicalUniversity, Zhanjiang, China., Zhanjiang/CN,[4]Department of Surgery, Competence Center of Thoracic Surgery, Charité University Hospital Berlin, Berlin, Germany, Berlin/DE,[5]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN

Introduction: Intraoperative pathological diagnosis is key for surgical strategies, including extensive lobectomy after diagnostic sublobar resection and extent of lymph node dissection. Frozen section requires sufficient time for sampling and high-level specialties in diagnosis based on the limited and sometimes poor-quality samples, which may lead to misdiagnosis or unidentifiability. We propose artificial intelligence models based on surgical resection images for intraoperative diagnosis and risk stratification of stage IA lung adenocarcinoma.

Methods: This study prospective enrolled patients with stage IA lung adenocarcinoma underwent complete resection between June 2020 and September 2023 in Guangdong Provincial People's Hospital (GDPH), Affiliated Hospital of Guangdong Medical University (GDMUAH), Meizhou People's Hospital (MPH). Surgical resection images of the LUAD were taken by smartphones in operating theaters under natural lighting condition (without flash or shadowless surgical lights). Artificial intelligence models based on surgical resection images and clinical characteristics were established for three tasks. Task1 tend to differentiate invasive lung adenocarcinoma (IAC) from non-IAC lesions. Task2 tend to classify pre-invasive lesion (PIL), minimally invasive adenocarcinoma (MIA) and IAC. Task3 tend to more specifically classify PIL, MIA, IAC Grade1, IAC Grade2 and IAC Grade3 according to 2021 IASLC Grading system in LUAD. Models were developed by combing clinical characteristics and coarse-fine fusion features from surgical resection images. Diagnostic performances were compared between thoracic surgeons, AI models and frozen section. The study was registered in Chinese Clinical Trial Registry (ChiCTR2300075999).

Results: We prospectively collected images of 1638 lung nodules in 1516 patients from GDPH, 122 lung nodules in 112 patients from GDMUAH and 89 lung nodules in 82 patients from MPH. For each tasks, we developed three models including coarse/fine models, coarse-fine fusion models and combined models with fusion features and clinical characteristics, with best diagnostic performance in combined models. In GDPH validation cohort, for task1 the diagnostic performances were 0.77 for coarse model, 0.79 for fusion model and 0.86 for combined model. In GDPH cohort, for task3 the diagnostic performances were 0.80 for fine model, 0.80 for fusion model and 0.86 for combined model. The proposed models have strong generalization ability in external validation cohort from GDMUAH and MPH for each task, and it could improve diagnostic performance of thoracic surgeons.

Conclusions: We developed intraoperative diagnostic models based on surgical resection images, which could comprehensively evaluate the whole section of nodules without the disturbance of sampling and reach a diagnosis rapidly to assist the decision of surgical strategies.

EP.07A EARLY-STAGE NON-SMALL CELL LUNG CANCER - EVOLVING SURGICAL APPROACHES
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07A.12 Association Between Preoperative Diaphragm Thickness and Postoperative Complications in Elderly Patients with Lung Cancer

S. Kuriyama, K. Imai, S. Takashima, H. Iwai, H. Suzuki, R. Demura, Y. Harata, S. Shibano, Y. Minamiya, Akita University Graduate School of Medicine, Akita/JP

Introduction: With the increasing number of elderly patients with lung cancer, sarcopenia has been frequently reported as a prognostic factor. However, the perioperative impact of respiratory sarcopenia, defined by a decrease in respiratory muscle mass and a decline in respiratory muscle strength, remains unclear. In the present study, we focused on the diaphragm, the major respiratory muscle, and investigated the association between preoperative diaphragm thickness (DT) measured on computed tomography (CT) scans and perioperative complications and outcomes.

Methods: We enrolled 101 patients aged 75 years or older who underwent radical lobectomy or segmentectomy for primary lung cancer in our institution between January 2013 and March 2018. DT at the level of the origin of the celiac artery was measured on axial and coronal CT images, and the mean DT (MDT) was calculated from the four measurements. The outcome was defined as postoperative complications of Clavien-Dindo classification grade II or higher.

Results: The median age was 78 years (range 75-87), with 62 male and 39 female patients. The surgical procedures included 77 lobectomies and 24 segmentectomies. The measured DT values were as follows: right/left on axial images, 3.90±1.40 mm / 3.39±1.34 mm, respectively; and right/left on coronal images, 3.63±1.30 mm / 3.03±1.08 mm, respectively. The MDT was 3.49±1.03 mm. Postoperative complications occurred in 24 cases (23.8%). The group with postoperative complications had a significantly lower MDT ($p = 0.0005$), with a cutoff value for MDT determined as 3.4 mm by receiver operating characteristic curve analysis. Univariate and multivariate logistic regression analyses revealed that DT ≤ 3.4 mm was an independent factor associated with postoperative complications (odds ratio: 5.89).

Conclusions: Patients with MDT ≤ 3.4 mm on preoperative CT scans are at higher risk of postoperative complications and may have poorer outcomes. Therefore, careful perioperative management is required for high-risk cases.

EP.07A.13 The Comparison of Early Surgical Outcomes and Lung Function Change after Complex Basal Segmentectomy and Lower Lobectomy

Y.H. Yang, H.E. Kim, B.J. Park, J.G. Lee, D.J. Kim, C.Y. Lee, Yonsei university college of medicine, Seoul/KR

Introduction: Complex basal segmentectomies are often precluded due to the perceived augmented risk of failure and for augmented potential post-operative complications. Few studies have evaluated the post-operative pulmonary function change in complex basal segmentectomy compared to lower lobectomy. This study aimed to assess peri-operative outcomes and the course of lung function in two groups.

Methods: Patients who underwent lung surgery at one institution from August 2018 to December 2021 were included. Among them, 258 patients who underwent lower lobectomy and complex basal segment resection were divided into two groups. The complex basal segmentectomy was defined as the anatomical resection of at least one subsegment composing the basilar pyramid, excluding S6 and S7-10 segmentectomy. We investigated complications, early outcomes, remaining pleural space, and changes in lung function after surgery.

Results: There was no difference in the preoperative clinical profile in the two groups. There were 5 patients (9.6%) who achieved conservation with lobectomy, and there was no difference in operative time or blood loss between the two groups. Chest tube drain, chest tube duration, and postoperative hospital stay were shorter in the segmentectomy group than in the lobectomy group. (p<0.0001) Postoperative complications such as prolonged air leak, pneumonia, and pleural effusion occurred in lobectomy but did not occur in segmentectomy. (p=0.004). The pleural space remaining after surgery was also significantly smaller in the segmentectomy group. In terms of postoperative pulmonary function, there was a difference between the two groups at 2 months and 6 months after surgery, but there was no statistically significant difference at 12 months.

Conclusions: Although the rate of lobectomy conversion was relatively high, complex basal segmentectomy could achieve better early surgical outcomes than lower lobectomy and enough resection margin. Complex basal segmentectomy could preserve early pulmonary function and reduce space problems significantly compared with lower lobectomy.

Keywords: Complex basal segmentectomy, pulmonary function, early outcome

EP.07A.14 The Postoperative Chest Tube Drainage Strategy of "Lesstube" Can Reduce Patient Pain and Shorten Hospital Stay

X. Zhang, B. Zheng, Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: Lung cancer is a leading cause of cancer-related deaths worldwide. Surgical resection remains the most effective treatment for the majority of early-stage lung cancer patients. With the latest advancements in minimally invasive thoracic surgery, the efficacy of single-incision video-assisted thoracoscopic surgery (VATS) has been supported by accumulating evidence. According to multiple studies, single-incision VATS offers advantages over multi-port VATS, including less postoperative pain, greater satisfaction with surgical incisions, and shorter hospital stays. However, there is still controversy regarding the selection and placement of chest tubes after single-incision VATS.

Methods: A retrospective analysis was conducted on 425 patients who underwent single-incision VATS lung surgery (lobectomy, segmentectomy, wedge resection, or their combinations) in the Department of Thoracic Surgery at Fujian Medical University Union Hospital between May 2023 and November 2023. Based on different drainage strategies, the patients were divided into three groups: the Single group (SD) with one Abel drain, the Double group (DD) with two Abel drains, and the Traditional group (TD) with one Abel drain and one large-caliber chest tube. Pain and cough assessments were performed using the Numeric Rating Scale (NRS) three times a day (every 8 hours) during the first three postoperative days. Clinical data, including drainage volume and length of hospital stay, were collected. The SD and DD groups were categorized as the small tube group, while the TD group was classified as the large tube group. Chest X-rays or computed tomography (CT) scans were obtained on postoperative day 1 and 1 month after surgery to compare lung images. Adverse events such as pleural effusion, subcutaneous emphysema, lung infection, and inadequate lung reexpansion were documented.

Results: Our study found that patients in the SD group had the lowest VAS scores, while the TD group had the highest pain scores, with a p-value of < 0.0001, indicating that placing only an Abel drain significantly reduces postoperative pain. Additionally, the average length of hospital stay was 3.32 days in the SD group, 4.27 days in the DD group, and 4.25 days in the TD group, demonstrating faster recovery in the SD group with an average reduction of 1 day in postoperative hospital stay. In terms of chest radiography comparison, the small tube group also showed significant advantages. When comparing the occurrence of pleural effusion, subcutaneous emphysema, lung infection, and inadequate lung reexpansion on chest X-rays taken on the first postoperative day, the incidence rates of these events were slightly higher in the small tube group compared to the large tube group, but they did not reach statistical significance. Furthermore, the chest X-rays taken one month after surgery indicated that both the small tube and large tube groups showed improvement or even returned to normal in the aforementioned adverse events. Therefore, it can be concluded that there is no significant difference in long-term complications between these two groups.

Conclusions: Placement of only an Abel drainage tube postoperatively can significantly alleviate patients' postoperative pain scores, shorten hospital stay, and does not increase the risk of long-term complications.

EP.07A.15 Prognosis after Surgical Treatment of Lung Cancer with Multifocal Ground-Glass Nodules: The Effect of Nodule Characteristics

J.H. Park[1], T. Yun[1], B. Na[1], K.J. Na[1], S. Park[1], C.H. Kang[1], Y.T. Kim[1], I.K. Park[1], [1]Seoul National University Hospital, Seoul/KR

Introduction: Clinical decision for the management of lung cancer with synchronous multifocal ground glass nodules (GGN) is complicated because of extremely heterogeneous nodule characteristics and distribution and there is still no clear clinical guideline for this disease entity. Thus, we analyzed the effect of radiologic nodule characteristics on long-term prognosis after surgical treatment of lung cancer with multifocal GGNs.

Methods: Total of 284 patients who underwent pulmonary resection for the treatment of lung cancer with synchronous multifocal GGNs from 2013 to 2019 were reviewed retrospectively. The most invasive nodule based on radiologic features was defined as a dominant nodule, which was the primary target of initial surgery. Patients were divided into three group according to the radiologic consolidation-tumor ratio (CTR) of dominant nodule. [PSN-1 (0≤CTR<0.5), PSN-2 (0.5≤CTR<1), Solid (CTR=1)]. Long-term prognoses of three groups were compared.

Results: There were 114 (40.2%) patients in the PSN-1, 106 (37.3%) patients in the PSN-2 and 64 (22.5%) patients in the solid group. The mean number of nodule was 4.6 (range: 2 - 23). The mean number of resected nodules at the initial surgery was 2.4 (range: 1 - 13). In 32 (11.3%) patients, only the dominant nodule was resected. Dominant nodules of 9 (3.2%) patients were non-adenocarcinoma histology. Pathologic T stage of dominant nodules were T1a in 67, T1b in 88, T1c in 31, and T2a≤ in 98 patients. After initial surgery, 177 (62.3%) patients had residual GGN(s) and the mean number of residual GGN was 3.4 (range: 1 - 17). During median 60.7 months of follow-up period, residual GGNs in 43 (24.3%) patients had progressed and second intervention was conducted in 35 (19.8%) patients (surgery - 27, radiotherapy - 8). The 5-year disease-free survival rate were 100%, 94.8%, and 81.8% for PSN-1, PSN-2, and solid group (p<0.001) and overall survival rates were 100%, 98%, and 93.1% (p=0.004), respectively. The total number of nodule, presence of residual nodules, and progression of residual nodules did not affect survival.

Conclusions: The invasiveness of dominant tumor was the most important prognostic factor in the surgical treatment of lung cancer with multifocal GGNs. The residual non-dominant nodules did not jeopardize the survival. Secondary intervention was necessary in about 20% of patients due to the progression of residual GGN.

EP.07A.16 The Prognostic Disparities Between the T3 Descriptors in Surgically Resected Primary Lung Cancer

A. Suzuki, M. Kawahara, Y. Yazaki, S. Yoshimine, J. Ichinose, Y. Matsuura, M. Nakao, S. Okumura, M. Mun, Cancer Institute Hospital of the Japanese Foundation for Cancer Research, Tokyo/JP

Introduction: Our aim was to study the disparities between the different T3 descriptors in surgically resected T3N0M0 primary lung cancer.

Methods: We retrieved data of completed resected primary lung cancer at our institute between 2010-2018. T3 lung cancer was divided into three groups, Size (S), Invasion (I), and Pulmonary metastasis within the same lobe (PM), according to the 8th TNM staging manual. Overall survival and recurrence free survival were compared using the Kaplan-Meier method with a log-rank test. A multivariable Cox regression model was performed to determine the prognostic factors.

Results: Among the 2488 cases of primary lung cancer with complete resection, 103 cases were pathologically diagnosed as T3N0M0. S, I, and PM included 30,46, and 27cases, respectively. Each group included 1 (3.7%), 2 (6.7%), and 18 (39.1%) cases with EGFR mutation. The RFS (Recurrence Free Survival) rate at 5 years for S, I, PM were 58.2%, 56.3%, and 72.7%, respectively (p=0.147). The OS (Overall Survival) rate at 5 years for S, I, PM were 62.2%, 71.0%, and 81.7%, respectively (p<0.01). The multivariable Cox regression test showed pT3 status (S vs PM, Hazard ration [HR]=0.31, 95% confidence interval [CI] 0.12-0.84, p=0.021) and mutation status (no mutation vs EGFR mutation, HR=2.81 95%CI:1.22-6.45, p=0.015) as statistically significant prognostic factors for RFS. Age (HR=1.08, 95%CI:1.04-1.13, p<0.01), surgical procedures (lobectomy vs wedge resection, HR=21.56, 95%CI:6.47-71.88, p<0.01) and pT3 status (S vs PM, HR=0.35, 95%CI:0.16-0.77, p<0.01) were statistically significant prognostic factors for OS.

Conclusions: Among the T3 descriptors, PM was a prognostic factor for both RFS and OS. EGFR mutation was a risk factor for recurrence, and considering the high rate of EGFR mutation in T3 cases with pulmonary metastasis, PM cases may have a better prognosis than the current study in the future, considering the results from the ADAURA trial. T3 descriptors should be validated in the future staging manual considering the disparities between the different T3 descriptors.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07A.17 One-Stage Versus Two-Stage Thoracoscopic Surgery for Synchronous Bilateral Pulmonary Nodules: A Propensity Score-Matched Analysis

Y. Han, F. Xiao, Q. Ma, Z. Zhang, D. Liu, C. Liang, China-Japan Friendship Hospital, Beijing/CN

Introduction: The aim of this study was to compare the surgical efficacy of one-stage and two-stage video-assisted thoracoscopic surgery (VATS) for bilateral multiple pulmonary nodules (BMPNs).

Methods: A retrospective analysis was made of 156 patients, 84 who underwent one-stage and 72 who underwent two-stage VATS for BMPNs at our department between January 2019 and December 2022. Clinical features and perioperative outcomes were compared between the two groups using propensity score-matched (PSM) analysis.

Results: There were 48 patients in each group after PSM. No significant difference was observed in operation time, blood loss, and rates of overall complications (p>0.50) between one-stage and two-stage groups. One-stage procedure was associated with shorter overall duration of drainage (3 days [IQR 3-4 days] vs. 6 days [IQR 5-7 days]; p<0.001), shorter length of stay (5 days [IQR 4-5.75 days] vs. 9 days [IQR 7-10 days]; p<0.001), as well as lower total cost (14626.3±4149.4 vs. 18975.9±3720.8 USD, p<0.001) compared to two-stage procedure. Tumor progression of the contralateral lesions happened in 13 (18.1%) patients before second operation in two-stage group.

Conclusions: One-stage and two-stage VATS for BMPNs are both safe and feasible in selected patients. One-stage procedure possess potential advantages in reducing hospital stay and cost, as well as preventing tumor progression.

EP.07A.18 Do Excessive Delays Affect Pathologic Upstaging for Early Lung Cancer?

J. Zhu, J. Zhang, R. Yip, C.I. Henschke, D.F. Yankelevitz, Mount Sinai Health System, New York/NY/USA

Introduction: Our past research into time-to-treatment for early-stage lung cancer found significant disparities, negatively affecting patients of Black or African American race, lower income, and those with vascular disease. Additionally, we found that patients who undergo radiotherapy for treatment of early-stage lung cancer face significant delays, compared to those who receive surgery. Despite these findings, we have yet to investigate the effects of excessive time delays on potentially worse lung cancer outcomes for clinical stage I lung cancers. The primary outcome of interest was pathologic upstaging, if the pathologic TNM stage was higher than the clinical TNM stage. The secondary outcome of interest was whether there were differences in lung cancer histology by each TTI quartile.

Methods: We reviewed all participants of the prospective cohort study, Initiative for Early Lung Cancer Research on Treatment (IELCART), from 2016-2024. Inclusion was limited to patients who received surgical resection for clinical stage I lung cancer (TNM 8th edition modified) with maximum diameter < 30mm (T1a-c). The median time from suspicious scan to surgery (TTI) was 84 days (IQR 57-124 days). Subsequently, the patients were split into four nearly equivalent quartiles from fastest to slowest TTI.

Conclusions: While the analyses did not yield statistically significant results, we found a trending increase in frequency of tumor size upstaging, with increasing TTI quartiles. This suggests a possible association with increasing time delays and increasing size. With complete data on recurrence and overall survival, we can better establish this connection. There were no notable differences in histology, besides more typical carcinoids in the third and fourth quartiles; this shows that providers are possibly treating all lung nodules < 30 mm equally, regardless of possible histology. Acting faster on more aggressive early-stage lung cancers needs to be a priority for future research.

EP.07A.19 Impact of Preoperative Pulmonary Function on Survival Following Lobectomy for Stage I and II Lung Cancer

K. Grapatsas[1], F. Doerr[2], F. Oezkan[2], N. Baldes[2], K. Darwiche[2], D. Theegarten[3], W. Eberhardt[2], T. Gauler[4], M. Stuschke[4], H. Hautzel[5], K. Herrmann[5], C. Taube[6], M. Forsting[7], M. Schuler[8], S. Bölükbas[9], [1]University Medical Center Essen-Ruhrlandklinik, Essen/DE,[2]University Medical Center Essen, Ruhrlandklinik, Essen/DE,[3]University Medical Center Essen, Ruhrlandklinik, Institute for Pathology/DE,[4]University Medical Center Essen, Department of Radiation Therapy/DE,[5]University Medical Center Essen, Department of Nuclear Medicine/DE,[6]University Medical Center Essen, Department of Pulmonary Medicine/DE,[7]University Medical Center Essen, Institute of Diagnostic and Interventional Radiolo/DE,[8]University Medical Center Essen, Ruhrlandklinik, Department of Medical Oncology/DE,[9]University Medical Center Essen, Ruhrlandklinik, Department of Thoracic Surgery/DE

Introduction: Determining a patient's operability is pivotal for planning surgery in early-stage lung cancer. The aim of this study is to examine the impact of preoperative lung function values on survival following lobectomy for stage I and II lung cancer.

Methods: Retrospective data were collected from a single center on patients who underwent lobectomy for lung cancer in postoperative stages I and II. Our cohort was divided into three groups according to preoperative pulmonary function. Group A included patients with normal pulmonary function, with both FEV1 and DLCO >80% predicted. Group B included patients if at least one of these values was between 60-80% predicted. Group C included patients if at least one of these values was <60% predicted.

Results: A cohort of 977 patients was included in the study, with a median age of 67.7 years. The distribution of disease stages was as follows: 68.8% were classified as stage I, while 31.2% were categorized as stage II. Lung adenocarcinoma was diagnosed in 55.2% of patients, squamous cell carcinoma in 28.4%, and neuroendocrine carcinoma in 6.2%. The most common operation was right upper lobectomy (33.9%) followed by left upper lobectomy (25.5%) and right lower lobectomy (17.3%). Group A included 14.4% of the study patients, Group B 43.1%, and Group C 42.2%. Preoperative pulmonary function showed statistical significance for survival in the log-rank test (p=0.01). In Group C, patients were more likely to be current smokers (p<0.01), a higher frequency of BMI <30 kg/m2 (p=0.01), a history of liver failure (p<0.01), ECOG status >1 (p=0.01), and COPD (p<0.01). Moreover, they underwent open surgery with thoracotomy more frequently (p<0.01). However, no statistical significance was found between the three groups regarding cardiovascular comorbidities, kidney morbidity, or diabetes (p>0.05). The 5-year survival for Group A was 77.2%, for Group B 59.9%, and for Group C 55.3%. Independent factors influencing survival in the multivariate analysis were liver failure (HR: 2.219, 95% CI: 1.2-4.3, p=0.01), higher lung cancer stage (HR: 1.152, 95% CI: 1.04-1.27, p=0.01), neo-adjuvant therapy (HR: 1.697, 95% CI: 1.096-2.629), and the performance of an open operation (HR: 0.604, 95% CI: 0.41-0.87, p=0.01).

Conclusions: Despite advancements in major medical technology and surgical techniques, preoperative pulmonary function remains a factor influencing survival in lung cancer patients. However, patients with impaired pulmonary function showed similar survival rates to patients with reduced pulmonary function. Therefore, patients with impaired pulmonary function should be thoroughly investigated and discussed in a multidisciplinary tumor board, and not excluded from surgery, as it could prolong survival.

EP.07A.20 Intraoperative Near-infrared Fluorescence Visualization of the Pulmonary Bronchus with Indocyanine Green Inhalation

H. Xu[1], X. Wu[2], S. Zhao[3], Z. Wang[4], G. Jiang[4], Y. Li[4], J. Zhou[4], [1]Peking University People's Hospital, Beijing/CN,[2]Beijing Aerospace General Hospital, Beijing/CN,[3]Peking University Health Science Center, Beijing/CN,[4]Peking University People's Hospital, Beijing/CN

Introduction: Intraoperative tracheobronchial injury is a rare but serious complication of lung surgery. With the increasing number of segmentectomies, surgeons need to locate finer and less easily identified segmental bronchi or even subsegmental bronchi. However, there is no simple or feasible method for visualizing the bronchus during surgery.

Methods: Herein, we report a case in which indocyanine green (ICG) inhalation was used to visualize the pulmonary bronchus during video-assisted thoracoscopic surgery. ICG (3.75 mg/ml) was inhaled into the lung of the operative side after single-lung ventilation for 5 minutes using a mesh nebulizer. Intraoperatively, fluorescence visualization of pulmonary bronchus was performed using near-infrared fluorescence (NIF) imaging system.

Results: The patient was a woman with a GGO located in the anterior segment of the right upper lobe, and thoracoscopic segmentectomy was scheduled. During surgery, the anterior segmental bronchus was difficult to locate accurately. ICG (3.75mg/ml) was inhaled into the lung of the operative side after single-lung ventilation for 5 minutes using a mesh nebulizer. Under the overlay imaging window of the NIF imaging system, the bronchus was shown in green, in sharp contrast to the surrounding lung tissue. We dissected the bronchi with the assistance of fluorescence imaging and were surprised to find that the bifurcation of the anterior and apical bronchi could be clearly identified by navigation via the inhaled ICG and NIF system. Segmentectomy was successfully performed, and no adverse events were recorded.

Conclusions: This case showed that ICG nebulization is feasible and safe for visualizing the pulmonary bronchus during thoracoscopic surgery. This method has great application potential for reducing intraoperative tracheobronchial injury.

Keywords: Pulmonary bronchus visualization, Near-infrared fluorescence, Thoracoscopic surgery

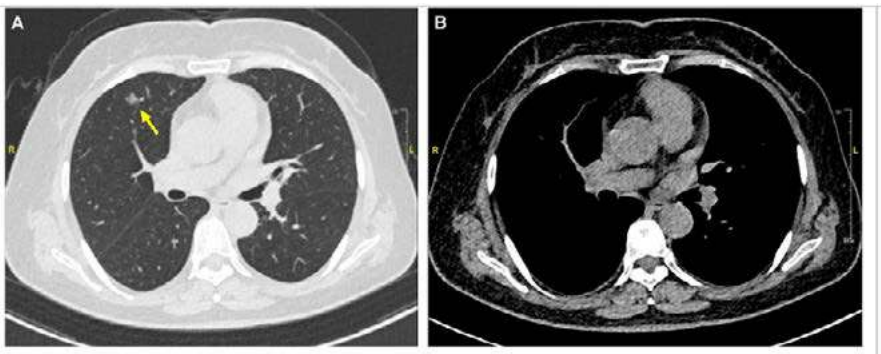

Figure 1. A chest CT revealed a GGO (yellow arrow) in the anterior segment of the right upper lobe (Subfigure A). The size of the GGO was approximately 11*9 mm in the lung window, and no visible solid component was observed in the mediastinal window (Subfigure B).

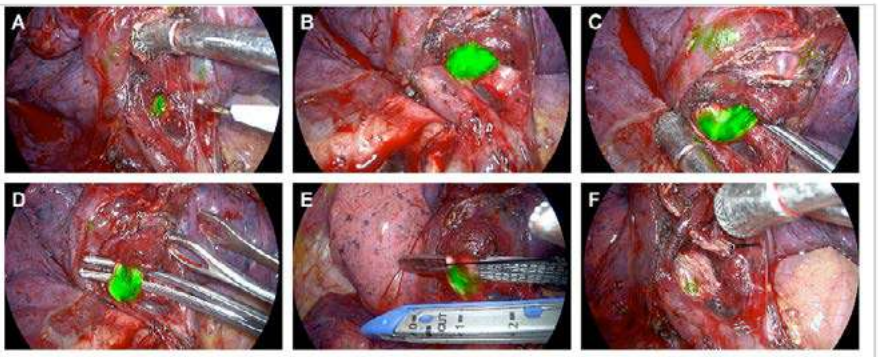

Figure 2. Under the overlay imaging window of the near-infrared fluorescence imaging system, the bronchi were shown in green, which contrasts with the surrounding lung tissue (Subfigures A and B). More importantly, the bifurcation of the anterior and apical bronchi could be clearly identified (Subfigures B and C). After the bronchus was fully dissected (Subfigure D), it was cut off with an endoscopic blue stapler (Subfigure E and F).

EP.07A.21 Tubeless Strategy after Thoracoscopic Pulmonary Wedge Resection: A Better Choice for Specific Patients

Y. Wu[1,2,3,4], H-J. Li[1,2], W-Z. Zhong[1,2,3,4], S. Zhang[1,3], [1]Guangdong Lung Cancer Institute, Guangzhou/CN,[2]Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangzhou/CN,[3]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Guangzhou/CN,[4]Southern Medical University, Guangzhou/CN

Introduction: The placement of a chest tube after pulmonary resection is generally considered necessary. However, discomfort of the drainage system impede the fast recovery of patients. Previously, we proved that catheter drainage was a safe alternative to chest tube for wedge resection and relieved postoperative pain. Here, we conducted this research to investigating the improvement of tubeless strategy compared to catheter drainage.

Methods: Patients who underwent pulmonary wedge resection under Video-assisted thoracoscopic surgery in our hospital between September 2020 and March 2024 were enrolled in this study. According to the presence or absence of postoperative thoracic drainage, the patients were divided into Catheter and No Intubation group. Propensity score matching method (PSM) was used and univariate analysis was performed to compare the clinical features and perioperative complications between the two groups.

Results: A total of 416 patients were included. PSM was used to identify 1:1 between the Catheter and No Intubation group. The matching factors were baseline characteristics, and 56 cases in each group were matched. The results showed that the operative time in the Catheter group was significantly longer than that in the No Intubation group (82.00 vs. 67.50 min, P <0.05). No significance was observed in postoperative complications, numerical rating scale score, reintubation rate and hospitalization stay.

Conclusions: It is feasible to omit thoracic drainage after surgery for some patients, resulting in a better experience, surgical satisfaction, and better wound recovery. This strategy should be extended to patients who undergo pulmonary wedge resection and are evaluated intraoperatively as having a low risk of complications.

EP.07A.22 The Optimal Surgical Procedure Based on the Risk of Recurrence in Clinical Stage 0 or IA Lung Adenocarcinoma

T. Takenaka[1], K. Ozono[1], M. Kohno[1], T. Akamine[1], F. Kinoshita[1], Y. Nakanishi[1], T. Yoshizumi[2], [1]Kyushu University Hospital, Fukuoka city/JP,[2]Kyushu University, Fukuoka city/JP

Introduction: Recently, two randomized controlled studies have proved noninferiority or superiority in survival after sublobar resection compared with lobectomy for peripheral lung cancers that are 2 cm or less. On the other hand, both trials defined inclusion criteria by maximum tumor diameter or consolidation tumor ratio (CTR), which diverges from the current tumor node metastasis (TNM) staging. In this study, we evaluated the optimal surgical procedures of clinical stage 0 or IA adenocarcinoma according to the TNM 8th edition and imaging features of tumors from the perspective of recurrence.

Methods: We retrospectively investigated 508 lung adenocarcinoma diagnosed as c-stage 0 or IA who underwent curative resection. Tumors were divided into pure GGO, part-solid tumors and solid tumors based on the CTR in thin-section CT: pure GGO, CTR=0; part-solid, 0<CTR<1; solid, CTR=1. A survival analysis was performed according to the clinical T descriptor, CT features and surgical procedures.

Results: The tumors were classified as follows: 74 with pure ground glass opacity (GGO), 237 part-solid tumors and 197 solid tumors. The types of surgical procedures were lobectomy (n=328), segmentectomy (n=73) and wedge resection (n=107). Clinical T descriptors were cTis in 74 patients, cT1mi in 68 patients, cT1a in 94 patients, cT1b in 181 patients and cT1c in 91 patients. For the entire cohort, the 5-year overall survival (OS) rate was 93.8%, and the 5-year disease-free survival (DFS) rate was 87.5%. The respective 5year OS and DFS rates by clinical descriptors were as follows: 97.6% and 97.6% in cTis, 95.4% and 95.4% in cT1mi, 96.4% and 93.9% in cT1a, 92.4% and 84.8% in cT1b and 89.2% and 70.8% in cT1c. Recurrence was observed 46 cases (9%), including 3 (3.1%) with cT1a, 23 (12.7%) with cT1b and 20 (22.0%) with cT1c. No recurrence was observed in cTis or cT1mi cases. Solid tumors with cT1b recurred more often than part-solid tumors among cT1b cases (16.8% vs. 6.8%) (p=0.046). There were no marked differences in the recurrence rate between part-solid and solid tumors in the cT1a and cT1c groups. The patients who received sublobar resection developed recurrence more often than the patients who received lobectomy among cT1b cases (21.4% vs. 10.1%) and cT1c cases (46.2% vs. 18.0%) (p=0.053 and p=0.023).

Conclusions: The cTis and cT1mi cases should be actively considered for sublobar resection, while cT1b (especially solid cT1b cases) and cT1c cases should be considered for lobectomy to prevent recurrence.

EP.07A.23 Initial Experience of Robotic Assisted Pulmonary Resection Using a Novel Surgical Robot with Haptic Feedback Function

Y. Ueda, J-i. Wakahara, S. Miyahara, H. Nakashima, Y. Masuda, R. Waseda, T. Shiraishi, T. Sato, Fukuoka university hospital, Fukuoka/JP

Introduction: Robotic-assisted thoracoscopic surgery (RATS) has the advantages of low patient burden and high precision without unsteady hand movements However, the lack of tactile sensations may result in unexpected iatrogenic organ damage.

Methods: The Saroa (Riverfield Inc., Tokyo, Japan) is a pneumatically driven robot that provides real-time haptic feedback to the surgeon. We performed the first thoracic surgery for lung cancer using the Saroa in the world in July 2023. A retrospective analysis was performed at our institution for patients who underwent lung resections using the da Vinci surgical system (Intuitive Surgical Inc. CA) and the Saroa from July 2023 to March 2024. The aim of this study is the evaluation of short-term outcomes, including intraoperative adverse events, operative time, blood loss, postoperative pain, and the feasibility and safety of thoracic surgery for lung cancer using the Saroa.

Results: Of 65 patients, 19 were performed using the Saroa. In terms of surgical procedure, six patients underwent segmentectomy and 13 underwent lobectomy in the Saroa group, and six patients underwent segmentectomy and 40 underwent lobectomy in the da Vinci group. We observed two patients and one converted to the thoracotomy due to pleural adhesion, respectively. No patient had postoperative complications of Clavien-Dindo classification IVa or higher, except two patients who died in the da Vinci group. The causes of death were cerebral infarction and acute exacerbation of interstitial pneumonia. Intraoperative adverse events didn't occur in both groups. No statistically significant difference was observed in terms of hospital stay:10 days for the Saroa group and 10 for the da Vinci group (p = 0.786). There was no significant difference in FEV 1.0% in the Saroa and the da Vinci group (68.68 % vs 68.86 %, p = 0.957), in operative time (213 min vs 237 min, p = 0.316), in blood loss (102 mL vs 249 mL, p = 0.428), in the Numerical Rating Scale (NRS) in the 1st p.o. day (2.95 vs 3.24, p = 0.617), but had a shorter console time (116 min vs 173 min, p= 0.00135) and a lower onset of prolonged air leakage (2/19 vs 6/46, p = 0.0371). Fifteen (78.9 %) patients in the Saroa group and 39 (84.8 %) in the da Vinci group had pathological stage I and II diseases.

Conclusions: This study found that robotic pulmonary resection for lung cancer using the Saroa can be safely performed.

Introduction: Patients with history of prior cancer are generally excluded from studies, however their incidence is increasing in clinical practice. They possess a genetically susceptible oncological profile that may influence both oncogenesis and treatment response. This study aimed to investigate whether history of prior cancer had different impact on oncologic outcomes of patients with peripheral early-stage non-small cell lung cancer (NSCLC) operated on by lobectomy or segmentectomy.

Methods: A retrospective multicenter study included patients with pathologically proven 2 cm or less N0M0 R0 NSCLC with or without history of prior cancer, operated on from 2015 to 2021 across nine European centers (one per country). Oncologic lung outcomes were assessed before and after propensity score matching (PSM) by cox regression (overall survival and recurrence-free survival) and competing regression analyses (lung cancer-specific survival) to adjust patients and tumor-related factors.

Results: 540 (28.2%) patients had history of prior cancer. Lobectomy and segmentectomy were performed in 1476 (77.3%) and 434 (22.7%) patients, respectively. Two matched sets of 408 patients each (operated on by lobectomy vs. segmentectomy) were formed using PSM. Following PSM: 1) 5-year overall survival was similar (p= 0.3) between patients who underwent lobectomy 86.5% (CI 95%: 82.8-90.4%) and segmentectomy 81.4% (CI 95%: 76.2-86.9%); 2) 5-year overall survival was statistically different (p= 0.02) between patients with history 80.5% (CI 95%: 74.3-86.5%) and without history of prior cancer 86.2% (CI 95%: 82.6-89.9%); 3) 5-year lung cancer specific survival was statistically different (p= 0.04) between patients who underwent lobectomy 95.2% (CI 95%: 92.8-97.6%) and segmentectomy 96.1% (CI 95%: 93.3-99%); 4) 5-year recurrence-free survival was similar (p= 0.1) between patients who underwent lobectomy 89.5% (CI 95%: 86-93.2%) and segmentectomy 89.1% (CI 95%: 84.9-93.4%); 5) 5-year lung cancer specific survival in patients with history of cancer was different (p= 0.01) between those who underwent lobectomy 88.9 % (CI 95%: 82.5-95.7%) and segmentectomy 94.9 % (CI 95%: 88.9-100%); 6) 5-year recurrence-free survival for patients with history of cancer was similar (p= 0.1) between patients who underwent lobectomy 85.3% (CI 95%: 77.6-93.6 %) and segmentectomy 89.5% (CI 95%: 82.3-97.3%); 7) 5-year recurrence-free survival for patients who underwent segmentectomy was similar (p= 0.9) between patients with history 89.5% (CI 95%: 82.3-97.3 %) and without history of cancer 88.6% (CI 95%: 83.5-94.1%). Locoregional recurrence (lobectomy 6.3% vs. segmentectomy 3.2%, p= 0.3) and distant recurrence (lobectomy 6.3% vs segmentectomy 6.4%, p=0.8) were the same in patients with history of prior cancer.Incidence of new primary lung cancer was similar (p= 0.7) in patients who underwent segmentectomy between those with (8.3%) and without history of prior cancer (10.2%). In cox-regression analysis segmentectomy did not influence survival, recurrence, it did not either impact lung cancer specific survival even in univariate analysis.

Conclusions: Compared to lobectomy, segmentectomy does not appear to be associated with inferior oncological outcomes in patients with peripheral pathologic early-stage NSCLC and with history of any prior cancer.

EP.07A.25 Portable Cone Beam CT for Intraoperative Marking of Small Pulmonary Nodules; Anywhere, Anytime!

N. Mitsuoka, S. Yokoyama, M. Kashihara, Y. Terazaki, M. Mitsuoka, Kurume University, Fukuoka/JP

Introduction: Intraoperative lung field marking using Cone Beam Computed Tomography (CBCT) is extremely useful because it avoids air embolism, has a high identification rate of small lesions, and can be completed in the operating room. However, there have been drawbacks such as the need for an operating room equipped with a CBCT imaging machine, the inability to bend the bed, the unreasonable position, and the fact that it can be difficult for physique patients. Therefore, we have been proposing the need for the development of portable CBCT, but it has not yet been developed. In this study, CiosSpin, which is mainly used in areas other than pulmonary resection, was applied to the lung field.

Methods: A portable CBCT machine CiosSpin (SIEMENS Co., Ltd., Germany) and an operating table MOT-VS600 (MIZUHO Co., Ltd., Japan) were used for four patients with small peripheral pulmonary nodules predicted to be difficult to palpable. The location of the lesion was confirmed by CBCT before surgery (pre-scan) under general anesthesia and the portable C-arm position was noted. A surgical clip was attached to the surface of visceral pleura that was anticipated to be closest to the nodule. After the C-arm was repositioned, intraoperative scan was performed. Partial pulmonary resection was performed by identifying the tumor from the position of the clip and nodule.

Results: There were 3 males and 1 female with mean age of 68.3 years (range: 64-76). The preoperative diagnosis was AIS, MIA, invasive adenocarcinoma, and metastatic pulmonary tumor in one case each. Eventually, lobectomy was performed in one case, segmentectomy in two cases, and partial resection in one case. In all cases, the lesion could be depicted by CBCT, and in 3 of 4 cases, the bed was able to bend without adjusting the patient's position after pre-scan. There were no complications associated with this method.

Conclusions: If this technique is established, it will be possible to confirm the location of lesions by CBCT even if it is not a hybrid operation room, and it can be an extremely useful tool. The CiosSpin is designed with wider panel width than other models, making it easy to accommodate the lateral decubitus position, and has high-quality imaging. We report on this method including some areas that we would like to further improve.

EP.07A.26 A Novel Four-Hook Puncture Needle for Accurate Localization of Small Pulmonary Nodules in VATS: A Single-Center Retrospective Study

B. liang, Q. Cai, The Fifth Affiliated Hospital, Southern Medical University, Guangzhou/CN

Introduction: Accurate localization of small pulmonary nodules is crucial for the success of video-assisted thoracoscopic surgery (VATS). Our center uses a Novel Four-Hook Puncture Needle for Accurate Localization (NFHPNAL), providing a minimally invasive and reliable method for precise localization. This retrospective study evaluated the accuracy and safety of pulmonary nodule resection guided by NFHPNAL.

Methods: This retrospective study describes a single-center study of NFHPNAL for preoperative localization of pulmonary nodules. Clinical, surgical, and pathological data were collected from patients undergoing pulmonary nodule localization from July 2023 to March 2024.

Results: The study reviewed 20 patients who underwent pulmonary nodule localization using NFHPNAL for guidance. A total of 20 pulmonary nodules were treated, with a median localization time of 12 minutes. Following localization, all patients underwent VATS with a median duration of 20 minutes. The median lesion size was 6.5 mm, and the distance between the lesion and the pleura or fissure ranged from 5 to 40 mm. No complications such as bleeding, chest infection, or dislodgement were observed. The overall malignancy rate was 75%. The use of NFHPNAL resulted in a 100% accuracy rate in localizing small pulmonary nodules, as confirmed by markers.

Conclusions: Pulmonary nodule resection guided by NFHPNAL is a safe and precise localization method, potentially minimizing the time spent searching for pulmonary nodules during surgery and simplifying the surgical process.

EP.07B.01 Definitions of Local Control after Stereotactic Body Radiation Therapy for Early-Stage Lung Cancer Reported in the Literature

N. Nourmohammadi[1], C. Kashani[1], J. Nikitas[1], T. Oughourlian[1], J. Bradley[2], M. Guckenberger[3], S. Siva[4], D. Palma[5], S.S. Yom[6], S. Senan[7], D. Moghanaki[1], [1]UCLA, Los Angeles/CA/USA,[2]University of Pennsylvania, Philadelphia/PA/USA,[3]University Hospital Zurich, University of Zurich, Zurich/CH,[4]University of Melbourne, Melbourne/AU,[5]Western University, London/ON/CA,[6]University of California San Francisco, San Francisco/CA/USA,[7]Amsterdam University Medical Centers, Amsterdam/NL

Introduction: Definitions of local control after stereotactic body radiation therapy (SBRT) are not standardized and include determinations of relapse in the primary tumor, same lobe, ipsilateral lung, and/or regional nodes. Furthermore, radiologic and metabolic features used to distinguish primary tumor control from relapse are generally not validated and may contribute to varying determinations. We set out to systematically review criteria defining local control reported in peer-reviewed literature and evaluate these trends over time.

Methods: The Preferred Reporting Items for Systematic Reviews and Meta-Analyses guideline was used to identify, appraise, and synthesize articles published in PubMed reporting local control rates after lung SBRT from 2006-2023. Reviews, reports lacking disease-control determinations, and abstracts not written in English were excluded. Remaining articles were eligible for analysis and individually reviewed by three authors to categorize reported local control definitions by anatomic sites and criteria used to distinguish local control from relapse.

Results: Out of 155 peer-reviewed articles, 114 were eligible for analysis. Local control determinations were termed "local control," "local failure," "local recurrence," and "primary tumor control (or failure)" in 39%, 32%, 24%, and 4% of studies, respectively. Anatomic sites evaluated for local control relied upon primary tumor site, same lobe, ipsilateral lung, and regional nodes in 68%, 11%, 4%, and 2%, respectively; 15% did not specify an anatomic location in their local control definition. There was no change in the percentage of studies specifying local control as "primary tumor control" over time (p=0.45). Local control determinations were reported in 94% of studies and relied on 12 different criteria including specific imaging modalities (computed tomography [CT] or positron emission tomography [PET]), minimum growth (serial growth, Response Evaluation Criteria in Solid Tumors [RECIST], or 20-50% size increase), period of growth (2-36 months or serial growth), or histopathological confirmation in 28%, 31%, 18%, and 1%, respectively.

Conclusions: There is substantial variability in definitions used to report local control after lung SBRT in peer-reviewed literature. Many studies include same lobe, ipsilateral lung, and regional nodes in their assessments of local control, with some not specifying what anatomic sites of relapse were considered in addition to primary tumor control. We identified multiple studies that omitted any specific parameters for local control determinations. There is a need to standardize post-SBRT local control definitions for greater accuracy in reporting primary tumor control rates and to facilitate more robust comparisons between studies.

EP.07B.02 Comparative Outcomes of Surgery and SBRT for Stage I Lung Cancer in Koreans: A Propensity Matched Multidisciplinary Cohort Study

E. Lee[1], Y.J. Suh[2], J.W. Park[2], S.H. Kwak[1], H.E. Kim[2], C.Y. Lee[2], J. Cho[2], E.Y. Kim[2], [1]Yonsei University College of Medicine, Yongin Severance Hospital, Yongin/KR,[2]Yonsei University College of Medicine, Seoul/KR

Introduction: With increasing life expectancy and active chest CT surveillance in South Korea, there has been a rise in early-stage lung cancer cases among the elderly and those with comorbidities. Stereotactic Body Radiotherapy (SBRT) is emerging as a preferred treatment for patients unable to undergo surgery for stage I lung cancer. However, there is limited research comparing SBRT and surgery outcomes for stage I cancer. This study aims to identify criteria indicating that the outcomes of SBRT are not inferior to standard surgery for early-stage lung cancer.

Methods: Between 2012 and 2021, patients with stage I lung cancer who underwent SBRT and those who received surgical treatment at Severance Hospital, Yonsei University, were retrospectively analyzed. Tumor size, location, radiologic characteristics, and pleural attachment on computed tomography (CT) images were assessed using an AI-based CAD software (CT AI-CAD) (AVIEW LCS, Coreline Soft, Seoul, South Korea). Patient demographics and tumor characteristics were matched using Propensity Score Matching to evaluate recurrence outcomes in each group.

Results: This study compared a total of 2,055 surgical patients and 219 SBRT patients for stage I lung cancer, revealing notable demographic and clinical differences. The surgery group was significantly younger than those receiving SBRT (63.5 vs. 77.7 years, $p<0.001$), with a higher proportion of females (54.3% vs. 29.2%, $p<0.001$). Adenocarcinoma was more prevalent among surgical patients (90.6% vs. 66.6%), while SBRT patients had a higher frequency of ever-smokers (60.7% vs. 36.4%, $p<0.001$). Surgery patients also exhibited more sub-solid nodules compared to SBRT-treated individuals (65.5% vs. 44.3%, $p<0.001$). Despite both groups predominantly consisting of stage IA diagnoses and no differences in average tumor size, the SBRT group experienced a higher overall recurrence rate (12.3% vs. 7% in surgery, $p=0.02$). However, when comparing matched groups of 150 patients from each treatment, adjusted for age, sex, smoking status, and tumor characteristics using chest CT AI software, the recurrence rates showed no significant difference (SBRT 11.4% vs. surgery 10.7%, log-rank $p=0.9$).

Conclusions: After adjusting for key patient and tumor characteristics, this study demonstrates that SBRT is not inferior to surgery in terms of recurrence rates among stage I lung cancer patients. While current practice largely assesses treatment modality based on patient age, pulmonary function, and comorbidities, incorporating tumor characteristics itself into predicting recurrence risk could facilitate personalized recommendations for safe and effective treatments in stage I lung cancer patients.

EP.07B EARLY-STAGE NON-SMALL CELL LUNG CANCER - RADIOTHERAPY OUTCOMES

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07B.03 Analysis of 30- And 90-day Mortality after Lung SBRT as an Indicator for Its Appropriateness

G. Videtic, C. Reddy, K. Stephans, Cleveland Clinic Foundation: Cleveland Clinic, Cleveland/OH/USA

Introduction: Surgeons analyze 30- and 90-day mortality rates after lung cancer resections as a quality metric. Although lung stereotactic body radiotherapy [SBRT] has minimal treatment-related toxicity, inoperable early-stage lung cancer [ES-LC] patients [pts] being considered for SBRT may have active competing co-morbidities at the time of decision making regarding SBRT. We therefore analyzed 30- and 90-day causes of death (CODs) after SBRT as a quality measure of appropriateness.

Methods: We surveyed our institutional review board-approved prospective lung SBRT data registry from 2003 to 2023 for medically inoperable ES-LC pts to study their CODs within 30 and 90 days following SBRT. Pts refusing surgical resection or deemed operable, with oligometastases, or treated for salvage were excluded. Selected pre-treatment pt and tumor factors were analyzed using logistic regression analysis to identify factors associated with 90-day mortality.

Results: For the 20-year interval, 1871 pts met study criteria, with 29.3% alive at analysis. Median follow up was 27.7 months. Patient characteristics included: female (52.5%), median age 74.1 years, median KPS 80. Among causes for pre-treatment inoperability, pulmonary [PULM] and cardiovascular [CV] disorders made up 57.5% and 14.5% of the total, respectively. Tumor characteristics included: median size 2.1 cm, median PET SUVmax 7.6, 67.5% with biopsy proven cancer, 26.0% central. The two most common SBRT schedules employed were 50 Gy/5 fractions (39.0%) and 34 Gy/1 fraction (27.5%). Fifty-seven (3.0%) pts died within 90 days of lung SBRT, of which 10 (0.5%) were within 30 days. No deaths were attributable to SBRT. When CODs were grouped by categories, CODs for 30-day and 90-day cohorts (in %) were CV (30.0; 38.6), PULM (10.0; 14.0), LUNG-CA (10.0; 12.2), infectious (20.0; 10.5) and other (30.0; 24.6), respectively. On multivariate analysis, male gender (p= 0.0399), lower body-mass index (p=0.0114), higher Charlson score (0.0008), and KPS <80 (p<0.0001) were associated with an increased risk of < 90-day mortality.

Conclusions: Early deaths after lung SBRT were rare. Although pre-treatment CV co-morbidities were the reason for inoperability in a minority of patients, the present analysis suggests CV diagnoses are the commonest causes of death within 90 days of lung SBRT. Notwithstanding the efficacy and long-term safety of lung SBRT with respect to cancer outcomes, these results suggest attention should be paid to competing CV risk factors when assessing pts for lung SBRT appropriateness.

Keywords: inoperable early stage lung cancer, SBRT, early causes of death

EP.07B EARLY-STAGE NON-SMALL CELL LUNG CANCER - RADIOTHERAPY OUTCOMES
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07B.04 Two-Stage Bilateral Video-Assisted Thoracic Surgery Combined with Gefitinib for Bilateral Primary Lung Cancer: A Case Report

B. liang, Q. Cai, T. Zhang, M. Shen, M. Kuang, The Fifth Affiliated Hospital, Southern Medical University, Guangzhou/CN

Introduction: Current guidelines advocate surgical intervention for early-stage bilateral primary lung cancer. This report presents a case located in the right upper and left lower lobes, addressed through a two-stage surgical approach after extensive multidisciplinary discussions. Adjuvant gefitinib therapy was provided during interim period between the surgeries, continuing after the second surgery.

Methods: Case report of two-stage bilateral video-assisted thoracoscopic surgery combined with gefitinib therapy in a patient with bilateral primary lung adenocarcinoma.

Results: A 70-year-old female with hypertension and coronary artery disease history experienced chest discomfort in June 2022. Chest CT identified a 3.0 cm lobulated mass in the right upper lobe and a 1.8 cm solid nodule in the left lower lobe, with no significant lymph node enlargement. Considering the patient's compromised cardiac function, a two-stage surgical approach was decided upon after comprehensive multidisciplinary discussion. The patient underwent video-assisted thoracoscopic surgery (VATS) for wedge resection of the left lower lobe in June 2022. Pathology reported adenocarcinoma, predominantly lepidic growth. High-throughput sequencing revealed EGFR Exon 21 L858R substitution mutation. Oral gefitinib 250 mg daily was initiated in July 2022. Three months post-treatment, an October 2022 chest CT revealed the right upper lobe lesion shrank to 1.8 cm. Following further multidisciplinary discussion, the patient underwent VATS for the resection of the right upper lobe and mediastinal lymph node dissection. Pathology confirmed adenocarcinoma with a predominantly lepidic growth pattern and interstitial fibrosis, and no evidence of lymph node metastasis. High-throughput sequencing revealed EGFR Exon 21 L858R substitution mutation and ALK Exon 24 R1231Q point mutation. Postoperatively, the original gefitinib regimen (250 mg daily) was maintained post-surgery, with no recurrence or metastasis observed at the 17-month follow-up.

Conclusions: In our case, adenocarcinomas were identified in distinct lobes of both lungs, posing a unique management challenge. Notably, the largest lesion in the right upper lobe significantly reduced in size after preoperative EGFR-TKI therapy, introducing uncertainty in accurate T staging. Through multidisciplinary discussions, we decided to base the patient's staging on the preoperative size of this lesion, designating it as T1N0M0, stage Ia, in line with guidelines that suggested no need for further adjuvant therapy post-surgery. However, given the positive response to gefitinib post-initial surgery, the team agreed to continue this treatment, anticipating further benefits for the patient. For oncologists managing similar rare cases, adopting a multidisciplinary discussion to determine the optimal treatment plan is recommended

EP.07B.05 Comparison of Image-Guided Thermal Ablation or Stereotactic Body Radiation Therapy for Primary Non-Small Cell Lung Cancer

J. Nikitas, C. Kashani, T. Oughourlian, N. Jahanshahi, M. Yokomizo, S. Tappuni, S. Nesbit, A. Lee, J. Deng, M. Steinberg, S. Genshaft, R. Suh, F. Abtin, D. Moghanaki, University of California, Los Angeles, Los Angeles/CA/USA

Introduction: Image-guided thermal ablation (IGTA) and stereotactic body radiation therapy (SBRT) are increasingly utilized for primary non-small cell lung cancer (NSCLC). Evidence comparing their relative efficacy and safety is limited, making treatment recommendations challenging when both modalities are options.

Methods: This was an IRB-approved, retrospective unmatched cohort study of patients with primary NSCLC treated at a tertiary academic medical center with either IGTA or SBRT for tumors measuring ≤30 mm in diameter. Treatment-site progression was assessed via clinical and radiographic reports. Acute (≤3 months from treatment) and late (>3 months from treatment) treatment-related adverse events (TRAEs) were identified from clinical notes and graded using the Common Terminology Criteria for Adverse Events, version 5. Rates of treatment-site progression and TRAEs following IGTA and SBRT were compared using Fisher's exact test.

Results: At the time of this analysis, 162 tumors were identified that were treated with IGTA (n=73, January 2011-December 2016) or SBRT (n=89, January 2009-December 2021). Patient and treatment characteristics are summarized in Table 1. Median follow-up time to last available imaging was 44.8 months for IGTA and 39.1 months for SBRT (p=0.32). Among the 134 tumors with follow-up time >12 months, treatment-site progression rates after IGTA and SBRT were 15.1% (8/53) and 0% (0/81) (p<0.001), respectively. For IGTA, treatment-site progression occurred in 0% (0/8), 25.8% (8/31), and 0% (0/14) of tumors ≤10 mm, >10-20 mm, and >20-30 mm, respectively; stratified by location, treatment-site progression occurred in 3.7% (1/27), 25.0% (4/16), and 30% (3/10) of tumors ≤2 cm, >2-4 cm, and >4 cm from the periphery, respectively. Grade ≥3 TRAE rates after IGTA and SBRT were 19.2% (14/73) and 3.4% (3/89) (p=0.001), respectively. Grade ≥3 TRAEs for IGTA included pneumothorax (n=11), pleural effusion (n=1), hemothorax (n=1), and acute respiratory failure leading to death (n=2); grade ≥3 TRAEs for SBRT included pneumonitis (n=2) and pneumothorax (n=1). Acute TRAE rates after IGTA and SBRT were 15.1% vs 0% for grade 3 (p<0.001), 2.7% vs 0% for grade 4 (p=0.20), and 1.4% vs 0% for grade 5 (p=0.45), respectively. Late TRAE rates after IGTA and SBRT were 0% vs 1.1% for grade 3 (p>0.99), 0% vs 2.3% for grade 4 (p=0.52), and 1.7% vs 0% for grade 5 (p=0.41), respectively.

Conclusions: These data represent over 13 years of experience delivering IGTA and SBRT for primary NSCLC. Our findings demonstrate significant differences in efficacy and TRAEs that can guide future research and clinical management decisions.

EP.07B.06 Transplant Patients with Medically Inoperable Early-Stage Lung Cancer Have Worse Outcomes When Treated with SBRT

G. Videtic, C. Reddy, K. Stephans, Cleveland Clinic Foundation: Cleveland Clinic, Cleveland/OH/USA

Introduction: Lung stereotactic body radiotherapy [SBRT] is the standard of care for curative management of medically inoperable early-stage lung cancer [ES-LC] due to its excellent local control and minimal treatment-related toxicity. Patients (pts) with organ transplants are chronically immunosuppressed, with increased risk of developing cancer. We wished to characterize outcomes for transplant pts with inoperable ES-LC treated with SBRT.

Methods: We surveyed our institutional review board-approved prospective lung SBRT data registry from 2003 to 2023 for medically inoperable ES-LC solid organ transplant pts. Patterns of failure were assessed, as well as overall survival (OS) and disease-free survival (DFS). Univariable prognostic factors for OS and PFS were identified with Cox proportional hazards regression.

Results: For the 20-year interval, 28 of 1976 definitive pts (1.4%) met study criteria, with 17.9% alive at analysis. Median follow up was 12.4 months. Pt characteristics included: male (52.9%), median pack-years smoking 34; 7.1% smoking at SBRT; median age 70.0 years, median KPS 80. Organs transplanted were lung (57.1%), liver (21.4%), heart (21.4%). Median time from transplant to SBRT was 5.7 years. Tumor characteristics included: median size 2.4 cm, median PET SUVmax 7.8, 85.7% with biopsy proven cancer. The median SBRT schedule was 50 Gy/5 fractions (32.1%). Toxicity was reported in 9 (32.1%) pts: grade 1/2 in 8 pts (28.6%) and grade 5 (pneumonitis) in 1 pt (3.5%), with no differences in rates by organ transplanted. Failure patterns were: local 21.4%, lobar 7.1%, nodal 10.7% and distant 32.1%. First site of failure was distant [alone or in combination] in 50.1% pts. Median DFS and OS were 17.1 and 14.5 months, respectively. Metastatic cancer was the cause of death in 25% patients. Univariate analysis revealed increasing pack-years smoking was associated with increased disease failure [p=0.0016], but not with any other patient, tumor or transplant factors. Multivariate analysis revealed OS significantly associated with KPS [p=0.0075] and tumor size [p=0.0181].

Conclusions: Compared to historical SBRT results for ES-LC, transplanted pts had higher local failure, decreased cancer control and poorer overall survival. To explain these findings, we hypothesize that transplant-associated immunosuppression promotes understaging at diagnosis, enhanced metastatic progression despite treatment and a tumor biology resistant to SBRT.

EP.07B.07 The Impact of Radiation Therapy on Lung Cancer Patients with Interstitial Lung Disease

S. Genet[1], E. Yogiaveetil[2], N. Shaverdian[2], A. Wu[2], C.B. Simone II[2], J. Shin[2], D.Y. Gelblum[2], P. Iyengar[2], A. Rimner[3], D.R. Gomez[2], A.F. Shepherd[2], [1]Mount Sinai, New York/NY/USA,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA,[3]Universitats Klinikum Freiburg, Freiburg/DE

Introduction: The purpose of this study was to evaluate the impact of radiation therapy (RT) on overall survival and pulmonary toxicity in lung cancer patients with interstitial lung disease (ILD).

Methods: We conducted an-IRB approved retrospective study of 38 consecutive patients with underlying ILD that were treated between 2001-2022 with RT for primary lung cancer. Because differentiating radiation pneumonitis from an ILD exacerbation is difficult, pulmonary complications were defined as new or increased use of steroids or supplementary oxygen. Survival rates were determined following completion of treatment by the Kaplan Meier method.

Results: Patients were predominantly male (61%) and were a median age of 73 years (range, 58-89 years). The KPS ranged from 50 to 90 with a median of 80. 34 (89%) patients had a smoking history (median pack years: 50). 19 (50%) patients had COPD in addition to ILD. The median FEV1 was 85% and DLCO was 43%. Prior to RT, 10 (26%) patients were on baseline prednisone and 17 (45%) were on oxygen (59% on 1-2L, 18% on 3-5L, 23% unknown). 19 patients had squamous cell carcinoma, 17 had adenocarcinoma, and 2 had SCLC. Patients were staged as I (n=17), II (n=2), III (n=16) and IV (n=3). 10 patients were treated with proton therapy. 12 patients were treated with SBRT (3-5 fractions to 24-50 Gy), 6 patients with definitive hypo-fractionated RT (60 Gy in 8 or 15 fractions), 3 patients with palliative RT (30 Gy in 10 fractions) and 17 patients with conventional fractionation to 54-80 Gy. The median follow-up time for survivors was 16.5 months (range: 8-42 months). The median overall survival from the end of RT was 12.1 months for all patients; 12.9 months for stage I-II patients and 8.4 months for stage III-IV patients. 71% patients required steroids or an increase in steroids after RT. 57% of patients developed a new requirement for oxygen or an increase in oxygen after RT.

Conclusions: ILD patients are at high risk for requiring an increased use of steroids and oxygen post-RT.

EP.07B.08 The Treatment Outcome of SBRT and Sublobar Resection for Vulnerable Elderly Patients with Stage IA Non-Small Cell Lung Cancer

M. Asami, S. Katsumata, K. Yasui, D. Yamaguchi, K. Matsushima, T. Masuda, K. Hayasaka, H. Kojima, H. Konno, M. Isaka, H. Harada, Y. Ohde, Shizuoka Cancer Center, Shizuoka/JP

Introduction: In Japan, about 60% of patients who underwent resection for lung cancer were aged 70 years or older and 14% of patients were octogenarian. Lobectomy has long been the standard radical treatment for lung cancer. However, sublobar resection has become one of the standard treatments based on the results of recent two randomized controlled trials. In practice, we often face cases where we cannot perform standard resection for vulnerable elderly patients. Sublobar resection or stereotactic body radiotherapy (SBRT) are considered for these patients. There are no randomized controlled trials comparing sublobar resection and SBRT, so that the treatment for these patients remains controversial, especially for those with solid-predominant tumors. We aimed to compare the survival and incidence of complications of SBRT with those of sublobar resection for vulnerable elderly patients with clinical stage IA non-small cell lung cancer (NSCLC).

Methods: Using the radiology database and the thoracic surgical database of the Shizuoka Cancer Center, patients ≥ 75 years of age with performance status (PS) 0-2 who underwent SBRT or sublobar resection with curative intent for solid-predominant clinical stage IA NSCLC with ≤3cm in size from January 2010 to December 2017 were included in this study. All surgical patients were judged as ineligible for lobectomy with mediastinal lymph node dissection by surgeon in charge for reasons such as poor pulmonary function, comorbidities, and advanced age. Patients underwent sublobar resection without mediastinal lymph node dissection. A total of 119 patients were investigated in this study. To reduce selection bias, a propensity score matching method was used. The propensity score model was estimated using a logistic regression model that adjusted for preoperatively detectable patient characteristics, including age, sex, PS, smoking status, preoperative lung function (using vital capacity), comorbidities, solid tumor size on thin-slice CT (TSCT) and tumor appearance (pure-solid/part-solid) on TSCT. We compared the SBRT group to the surgery group on complications within 90 days after treatment and survival outcome.

Results: Of the 119 patients included, 86 underwent SBRT and 33 underwent sublobar resection. The median follow-up periods for surgery and SBRT were 5.1 and 4.2 years, respectively. The SBRT group included significantly older patients (median: 82 vs 79) and larger tumors (median: 18 vs 16 mm) than the surgery group. After matching, we analyzed 24 patients in each group. The incidence of ≥Grade 2 complications was not significantly different between the two groups (12.5% and 29.1%, p=0.286). Overall survival rate at 3 years was 77.1% in the SBRT group compared with 75% in the surgery group (p=0.343). Recurrence-free survival rate at 3 years was 69.4% in the SBRT group and 66.7% in the surgery group (p=0.336). There were no significant differences in survival between the two groups.

Conclusions: Our results suggest that SBRT might be relatively safer compared to surgery and post-treatment survival outcomes of SBRT may be comparable to those of surgery for vulnerable elderly patients. SBRT may be an effective treatment option for these patients. Randomized controlled trials are required to confirm these results.

Keywords: SBRT, sublobar resection, NSCLC

EP.07B.09 Lymph Node Evaluation for Stage Cia Non-Small Cell Lung Cancer: Findings from a Single Institution

Z. Chen[1], W. Huang[2], L. Liu[2], Y. Wang[2], K. Xu[2], X. Qiu[2], Q. Zhou[2], [1]Lung Cancer Center/Lung Cancer Institute, West China Hospital, Sichuan University,, Chengdu/CN,[2]Lung Cancer Center/Lung Cancer Institute, West China Hospital, Sichuan University, Chengdu, Sichuan [610041], China;, Chengdu/CN

Introduction: Uncertainties persist regarding lymph node dissection protocols in individuals diagnosed with clinical stage IA non-small cell lung cancer.

Methods: We conducted a retrospective study on patients diagnosed with clinical stage IA non-small cell lung cancer between August 2014 and November 2018. Categorical variables were evaluated using the Chi-square test, while continuous variables were assessed using the T-test. Cox regression analysis was employed to investigate the relationship between lymph node characteristics and recurrence-free survival (RFS), accounting for potential confounding factors. Subgroup analysis was performed based on tumor size and the proportion of real tumor components. All statistical analyses were performed using R version 4.3.0.

Results: A total of 556 patients were included in the study, with a median age of 59 years (range: 26-83 years). Among them, 478 (86.0%) had adenocarcinoma, 43 (7.7%) had squamous cell carcinoma, and 245 (44.1%) were male. The median follow-up time for the entire study population was 57 months. ELN-positive patients exhibited a higher number of examined lymph nodes (ELNs) (p=0.001) and shorter disease-free survival (DFS) (p<0.001). Elevated consolidation tumor ratio (CTR) was significantly associated with reduced DFS in patients with comparable numbers and stations of ELNs. Lymph node dissection did not yield significant benefits for patients with a solid component comprising less than 50% of the tumor. However, in patients with a solid component exceeding 50%, there may be potential benefits when the number of ELNs ranges from 8 to 23 (HR < 1).

Conclusions: Sufficient lymph node assessment might not be necessary in stage cIA1 NSCLC, whilt it was required in stage cIA2-3 diseases. Proper lymph node examination might help to detect potential lymphatic metastasis in the malignancy with ≥1 in size and more solid componants, and prospective studies are required to indicate the compatible lymph node examination for survival and adverse events.

EP.07C.01 Neoadjuvantimmunochemotherapy Versus Chemotherapy for Elderly Patients with IB-IIIB Non-Small-Cell Lung Cancerin Real-World Practice

Y. Yang[1], J. Liu[2], J. Hu[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN,[2]the First Affiliated Hospital, Zhejiang University School of Medicine, No. [79] Qingchun Road/CN

Introduction: The efficacy and safety of immunochemotherapy in elderly patients (≥ 65 years) have not been clarified. Therefore, we compare the safety and efficacy of neoadjuvant immunochemotherapy and chemotherapy in elderly patients (≥ 65 years) with stage IB-IIIB NSCLC.

Methods: This retrospective study consecutively included all IB-IIIB NSCLC elderly patients (≥ 65 years) who received 2-4 cycles preoperative immunochemotherapy or chemotherapy at the Department of Thoracic Surgery, the First Affiliated Hospital, Zhejiang University School of Medicine from 2016 to 2022. The primary endpoints were disease-free survival (DFS) and overall survival (OS). The secondary endpoints of this study were objective response rate (ORR), adverse events (AEs) and pathological response.

Results: A total of 140 patients were included in our study and were divided into two groups according to neoadjuvant treatment regimen: chemotherapy (n=47) and immunochemotherapy (n=93). The ORR in the immunochemotherapy group was significantly higher than in the chemotherapy group (73.1% vs 29.8%, P<0.001). The incidence of grade 3-4 AEs in the immunochemotherapy group was 19.4% and 8.5% in thechemotherapy (P=0.156). The rate of major pathologic response (MPR) in the immunochemotherapy group was significantly higher than in the chemotherapy group (64.4% vs 25.8%, P<0.001). The rate of pathologic complete response (pCR) in immunochemotherapy group was 32.2%, with 16.1% in the chemotherapy group (P=0.101). The median DFS in the chemotherapy group was 14.1 months (95% CI, 3.7 to 24.5) and not reached in the immunochemotherapy group (hazard ratio [HR], 0.243; 95% CI, 0.115 to 0.634; P<0.001). The median OS of the immunochemotherapy group was not achieved (HR,0.382; 95% CI, 0.162 to 0.896; P=0.027), with the chemotherapy group 33.9 months (95% CI, 25.4 to 42.4).

Conclusions: Neoadjuvant immunochemotherapy can produce longer survival, higher ORR and MPR rate than chemotherapy alone in elderly patients (≥ 65 years) with IB-IIIB NSCLC without increasing AEs.

Keywords: neoadjuvant treatment, non-small-cell lung cancer (NSCLC), elderly patients (≥ 65 years)

Table 2. Grade 3-4 AEs of neoadjuvant therapy in the ITT population (n = 140)

EP.07C.02 Perioperative Cadonilimab and Chemotherapy in Stage II-IIIA Non-Small-Cell Lung Cancer: Preliminary Results from a Phase II Study

H. Wang, W. Xing, Z. Ma, Y. Ba, G. Zhang, X. Zhang, G. Liang, The Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou/CN

Introduction: Neoadjuvant and adjuvant immunotherapy have improved clinical outcomes for patients with resectable non-small cell lung cancer (NSCLC). However, the optimal perioperative regimen remains unknown. Bispecific antibodies, which target immunomodulatory checkpoints, have demonstrated encouraging antitumor activity and safety profiles in advanced NSCLC. Cadonilimab is a bispecific antibody that simultaneously targets PD-1 and CTLA-4. We conduct a prospective, single-arm, phase 2 study to evaluate perioperative cadonilimab in patients with early-stage NSCLC.

Methods: Participants with resectable stage II to IIIA NSCLC received platinum-based chemotherapy (nanoparticle albumin-bound paclitaxel 260mg/m2, carboplatin AUC 5) plus cadonilimab (10 mg/kg) administered intravenously every 3 weeks for 3 cycles before surgery, followed by adjuvant cadonilimab intravenously every 3 weeks for 9 cycles. The primary endpoint was pathological complete response (pCR). Key secondary endpoints included major pathological response (MPR), objective response rate (ORR), event-free survival (EFS) and safety. Simon's two-stage design was applied, with 20 patients recruited in the first stage and 18 patients to be continued in the second stage.

Results: The first eight patients who have completed neoadjuvant treatment were included in this analysis (data as of 15 March 2024). Six patients underwent resection and all achieved R0 resection. Four patients in the intention-to-treat population achieved a MPR, including two patients who achieved a pCR. No patients had radiographic evidence of disease progression pre-surgery and seven patients achieved objective response. A surgical complication of grade 4 ketoacidosis was observed in one patient. No unexpected treatment-related toxic effects were identified. Treatment-related adverse events were predominantly of grade 1 or 2. Treatment-related grade 3 adverse events included one patient with hypothyroidism and one patient with third-degree atrioventricular block that resulted in surgical cancellation. No treatment-related grade 4 adverse events or deaths occurred.

Conclusions: This preliminary analysis indicates that incorporating cadonilimab into neoadjuvant chemotherapy led to a promising pathological response for patients with resectable stage II to IIIA NSCLC, alongside a well-tolerated safety profile. Enrollment is ongoing, and extended follow-up is required to assess event-free survival accurately. (ClinicalTrials.gov number: NCT05377658.)

EP.07C.03 Oncological Outcomes after Lobe-Specific Mediastinal Lymph Node Dissection in Thoracoscopic Right Upper Lobectomy for Clinical N0 NSCLC

M. Mun, M. Nakao, Y. Matsuura, J. Ichinose, A. Suzuki, Cancer Insitute Hospital of JFCR, Tokyo/JP

Introduction: Mediastinal lymph node dissection (MLND) during lung cancer treatment has significance for local control. In particular, station 4R LND in right upper lobectomy (RUL) is the most significant because it is closest to the tumor.

Methods: Between 2008 and 2018, 370 patients underwent thoracoscopic RUL with lobe-specific MLND for clinical N0 non-small cell lung cancer (NSCLC). Thoracoscopic lobectomy was performed by 3 or 4 port VATS. Regarding the lobe-specific MLND in RUL, subcarinal LND was omitted even in patient with hilar and upper zone mediastinal lymph node metastasis. To perform a precise dissection of lymph nodes (LNs) at station 4R, the pericardium is first exposed on the cranial side of the azygos vein. Then the pericardium is dissected towards the right main trunk of the pulmonary artery without breaking the station 4R LNs (RPE; retrograde pericardial exposure). We evaluated their oncological outcomes.

Results: The study patients comprised 176 men and 194 women (mean age, 65 years; range, 16-79 years). Clinical factor was T1mi in 44, T1a in 81, T1b in 155, T1c in 60, T2a in 21, T2b in 5, and T3 in 4. All cases were clinical N0 and performed complete surgical resection. The histological analysis showed adenocarcinoma in 337 (%), squamous cell carcinoma in 18, large cell neuroendocrine tumor in 7, adenosquamous cell carcinoma in 5, Pleomorphic carcinoma in 2, and large cell carcinoma in 1. Pathologic factor was Tis in 20, T1mi in 44, T1a in 93, T1b in 121, T1c in 36, T2a in 39, T2b in 4, T3 in 12, and T4 in 1. Pathologic stage was 0 in 20, IA1 in 135, IA2 in 109, IA3 in 32, IB in 32, IIA in 3, IIB in 19, IIIA in 16, and IIIB in 4. Nodal up-staging was seen in 30 patients (8.1%). Adjuvant therapy was performed in 32 (43%) out of 74 patients, including stage IB, II, and III. Median follow-up period for all 370 patients was 99 months. The actuarial 5-year and 10-year overall survival rates were 91.3% and 79.2%, respectively. The 5-year and 10-year recurrence-free survival rates were 87.3% and 75.4%, respectively. Thirty-five (9.5%) patients experienced recurrence during follow-up, including locoregional recurrence in 21 patients. Seven of 21 patients had recurrence in lymph node. Only one case had recurrence in the dissected area at the station 4R.

Conclusions: Precise dissection prevented recurrence at the pulmonary hilum and the dissected mediastinal zone.

EP.07C.04 Adjuvant Aumolertinib in Resected Stage I EGFR-Mutated NSCLC: Prospectively Evaluating Efficacy in Residual GGN Lesions

C.B. Huang, Tianjin Medical University Cancer Institute & Hospital, Tianjin/CN

Introduction: The efficacy of postoperative EGFR-TKIs in treating unresected residual ground glass nodules (GGN) remains controversial, especially in pts with synchronous multiple primary lung cancer (sMPLC) who are at risk of disease progression.This study is a prospective, single-center, phase II clinical trial designed to assess the efficacy and safety of the third-generation EGFR TKI aumolertinib as adjuvant therapy. The main focus is to evaluate its performance in treating unresected residual GGN lesions. (ChiCTR2200066768).

Methods: Patients(Pts) with stage I EGFR-mutated NSCLC should have one or more residual GGN (<3 cm) whose malignancy were confirmed by both a radiologist and a thoracic surgeon after target lesions surgery. They received aumolertinib of 110 mg for 2 years. The primary endpoint is response rate of GGN lesions, while secondary endpoints include objective response rate, 3-year disease free survival, safety and tolerability.

Results: From June 2021 to July 2023, a total of 31 pts with EGFR positive mutation (19Del or L858R) were enrolled, and 45.2% (14/31) of them had co-mutations. Most were invasive adenocarcinoma (93.5%,29/31). At the data cutoff, all pts were alive with no tumor recurrence, 23(74.2%) pts had been followed up for over 1 year, 13 (41.9%) pts were followed up for at least 18 months. The 1-year DFS rate is 100%. In terms of lesions, the response rate (RR) was 69.4% (25/36). Lesions shrinkage were observed in 22 pts, the preliminary overall ORR was 71.0% (22/31). The ORR of residual GGN lesions ≥8mm (n=19) or <8mm (n=12) was 73.7% and 66.7% respectively. Notably, there were 7 pts with GGN completely disappeared including 2 pts with pure GGN (pGGN) and 5 pts with part-solid nodule (PSN), all of which were L858R mutation. Among the four pts with multiple GGNs, three achieved partial response (PR) remission, while the other maintained stable disease (SD).During aumolertinib therapy, rash (22.6%), pruritus (19.4%), diarrhea (9.7%), mouth ulcers (6.5%) and alopecia (3.2%) were common adverse events and no pts withdrew from therapy.

Conclusions: Our study provides evidence for the efficacy of aumolertinib in the treatment of stage I EGFR-mutated NSCLC with GGN lesions remaining after surgery. The potential benefits for pts with more remaining lesions, mixed component lesions, and L858R mutation deserve further exploration.

EP.07C.05 Efficacy and Safety of Aumolertinib in Stage IB-IIIA NSCLC after R0 Resection and the Correlation Between Efficacy and Postoperative MRD Status

S. Yang, X. Zhang, Z. Chen, Y. Xiong, C. Zeng, M. Pan, Q. Chen, The first people's hospital of foshan, foshan/CN

Introduction: For patients with early-stage non-small cell lung cancer (NSCLC), surgical radical resection is an important treatment for the patients. However, patients are still at risk of tumor recurrence and metastasis after complete resection, and the risk increases with the increase of the stage according to the 9th edition TNM standard. ADAURA study has proved that stage IB-IIIA patients after R0 resection with or without standard chemotherapy could both benefit from Osimertinib. The primary endpoint DFS was significantly prolonged (NR vs 19.6 months, HR 0.17). However, the one-size-fits-all strategy and long-term treatment may cause unnecessary toxic side effects and psychological burden to patients. Minimal residual disease (MRD) status may be promising in personalized adjuvant therapy and it is recognized that patients with detectable MRD after resection have a worse prognosis than those undetectable. Therefore, whether MRD can play a guide role in adjuvant therapy urgently needs to be answered. Aumolertinib is a third-generation EGFR-TKI independently developed in China with high selectivity and low toxicity for EGFR mutations. Our study (ChiCTR2200059566) is designed to explore the efficacy of Aumolertinib for stage IB-IIIA NSCLC after R0 resection, and correlation between MRD status and efficacy. It may provide some hints for personalized postoperative treatment based on MRD.

Methods: A total of 120 patients with stage IB-IIIA NSCLC after R0 resection with EGFR mutations positive (19del and L858R) will be enrolled, and receive Aumolertinib (110 mg) once daily. The primary endpoint is disease free survival (DFS) rate at 2-year. Secondary endpoints included DFS rate at 2-year in patients with ctDNA status changes (positive to negative/negative to positive) and that for ctDNA continuously positive or negative patients.

Results: At date cut off March 25, 2024, we recruited 33 patient of stage I-IIIA NSCLC harboring EGFRm. In the total population, 27(81.8%) patients were female, 17(51.5%) patients harboring exon 19 deletion, 10 (30.3%) patients had 21L858R mutation, while 5(15.2%) patients had rare mutations. Additionally, 26 patients were stage I and 7 patients were stage II-IIIA. All the patients were administrated Aumolertinib (110 mg daily) after R0 surgical resection. At data cutoff, total 3 patients were dropped out because of adverse events or postoperative complications, and 16 patients received Aumolertinib adjuvant therapy and followed up more than 1 year, while 14 patients less 1 year. All patients are alive, and there is no patient presented with metastasis. The 1-year disease free survival (DFS) are 100% and 2-year DFS doesn't reach.

Conclusions: Our study demonstrates the primary efficacy and safety profile of Aumolertinib in the adjuvant treatment of NSCLC. Long term follow-up of our study is ongoing to investigate further survival outcomes.

EP.07C.07 Superiority of Modified-MPR in Prediction of Survival for Patients with Lung Cancer after Neoadjuvant Therapy

Y. Wu[1,2,3,4], J-T. Lin[1,2,3,4], W-J. Pan[5], L-S. Peng[1,2,3,4], Y-J. Su[5], W-Z. Zhong[1,2,3,4], [1]Guangdong Lung Cancer Institute, Guangzhou/CN,[2]Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangzhou/CN,[3]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Guangzhou/CN,[4]Southern Medical University, Guangzhou/CN,[5]Jinfeng Laboratory, Chongqin/CN

Introduction: Major pathologic response (MPR) after neoadjuvant therapy for lung cancer has the potential to serve as surrogate endpoint for survival. However, efficiency of MPR were moderate and unsatisfied, which may result from difficulty in determining tumor bed and residual tumor. In this study, we aimed to evaluate CT or PET-measured tumor bed and residual tumor based on artificial intelligence in pathologic response evaluation. And we explored the feasibility of modified-MPR as an alternative endpoint.

Methods: A total of 237 patients with lung cancer who received neoadjuvant therapy from Aug, 2019 to Oct, 2023 were retrospectively collected. The maximum tumor or metabolic area on baseline PET or CT were measured as tumor bed. Percentage of residual viable tumor (RVT%) was assess by deep learning model. CT or PET-based residual viable tumor% (CT-RVT%, PET-RVT%) represented RVT area divided by tumor bed assessed by CT or PET, respectively. Disease-free survival (DFS) and overall survival (OS) were analyzed by Kaplan-Meier approach and compared with log-rank test. The efficacy of CT-RVT%, PET-RVT%, and RVT% was compared by receiver operating characteristic (ROC) curve.

Results: Here, we reported preliminary result of 33 patients (median age: 58-year-old, range: 29-67 years; 28 men) from Aug, 2019 to Sep, 2020. There were 10, 17, and 10 patients achieved MPR in RVT%, CT-RVT%, and PET-RVT% groups respectively. In RVT% group, no survival difference (DFS or OS) was found between MRP and non-MPR patients. While grouping by CT-RVT% and PET-RVT%, patients who achieved MPR had superior DFS (P<0.001) and OS. Moreover, PET-RVT% and CT-RVT% show higher area under ROC curve (AUC) when compared to RVT% in DFS (0.841 vs 0.778 vs 0.626, p<0.001) and OS (0.865 vs 0.819 vs 0.593, p<0.001).

Conclusions: Our modified-MPR combining PET-CT and deep learning model showed better efficacy as predictor of DFS and OS.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07C.08 Surgical Factors and Adjuvant Therapy Use after Neoadjuvant Therapy for Patients with Resected Stage II-IIIB(N2) NSCLC

B. Stiles[1], N.P. Chudgar[1], X. Hu[2], Y-H. Kao[2], A. Arunachalam[2], N.M. Shariati[2], [1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx/NY/USA,[2]Merck & Co., Inc., Rahway/NJ/USA

Introduction: The current standard of care for resectable NSCLC includes immune checkpoint inhibitors (ICIs) administered in combination with platinum-based chemotherapy as neoadjuvant or perioperative regimens. In the US, neoadjuvant nivolumab plus chemotherapy was approved in 2022 and neoadjuvant pembrolizumab plus chemotherapy followed by adjuvant pembrolizumab in 2023. This retrospective study aimed to understand surgical approach and subsequent use of adjuvant therapy among real-world patients receiving neoadjuvant therapy with or without ICI.

Methods: We drew on data originating from ~280 cancer clinics included in the US nationwide Flatiron Health electronic health record-derived, deidentified database. Patients with diagnosis from 1/1/2019 to 3/31/2023 of clinical stage II, IIIA, or IIIB(N2) NSCLC, who received neoadjuvant therapy and underwent tumor resection by 9/30/2023 (excluding clinical trial participants) were eligible. Data cutoff was 12/31/2023.

Results: Among 1550 patients with cII-IIIB NSCLC undergoing resection, only 159 (10%) received neoadjuvant therapy, including 76 (48%) with an ICI-based and 83 (52%) with non-ICI neoadjuvant. Patients receiving ICI-based neoadjuvant were older, with a later diagnosis year (Table). Oncology practice type and insurance coverage were similar in the two cohorts. Tumor characteristics that differed numerically included lower percentages of patients with stage cIIIA and greater percentages with stage cII and with squamous NSCLC who received ICI-based (vs. non-ICI) neoadjuvant (Table). Similar percentages underwent lobectomy, and pneumonectomy rates were low. Numerically greater percentages underwent a minimally invasive resection after ICI-based neoadjuvant, including >70% with robotic-assisted surgery (Figure). Adjuvant systemic therapy was administered to 43% in ICI-based and 53% in non-ICI neoadjuvant cohorts, respectively.

Conclusions: This study illustrates changing approaches to surgical resection and neoadjuvant/perioperative therapy for stages cII-IIIB(N2) NSCLC. Uptake of ICI-based neoadjuvant therapy remains low, but its use does not compromise ability to perform minimally invasive resection. Factors influencing use of adjuvant therapy after neoadjuvant therapy should be more closely examined.

Keywords: neoadjuvant therapy, adjuvant therapy, surgical resection

EP.07C.09 Neoadjuvant Chemoimmunotherapy (CIT) In Resectable Non-Small Cell Lung Cancer (NSCLC): Real-World Treatment Patterns and Surgical Outcomes

A.J. Gibson[1], M.L. Dean[1], I. Litt[1], V. Navani[2], [1]University of Calgary - Cumming School of Medicine, Calgary/AB/CA,[2]University of Calgary; Alberta Health Services, Calgary/AB/CA

Introduction: Surgical resection continues to be the standard of care for early-stage resectable NSCLC, but post-surgical recurrence rates are as high as 50%. Improved event-free and overall survival have been demonstrated in clinical trials exploring neoadjuvant and peri-operative CIT; as such, use of neoadjuvant CIT (platinum doublet + nivolumab) has become part of the current treatment paradigm. Treatment patterns, response, toxicity and surgical outcomes in routine clinical practice from this evolving treatment approach is a current knowledge gap. We aim to characterize the characteristics, treatment response and surgical outcomes of a real-world neoadjuvant CIT-treated NSCLC cohort.

Methods: Demographic, clinical, treatment and outcome details were extracted from a province-wide, real-world outcomes registry of patients treated in routine practice. A population-level cohort of patients receiving neoadjuvant CIT were analyzed. Our primary endpoint was major pathological response (MPR) rate, with secondary endpoints including pathological complete response rate (pCR), objective response rate (ORR), surgical outcomes and adverse events (AE).

Results: Fifty-five patients received neoadjuvant CIT (Table 1). 87% received the recommended 3 cycles, eliciting an objective complete response in 8% and ORR of 67% (63% in PD-L1 >=50%). 29% had serious treatment related AEs requiring treatment delay/discontinuation; primarily nausea/vomiting. 7% experienced immune-related AE (n=1: colitis; n=3: rash; n=1: pneumonitis).To date, n=40 had surgical resection; surgery pending for 13%. 15% were ineligible for surgery post-CIT (n=3: residual N2 or progression; n=1: non-oncology related death; n=1: complete response, n=3: unfit for surgery). 98% of resections had R0 surgical margins. 13% received adjuvant platinum-pemetrexed/paclitaxel post CIT. Downstaging to from cN2 to yN0 occurred in 46% of patients. 43% MPR (53% in PD-L1 >=50%), 25% pCR (32% in PD-L1 >=50%; 35% in Stage III patients). Surgical complications occurred in 15 (37%), most commonly air leaks with spontaneous resolution (10%). Serious complications included sepsis (n=1) & hypoxemic respiratory failure with NSTEMI and immune pneumonitis (n=1). Combined, surgical complications resulted in a median 6-day hospitalization (range 2 - 180). The median follow-up time was 4 months, recurrence was noted ≤12 months post-surgery in n=3 (8%) of resected patients (n=2: local/regional, n=1: distant).

Conclusions: Surgical resection post-neoadjuvant CIT is a pragmatic management approach for resectable NSCLC. Treatment protocol completion, surgical outcomes and adverse event rates were similar to pivotal studies. Neoadjuvant CIT delivers meaningful pathological response in a real-world unselected clinical population, with Stage III disease deriving substantial benefit in this context.

EP.07C EARLY-STAGE NON-SMALL CELL LUNG CANCER - PERIOPERATIVE THERAPY
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07C.10 Real-World Outcomes of Patients Treated with Neoadjuvant Immunotherapy for Resectable Non-Small Cell Lung Cancer

T. Ermer, S.Y. Kim, S. Goldberg, E.J. Zolfaghari, J.D. Blasberg, D.J. Boffa, R. Herbst, K. Politi, K. Schalper, S. Dacic, G.A. Woodard, Yale School of Medicine, New Haven/CT/USA

Introduction: Neoadjuvant immunotherapy + chemotherapy (NAIO) has shown significant benefit over platinum-based chemotherapy (CT) alone in multiple clinical trials. However, the efficacy in real-world patient populations remains understudied.

Methods: Patients with stage IB-IIIA NSCLC who underwent NAIO or CT followed by surgical resection at YNHH from October 2015 - August 2023 were included. Demographics, stage, treatment data, surgical details, pathologic information including pathologic complete response (pCR), and survival outcomes between NAIO vs CT were compared by Chi-square or Fisher's exact test, and Kaplan-Meier survival curves using SAS 9.4.

Results: Among 53 consecutive patents (30 neoadjuvant CT, 23 neoadjuvant IO+CT), demographics did not differ significantly between groups and resembled CheckMate 816 participants (age, smoking status, clinical stage) but included more females (38%) and adenocarcinoma histology (60.4%). Similar to CheckMate816, the majority of patients in both groups received cisplatin as their chemotherapeutic agent (53.3% and 56.5%). The NAIO group more often had a known and high pre-op PD-L1 status (p=0.06); 6 patients (26.1%) received IO with PD-L1<1%. Patients who received NAIO were less likely to receive adjuvant treatment (17.4%, vs 46.7% p=0.03). IO was not significantly associated with differences in extent of surgical resection, sleeve rates, conversion rates, or operative time. Patients who received NAIO had a numerically higher pCR (21.7% vs 6.7%, p=0.22) and lower recurrence rate compared with those who received CT (17.4% vs 36.7%, p=0.14). Overall and disease-free survival curves diverged, favoring NAIO, but did not reach statistical significance (p=0.39 and 0.43).

Conclusions: In a real-world patient population, NAIO is well tolerated without impact on surgical outcomes compared to CT. In alignment with randomized trials, patients who received NAIO had a trend towards higher rates of pCR and appeared less likely to experience recurrence or death following surgery. Further updated data will be presented at IASLC 2024 WCLC.

1 Lobectomy or less = any type of sublobar lung resection (e.g., wedge, segment) or lobectomy, bilobectomy = either two complete lobes or one complete lobe + sublobar lung resection of an additional lobe

2 Sleeve resection means a more complex lung resection with circumferential excision of involved lung tissue around a bronchus or pulmonary artery branch

3 VATS= video-assisted thoracoscopic surgery, RATS = robotic-assisted thoracoscopic surgery

4 Conversion means that a surgery that was initially started minimally invasively (i.e., VATS or RATS) was converted to an open thoracotomy intraoperatively for any reason. Common reasons include lack of exposure due to scars, or uncontrollable bleeding.

EP.07C.11 Adjuvant Immunotherapy for Patients with Resectable NSCLC after Pathologic Complete Response

J. Jiang, Z. Zhang, N. Du, M. Zhang, J. Zeng, Z. Yu, J. Li, Y. Gao, M. Li, Central South University Xiangya Hospital, Changsha/CN

Introduction: Neoadjuvant therapy combining immune checkpoint inhibitors with chemotherapy has significantly improved pathologic response and survival in patients with resectable NSCLC. However, it remains controversial whether adjuvant immunotherapy should be given for patients who achieve pathologic complete response (pCR).

Methods: A real-world prospective cohort study was performed in a single-center setting from April 2020 to March 2024. Patients who were diagnosed with resectable stage IB-IIIB NSCLC and achieved pCR after three cycles of neoadjuvant immunochemotherapy were enrolled. Patients receiving adjuvant immunotherapy for one year were assigned to adjuvant immunotherapy group (N=36), while others were assigned to no adjuvant immunotherapy group (N=27). The primary outcome of this study was disease-free survival (DFS). Treatment-related adverse events were evaluated during adjuvant immunotherapy.

Results: The age, gender, proportions of smokers and squamous cell carcinoma were generally similar between the two groups. Compared to the adjuvant immunotherapy group, the proportion of patients in stage IIIA was higher (70.4% vs. 52.8%) and the proportion in stage IIIB was lower (14.8% vs. 30.6%) among those who did not receive adjuvant immunotherapy, but no statistical difference was observed. The median follow-up time for the two groups of patients was 24.0 and 25.5 months (P=0.856), respectively. Only two patients (5.6%) experienced lung cancer recurrence in the adjuvant immunotherapy group, while only one patient (3.7%) who did not receive adjuvant immunotherapy experienced recurrence. The DFS survival curves for the two groups largely overlap (P=0.6325), and the median DFS has not been identified yet. During adjuvant immunotherapy for one year, there is no severe (≥grade 3) treatment-related adverse events reported in the adjuvant immunotherapy group.

Conclusions: After a follow-up period of 24 months, postoperative adjuvant immunotherapy has not led to a tendency of DFS benefit in these patients. Longer follow-up time is required to compare DFS between the two groups.

EP.07C.13 Aumolertinib as Adjuvant Therapy in Postoperative EGFR-Mutated Stage I NSCLC with Multiple High-Risk Factors

Q. Wu[1], M. Ni[1], F. Xue[1], X. Wu[1], T. Jiang[1], [1]the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an/CN

Introduction: Surgery is the standard treatment regimen for early NSCLC. However, there are still about 20% of stage I patients(pts) who are at risk of early recurrence or metastasis, even after complete surgical resection. The high-risk factors for lung cancer are important factors affecting the survival of stage I pts, including imaging, pathology, surgical methods, gene mutation types, and MRD ctDNA positivity. Stage I postoperative NSLCL patients combined with risk factors had worse prognosis, and the more risk factors combined, the worse prognosis will be.

Methods: A total of 26 pts with stage I EGFR-mutated lung adenocarcinoma who underwent radical surgery from Apr 2021 to Jan 2024 were enrolled, including 5 pts with stage IA and 21 pts with stage IB. Up to 17 pts (65%) had high-risk factors, and 13 pts (50%) were combined with ≥ 2 high-risk factors. The risk factors that threaten survival identified from the basic variables of enrolled pts include the presence of solid, micropapillary, or complex gland components, poorly differentiated carcinoma, visceral pleural invasion (VPI), non-EGFR co-mutations, surgical approach, smoking history, etc. All patients received adjuvant treatment with the third-generation EGFR-TKI aumolertinib (110mg, orally QD).

Results: At data cut-off, all patients have no symptoms of tumor recurrence and continued to administrate aumolertinib. 13 pts (57%) have been followed up for over 1 year, and 100% pts were alive and disease-free at 12 months, the 1-year DFS was 100%. During aumolertinib therapy, only 1 pts suffered a mild rash.

Conclusions: Our study first time demonstrate that the third-generation EGFR-TKI aumolertinib has efficacy and tolerable safety profile in pts with completely resected stage I EGFR-mutated NSCLC with multiple high-risk factors. This study is still progress and further analyses are undergoing to determine longer-term outcomes.

EP.07C.14 Clinical Outcomes of Neoadjuvant Immunotherapy in Stage I-II Non-Small Cell Lung Cancer: A Real-World Study and Meta-Analysis

H. Zhou[1], W. Zhan[1], C. Cai[2], S. Wu[1], Y. Lei[1], Q. Chen[3], [1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN,[2]Shantou University Medical College, Shantou/CN,[3]Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou/CN

Introduction: Neoadjuvant immunotherapy (neoIO) brought an evolution for resectable early-stage non-small cell lung cancer (NSCLC). Although the multimodality management with immunotherapy prior surgery for stage III diseases were fully reported in several phase 3 clinical trials, few studies investigated the role of neoIO in the management for stage IB and II patients (pts). To address this knowledge gap, we aimed to evaluate the efficacy of neoIO for stage IB and II NSCLC from a real-world study and further confirm through a meta-analysis on prospective clinical trials.

Methods: Stage I-II (AJCC 8th edition) NSCLC pts receiving neoIO followed by radical surgery between May 2019 and April 2023 in our institution were retrospectively collected. The clinical characteristics and oncological outcomes were reviewed and analyzed. Besides, a meta-analysis study registered at the PROSPERO database (No. CRD42023411932) was conducted. To identify relevant clinical trials investigating neoIO for stage I-II resectable NSCLC, a comprehensive search was performed across multiple literature databases and oncology conferences up to March 10th, 2024. The primary outcomes were major pathologic response (MPR) and pathologic complete response (pCR).

Results: In retrospective cohort, 49 pts with a mean age of 61.9±8.5 years were included, and 87.8% being males. 34 pts (69.4%) had squamous subtype. All pts were administrated with PD-1 inhibitors, among which 93.9% (n=46) with chemotherapy, and the other 3 with monotherapy. The ORR rate (RECIST 1.1) was 71.0% (95% CI: 56.6 to 82.2). 47 pts (95.9%) underwent minimal invasive surgery with R0 resection rate of 98.0% (95% CI: 89.3 to 99.9). The MPR rate and pCR rate were 59.2% (n=29, 95% CI: 45.2 to 71.8) and 44.9% (n=23, 95% CI: 31.9 to 58.7), respectively (Figure 1A). Moreover, a meta-analysis including 1398 pts from 6 randomized control trials and 18 prospective studies revealed a pooled MPR rate of 35.9% (95% CI: 28.3 to 43.8) (Figure 1B) and pooled pCR rate of 19.3% (95% CI: 11.4 to 28.3) (Figure 1C). As for subgroup analysis of treatment regimens, promising pathological response rates in neoadjuvant immunochemotherapy (MPR, 41.6%; 95% CI: 33.2 to 50.2; pCR, 27.1%; 95% CI: 20.5 to 34.1) were reported. Interestingly, a high pathologic regression but with significant heterogeneity in neoIO combined with other agents was observed.

Conclusions: This retrospective real-world study and meta-analysis on stage I-II NSCLC suggested perioperative oncological benefits of neoIO. More evidence of long-term outcomes and optimal regimens is guaranteed for the use of neoIO in earlier-stage NSCLC.

EP.07C.15 Neoadjuvant Immuno-Chemotherapy in Resectable Non-Small Cell Lung Cancer - A Retrospective Cohort Study

S. Verma, M.D. Vincent, M. Black, R. Nayak, M. Cecchini, R. Malthaner, J. Raphael, R. Inculet, D. Fortin, P. Blanchette, S. Kuruvilla, M. Qiabi, J. Younus, D.A. Breadner, London Regional Cancer Program, Schulich School of Medicine and Dentistry, Western University, London/ON/CA

Introduction: Neoadjuvant (NA) nivolumab-chemotherapy (nivo-chemo) has shown an improved survival and pathological complete response (pCR) rate, vs chemo alone, in early-stage, resectable non-small cell lung cancer (NSCLC). Nevertheless, there is a paucity of real-world data.

Methods: We performed a real-world, retrospective analysis of outcomes and toxicities in patients with resectable NSCLC (stage IB-IIIA; EGFR/ALK alterations excluded) treated with three cycles of NA nivo-chemo followed by surgery at a single, tertiary-level Canadian cancer centre from September 2022 to March 2024.

Results: Eighteen consecutive patients were treated with NA nivo-chemo. The median age was 69.5 years (range, 58 to 79) and 66% were males. 39% (n-7/18) and 11% (n-2/18) had N1 and N2 nodes, respectively. All patients completed three cycles of NA nivo-chemo. Objective response rate was 77% (n-14/18), as per RECIST1.1 (including two complete responses). Progression was noted in two patients (the CT predated initiation of treatment by more than 8 weeks in these patients). The median time to surgery was 10.6 weeks (range, 6-17.6). 83% patients (n-15/18) had a surgery (2 pneumonectomy, 13 lobectomies); and of these, 86% (n-13/15) are on surveillance while two patients had an event (death or progression). All (n-14/15) had R0 resection except one. 33% patients (n-6/18) had a pCR, including two with stage IIIA disease (PD-L1 TPS < 1% in four patients, PD-L1 TPS ≥ 50% in two patients). 61% (n-11/18) patients were started at a reduced chemo dose in cycle 1. 44% patients required further dose reduction in cycle 2. Grade 3 or 4 toxicities were seen in 22% patients (n-4/18), (neutropenia (n-2), febrile neutropenia (n-1) and pneumonitis (n-1, unresolved, grade 3 and resulting in decreased pulmonary reserve precluding surgery; patient is on close surveillance). Peri-operative (within 7 days) complications unrelated to systemic treatment were seen in 66% patients (n-10/15). One patient died on post-operative day 2 due to postoperative intra-thoracic bleed from pulmonary artery stump.

Conclusions: NA nivo-chemo in resectable NSCLC is safe and associated with improved pCR rate. A few patients may progress on NA treatment or have a grade 3-5 toxicity precluding curative surgery. Hence, individualized informed decisions should be made. There is an unmet need of biomarkers/models that can predict pCR/toxicity for better patient selection.

EP.07C.16 Real-World Outcomes of Patients with Resectable Early-Stage Non-Small Cell Lung Cancer Treated with Neoadjuvant Chemoimmunotherapy

A. Hazim[1], A. Xiao[1], A. Singh[1], K. Chung[2], P. A Reck dos Santos[2], J. D'Cunha[2], M. Shanshal[1], A. Dimou[1], K. Parikh[1], Y. Lou[3], R. Manochakian[3], K. Leventakos[1], J. Molina[1], A. Mansfield[1], V. Ernani[2], [1]Mayo Clinic, Rochester/MN/USA,[2]Mayo Clinic, Scottsdale/AZ/USA,[3]Mayo Clinic, Jacksonville/FL/USA

Introduction: Chemoimmunotherapy has emerged as a promising treatment for resectable stage IB-IIIA non-small cell lung cancer (NSCLC). Neoadjuvant nivolumab in combination with chemotherapy, according to the Checkmate-816 study, is associated with improved pathological complete response (pCR), major pathological response (mPR), and event-free survival (EFS) as compared to neoadjuvant chemotherapy. We aim to evaluate the real-world outcomes of this regimen.

Methods: We conducted a retrospective analysis of patients with stage IB-IIIA NSCLC treated at Mayo Clinic with neoadjuvant nivolumab plus chemotherapy between March 2022 and December 2023. pCR was defined as no evidence of residual invasive cancer in the resected primary tumor and lymph nodes. mPR was defined as ≤10% viable tumor cells in the resected primary tumor and lymph nodes. EFS was defined as the time from initiation of neoadjuvant systemic therapy to any progression, recurrence, or death. Descriptive statistical analyses were performed with BlueSkyStatistics 7.40.

Results: Twenty-six patients (median age 67) were included and 12 (48%) were male. Ten (38%) had stage IIB, 15 (58%) stage IIIA, and 1 (4%) stage IVB. Seventeen (65%) had N0, 4 (16%) N1, and 5 (19%) N2. Of the N2, one had multinodal station involvement and one had bulky nodal disease (≥ 3 cm). Eighteen (69%) were adenocarcinoma, 6 (23%) squamous, and 2 (8%) adenosquamous. Two (8%) had EGFR exon 19 deletion, 2 (8%) MET exon 14 skipping mutation, 1 (4%) EGFR exon 18 mutation, and 1 (4%) EML4-ALK translocation. Two with PD-L1 expression of 0%, 7 with 1-49%, and 8 with > 50%. All patients received neoadjuvant nivolumab. Eighteen (69%) received carboplatin/pemetrexed, 6 (23%) carboplatin/paclitaxel, and 2 (8%) carboplatin/gemcitabine for a median of 3 cycles (range 2-4). Seven (27%) developed immunotherapy-related toxicity; 2 required hospitalization for grade 3/4 toxicity (one patient with hepatitis and one patient with colitis). All patients underwent surgical resection via lobectomy. Two (8%) developed life-threatening post-operative complications resulting in death: one cardiac arrest, and one post-operative chyle leak and multiorgan failure. Twelve (46%) achieved pCR and 2 (8%) achieved mPR. Five (19%) received adjuvant therapy; 3 (12%) nivolumab and 2 (8%) targeted therapies (one osimertinib and one alectinib). Twenty-four (92%) were alive at the end of this study's analysis. The median EFS for the entire cohort was not reached.

Conclusions: In this small retrospective analysis of patients with stage IB-IIIA NSCLC treated with neoadjuvant nivolumab plus chemotherapy, 54% achieved a mPR or cPR. All patients were able to undergo surgical resection via lobectomy suggesting room for outcome improvement. Results from this study corroborate the use of neoadjuvant chemoimmunotherapy in the real-world setting.

EP.07C.17 A Nomogram Prediction Model for Assessing the Risk of Recurrence in NSCLC Patients Underwent Neoadjuvant Immunotherapy: A Retrospective Study

L. Peng, J. Lin, Y. Wu, Y. Wu, W. Zhong, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, Guangdong, China, Guangzhou/CN

Introduction: Neoadjuvant immunotherapy notably enhances the prognosis of NSCLC patients by regulating the tumor microenvironment. However, some patients still suffer from recurrence after a radical operation with neoadjuvant treatment. This study aimed to estimate the blood markers at the beginning of treatment and before surgery, as well as other clinical characteristics and their relationship with recurrence.

Methods: IB-IIIB NSCLC patients undergoing surgery after neoadjuvant immunotherapy and at least one blood test were included.70% of patients were randomized to the training group and others to the validation group. A least absolute shrinkage and selection operator (LASSO)-derived Cox regression was used to figure out the risk factor to build a nomogram model. And evaluate the model through analysis of area under the curve (AUC), C-index, calibration plot, and decision curve analysis.

Results: 296 patients at Guangdong Provincial People's Hospital from 2019-2023 were enrolled, including 207 for the training group. Retrospectively collected patient profiles, treatment information, and blood examination findings. After filtering, NSE and PCR were selected for the nomogram. The model showed well in the calibration plot for both the training group and the testing group. The area under the curve (AUC) was 0.87 in the 3-year group, but only 0.525 in the validation group. The C-index was 0.757 in the training group and 0.55 in the test group.

Conclusions: In our study, we develop a nomogram model in order to identify recurrence.

EP.07D.01 Regional Longitudinal Evaluation of Treatment Patterns in Early-Stage Non-Small Cell Lung Cancer (ELEVATE)

M-J. Ahn[1], D.S-W. Tan[2], M. Windsor[3], B-H. Ong[4], J. Ho[5], H.K. Kim[6], V.H-F. Lee[7], F-M. Hsu[8], J-Y. Shih[8], D.N.M. Pham[9], C.P. Pham[10], S.Y.L. Chua[11], S-H. Yeo[11], I. De Dios[12], [1]Samsung Medical Center, Seoul/KR,[2]Singapore National Cancer Center, Singapre/SG,[3]St Vincent's Private Hospital, Brisbane/AU,[4]National Heart Center, Singapore/SG,[5]Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong/HK,[6]Samsung Medical Center, Seoul/KP,[7]The University of Hong Kong, Hong Kong/HK,[8]National Taiwan University Hospital, Taipei/TW,[9]HCM City Oncology Hospital, Ho Chi Minh/VN,[10]Bach Mai Hospital, Hanoi/VN,[11]Real World Solutions, IQVIA Solutions Asia, Singapore/SG,[12]Global Medical & Scientific Affairs, MSD, Manila/PH

Introduction: Given the evolving treatment landscape in non-small cell lung cancer (NSCLC), varying management approaches and disparate factors affecting treatment decision across territories, understanding these differences is key to support more effective clinical practice. This study aimed to describe early-stage NSCLC treatment patterns and factors behind treatment choice in the Asia-Pacific (APAC) region.

Methods: Lung cancer specialists were recruited between June 2022 and July 2023. A cross-sectional survey was administered to eligible specialists. Responses related to treatment choice and considerations in early-stage NSC

Results: 212 specialists were recruited from Australia (n = 32), Hong Kong (n = 27), Singapore (n = 27), South Korea (n = 42), Taiwan (n = 42) and Vietnam (n = 42). Surgery followed by adjuvant chemotherapy was most commonly selected by respondents for Group A (62.6%-77.7%) and Group B (47.2%-63.5%) patients across territories. However, definitive chemoradiation was more commonly chosen for Group C. For adjuvant therapy, more respondents selected regimens with targeted therapy and immunotherapy for patients with oncogenic mutation (OM) and without OM, respectively. Overall, the proportion of respondents who selected regimens with targeted therapy (for patients with OM) or immunotherapy (for those without OM) was lower in Australia, compared with Hong Kong and Taiwan. Tumor size, Eastern Cooperative Oncology Group performance status (ECOG PS), nodal stage and lymphovascular invasion were some of the top factors considered by respondents when choosing neoadjuvant or adjuvant systemic treatments for patients with early-stage NSCLC. For Group A, there was a wide discrepancy in neoadjuvant treatment considerations between territories (e.g., 21.1% of Australian respondents selected presence of targetable biomarker, compared with 71.4% of Hong Kong respondents). Furthermore, when considering adjuvant therapy in Group C, 37.5% and 80.8% of respondents in Vietnam and Hong Kong selected ECOG PS of 0, respectively.

Conclusions: This study showed that treatment choice and considerations in early-stage NSCLC management differ widely across APAC territories. These may be due to drug reimbursement, local practices and patient factors (e.g. presence of OM). Our findings provide useful insights on whether real-world practice aligns with clinical guidelines, and enable clinicians to make more informed decisions.

EP.07D.02 Comprehensive Treatment Availability is Associated with Improved Outcomes Among Veterans with Early-Stage Lung Cancer Treated at VA Hospitals

B. Heiden[1], D. Eaton[2], S-H. Chang[1], Y. Yan[1], A. Baumann[1], T. Thomas[2], M. Schoen[2], S. Tohmasi[1], N. Rossetti[1], M. Patel[2], D. Kreisel[1], R. Nava[1], B. Meyers[1], B. Kozower[1], V. Puri[1], D. Moghanaki[3,4], [1]Washington University School of Medicine, St. Louis/MO/USA,[2]VA St. Louis Health System, St. Louis/MO/USA,[3]University of California Los Angeles, Los Angeles/CA/USA,[4]VA Greater Los Angeles Medical Center, Los Angeles/CA/USA

Introduction: Comprehensive, multidisciplinary care is essential for the management of early-stage lung cancer, for which the predominant treatment is either lung resection or stereotactic body radiotherapy (SBRT). The Veterans Health Administration (VHA) - the nation's largest integrated healthcare network - performs lung resections at approximately 100 different VHA medical centers; however, in-house SBRT is available in fewer than half of these centers. Therefore, comprehensive lung cancer care (i.e., availability of both surgery and SBRT) remains highly variable across VA sites. We sought to evaluate the association between variable access to SBRT and outcomes among Veterans with early-stage lung cancer receiving care within the VHA.

Methods: We performed a retrospective cohort study analyzing patients with clinical early-stage (≤5cm, N0) NSCLC treated with lung resection at a VHA medical center. Of the facilities performing lung cancer surgery, we further queried whether these centers had SBRT capabilities and, if so, confirmed when these capabilities were established. Patients were grouped by whether they underwent lung resection at a site with surgery-only versus a site with surgery + SBRT on the date of surgery. We compared short-term and long-term outcomes between surgery-only versus surgery + SBRT sites, including metrics related to quality of care (i.e., VALCAN-O operative quality score), patient selection (i.e., VALCAN-M mortality risk score), and overall survival.

Results: We identified 6,289 patients undergoing lung resection from 2006 to 2016, with 4,673 (74.3%) and 1,616 (26.7%) patients receiving care at a surgery-only versus a surgery + SBRT site, respectively. Sociodemographic factors were similar between the two cohorts. Patients undergoing lung resection at surgery + SBRT sites had significantly higher operative quality scores (point estimate 0.569, 95% CI 0.458-0.679, p<0.001) and lower operative mortality risk scores (point estimate -1.362, 95% CI -1.675--1.049, p<0.001). Short-term outcomes were better at surgery + SBRT sites with lower rates of 30-day major complication (OR 0.830, 95% CI 0.700-0.985), 30-day mortality (OR 0.552, 95% CI 0.348-0.874), and 90-day mortality (OR 0.588, 95% CI 0.424-0.815). With a median (IQR) follow-up of 6.3 (2.6-11.6) years, 5-year overall survival was higher at surgery + SBRT sites (59.4% vs 56.9%, p=0.02, Figure).

Conclusions: The short-term and long-term outcomes for Veterans with early-stage NSCLC undergoing lung resection were better at VA facilities with both thoracic surgery and SBRT capabilities. These findings support recommendations to increase the availability of SBRT at all VA medical centers offering lung cancer care.

EP.07D.03 A Quality Improvement Initiative to Address Biomarker Testing and Quality of Care Delivery for Early-Stage NSCLC at 3 Cancer Centers in the US

M. Smeltzer[1], J. Kim[2], B. Alvarez[3], M. Shiller[4], E. Plotkin[3], A. Lile[3], R. Emara[3], J.L. Studts[5], P. Lee[6], [1]University of Memphis, MEMPHIS/TN/USA,[2]Xaf Solutions, Philadelphia/PA/USA,[3]Association of Cancer Care Centers, Rockville/MD/USA,[4]PathGroup, Dallas/TX/USA,[5]University of Colorado Cancer Center, Aurora/CO/USA,[6]City of Hope Lennar Foundation Cancer Center, Irvine/CA/USA

Introduction: Despite advances in therapeutic options for non-small cell lung cancer (NSCLC), overall survival remains lower than other common malignancies. Those with early-stage NSCLC have the best opportunity for long-term survival, but suboptimal implementation of evidence-based diagnostics and therapies may negatively influence outcomes. In the US, cancer care in the community setting, where >80% of individuals with lung cancer receive care, is particularly susceptible to gaps in quality-of-care delivery. To address this, the Association of Cancer Care Centers (ACCC) has launched a two-phase quality improvement initiative to improve care for early-stage NSCLC in community and academic cancer centers.

Methods: Phase I included a national survey of providers to identify barriers to and facilitators of optimal care for early-stage NSCLC. In Phase II, survey results are used to guide selection of target areas (or key areas) for quality improvement projects at 3 cancer centers. The process included evaluating baseline data at each site to assess current patterns of care followed by a facilitated, multidisciplinary workshop, a 1-month follow-up, and 3-6-month interval QI project. Baseline data collection included patient demographics, biomarker testing rates, multidisciplinary tumor board (MTB) use, and patterns of adjuvant and neoadjuvant therapy delivery. Process-level data and descriptive statistics are reported as frequencies or percentages.

Results: Baseline data were evaluated on individuals with stage IB-IIIA lung cancers from 2020-2021 at 3 sites. Respectively, sites 1/2/3 had 20/40/10 lung cancers diagnosed; average ages of patients were 69/71/67 years; were 65%/50%/50% female; with histology that was 65%/52%/70% adenocarcinoma, 30%/40%/30% squamous cell, 5%/5%/0% other. Overall, 65%/62%/90% of these cases were discussed at MTB. EGFR testing was performed in 55%/45%/80% of cases, while PDL1 was performed in 55%/95%/80%. During each workshop, potential quality improvement solutions around key areas included biomarker testing, improving MTB reach, survivorship planning, and nurse navigation, shown in Table 1.

Conclusions: Biomarker testing proportions showed room for improvement, as did MTB use at two sites. Updated guidelines for biomarker testing are not sufficient to drive process change in cancer centers. A concentrated, multidisciplinary team effort is critical to ensuring equitable, efficient testing and optimized comprehensive care delivery.

Keywords: Biomarker, Quality, Multidisciplinary

Table 1.

	Problem Statements	Root Causes	Potential Solutions
Site 1	55% of patients with early-stage (IB to IIIA) NSCLC are not receiving actionable biomarker testing (*EGFR* and PD-L1), information critical to informing neoadjuvant and/or adjuvant treatment plans. On average, tests are ordered 13 days post-surgery (range of 0-56 days post- surgery). **Recommendation:** Order *EGFR, ALK*, and PD-L1 for all patients with early-stage (IB to IIIA) NSCLC at time of diagnosis.	Variations in what is ordered (PD-L1 vs *EGFR* vs both), when tests are ordered, and which reference labs perform testing. Lack of an automatic (pathology-driven reflex) testing protocol for early-stage NSCLC.	Develop and implement a pathology-driven reflex biomarker testing protocol for new patients diagnosed with early-stage NSCLC.
Site 2	45% of patients (n=40) with early-stage NSCLC were tested for EGFR. Among 22 patients with an adenocarcinoma component, 59% were tested for EGFR. **Recommendation:** Order *EGFR, ALK*, and PD-L1 for all patients with early-stage (IB to IIIA) NSCLC at time of diagnosis to guide treatment decisions regarding neoadjuvant and/or adjuvant treatment.	Lack of a standardized automatic (pathology-driven reflex) testing protocol for early-stage NSCLC. When tissue quantity is not sufficient (QNS), testing is not performed. Liquid biopsy (plasma testing) is not ordered.	Implementing a pathology-driven reflex biomarker testing protocol for new patients diagnosed with early-stage NSCLC. Issues to consider: Who will order the test? When will the test get ordered (at time of diagnosis vs at time of surgical resection)? If tissue is QNS, then who will order the liquid biopsy?
Site 3	Among patients with early-stage NSCLC, 90% of patients received biomarker testing at the time of surgical resection or later. Only 10% received biomarker testing at the time of initial diagnosis. **Recommendation:** Order *EGFR, ALK*, and PD-L1 at time of initial diagnosis to guide neoadjuvant treatment decisions.	Lack of biomarker testing protocol at the time of initial diagnosis. Test order may be delayed if patient is hospitalized (inpatient Medicare 14-day rule).	Implementing a pathology-driven reflex biomarker testing protocol for new patients diagnosed with early-stage NSCLC.

EP.07D.04 Outcomes with Evolving Patterns of Neoadjuvant Therapy: A Population-Based Analysis

O. Akinbobola[1], M.P. Smeltzer[2], A. Minhas[1], O. Ogbeide[3], S. Ely[4], A. Saulsberry[3], K. Dortch[3], C. Fehnel[3], T. Ng[1], J. Zhao[1], M. Ray[2], R.U. Osarogiagbon[3], [1]Baptist Memorial Hospital, Memphis/TN/USA,[2]University of Memphis, Memphis/TN/USA,[3]Baptist Cancer Center, Memphis/TN/USA,[4]George Washington University, Washington/DC/USA

Introduction: Neoadjuvant chemo-immunotherapy is expanding surgical treatment options for patients with locally-advanced non-small cell lung cancer (NSCLC). We evaluated emerging trends in use of neoadjuvant therapy for resected NSCLC in a regional population-based cohort.

Methods: We categorized the Mid-South Quality of Surgical Resection cohort into patients with primary resection and neoadjuvant therapy. Neoadjuvant therapy was classified as: systemic therapy (chemotherapy and/or immunotherapy), radiation therapy only, and chemoradiation. We assessed treatment trends within the neoadjuvant categories using the Cochran-Mantel-Haenszel test and overall survival (OS) across treatment groups using standard statistical methods. With the primary surgery only cohort as reference, we constructed a Cox proportional hazards model including age, sex, race, aggregate clinical stage, and extent of resection.

Results: Of 6137 patients, 6.1% received neoadjuvant therapy: 3% received systemic therapy, 0.6% radiation therapy alone, and 2.5% chemoradiation. The use of neoadjuvant systemic therapy increased sharply in 2021, rising from 4% to 12% in 2023. Neoadjuvant chemoradiation decreased from 4% in 2009 to 1% in 2023 (p<0.0001; Figure Panel A). Survival of the neoadjuvant radiation therapy cohort was worse than others (Figure Panel B). In the Cox model, chemoradiation (aHR: 1.503, 95% CI: 1.222-1.848, p=0.0001) was associated with greater hazard than primary surgical resection (Table). Systemic therapy (aHR: 0.762, 95% CI: 0.583-0.998, p=0.0479) was associated with a lower risk of death, while neoadjuvant radiation only did not differ significantly (aHR: 0.707, 95% CI: 0.4-1.251, p=0.2335).

Conclusions: The use of neoadjuvant systemic therapy has rapidly risen since 2021, likely due to the increasing use of chemo-immunotherapy combinations. Neoadjuvant systemic therapy was associated with improved survival rates compared to chemoradiation and may also be associated with improved survival over primary surgical resection.

EP.07D.05 Molecular Testing Care Gap Analysis of EGFR Mutation for Early-Stage NSCLC Patients in Community Practices

J. Dow[1], N. Zimmerman[1], S. Monzon[1], W. Zhao[1], A. Barrett[1], V. Erese[1], C. Gurbatri[1], E. Cohen[1], C. ScottoDiVetta[1], I. Huerga[1], H. Nimeiri[1], D.H. Owen[2], J.D. Patel[3], [1]Tempus AI, Chicago/IL/USA,[2]The Ohio State University, Columbus/OH/USA,[3]Northwestern Feinberg School of Medicine, Chicago/IL/USA

Introduction: Approvals of targeted therapies have rapidly increased over the past decade, leading to complex and frequently updated clinical guidelines. This trend has contributed to pervasive gaps in NCCN guideline-directed care. Here we report a care pathway analysis to characterize NCCN-recommended molecular testing rates in early stage NSCLC (eNSCLC).

Methods: The study analyzed de-identified data from Tempus' nationwide longitudinal electronic health records database, focusing on 18-89 year-old patients newly diagnosed with lung cancer in 2022. Patients were randomly sampled for abstraction of >120 data elements from their unstructured clinical documents, including progress notes, pathology reports, discharge summaries, and genomic testing results. 913 patients (289,317 unstructured clinical documents) across 4 community practices in the US were included. Curated data were independently reviewed by an oncologist and clinical data director and cross checked against ML/AI predictions to ensure data quality.

Results: 39 non-squamous, resected NSCLC patients with pathologic stage IB-IIIB [T3, N2] (n=39) were identified as qualifying for EGFR testing according to 2022 NCCN NSCLC Guidelines. 13/39 (33%) of these patients did not receive molecular testing for EGFR mutation. 10/13 (77%) untested patients had an actionable biomarker testing care gap (e.g. negative nodes or margins after surgery, no specified reason). 3/13 untested patients had no actionable biomarker testing care gap (e.g. unresectable via surgical attempt, patient refused treatment).

Of 26 EGFR tested patients, 22 (85%) patients received testing prior to adjuvant treatment to inform therapy selection. 4/26 (15%) of these patients harbored an actionable EGFR mutation. Patient demographics and insurance type were analyzed as possible explanations for care gaps.

Conclusions: This analysis revealed a significant care gap in eNSCLC patients receiving EGFR molecular testing, which is necessary for adjuvant TKI therapy eligibility per NCCN guidelines. Addressing this gap through healthcare interventions, such as care pathway automation tools, could improve adherence to guidelines, ultimately enhancing patient outcomes.

EP.07D.06 Characteristics of and Long-Term Outcomes of Non-Small-Cell Lung Cancer Diagnosed Among Young Adults in the United States

C.S. Haridas, A. Potter, P. Senthil, D. Wang, C-F.J. Yang, Massachusetts General Hospital, Boston/MA/USA

Introduction: Recent studies have shown that overall survival among patients with resected stage I non-small-cell lung cancer (NSCLC) remains suboptimal, with only 70% of patients surviving 5 years after surgery. However, given that >95% of lung cancers are diagnosed among individuals aged >50 years, most analyses evaluating survival after lung cancer resection reflect outcomes among older adults and not younger adults. We evaluated the characteristics of and long-term outcomes of NSCLC diagnosed among young adults in the U.S.

Methods: Patients aged 20-49 years diagnosed with NSCLC from 2004-2020 in the National Cancer Database were identified. Patients were grouped by age (i.e., 20-39, 40-49). We evaluated the tumor characteristics (e.g., stage at diagnosis, histology) within each age group. Among patients diagnosed with stage I NSCLC, we evaluated patterns in the receipt of surgery. Lastly, among patients undergoing surgery for stage I NSCLC, we evaluated 10-year overall survival stratified by age group and histologic subtype.

Results: A total of 60,647 patients met study inclusion criteria, of which 8,685 (14.3%) were aged 20-39 and 51,962 (85.7%) were aged 40-49. The proportion of patients aged 20-39 and 40-49 diagnosed with stage I lung cancer (as opposed to other stages) was 22.6% (n=1,962) and 15.0% (n=7,778), respectively. Over 20% (n=1,182) of lung cancers diagnosed among patients aged 20-39 were carcinoid tumors, compared to 5.6% (n=2,894) of lung cancers diagnosed among patients aged 40-49. Among patients with stage I disease, 93.4% and 91.3% underwent surgery, respectively. Ten-year survival for patients with resected stage I carcinoid tumors was very high, ranging from 93.5-96.1% (Figure 1). In contrast, 10-year survival among patients with resected stage I non-carcinoid tumors was only 78.0% (95% CI: 72.7-82.4) for patients aged 20-39 and 66.6% (95% CI: 64.9-68.2) for patients aged 40-49 (Figure 1).

Conclusions: In this national analysis of young adults diagnosed with NSCLC, only 15-22% of patients aged 20-49 were diagnosed with stage I NSCLC. Carcinoid histology comprised a considerable proportion of lung cancers in this age group, especially among patients aged 20-39. While 10-year survival among patients with resected stage I carcinoid tumors was excellent—ranging from 93-96%--long-term survival among young adults with resected stage I non-carcinoid tumors was notably worse, ranging from 67-78%.

EP.07D.07 Assessing the Adoption of Combined Immunotherapy and Chemotherapy in Eligible Patients with Non-Small Cell Lung Cancer

R. Ribeiro Barcelos[1], M. A. McAllister[1], E. A. Sugarbaker[2], R. Leo[1], S. Kim[3], F. Pezeshkian[1], A. Singh[1], S. J. Swanson[1], P. Ugalde Figueroa[1], [1]Brigham and Women's Hospital, Boston/MA/USA,[2]Baylor Medical School, Houston/TX/USA,[3]University of Pittsburgh Medical Center, Pittsburg/PA/USA

Introduction: Phase III trials of neoadjuvant chemoimmunotherapy utilizing immune checkpoint inhibitors followed by surgery have demonstrated favorable oncological outcomes in patients with resectable NSCLC. As a result, international guidelines now recommend neoadjuvant chemoimmunotherapy followed by surgery as standard of care. We assessed the adoption of neoadjuvant chemoimmunotherapy at our center after FDA approval in March 2022.

Methods: Patients who underwent surgery for NSCLC with tumors ≥4 cm or positive nodal disease from June 2022 through March 2024 were identified using an institutional database. Patients with N3 or oligometastatic disease were excluded. Demographics and preoperative workup were compared between patients who received neoadjuvant therapy (chemotherapy+/-radiation or chemoimmunotherapy) and patients with upfront surgery. Linear and logistic regression analyses were used to assess temporal trends in treatment.

Results: Of 103 patients who underwent resection of clinical stage IB-IIIB NSCLC during the study period, 69 (67%) received neoadjuvant therapy (52 chemoimmunotherapy, 17 chemotherapy+/-radiation). The patients who received neoadjuvant therapy were younger than patients with upfront surgery (66 vs. 72 years, p<0.001). Primary tumor size did not differ between groups, however, patients with cN1-2 disease received neoadjuvant treatment more frequently than patients with lesions ≥4 cm and negative lymph nodes (p<0.001). Significantly more patients who received neoadjuvant therapy underwent invasive mediastinal staging as compared with patients with upfront surgery (94% vs. 65%, p<0.001). Mutational testing was also more common among patients who received neoadjuvant therapy (PDL1 80% vs. 35%, p<0.001; EGFR 44% vs. 12%, p=0.003; ALK 45% vs. 12%, p=0.002). The use of neoadjuvant chemoimmunotherapy increased 6% per quarter (p=0.04) during the study period, while use of neoadjuvant chemotherapy+/-radiation and upfront surgery declined (p=0.009, p=0.10). (Figure 1A) Increasing age (OR=0.89, 95%CI 0.81-0.96), tumor size (OR=1.60, 95%CI 1.09-2.52), nodal involvement (OR=34.0, 95%CI 6.43-281.1), and time (OR=1.31, 95%CI 0.96-1.82) were associated with neoadjuvant treatment. Multinomial regression adjusting for these clinical factors demonstrated that patients were less likely to undergo chemotherapy+/-radiation (OR=0.71, 95%CI 0.50-1.02) or upfront surgery (OR=0.68, 95%CI 0.48-0.96), as compared with chemoimmunotherapy, as the study period progressed.

Conclusions: At our institution, the use of neoadjuvant chemoimmunotherapy in eligible patients with resectable NSCLC has increased significantly since June 2022, especially in patients with lymph node metastasis and large tumors. Multidisciplinary efforts are needed to ensure guideline-concordant care. Further real-world data showing trends in care and outcomes for patients with resectable NSCLC are needed to improve our decision-making as new treatment paradigms skyrocket.

EP.07D.09 A Global Study to Evaluate Access and Dynamics of Multidisciplinary Teams Care and Biomarker Testing in Early-Stage NSCLC

T. Leal[1], H. Bahig[2], S. Schmid[3], T.D. Alves Pinto[4], D. Simmons[5], M. Shanahan[6], L. Qiao[5], M.K. McCann[5,7], R. Rawlinson[8], M. Strebl-Bantillo[8], T.R. Rasmussen[9], [1]Winship Cancer Institute, Emory University School of Medicine, Atlanta/GA/USA,[2]Radiation Oncology and Nuclear Medicine, Université de Montréal, Montréal/QC/CA,[3]University Medical Centre Freiburg, Freiburg im Breisgau/DE,[4]Federal District Base Hospital, Brasília/BR,[5]AstraZeneca, Gaithersburg/MD/USA,[6]AstraZeneca, Cambridge/GB,[7]Rutgers University, New Jersey/NJ/USA,[8]Lumanity, London/GB,[9]Department of Respiratory Diseases and Allergy, Aarhus University Hospital, Aarhus/DK

Introduction: The treatment landscape in early-stage non-small cell lung cancer (NSCLC) has evolved significantly with approvals of perioperative treatment options. Multidisciplinary team (MDT) care is increasingly important given the multitude of treatment options and higher complexity in the decision making process. This ongoing study aims to understand access and dynamics of MDT care (including biomarker testing) in early-stage NSCLC and its impact on treatment selection across global geographies. To date, literature review has been completed with results presented in this abstract.

Methods: Our study employs a mixed-methods approach with three phases: 1) targeted literature review, 2) qualitative interview, and 3) quantitative online survey and patient chart review, in US, UK, Germany, Spain, Italy, Japan, Brazil, Turkey, Switzerland, Canada, and Mexico. Literature review was performed to identify existing evidence and clinical guidelines related to MDT care and biomarker testing in early-stage NSCLC. Pubmed was searched from inception to December 2023 using a combination of search terms related to MDT, NSCLC, and countries.

Results: Overall, 195 papers and 14 guidelines were identified, of which 90 papers and all 14 guidelines were included in the final review. Six of the 11 countries had guidelines recommending MDT care in early-stage NSCLC (Table 1). Furthermore, nation-specific guidelines from five countries mentioned biomarker testing for early-stage NSCLC. The most frequent topics reported in literature included time from diagnosis and staging to MDT care, patient outcomes associated with MDT, adherence to MDT and national treatment recommendations, and MDT member composition, logistics, and economic impact. Management of NSCLC by MDT was found to be associated with better survival outcomes. Key knowledge gaps in MDT literature include identifying ideal patient candidates for MDT care, and access to and outcomes from MDT care by patient characteristics such as disease stage. In addition, most published literature was generated from retrospective cohort analyses and primarily based on regional or single-clinic evaluation of MDT care. Regarding biomarker testing, timing of which could affect treatment decisions, most national guidelines did not reference early stage, and differences in access to and type of testing were identified.

Conclusions: While there are clinical guidelines recommending MDT care and biomarker testing in early-stage NSCLC, there is a lack of studies evaluating MDT and biomarker practices in NSCLC across global geographies, and the impact these practices have on treatment selection. Subsequent phases of this study aim to address the evidence gap through physician interview and survey across global geographies.

EP.07D.10 Deciphering Destiny: Is Curation of NSCLC Limited to Stage IA?

F. Doerr[1], G. Grapatsas[1], N. Baldes[1], F. Oezkan[2], D. Theegarten[3], K. Darwiche[2,4], W.E.E. Eberhardt[5], M. Stuschke[4,6], H. Hautzel[4,7], K. Herrmann[4,7], C. Taube[2], M. Forsting[8], M. Schuler[4,5], S. Bölükbas[1,4], [1]University Medical Center Essen, West German Cancer Center, Ruhrlandklinik, Department of Thoracic Surgery, Essen/DE,[2]University Medical Center Essen, West German Cancer Center, Ruhrlandklinik, Department of Pulmonary Medicine, Essen/DE,[3]University Medical Center Essen, Institute for Pathology, Essen/DE,[4]National Center for Tumor Diseases (NCT) West, Essen/DE,[5]University Medical Center Essen, West German Cancer Center, Department of Medical Oncology, Essen/DE,[6]University Medical Center Essen, West German Cancer Center, Department of Radiation Therapy, Essen/DE,[7]University Medical Center Essen, Department of Nuclear Medicine, Essen/DE,[8]University Medical Center Essen, Institute of Diagnostic and Interventional Radiology, Essen/DE

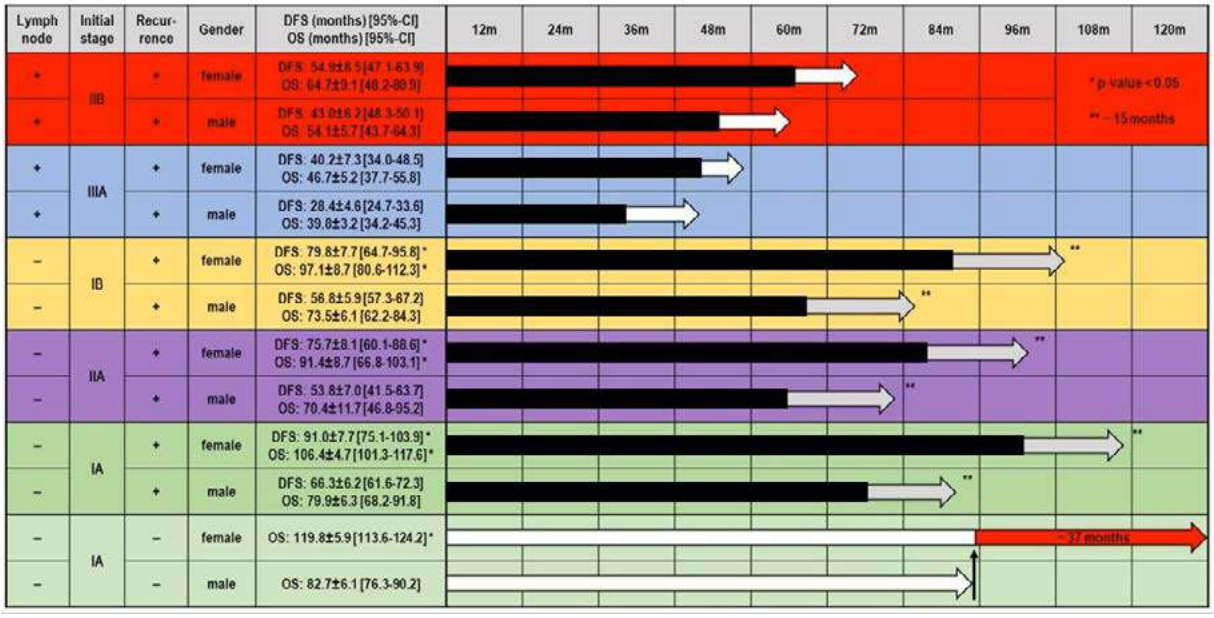
Introduction: 'Curative treatment' is offered to the majority of patients with localized NSCLC. According to the WHO, healthy women in industrialized countries have an approximately 39 months longer life expectancy than healthy men. Against this background, we analyzed gender-specific long-term survival in NSCLC patients and evaluated if cure with unrestricted life expectancy is achieved.

Methods: After applying the exclusion criteria (stage >IIIA, neoadjuvant therapy, positive resection margin, survival <90 days, non-adenocarcinoma or non-squamous cell carcinoma) we analyzed all consecutive patients who were anatomically resected for NSCLC at our institution between 2010 and 2022. Patients received adjuvant treatment in accordance with current guidelines. We compared female to male patients according to NSCLC stage and calculated overall survival (OS; months) and disease-free survival (DFS; months) defined as freedom from locoregional and distant metastasis. In early stage NSCLC we performed a propensity score matching (PSM) to avoid external factors influencing survival.

Results: A total of 4,052 resected patients were included. The patients' mean age was 66.2±8.9 years. We analyzed 1791 (44.2%) female and 2261 (55.8%) male patients. Metastatic lymph node involvement was a strong negative prognosticator affecting DFS (stage IIB: 54.9 vs. 43.0. p=0.177; stage IIIA: 40.2 vs. 28.4. p=0.303) and OS (stage IIB: 64.7 vs. 54.1. p=0.236; stage IIIA: 46.7 vs. 39.8. p=0.081) equally in all patients. Lymph node negative females had significant longer DFS (stage IB: 79.8 vs. 56.8. p=0.024; stage IIA: 75.7 vs. 53.8. p=0.029) and OS (stage IB: 97.1 vs. 73.5. p=0.036; stage IIA: 91.4 vs. 70.4. p=0.041) than male patients. In recurrence, patients with initial stage IB and IIA had a median OS of 15 months. In stage IA with PSM (p>0.05) for age, comorbidities, surgical access, smoking history and patients' fitness DFS and OS of female (n=457) patients were significantly longer than for males (n=457) (DFS: 91.0 vs. 66.3. p=0.008; OS: 106.4 vs. 79.9. p<0.0001). Interestingly, in a subgroup analysis of recurrence-free patients we found an approximately 37-month OS benefit for females over males in stage IA (119.8 vs. 82.7. p<0.0001). The hazard ratio was 2.39 [95%-CI: 1.24-5.06] for male versus female gender.

Conclusions: Due to earlier recurrence, male gender seems to have a negative impact on long-term survival after resection for NSCLC. Recurrence-free long-term survival in female patients is almost identical to the longer life expectancy of women in the healthy population. Consequently, one might argue that NSCLC can only be considered 'cured' at stage IA.

Keywords: gender-specific long-term survival, localized NSCLC, anatomic resection



EP.07E EARLY-STAGE NON-SMALL CELL LUNG CANCER- DEVELOPMENTS IN EGFR MUTATED EARLY STAGE NSCLC, SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07E.01 Intrinsic Impacts of the Expression of PD-L1 On Postoperative Recurrence in EGFR-Mutated Lung Adenocarcinoma

A. Ito, S. Kano, T. Tarukawa, Y. Suzuki, T. Sakaguchi, K. Ito, Y. Nishii, O. Taguchi, H. Yasui, O. Hataji, Matsusaka Municipal Hospital, Matsusaka/JP

Introduction: The emergence of molecular-targeted agents and immune checkpoint inhibitors (ICIs) has resulted in a substantial paradigm shift in the perioperative treatment of early-stage non-small cell lung cancer (NSCLC). Therefore, information on EGFR mutations and the expression of PD-L1 is extremely important for the development of postoperative therapeutic strategies. However, the intrinsic impact of the PD-L1 expression status on postoperative recurrence in EGFR-mutated lung adenocarcinoma remains unknown. In this study, we explored the intrinsic impacts of the PD-L1 expression status on postoperative recurrence in patients with surgically resected EGFR-mutated lung adenocarcinoma.

Methods: Data from 221 surgically resected pathological stage IA-IIIA lung adenocarcinomas, collected between January 1st, 2017, and December 31st, 2019, were analyzed. This included measurements of EGFR mutations and the PD-L1 expression. Recurrence-free survival (RFS) and overall survival (OS) were estimated using a Kaplan-Meier analysis and log-rank test. The independent risk factors for RFS were assessed using univariate and multivariate analyses.

Results: Among the patients, 140 were PD-L1-negative (<1%), while 81 were PD-L1-positive (≥1%). PD-L1 positivity was significantly associated with male sex (p=0.038), smoking habit (p=0.005), ND2 lymph node dissection (p=0.013), higher malignant subtype (p=0.003), higher histological grade (p=0.001), and advanced pathological stage (p=0.004). Conversely, EGFR mutations were more common in the PD-L1-negative group than in the PD-L1-positive group (p=0.006). Patients were categorized into four groups based on their EGFR mutation status and PD-L1 expression status: PD-L1-positive (≥1%) with or without EGFR mutations (EGFR(+)/PD-L1≥1% or EGFR(-)/PD-L1≥1%), and PD-L1-negative (<1%) with or without EGFR mutations (EGFR(+)/PD-L1<1% or EGFR(-)/PD-L1<1%). Among these groups, EGFR(+)/PD-L1≥1% cases exhibited the worst 5-year RFS (log-rank, p=0.010)(FigureA), while there was no significant difference in 5-year OS (log-rank, p=0.122) (FigureB). Furthermore, a multivariate analysis revealed that PD-L1 positivity was an independent significant factor for RFS in EGFR-mutated lung adenocarcinoma (p=0.013).

Conclusions: PD-L1 positivity emerged as an independent risk factor for RFS in patients with EGFR-mutant resected lung adenocarcinoma. These findings may provide valuable insights into the prognostic impact of PD-L1 expression and guide the implementation of postoperative adjuvant therapy in this patient population.

EP.07E.02 Physician Prescribing Preferences for Adjuvant Osimertinib in Early-Stage EGFR-Mutated Non-Small Cell Lung Cancer

Y. Liang[1], K. Krupsky[2], J. Lankin[2], J. Cohn[2], N. Kashine[2], R. Honomichl[2], Y. Rattigan-Brown[1], A. Shehu[1], R. Salomonsen[1], [1]AstraZeneca, Gaithersburg/MD/USA,[2]Oracle Life Sciences, Austin/TX/USA

Introduction: Following survival benefits demonstrated in the ADAURA trial, osimertinib, a third-generation EGFR-tyrosine kinase inhibitor (TKI), was approved for early-stage EGFRm non-small cell lung cancer (NSCLC) in many countries and recommended by major clinical guidelines as standard of care for adjuvant treatment. However, some eligible patients might not receive adjuvant osimertinib due to physician or patient prescribing barriers. Understanding the influence of treatment- and patient characteristics on physician prescribing preferences may help address such barriers. We aimed to understand physician preferences in prescribing adjuvant osimertinib for early-stage EGFRm NSCLC.

Methods: A two-phased study was conducted among board certified/eligible surgeons and medical oncologists (MOs) in the USA with experience treating NSCLC patients. Phase 1 included in-depth interviews to identify treatment- and patient-attributes influencing physicians' treatment decisions; phase 2 utilized a cross-sectional, internet-based survey to quantify the influence of those attributes. For MOs only, the survey included a rank-ordering exercise to evaluate treatment attributes relative to osimertinib prescribing behaviors and a Discrete Choice Experiment (DCE) to assess the influence of patient characteristics on prescribing osimertinib verses choosing to not prescribe osimertinib. Survey variables were analyzed descriptively and attribute-level preference weights from the DCE were estimated using hierarchical Bayesian models.

Results: Qualitative findings noted that MOs were the primary decision-makers for treatment selection, though surgeons were important for determining patients' eligibility for adjuvant treatment. In total, 154 physicians participated in the quantitative phase. Surgeons (N=54) perceived patients' NSCLC stage and resection margins as the most important factors for determining eligibility. The DCE found that 95% of the time, MOs chose to prescribe osimertinib over opting out, regardless of the combination of patient characteristics shown. MOs' preferences for prescribing adjuvant osimertinib were most influenced by patient hesitancy, NSCLC staging, and age, and least influenced by patients' prior treatment with neoadjuvant chemotherapy, with or without immuno-oncology agents (Table). Five-year overall survival of 85% and disease-free survival of 66 months were treatment characteristics most frequently ranked as facilitators to prescribing adjuvant osimertinib; costs (to patients and healthcare systems) were most frequently ranked as prescribing barriers.

Conclusions: MOs are key decision-makers on patients' eligibility for adjuvant osimertinib, and their decisions are predominately influenced by survival benefit from treatment and patients' willingness to adhere to treatment regimens. These results highlight the importance of ensuring clear patient communication and education on the benefits of adjuvant osimertinib.

[1]In the DCE, medical oncologists were shown a series of choice tasks with 2 hypothetical patient profiles that varied on the 6 attributes above. Oncologists were prompted to select which profile they were more likely to prescribe osimertinib to as adjuvant therapy, either alone or sequentially after chemotherapy. The absolute difference between the most and least preferred levels for each attribute represent the magnitude of influence an attribute had on preferences, relative to other attributes assessed.
Abbreviations: DCE: discrete choice experiment; NSCLC: non-small cell lung cancer; IO: immuno-oncology; ECOG: Eastern Cooperative Oncology Group

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07E.03 TP53 Co-Mutations Increase Risk of Recurrence in EGFR-Mutated Stage I Lung Adenocarcinoma

F.T. Gallina[1], D. Marinelli[2], R. Tajè[3], E. Melis[3], P. Visca[3], S. Buglioni[3], F. Cappuzzo[3], S. Najmeh[1], J. Cools-Lartigue[4], L. Ferri[1], S. Camilleri Broet[1], P.O. Fiset[1], J. Spicer[1], [1]McGill University, Montreal, QC, Canada., Montreal/QC/CA,[2]Sapienza University, Rome/IT,[3]IRCCS Regina Elena National Cancer Institute, Rome/IT,[4]IRCCS Regina Elena National Cancer Institute, Montreal/QC/CA

Introduction: EGFR mutations are the most prevalent oncogenic driver with a frequency in advanced LUAD ranging from around 10% in Western Europe to as high as 64% in East Asia. The ADAURA trial demonstrated significant clinical benefits in disease-free survival (DFS) and overall survival (OS) with the addition of adjuvant osimertinib in patients with resected EGFR-mutated stage IB to IIIA lung adenocarcinoma. However, beyond the ADAURA trial, the understanding of the prognostic implications of EGFR mutations in early-stage NSCLC remains rather limited. This study aims to assess the survival outcomes among patients with resected stage I LUAD with EGFR mutations by conducting a retrospective analysis using a multi-center cohort of patients.

Methods: Patients who underwent radical surgical treatment for stage I LUAD in two high volume centers with available postoperative molecular testing were collected between January 2017 to December 2022. Multivariate Cox regression was used to quantify the association between clinical and biological variables and the disease-free survival, in addition to hazard ratios and their 95% confidence intervals. Survival analysis and curves were achieved according to the Kaplan-Meier method. Disease-free survival (DFS) was compared using a log rank statistic.

Results: A total of 389 patients were included from two high volume centers. 73% of patients were male and a history of smoking was found in 301 patients. Most surgeries were performed via minimally invasive approaches (170 VATS and 98 Robot). The most frequent predominant histology was acinar LUAD (36.2%). On surgical pathology, 66 patients had lympho-vascular (LV) invasion and 83 had visceral-pleura (PL) invasion. EGFR mutation was found in 81 patients of which 10 harboured EGFR+TP53 co-mutations. In multivariable analysis, history of smoking (HR 2.35 95%CI 1.26-4-4, p=0.007), pT3 (HR 1.79 95%CI 1.04-3.1, p=0.035), MET amplification (HR 3.27 95%CI 1.14-9.4) and EGFR+TP53 co-mutation (HR 3.84 95%CI 1.32-11.2, p=0.013) were significantly associated with worse DFS. The survival analysis showed a significantly worse DFS for EGFR+TP53 co-mutation when compared to EGFR wild-type and EGFR single-mutation (fig 1, p=0.0001).

Conclusions: Our results suggest that TP53 co-mutation with EGFR for patients with completely resected stage I LUAD is a risk factor for early recurrence or death. These findings corroborate the aggressive biology associated with these molecular findings in metastatic patients.

EP.07E.04 Efficacy and Safety of Anlotinib Plus EGFR-TKIs in Slowly or Locally Progressing NSCLC after Adjuvant Therapy with EGFR-TKIs

J. Ye[1], J. Liu[1], Y. Yang[1], W. Lv[1], W. Xu[2], P. Xia[1], L. Wang[1], L. Zhu[1], J. Hu[1,3], [1]The First Affiliated Hospital of Zhejiang University, Hangzhou/CN,[2]Sanmen People's Hospital, Taizhou/CN,[3]Key Laboratory of Clinical Evaluation Technology for Medical Device of Zhejiang Province, Hangzhou/CN

Introduction: Anlotinib, a small molecule multi-targeting tyrosine kinase inhibitor (TKI), exhibits anti-tumor angiogenesis and inhibits malignant tumor progression. Due to the unclear mechanism of resistance to epidermal growth factor receptor (EGFR)-TKIs, new treatment strategies after resistance to EGFR-TKIs are continuously being explored in clinical practice. Combination therapy with EGFR-TKIs and anlotinib has been shown to inhibit tumors through multiple signaling pathways and improve the efficacy of EGFR-positive non-small cell lung cancer (NSCLC). This study evaluated the efficacy and safety of anlotinib combined with EGFR-TKIs for patients with NSCLC who developed resistance after postoperative adjuvant therapy with EGFR-TKIs.

Methods: From January 1, 2020, to December 31, 2023, 48 patients who underwent surgery at the Department of Thoracic Surgery, the First Affiliated Hospital of Zhejiang University School of Medicine and received adjuvant therapy with EGFR-TKIs but developed resistance (experiencing slow progression or local progression, or having a risk of potential disease progression) were included in this retrospective study. All patients were treated with anlotinib (10 mg, po, d1-14, q3w) plus EGFR-TKIs (original medication regimen). The primary endpoint was progression-free survival (PFS). Secondary endpoints included the 6-month and 12-month PFS rates, overall survival (OS), and safety. PFS was defined as the time from the start of treatment to disease progression or death. OS was defined as the time from the start of treatment to death from any cause.

Results: Of the 48 patients, 23 previously received first- or second-generation EGFR-TKIs, and 25 received third-generation EGFR-TKIs. As of March 25, 2024, the median follow-up time was 33.3 months (95% CI: 23.2-43.3). Thirty-three patients experienced disease progression or death, with a median PFS of 9.5 months (95% CI: 4.8-14.3), a 6-month PFS of 70.8%, and a 12-month PFS of 47.9%. For patients previously treated with first-/second- and third-generation EGFR-TKIs , median PFS were 10.3 months (95% CI: 6.1-14.4) and 7.7 months (95% CI: 4.8-10.6), with 6-month PFS of 69.6% and 72.0%, and 12-month PFS of 47.8% and 48.0%, respectively. The median OS was 31.0 months (95% CI: not reached [NR]-NR), with 6-month, 12-month, and 24-month OS rates of 91.7%, 85.4%, and 62.5%, respectively. For patients previously treated with first-/second- and third-generation EGFR-TKIs, median OS were NR and 20.3 months (95% CI: 10.7-30.0), respectively. Besides, OS rates were 95.7% and 88.0% at 6 months, 91.3% and 80.0% at 12 months, and 60.9% and 64.0% at 24 months. The incidence rates of any grade and grade ≥3 treatment-related adverse events (TRAEs) were 75.0% (36/48) and 10.4% (5/48), respectively . The most common TRAEs included hypertension (35.4%, 17/48), proteinuria (31.3%, 15/48), rash (22.9%, 11/48), fatigue (10.4%, 5/48), and diarrhea (8.3%, 4/48), with no new safety events reported. Dose reduction and discontinuation of anlotinib were reported in 4 (8.3%) and 5 (10.4%) patients, respectively.

Conclusions: For patients with NSCLC who experienced slow or local progression after postoperative adjuvant therapy with EGFR-TKIs, anlotinib in combination with EGFR-TKIs showed promising efficacy and manageable safety, providing such patients with a longer treatment window and survival opportunity.

EP.07E.05 Prevalence of EGFR Mutations (EGFRm)in Patients with Early-Stage NSCLC - Results from EARLY-EGFR Thailand Study

T. Thamrongjirapat[1], C. Akewanlop[2], K. Khiewngam[3], A. Tantraworasin[4], P. Danchaivijitr[2], T. Reungwetwattana[1], S. Saeteng[4], [1]Division of Medical Oncology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/TH,[2]Division of Medical Oncology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok/TH,[3]Department of Medicine, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/TH,[4]Department of Surgery, Faculty of Medicine, Chiang Mai University, Chiang Mai/TH

Introduction: There is limited data on prevalence of EGFRm in early-stage NSCLC in Thailand. We report the prevalence of EGFRm and treatment patterns in patients with stage I-III NSCLC in the Thai subset of the EARLY-EGFR study.

Methods: EARLY-EGFR (NCT04742192), a prospective, multicountry, non-interventional study, enrolled patients with resected stage IA-IIIB (per AJCC 8th edition) non-squamous NSCLC from Mar 2021 to Oct 2022. The primary endpoint was EGFRm prevalence. Secondary endpoints included demographics, clinicopathological characteristics, EGFRm subtypes and treatment patterns. Categorical variables were compared with EGFRm using Fisher's exact test with Monte Carlo and logistic regression model to evaluate potential factors associated with having EGFRm.

Results: A total of 145 patients (median [range] age 64.0 [32.0-86.0] years) were enrolled at 3 centers; 70.3% were females and 77.2% were never-smokers. Of 145, most patients had stage I NSCLC (IA: 57.9%, IB:20.0%), tumor in right lung (70.3%), T1 tumor (60.0%), pN0 (88.3%), and adenocarcinoma histology (99.3%). High-risk pathological features were reported in 63.5% (61/96) of patients. The majority (69.0%; 100/145) of patients were diagnosed through a screening program. Multidisciplinary team discussions were conducted for 49.3% (71/144) patients. The overall prevalence of EGFRm was 63.4% (92/145) without significant differences between the stages and clinicodemographic characteristics. The prevalence of Exon-19 deletions and Exon-21 L858R were 44.6% (41/92) and 46.7% (43/92), respectively. Uncommon mutations included INS20 (n=2) and G719X, G719X+L861Q, G719X+S768I and other (n=1 each). Eight of 12 patients tested were PD-L1 positive (≥1%), of which 5 patients had EGFRm. Women had higher EGFRm rate than men (70.6% vs 46.5%; p=0.006). Most patients (87.6%) underwent only surgical resection with lobectomy (83.4%) with R0 resection (98.6%). Overall, adjuvant systemic therapy was prescribed in 18/145 patients (platinum-based chemotherapy [n=15], EGFR-TKI [n=2], immune checkpoint inhibitor [n=1]). In patients with stage IIA-IIIB NSCLC, adjuvant systemic therapy was prescribed in 46.9% (15/32). In the regression analysis, female gender was associated with an increased EGFRm rate (unadjusted odds ratio [OR], 2.76 [95% CI, 1.32-5.76], p=0.007; adjusted OR, 2.99 [95% CI, 1.07-8.34], p=0.036).

Conclusions: This real-world study reported a high prevalence (63.4%) of EGFRm in Thai patients with resected early-stage NSCLC, which was similar to the prevalence in metastatic disease. Majority of patients were stage I which demonstrated the early detection and treatment, but less than 50% of patients with stage IIA-IIIB were prescribed adjuvant systemic therapy, thus increasing access to adjuvant treatment in our population may help to optimize patient outcomes.

	T3	13 (9.0)	9	4	69.2
	T4	3 (2.1)	2	1	66.7

Note: No significant difference was reported for *EGFRm* rate as per smoking status, pathological stage, and lymph node metastasis. p-value not calculated for rest of the parameters.

EP.07E EARLY-STAGE NON-SMALL CELL LUNG CANCER- DEVELOPMENTS IN EGFR MUTATED EARLY STAGE NSCLC
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07E.06 Long-Term Outcomes of Resected EGFR-Mutated Lung Adenocarcinoma - A Single Centre UK Experience

T.N. Oyebanji, D. Lawlor, C. Crean, F. McKay, L. Campbell, C. Boyd, R. Beattie, Royal Victoria Hospital, Belfast/GB

Introduction: Epidermal growth factor receptor (EGFR) mutations are highly prevalent in specific lung adenocarcinoma subpopulations, including those with never-smoker status, East Asian ethnicity, and female gender1. Adjuvant third-generation Tyrosine Kinase Inhibitors (TKIs) improves survival in patients with resected EGFR mutation-positive NSCLC compared to adjuvant chemotherapy or placebo2. Despite their significance, limited data exists about the disease pattern of EGFR-mutated lung cancer in the United Kingdom (UK). This study aimed to identify patient characteristics and long-term outcomes after resection in patients with EGFR-mutated adenocarcinoma.

Methods: We conducted a retrospective, single-centre analysis of a prospectively maintained database. All EGFR-mutated resected lung cancers between 2013-2024 were included. A comparative group of EGFR-negative patients resected between 2017-2018 was used. Data collected included patient demographics, smoking history, EGFR status, treatment, recurrence, and survival. Primary outcomes were overall and disease-free survival. Statistical analysis employed Kaplan-Meier curves, log-rank tests, and Cox regression models to assess risk factors associated with mortality.

Results: We retrieved data for 135 EGFR-positive and 129 EGFR-negative patients with resected lung adenocarcinoma. Over 99% of patients were Caucasian and the incidence of EGFR mutation was 9.7%. Patients with EGFR-positive disease were more likely to be female (p=0.02) and never-smokers (p<0.001). 13.3% of EGFR mutation patients received adjuvant TKI therapy. After a mean follow-up of 55.5±30.26 months (median - 64 months), 94 (35.6%) patients had died, with significantly lower mortality in the EGFR-positive group (12.9% vs. 22.7%, p<0.001). EGFR-positive status was associated with improved overall survival (86.6 vs. 56.9 months, p=0.046) and cause-specific mortality (p=0.008) [see Figures 1&2]. Recurrence rates were similar between groups (p=0.24) as was recurrence-free survival (75.6 vs 58.3 months; p=0.95) [Figure 3]. Salvage TKI therapy was used in 54.1% of EGFR-positive patients with recurrent disease.

Conclusions: Our findings in this UK cohort align with reported epidemiologic trends in EGFR-mutated lung cancer. Although there was no difference in disease-free survival, overall survival was longer in EGFR-positive patients. This is likely, at least in part, due to salvage TKI therapy. This study underscores the prognostic significance of EGFR mutation in resected lung cancer. Limitations This study was single-centre and retrospective. The majority of patients underwent lung resection in the pre-adjuvant TKI era.REFERENCES1. Shigematsu H, Gazdar AF. EP.07E.07 Adjuvant Aumolertinib in Patients with Completely Resected, Stage IA2-IIIA Non-Small-Cell Lung Cancer with Uncommon EGFR Mutations

Q. Zhang[1], L. Ke[1], S. Huang[2], Y. Yang[1], T. He[1], H. Sun[3], Z. Wu[1], X. Zhang[4], W. Lv[1], J. Hu[1], J. Ye[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN,[2]Sir Run Run Shaw Hospital, Zhejiang University, Hangzhou/CN,[3]Taizhou Hospital, Zhejiang University, Taizhou/CN,[4]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou/CN

Introduction: Epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) exhibit reduced sensitivity and suboptimal treatment outcomes in non-small cell lung cancer (NSCLC) patients with uncommon EGFR mutations (EGFRm) compared to those with common EGFRm. Several real-world studies have demonstrated that adjuvant aumolertinib treatment exhibits excellent efficacy and safety among stage I to III NSCLC patients who have undergone complete tumor resection. However, Data on adjuvant aumolertinib treatment in NSCLC with uncommon EGFRm is not available. Therefore, this study aims to assess the efficacy and safety of adjuvant aumolertinib in completely resected NSCLC patients with uncommon EGFRm.

Methods: Completely resected, histologically confirmed stage IA2-IIIA non-squamous NSCLC patients with any uncommon EGFRm except EGFR Ex19del/L858R will be eligible for enrollment. Patients will receive oral aumolertinib at a dose of 110 mg once daily for 6 months to 3 years, depending on the pathological stage and individual physical conditions, until the discontinuation criteria are met. Disease-free survival (DFS), safety, and tolerability will be assessed, with patterns of recurrence and central nervous system (CNS) DFS designated as prespecified exploratory endpoints.

Results: We retrospectively collected the data of 8 patients with stage IA2-IIIA NSCLC patients and uncommon EGFRm. Among them, 5, 1, and 2 patients had G719X/L861Q/S768I, exon 20 insertion, and other mutations, respectively. The median age was 68.5 years (range 59-75), with 50% being female. At the data cutoff, the median follow-up duration was 18.9 months, and only one patient with exon 20 insertion mutations experienced mediastinal lymph node recurrence. No CNS recurrence was observed. DFS has not yet been reached, with 1- and 2-year DFS rates of 100% and 80% in the overall population, respectively. For stage I disease, the 2-year DFS rate was 100%. During aumolertinib treatment, no adverse events of grade ≥3 were reported. There were no new safety signals or concerns identified. Two patients (25%) experienced drug-related adverse reactions, presenting with rash (1/8, 12.5%) and cough (1/8, 5.5%).

Conclusions: This study represents the first investigation of third-generation EGFR-TKI adjuvant therapy in uncommon EGFR mutations. These findings highlight the promising efficacy of aumolertinib in the postoperative adjuvant treatment of NSCLC with uncommon EGFRm, coupled with an excellent safety profile. Long-term follow-up for our study is ongoing to explore additional survival outcomes.

EP.07F EARLY-STAGE NON-SMALL CELL LUNG CANCER - MOLECULAR, MUTATIONAL, AND IMMUNOLOGIC FACTORS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07F.01 Extracellular Matrix in Early Lung Tumors Drive FAK Activation and Tumor Progression

M.C. Mendoza[1], S. Samson[2], A. Rojas[1], [1]University of Utah, Salt Lake City/UT/USA,[2]University of Utah, Huntsman Cancer Institute, Salt Lake City/UT/USA

Introduction: Pre-cancerous lung lesions are initiated by activating mutations in upstream components of the RAS/ERK pathway, but do not transition to lung adenocarcinomas (LUAD) without additional mutations and events. Alterations in the tumor microenvironment can contribute to early progression and are interesting for their potential to be modified by environmental exposures. The extracellular matrix (ECM) glycoprotein Tenascin-C (TNC) promote epithelial cell division and migration and is normally expressed by lung fibroblasts during developmental branching morphogenesis and alveolarization. Exposure to particulate matter and fibrosis reactions can induce transient re-expression of TNC. Given the potential for pathological lung states to increase TNC expression, we investigated the role of TNC in early LUAD.

Methods: Using a KRAS-driven genetically engineered mouse model and clinical samples, we tested if TNC has a role in the transition of pre-neoplastic lesions to early LUAD. We deduced the mechanism of TNC signaling using a combination of direct in vitro assays and studies in precision cut lung slices and tumor tissue.

Results: We show that TNC is increased in the earliest stages of mouse model and human LUAD. TNC is produced by resident fibroblasts surrounding early LUADs, as well as tumor cells in some patients. KRAS-driven GEMMs of LUAD lacking TNC exhibit reduced tumor progression. Without TNC, the tumor cells at the tumor-stroma interface exhibited reduced FAK activity and S phase entry. TNC-mediated tumor cell FAK activation required integrin signaling, but not structural or mechanical changes in the tumor microenvironment.

Conclusions: We conclude that the activation of resident fibroblasts to produce TNC can drive early tumor growth and dissemination before the development of desmoplastic stroma. This suggests that TNC status could be used to prevent the overtreatment of early LUADs detected in early screening.

EP.07F.02 Preoperative Tumor-Derived Exosomes Enhanced the Accuracy of Identifying Spread Through Air Spaces from Intraoperative Frozen Sections

L. Chen[1], X. Xu[1], D. Chen[2], Y. Mi[3], S. Duan[1], Y. Chen[1], [1]The Second Affiliated Hospital of Soochow University, Suzhou/CN,[2]Zhongshan Hospital of Fudan University, Shanghai/CN,[3]Jiangyin people's Hospital of Southeast University, Jiangyin/CN

Introduction: Lobectomy has been recommended as the preferred surgical procedure on stage IA patients with lung cancer spreading through air spaces (STAS). However, it posed an obstacle to identify STAS-positive disease intraoperatively as frozen sections were reported to have a low sensitivity. Our study aimed to establish a paradigm for recognition of STAS by combining preoperative blood test for tumor-derived exosomes with intraoperative frozen sections.

Methods: Blood samples were collected from a total of 700 patients with stage IA lung cancer in the Second Affiliated Hospital of Soochow University during August 2020 to August 2022 for detecting candidate genes within tumor-derived exosomes. Logistic regression analyses were performed to determine independent predictors of STAS. ROC curves were adopted to determine whether preoperative blood test could help improve the accuracy of intraoperative frozen sections for identifying presence of STAS.

Results: From our data, the sensitivity and specificity of intraoperative frozen section STAS were 46.3% and 92.2%, respectively. Regarding the candidate genes within tumor-derived exosomes, multivariable logistic regression confirmed MTA1, Twist, Slug and β-Catenin expression and ALK mutation were predictors of presence of STAS. Combination of preoperative blood test with intraoperative frozen sections significantly ameliorated the accuracy for identifying STAS with an area under curve of 0.937 (95% CI: 0.891-0.946).

Conclusions: A promising paradigm was established to recognize STAS in stage IA disease by detecting the five-gene signature within tumor-derived exosomes preoperatively combined with intraoperative frozen sections.

EP.07F.03 The Mutation Landscape & Clinical Features of Taiwanese NSCLC Detected by Low-Dose CT

H-C. Huang[1,2,3], C-j. Huang[3], Y-H. Luo[1,2], H-S. Hsu[2,4,5], Y-C. Yeh[1,2,3], Y-M. Chen[1,2], Y-C. Wang[3], [1]Taipei Veterans General Hospital, Taipei/TW,[2]School of Medicine, National Yang Ming Chiao Tung University, Taipei/TW,[3]Institue of bioinformatics, National Yang Ming Chiao Tung University, Taipei/TW,[4]Taipei Veterans General Hospita, Taipei/TW,[5]Institute of Emergency and Critical Care Medicine, National Yang-Ming University, Taipei/TW

Introduction: Low-dose CT(LDCT)' role in early lung cancer detection had been well established in heavy smoker. Taiwan Lung Cancer Screening in Never-Smoker Trial (TALENT) had also showed LDCT can be beneficial for non-smoker with family history. Health Promotion Administration, Ministry of Health and Welfare (HPA) of Taiwan, had conducted a free LDCT program for people for both heavy smokers and non-smokers with family history since July, 2022. This policy had drawn public awareness of LDCT application. Hence, we would like to explore the clinical features and mutation landscape of NSCLC patients detected by LDCT.

Methods: Taipei Veterans General Hospital NSCLC Cancer Database will be used to search from May 2021 to December 2022. De-identification paired genomics, pulmonary CT findings and patients' clinical factors were reviewed. For whole exome sequencing (WES) analysis, predefined pipeline was applied for sequence quality control, sequence alignment and variant calling.

Results: A total of 235 patients were included in this study, 169(69.4%) were non-smoker, 149 were female(63.6%), and 219(93.2%) were adenocarcinoma. Seventy-nine patients were detected by LDCT. There were no difference regarding age, sex, tobacco use and family history among patients detected by LDCT or not detected by LDCT. However, in LDCT group, there're more ground glass nodules (GGN) on CT (p<0.001), more early stage (p <0.001), and lower grading of adenocarcinoma (p <0.001). As for WES analysis, mutation counts was significantly lower in LDCT group; while single base substitution (SBS) 2 and SBS13, indicating the activity of APOBEC family of cytidine deaminases, were higher among non-LDCT group.

Conclusions: NSCLC patients detected by LDCT are clinically earlier in the disease status, and most patients detected by LDCT in our institute are never smokers. The WES analysis showed differenced among 2 groups, which should be further elucidated the underlying causes.

EP.07F.04 Differences in High-Order, Three-Dimensional Chromatin Structure Between Tumor and Adjacent Normal Tissues in Lung Adenocarcinoma

L. Li[1], Y. Dong[1], N. Liu[1], J. Li[1], S. Yuan[1,2], [1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan/CN,[2]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, Anhui, China., Hefei/CN

Introduction: Lung adenocarcinoma (LUAD) involves a complex interaction of gene expression alterations, resulting in variable modulation of key pathways that contribute to tumor cell growth. The higher order, three-dimensional (3-D) chromatin structure is often disturbed in cancer, and differences in genome-wide, higher-order 3-D chromatin structures in LUAD have yet to be characterized.

Methods: Thirty patients who had tumors occupying lung space on chest computed tomography (CT) and were prepared for prospective surgical treatment were prospectively enrolled. Sixteen paired tumor and adjacent normal tissue samples were included in the final analysis. One patient's (No. 10) samples were collected for Hi-C chromosome conformation experiments, and variances in 3-D chromatin structure and interactions in comparison to adjacent tissues were profiled. Long non-coding RNA (lncRNA)/RNA-seq data for all patients' samples were integrated to explore functional roles and mechanisms. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes Genes and Genomes (KEGG) pathway enrichment analyses were used to investigate their underlying functions.

Results: Hi-C heatmaps comparing the whole genome between adjacent normal and tumor tissues revealed interactions between chromosomes 6 and 8 and chromosomes 13 and 15 in tumor tissues. Analysis of inter-chromosomal interactions by Circos plot demonstrated increased interactions from chromosome 17 to 11 and chromosome 15 to 5 in the tumor versus adjacent normal tissues. Chromosome X was confirmed to have decreased interaction with chromosomes 2 and 3 compared to the adjacent normal tissues. According to Hi-C analyses, chromosomes 11, 15 and X had a greater number of topologically associated domains (TADs) that were merged and shifted to intra-TAD boundaries in tumor tissues. The computerized Pearson correlation matrix indicated increases in component A/B location switching in chromosomes 11, 15 and X in tumor tissues. Especially in chromosome X, over 40% of the A compartment was switched to the B compartment in tumor tissues, indicating the gene loci may be switched from activated to inactivated.More up-regulated lncRNAs than down-regulated lncRNAs were found in chromosomes 15 and X in tumor tissues according to RNA-sequencing analysis. GO and KEGG pathway enrichment analyses demonstrated that many genes differentially expressed in tumor tissues were significantly enriched in biology regulation and metabolic processes. The 10 most up-regulated lncRNAs were located in the A compartment and shifted TAD boundaries of chromosomes 11, 15 and X.

Conclusions: Analyzing chromatin structure may be a potential method for identifying candidate biomarkers and molecular targets for gene therapies, and thus, may provide a valuable tool to better understand the gene and lncRNA regulatory networks responsible for LUAD.

Keywords: 3-D chromatin structure, lung cancer, Hi-C

EP.07F.05 The Neutrophil/Lymphocyte Ratio Predict Lymph Node Metastasis in Patients with Clinical Stage T2 Non-Small Cell Lung Cancer.

S. Mizuguchi, T. Higashiyama, S. Yamamoto, A. Ueno, K. Chung, R. Nakajima, Osaka City General Hospital, Osaka/JP

Introduction: Interest in the relationship between systemic inflammation and the development of cancer is increasing. The neutrophil-lymphocyte ratio (NLR) is used as an systemic inflammation marker, and its prognostic value in lung cancer patients has been recently reported. However, its impact on preoperative staging is still unknown. We investigated whether preoperative NLR can predict lymph node metastasis in patients with completely resected clinical T2 non-small cell lung cancer (NSCLC).

Methods: We performed 1019 lung cancer surgeries (tumor diameter between 3 cm and 5 cm) between 1993 and 2017. Patients with partial resection, bilobectomy, pneumonectomy, resection of surrounding organs, neoadjuvant therapy administration, loss of blood examination within 1month prior to surgery and those without radical mediastinal lymph node dissection were excluded from the study. Ultimately, the records of the 540 remaining patients (365 male and 175 fema1e, median age 69 years; range, 31-88) with clinical T2 NSCLC were evaluated retrospectively. Patients were divided into two groups according to lymph node metastasis: pathological nodal negative (pN0, n=373) and positive (pN1-3, n=167). We evaluated clinicopathological characteristics and preoperative NLR between the two groups.

Results: Median tumor diameter was 38 (31-50) mm. Median preoperative NLR, CEA, CRP and CRP/Alb ratio were 2.21 (range; 0.38-19.3), 4.5 (0.6-478) ng/ml, 0.13 (0-16.4) mg/dl, and 0.033 (0-5.11), respectively. There was no difference in age, gender, tumor size, tumor location, histological type, CRP, and CRP/Alb ratio between pN0 and pN1-3 groups. The ratio of lobectomy (91.4 vs 96.4%) and CEA (4 vs 5.6 ng/ml) were significantly lower in pN0 group compared to those of pN1-3 group, respectively. Median NLR were significantly lower in the pN0 group (2.14; range 0.34-19.3) compared to pN1-3 group (2.30; range 0.87-10.2) (p=0.045). When preoperative NLR were stratified by CRP, of the 395 patients with low CRP (≦0.5mg/dl), preoperative NLR was significantly lower in the pN0 group (1.99; range 0.38-6.12) (n=270) compared to those (2.22; range 0.59-7.64) in the pN1-3 group (n=125) (p=0.016). Although NLR increases with elevated CRP, there was no difference between two groups in patients with intermediate CRP (0.5-1 mg/dl) (2.39 in pN0 versus 2.94 in pN1-3, p=0.106) and high CRP(>1mg/dl) (3.09 in pN0 versus 2.86 in pN1-3, p=0.585), respectively.

Conclusions: Preoperative NLR, systemic inflammatory status, may be a predictor of lymph node metastasis in clinical T2 non-small cell lung cancer, especially in groups stratified by low CRP.

EP.07F.06 Prospective Study of Breath Hold During SBRT Treatment of the Lung: Analysis Reliability of Surface Guidance Alone for Breath Hold

J. Heinzerling[1], M. Robinson[2], R. Prabhu[1], M. Ward[1], J. Gregory[3], S. Burri[1], R. Foster[3], [1]Atrium Health Levine Cancer/Wake Forest School of Medicine, Charlotte/NC/USA,[2]Atrium Health Levine Cancer, Charlotte/NC/USA,[3]Levine Cancer Atrium Health, Charlotte/NC/USA

Introduction: Respiratory motion management with breath hold (BH) is one technique to limit normal lung and other organ dose during SBRT treatments of the lung. Surface guidance (SGRT) using non ionizing 3D stereoscopic cameras to track the patient surface has been utilized for BH in larger targets such as breast cancer, but its reliability in BH treatments of small targets has not been investigated. We report the results of the reliability of utilizing SGRT alone as a technique for BH during a prospective study of treatment of primary and metastatic lung tumors.

Methods: An IRB approved prospective study was conducted in patients (pts) with primary NSCLC or lung metastasis undergoing SBRT. Eligible pts had at least 1 cm of respiratory associated motion on free breathing 4DCT. Pts underwent planning CT with BH either in end inspiration or expiration per investigator choice. During each SBRT treatment, pts performed BH and were aligned within tolerance based on the reference BH surface capture created from the BH planning CT. Pts underwent short-arc cone beam CT (CBCT) during BH for volumetric match of the target. Pts were then treated in BH with a tolerance of 3mm translations and 2 degree rotations. Treatment was stopped if pts fell outside of the predefined tolerances. Midway through treatment, pts underwent a second short arc CBCT during BH to verify the reliability of target position during BH treatment utilizing SGRT. Any subsequent shifts on target volumetric match after the second CBCT were recorded. Linear mixed models for repeated measures were used to analyze rotational and translational shift measurements.

Results: 21 pts and 65 SBRT fractions were treated utilizing SGRT alone for BH. 20 pts were treated with 54 Gy in 3 fractions and one patient had a central tumor treated to 50 Gy in 5 fractions. Mean free breathing range of motion (4D ROM) was 1.5 cm. Mean displacements after mid-treatment CBCT were minimal in all directions as shown in Table 1. Factors evaluated for association with shift magnitude included age, BMI, gender, tumor location, 4D ROM, and GTV and PTV size, but none of these were associated with increased shift amounts.

Conclusions: SGRT provides a reliable technique for BH SBRT treatments of the lung. Minimal target displacements on mid treatment BH CBCT were observed. Patients will be followed for toxicity and local control with comparison to free breathing SBRT to be reported in a subsequent analysis.

EP.07F.07 Role of Microbiome in the Outcome of the Preinvasive Lung Cancer Lesions

I. alqahtani[1,2], S. Ragavan[1], S. Rofael[1], A. Alhindi[1], Z. Whiteman[1], H. Harshad Pattani[1], R. Alkaraki[1], T. Alsabhan[1], M. Rabii[1], F. Koutentaki[1], G. Hewamana[1], C. shan[1], S. Gomez Lopez[1], A. Pennycuick[1], P. Durrenberger[1], L. Kalinke[1], M. Altammami[2,3], T. D. McHugh[4], S. Janes[1], V. H. Teixeira[1], [1]UCL, London/GB,[2]King Abdulaziz City for Science and Technology, Riyadh/SA,[3]Imperial college london, london/GB,[4]UCL, londom/GB

Introduction: Lung microbiota has received a lot of attention recently due to its potential role in the development and progression of many respiratory diseases, including lung cancer. However, the mechanisms by which the lung microbiota can influence lung cancer progression are not fully understood. Before the development of lung squamous cell carcinoma (LUSC), pre-invasive lesions can be observed in the airways. Longitudinal bronchoscopic surveillance of such lesions showed that the progression of these CIS lesions to cancer is not inevitable; only 50% of high-grade CIS lesions will progress to cancer within two years, whereas 30% will spontaneously regress. In this project, we aimed to dissect the role of the pre-invasive LUSC lesions' microbiome microenvironment in influencing the outcome of these lesions.

Methods: To identify the microbiome profile in pre-invasive CIS lesions, our whole-genome sequencing (WGS) data of 29 progressive and 10 regressive pre-invasive CIS samples (Teixeira VH et al, 2019) was analysed using different bioinformatic tools. Using 16S rRNA gene sequencing, the microbiome profile was identified in a new cohort of 30 progressive, 26 regressive CIS lesions and 21 matched normal lung epithelial tissue. Longitudinal microbiome changes were also defined in progressive preinvasive lesions (62 samples) in four different patients who underwent bronchoscopy every 6 months throughout 3 years. Bioinformatic analysis was done using Qiime2 platform. All statistical analysis was conducted in R (V4.1).

Results: Analysis of WGS data revealed that regressive CIS lesions exhibited higher bacterial alpha diversity compared to progressive CIS lesions. Furthermore, there was a difference in bacterial composition (beta diversity) between regressive and progressive CIS lesions. Regressive lesions displayed a higher abundance of Staphylococcus and Neisseria spp., while Haemophilus influenzae and Pseudomonas aeruginosa were predominant in progressive samples. These findings were consistent with the results of 16S rRNA gene sequencing, showing higher alpha diversity in regressive CIS lesions compared to progressive CIS lesions, and a difference in bacterial composition (beta diversity) between both groups. Significant differences were found in alpha and beta diversity between CIS lesions and normal epithelium, where normal samples showed higher diversity compared to CIS lesions. Moreover, variations in relative abundance and diversity were observed among longitudinal patient samples. the enrichment of the bacterial genera Sphingomonas, Corynebacterium, Staphylococcus, Enterococcus, and Streptococcus were found in CIS lesions. Additionally, the Cutibacterium genus was present in all CIS samples and increased during the transition to invasive cancer.

Conclusions: The difference in the bacterial diversity and composition between regressive and progressive CIS lesions might predict the outcome of these lesions. Regressive lesions have higher diversity, which might be correlated with immune surveillance. Certain bacterial species such as Haemophilus influenzae and Pseudomonas aeruginosa that identified in our study may contribute to lung cancer development and progression. Further experiments and data analysis are needed to validate the whole-genome and 16S rRNA gene sequencing analysis findings.

EP.07F.08 Clinical Significance of Endothelial Programmed Cell Death Ligand 1 Expression in Patients with Non-Small Cell Lung Cancer

T. Saito[1], M. Ishida[2], N. Maru[1], T. Utsumi[1], H. Matsui[1], Y. Taniguchi[1], H. Hino[1], T. Murakawa[1], [1]Kansai Medical University, Osaka/JP,[2]Osaka Medical and Pharmaceutical University, Osaka/JP

Introduction: Tumor endothelial cells (TECs) have been shown to promote immunosuppressive microenvironment by expressing co-inhibitory molecules such as programmed cell death ligand 1 (PD-L1). Our aim was to investigate clinical significance of PD-L1 expression on TECs in patients with lung cancer.

Methods: Three hundred and ninety-five patients with completely resected pathological stages IA to IIIA invasive non-small cell lung cancer (NSCLC) were investigated. Tumoral and endothelial expressions of PD-L1 were evaluated by immunostaining with 22C3 antibody. Primary endpoint was recurrence-free survival (RFS). The Kaplan-Meier estimation curve was used to visually analyze the RFS. The log-rank test was used to determine differences in RFS. Univariate and multivariate Cox proportional hazard models were used to evaluate association of RFS with clinical and pathological characteristics. Patients' characteristics included age, sex, body mass index, smoking status, carcinoembryonic antigen level, histologic type, pathological stage, vascular invasion, lymphatic permeation, tumoral PD-L1 expression, and endothelial PD-L1 expression. Multivariate analysis included the factors showing P < 0.05 in univariate analysis. P < 0.05 was considered as statistically significant.

Results: : Median age was 69 years (range, 37 to 88), and male accounted for 63.8% (252 of 395). Pathological stages IA and IB accounted for 51.4% (203 of 395) and 26.1% (103 of 395), respectively. Adenocarcinoma accounted for 72.9% (288 o 395). Hundred and sixty-two (41.0%) out of 395 patients experienced postoperative recurrence. Endothelial PD-L1 expression was observed in 10 (2.5%) of 395 patients, whereas tumoral PD-L1 expression (≥1%) was detected in 142 patients (35.9%). Univariate analysis detected age, sex, smoking status, serum carcinoembryonic antigen level, pathological stage, vascular invasion, tumoral PD-L1 expression, and endothelial PD-L1 expression as potential prognosticators. Multivariate analysis revealed age, pathological stage, vascular invasion, and endothelial PD-L1 expression as independent prognostic factors (P = 0.028, < 0.001, < 0.001, and 0.008, respectively). Hazard ratio of endothelial PD-L1 expression was 2.69 with confidence interval of 1.30-5.58.

Conclusions: Our results indicated that endothelial PD-L1 expression might be associated with poor prognosis. Further investigation is necessary to validate our results.

EP.07G.01 Computed Tomography Features of Pathological Stage IA Lung Adenocarcinoma Showing Spread Through Air Spaces.

T. Saito[1], Y. Kono[1], Y. Ueno[1], N. Maru[1], T. Utsumi[1], H. Matsui[1], Y. Taniguchi[1], H. Hino[1], K. Tsuta[1], O. Honda[1,2], T. Murakawa[1], [1]Kansai Medical University, Osaka/JP,[2]Himedic Clinic WEST, Osaka/JP

Introduction: Our aim of this study was to characterize radiological features on computed tomography of pathological stage IA lung invasive adenocarcinoma showing spread through air spaces (STAS).

Methods: Hundred and ninety-five patients undergoing complete resection with lobectomy for pStage IA lung invasive adenocarcinoma were included in this study. Following radiological characteristics on preoperative computed tomography (CT) were retrospectively reviewed: total size, solid size, consolidation-to-tumor ratio, vascular convergence, air bronchogram, cavitation, lobulation/notch, pleural indentation, and spiculation. In this study, two radiologists (Y.K. and O.H.) independently assessed the CT characteristics. If the initial assessments showed disagreement, a final decision was made by the third radiologist (Y.U.). All the three radiologists were blinded to the STAS status of the assessed patients. Univariate regression analysis was used to explore association between STAS and patients' characteristics (i.e. CT features and baseline characteristics [age, sex, body mass index, preoperative carcinoembryonic antigen level, and cStage]). Multivariate logistic regression analysis that included the factors showing $P < 0.05$ in univariate analysis was used to identify independent factors associated with STAS. $P < 0.05$ was considered as statistically significant.

Results: Median age was 69 years (range, 38 to 84), and male accounted for 53.3% (104 of 195). Both recurrence-free and overall survival was significantly worse in patients with STAS ($P < 0.001$ and $P = 0.009$, respectively). Univariate analysis revealed presence of vascular convergence, absence of air bronchogram, presence of cavitation, and presence of ground-glass opacification as candidate predictive factors of STAS. Multivariate analysis revealed presence of vascular convergence, absence of air bronchogram, and presence of cavity as independent predictors of STAS (odds ratio, 3.48, 95% confidence interval, 1.61-7.72, $P = 0.001$; odds ratio, 2.92, 95% confidence interval, 1.23-6.93, $P = 0.012$; odds ratio, 3.01, 95% confidence interval, 1.04-8.72, $P = 0.048$, respectively).

Conclusions: Our results indicated that vascular convergence, air bronchogram, and cavity might be predictive of STAS in pStage IA lung adenocarcinoma. Further investigation with prospective study is necessary to identify preoperative predictors of STAS.

EP.07G.02 Nomogram Model for Predicting Risk of Spread Through Air Space in Stage IA Sub-centimeter Non-Small Cell Lung Cancer

X. Wang, Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, Nanjing/CN

Introduction: To investigate the correlation between spread through air space (STAS) of stage IA sub-centimeter non-small cell lung cancer and clinical features and imaging features, constructing a nomogram risk prediction model to provide a reference for the preoperative planning of sub-centimeter lung cancer patients.

Methods: The data of patients with stage IA sub-centimeter non-small cell lung cancer who underwent surgical treatment in Nanjing Drum Tower Hospital Nanjing University from January 2022 to October 2023 were retrospectively collected. Based on the presence or absence of STAS in pathology results, they were divided into STAS positive and STAS negative groups. The independent risk predictors of STAS in clinical and imaging characteristics were selected by univariate and multivariate logistic regression analysis and then used to construct a nomogram. The sensitivity and specificity were calculated based on the Youden index, concordance index (C-index), receiver operating characteristic (ROC) curve and calibration plots were used to evaluate the performance of the model.

Results: A total of 112 patients were collected, including 17 patients in the STAS positive group and 95 patients in the STAS negative group. Univariate logistic regression analysis showed that male, anti-GAGE7 antibody positive, mean CT value and spiculation were associated with the occurrence of STAS; multivariate logistic regression analysis showed that male(OR=5.974, 95%CI: 1.495-23.872), anti-GAGE7 antibody positive(OR=11.760, 95%CI: 1.619-85.408) and mean CT value (OR=1.008, 95%CI: 1.004-1.013) were independent predictors of STAS positivity. The nomogram based on the above factors achieved good predictive performance for STAS; C-index was 0.890, sensitivity was 0.765, specificity was 0.916 and calibration curve was well-fitted.

Conclusions: Male, anti-GAGE7 antibody positive and mean CT value were independent predictors of STAS positivity of stage IA sub-centimeter non-small cell lung cancer, the nomogram model established in this study had good predictive performance, and provide reference significance for preoperative planning of patients.

EP.07G.03 Radiologic Predictors of Angiolymphatic Invasion in Patients with Non-Small Cell Lung Cancer (3.0mm-30.0mm)

Q. Sun[1,2], P. Li[1,2], J. Zhang[2], R. Yip[2], D. Yankelevitz[2], C. Henschke[2], [1]Harbin Medical University Cancer Hospital, Harbin/CN,[2]Icahn School of Medicine at Mount Sinai, New York/NY/USA

Introduction: Angiolymphatic invasion (ALI) has been recognized as an important prognostic indicator for NSCLC patients. However, few studies focus on radiologic features for predicting ALI for patients with small-sized NSCLCs (3.0mm-30.0mm). The aim is to identify radiologic features for predicting ALI in patients with non-small cell lung cancer (NSCLC) (3.0mm-30.0mm).

Methods: Retrospective review of patients enrolled in XXX Hospital between 2016 and 2023. Preoperative diagnostic radiologic features suggestive of ALI were evaluated. Multivariable logistic regression analysis, adjusted for sex, age, nodule size, and smoking status, was used to determine predictors of ALI. Model performance was analyzed with the area-under-the-receiver-operating-characteristic-curve (AUC).

Results: Of 778 NSCLC patients with resected NSCLCs 3.0mm -30.0mm in maximum diameter, 715(92%) had solid NSCLCs, 41(5%) had part-solid NSCLCs and 22(3%) had nonsolid NSCLCs. 271(34%) of 778 had documented ALI, all in solid NSCLCs, none in subsolid NSCLCs. For these 715 solid NSCLCs (41% male and 59% female, median age 69 years [IQR: 63-76]), multivariable logistic regression analysis showed that lollipop sign (OR=4.12, P<.001) and spiculation (OR=2.13, P=.004) were independent predictors of ALI, with AUC of 0.77. When considering only patients on whom volume doubling time (VDT) could be calculated, multivariable logistic regression suggested that VDT was also a significant predictor for ALI (OR=0.96, P<.001) and incorporating VDT into the model led to an improved ALI prediction (AUC=0.82, P<.001)

Conclusions: For patients with NSCLC ≤30.0mm, ALI was only present in solid NSCLCs. Among solid NSCLCs, lollipop sign, spiculation and volume doubling time were independent radiologic predictors of ALI.

EP.07G.04 Clinical Implications of Spread Through Air Spread as Prognostic and Predictive Factors for Patients with Stage IA-B Non-Small Cell Lung Cancer

A. Patiluntakankul[1], N. Naiyarat Prasongsook[2], K. Satayasoontorn[2], [1]Phrapokklao hospital, Chantaburi/TH,[2]Phramongkutglao hospital, Bangkok/TH

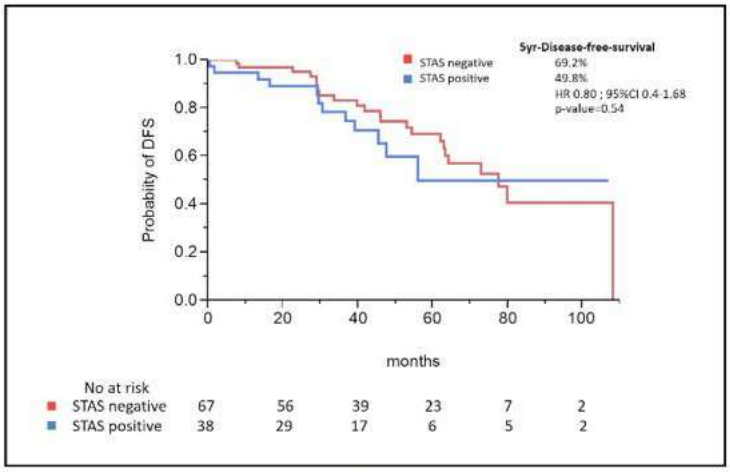
Introduction: Spread through airspaces (STAS) is recognized in the new 2021 WHO Classification of Lung Tumors as a histological feature with worse prognostic significance in early stage of adenocarcinoma of lung. This study aimed to elucidate the correlation between the histological feature of STAS and survival outcomes, and to investigate the effect of adjuvant chemotherapy in stage IA/B of adenocarcinoma of lung with STAS-positive patients.

Methods: This study was historical (retrospective) cohort design with data collected via chart and histology reviews of patients with stage IA/B of NSCLC who were undergone resection in Phramongkutklao hospital between January 2013 and December 2021. Demographics, comorbidities, pathological findings were collected. Disease-free survival was compared among patients stratified by STAS subtypes as primary endpoint. Secondary end points were univariate and multivariate correlations between clinicopathological features and DFS.

Results: One hundred and five eligible patients were enrolled. 67 of 105 patients (63.8%) were STAS-negative, and 38 of 105 patients (%36.2) STAS-positive. There was no significant difference among other aggressive histologic features between two groups. The 5-year DFS of patients with STAS-negative, and -positive were 69.2%, and 49.8%, respectively. The difference between patients with STAS-negative, and -positive was not statistically significant in either group (p-value = 0.23). Univariate analysis showed a statistically significant association with stage IA-IB, well-, moderate-differentiation, number of lymph node involvement, ALK status, receiving adjuvant chemotherapy, and schedule of follow-up visits with imaging. Multivariate analysis showed that well-differentiation, number of lymph node involvement, and schedule of follow-up visits with imaging were independent prognostic factors on DFS.

Conclusions: Patients with STAS-positive was insignificant correlated with worse DFS. The presence of STAS may be useful in predicting the clinicopathological significance and prognosis of patients with early stage of NSCLC. Therefore, STAS status might be another significant impact on decision marking for patients with early-stage NSCLC.

Keywords: Spread through airspaces (STAS), Non-Small Cell Lung Cancer (NSCLC), progression free survival (PFS)



Kaplan-Meier curves for disease-free survival (DFS). Patients with stage I NSCLC; patients with the STAS-positive (group A), and patients with STAS-negative (group B).

EP.07G.05 Maximum Standardized Uptake Value and Cell-Free DNA to Predict Adjuvant Therapy in Resectable Non-Small Cell Lung Cancer

E. Azkona Uribelarrea, J. Aurrekoetxea Oribe, H. Portilla-Quattrociocchi, R. Casas, B. Ortega Gallastegi, M.B. Calvo Martinez, Cruces University Hospital, Barakaldo/ES

Introduction: Non-small cell lung cancer (NSCLC) represents 80% of newly diagnosed lung cancers. Accurate staging is critical for prognosis. The maximum standardized uptake value (maxSUV) is a semiquantitative measure of tissue uptake of Fluorine-18 fluorodeoxyglucose (18F-FDG) positron emission tomography/computed tomography (PET/CT). It is used for the assessment of tumor metabolic activity and disease stage. Increased levels of circulating cell-free DNA (cfDNA) are detected in cancer patients due to various mechanisms, including tumor cell necrosis, apoptosis, and macrophage digestion, with subsequent release of tumor DNA fragments into the bloodstream. The purpose of this study was to evaluate the relationship between maxSUV and cfDNA concentration to predict adjuvant therapy requirements in patients with early-stage, resectable NSCLC.

Methods: Patients with resectable NSCLC who underwent preoperative PET/CT scanning at the University Hospital of Cruces between 2021 and 2023 were included in this prospective cohort study. Patients were injected with 18F-FDG according to their weight and images were acquired using a GE Discovery™ MI PET/CT system. The maxSUV of the tumor was defined as the peak SUV of 1 pixel with the highest count within the tumor in chest. The software used was the advantage workstation (GE, ADW PET/CT). Prior to surgery, venous blood was collected in Streck Cell-Free DNA blood collection tubes. DNA was extracted from 3 ml of plasma using the QIAamp Circulating Nucleic Acid Kit and was measured using the Qubit™ dsDNA HS Assay Kit. The relationship between maxSUV, cfDNA and clinical variables was evaluated with Wilcoxon test or Dunn test, as appropriate. A Leave-One-Out Cross Validation (LOOCV) multivariate logistic regression was generated through a forward stepwise selection. Model performance was evaluated based on accuracy, which was considered statistically significant by a one-sample t-test if it exceeded the percentage of non-adjuvant cases.

Results: Ninety patients (37 females and 53 males) with a mean age of 65.2 ± 6.81 years in stage I (56.66%), II (26.66%) and III (16.66%) were included. The 30% of patients received guideline-recommended adjuvant chemotherapy after surgery. Analysis of maxSUV revealed significant differences ($p < 0.05$) with respect to tobacco consumption, type of surgery, histology, stage and adjuvant therapy requirements. The concentration of cfDNA was significantly associated with the type of surgery, the stage and the need for postoperative therapy ($p < 0.05$). There was no correlation (Spearman $R < 0.10$) between cfDNA concentration and maxSUV. Logistic regression models showed that stage alone could not predict the need for an adjuvant therapy. However, moderate predictive capacity was observed after adding cfDNA concentration (cfDNA-stage, accuracy = 0.78, $p = 0.04$) or maxSUV (maxSUV-stage, accuracy = 0.80, $p = 0.02$), particularly with the latter combination.

Conclusions: This work highlights the importance of combining different clinical characteristics to predict which patients will have the greatest benefit from postoperative therapies. Different but simple combinations, such as maxSUV and stage, may help to improve adjuvant therapy decision making.

Keywords: maxSUV, cfDNA, adjuvant therapy

EP.07G EARLY-STAGE NON-SMALL CELL LUNG CANCER - STRATIFYING RECURRENCE RISK

EP.07G.06 Utilization of Tissue-Free Minimal Residual Disease MRD Testing in Early-Stage Lung Cancer Patients from Asia and the Middle East

C.M. Tsai[1], S. Jain[2], S.S. Hsing[2], H-Y. Jen[2], [1]Cathay General Hospital, Taipei/TW,[2]Guardant Health, Singapore/SG

Introduction: Detecting minimal residual disease in plasma is emerging prognostic biomarker for early-stage cancer patients. Few clinical trials have described MRD detection after curative-intent treatment for early-stage non-small cell lung cancer (eNSCLC). We describe real-world use of a tissue-free plasma cell-free DNA (cfDNA) next-generation sequencing (NGS) in eNSCLC patients from Asia and the Middle East.

Methods: eNSCLC patients in this region receiving Guardant Reveal testing in clinical practice were included in this retrospective analysis. This assay determines the presence of MRD by evaluating epigenomic signals in cfDNA without the need for prior tumor tissue analysis. Data analyzed for samples received from July 2023 to March 2024 and classified as post-resection (<12 weeks after surgery) or surveillance (>12 weeks after surgery). Clinical factors extracted from test requisition forms filled by physicians.

Results: 41 consecutive patients (57 samples) with stage I (n=2), II (n=12), or III (n=27). 40/41 patients had adenocarcinoma, 51% male. 60% of samples from Taiwanese patients, 40% from rest of the region. Median follow-up since testing was 4.3 months. Regardless of cancer stage, the majority of tests (75%) were ordered during surveillance up to 5 years after surgery(fig1). Overall, 12% had MRD detected in their first test, with the increasing frequency of detection in advanced tumor stage: stage I, 0%; stage II, 8%; stage III, 15% (fig 2). Median turnaround time(TAT) from sample reaching laboratory to report release was 8 days (range: 5-20). A patient with MRD detected 22 weeks after surgery was confirmed to have radiographic lymph node recurrence five days later, resulting in additional adjuvant immunotherapy. Follow-up is ongoing for all the patients to assess sensitivity and specificity of the MRD test.

Conclusions: Preliminary real-world experience with a tissue-free cfDNA MRD test in eNSCLC patients demonstrated similar performance to that reported for tissue-informed assays with fast TAT.

Keywords: MRD, ctDNA, residual disease

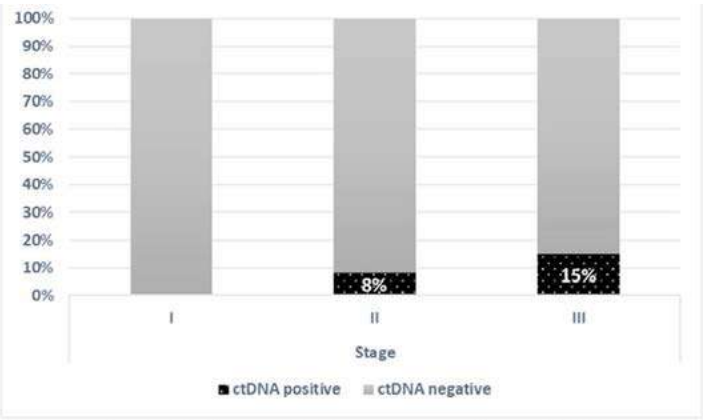

Figure 1. ctDNA positivity rate at first MRD test by cancer stage. Stage I, n=0; stage II, n=1; stage III, n=4.

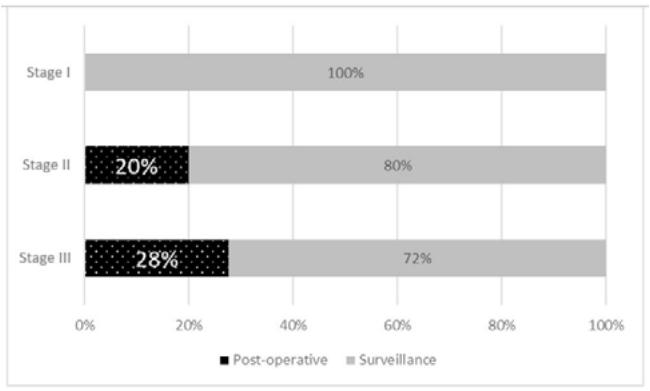

Figure 2. Timing of MRD test order for stage I (2 patients, 2 samples), stage II (12 patients, 15 samples) and stage III (27 patients, 40 samples)

EP.07G EARLY-STAGE NON-SMALL CELL LUNG CANCER - STRATIFYING RECURRENCE RISK
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.07G.07 Risk and Outcomes of Secondary Malignancy Among Non-Small Cell Lung Cancer Survivors Following Definitive Treatment

O. Yariv[1,2,3], S. Raoof[1], J.M. Isbell[4], B.J. Park[4], D.R. Jones[4], N. Shaverdian[1], J. Ruggiero[1], U. Jackson[1], B. Li[5], P. Iyengar[1], D. Gomez[1], [1]Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/USA,[2]Radiation Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda/MD/USA,[3]Davidoff Cancer Center, Rabin Medical Center, Petach Tikva/IL,[4]Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/USA,[5]Thoracic Oncology Service, Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Outcomes in non-small cell lung cancer (NSCLC) have improved over the past decade, leading to more long-term survivors. These patients remain at high risk for both disease recurrence and secondary malignancy. However, limited data exist that delineate the characteristics of non-lung secondary malignancies (NLSM) and disease outcomes for patients that develop NLSM. We assessed consecutive patients visiting a survivorship clinic in a tertiary cancer center to better characterize subtypes of NLSMs and elucidate outcomes of subsequent malignancies in this patient population.

Methods: We analyzed consecutive lung cancer survivors who visited our institutional survivorship clinic from January to May 2019 and met the following criteria: a) an initial diagnosis of stage I-III NSCLC; b) completion of definitive treatment with either surgery or radiation; and c) disease-free for at least 12 months following the completion of local therapy. Recurrence of disease, new lung primaries, and NLSM (which are not consistently detected by routine surveillance) were recorded. New lung primaries were differentiated from recurrence using the Martini and Melamed criteria in the absence of molecular sequencing data that could provide this categorization. The risk over time for developing NLSM was estimated using the Kaplan-Meier method, and clinical outcomes of these patients were collected.

Results: A total of 300 consecutive patients were analyzed, including 203 (67%) pathologic stages I, 41 (14%) II, and 56 (19%) III NSCLC survivors who completed definitive treatment. At a median follow-up of 6 years, 51 patients (17%) had cancer recurrence; of these, 35% were initially local, 25% regional, and 40% distant +/- locoregional. The median time to recurrence was 31 months (range, 12-177). Secondary malignancy occurred in 68 survivors (23%) within a median time of 58 months (range, 7-193), with second primary lung cancer being the predominant type (56% of secondary malignancies). NLSM occurred in 30 patients (10%) and emerged over a median time of 47.5 months (range, 2-84). The cumulative risk of developing NLSM was 1%, 3%, 5%, 7.3%, and 10% within the first 24, 36, 48, 60, and over 60 months post-treatment, respectively. Prostate (17%), breast (13%), pancreatic (10%), and head and neck (10%) cancers accounted for half of these cancers, with 17% of patients diagnosed with metastatic disease. Median overall survival (OS) and progression-free survival (PFS) of patients with NLSM were 26 months (range, 0.6-91) and 19 months (range, 0.6-91), respectively. The median OS of metastatic NLSM patients was 6 months (range, 0.6-26).

Conclusions: While recurrence rates decrease with time after definitive therapy for NSCLC, seven years after treatment completion, 10% of patients developed an NLSM, the majority of which were diagnosed more than 3 years post-treatment. Among patients with an NLSM, 17% were diagnosed with metastatic disease, with a median OS of 6 months. Given that the majority of the NLSMs are not captured in a routine CT scan of the chest, these findings suggest that patients should continue to be followed for second malignancies indefinitely. These data highlight the need for alternative approaches of comprehensive surveillance in this population.

EP.07G.08 Predicting Lung Cancer Recurrence in the Pre-Operative Setting Using AI/radiomics: A Study Based on US and European Cohorts

A. Valter[1], T. Kordemets[1], A. Cambray[2], A. Gasimova[2], N. Waterfield Price[2], L. Freitag[2], A. Vachani[3], D. Carbone[4], K. Oselin[1], [1]North Estonia Medical Centre, Tallinn/EE,[2]Optellum, Oxford/GB,[3]University of Pennsylvania, Philadelphia/PA/USA,[4]The Ohio State University Comprehensive Cancer Center and the Pelotonia Institute for Immuno-Oncology, Columbus/OH/USA

Introduction: Lung cancer recurrence after surgical resection presents a significant clinical challenge, with reported recurrence rates of 30%-55%. Biomarkers that allow accurate estimates of recurrence risk may provide critical evidence to inform personalized treatment decisions, such as the extent of lung resection, the use of (neo-)adjuvant therapies, and guide post-treatment monitoring. In this study, we report a novel preoperative machine learning model that leverages computed tomography (CT) images and clinical information to predict lung cancer recurrence after surgery.

Methods: We created a retrospective cohort of 947 patients with stage I-IIIA lung cancer who underwent surgical resection. 287 patients developed recurrent disease after surgical resection. The cohort includes CT images and clinical data from patients in both screening and clinical settings from the US National Lung Screening Trial (445), Stanford University School of Medicine and Palo Alto Veterans Affairs Healthcare System (180), and North Estonia Medical Centre (322). The model was trained to predict the likelihood of recurrence using radiomic features extracted from CT images and relevant pre-operative clinical variables. The model training employed using 8-fold cross-validation, where, in each fold, 6 of the subsets were used for training, one for model tuning and one held out for validation. We compare the resulting model to a clinical TNM staging. Performance was evaluated using the Area-Under-the-ROC-Curve (AUC).

Results: Lung cancer recurrence prediction results are tabulated below for the overall cohort, stratified by US and European subpopulations. The machine learning model performs significantly better than staging alone (AUC 0.66 vs 0.59, p-value=0.008). The improvement in recurrence prediction was similar in both the US and European sub-populations.

Conclusions: This analysis demonstrates that a radiomic model can more accurately predict lung cancer recurrence after surgical resection compared to cancer stage. With further development, this approach may provide a valuable tool to guide treatment of patients with Stage I-IIIA lung cancer.

	AUC		
Predictor	Whole cohort	US cohort	EU cohort
cTNM	0.59	0.58	0.65
Radiomic model	0.66	0.64	0.70

EP.07H.01 Analysis of Variables Predicting pCR and irAEs in Resectable NSCLC Receiving Neoadjuvant Immunotherapy with Chemotherapy (Pre-PLaN)

S. Verma[1], D. Breadner[1], R. Nayak[1], M. Black[1], R. Malthaner[1], J. Raphael[1], T. Appleton[2], M. Silverman[2], M. Sanatani[1], R. Inculet[1], D. Fortin[1], P. Blanchette[1], S. Kuruvilla[1], M. Qiabi[1], J. Younus[1], D. Logan[1], B. Hedley[2], I. Chin-Yee[2], J. Burton[2], M. Vincent[1], [1]London Health Sciences Centre, Schulich School of Medicine and Dentistry, Western University, London/ON/CA,[2]Schulich School of Medicine and Dentistry, Western University, London/ON/CA

Introduction: Neoadjuvant (NA) chemo-immunotherapy (C-IO) has shown an improved event-free survival (EFS) and markedly increased pathological complete responses (pCR), vs chemo-alone, in resectable non-small cell lung cancer (NSCLC) in recent trials. In these trials, achievement of pCR is associated with better survival. This approach is becoming the new SoC and is being widely adopted. Given the importance of achieving pCRs, there is an increasing interest in predicting its occurrence. Also, around one in three patients has grade 3 immune related adverse events (irAEs) with this approach. The response as well as toxicity are related to interplay between host's immunity and tumor variables. We propose to analyze the predictors of pCR and irAEs with NA C-IO in resectable NSCLC, employing a range of wider and more sophisticated parameters (utilizing ctDNA, radiomics, body composition, spatial transcriptomics, proteomics, genomics, microbiome, immune cell subsets etc.), that reflect both the tumor and the integrity of host's immune system. We will then seek to develop an initial integrated predictive model for pCR/non-pCR, and irAEs, with a good sensitivity/specificity, as a prelude to testing (and if necessary, refining) the model in future. Such a model can inform patient selection.

Methods: This is single center, prospective cohort study enrolling patients with stage IB-IIIA NSCLC, ECOG performance status (PS) 0-2 without EGFR and ALK alterations/fusions. Patients will be treated with NA nivolumab plus platinum doublet chemotherapy. The planned accrual is for 60 patients. The primary hypothesis is that a model combining predictive variables for pCR in patients with resectable NSCLC treated with NA C-IO can predict a pCR with an AUC of at least 0.8. The primary objectives are to explore the feasibility of acquiring a combination of baseline and treatment-emergent potentially predictive variables (listed below); to determine the predictive power of these variables; and to develop a precise model to predict pCR and irAEs. The secondary objectives are to assess pCR, major pathological response (MPR), objective response rates (ORRs), and irAEs; to evaluate exploratory and entirely novel potential biomarkers for predicting responses and irAEs and to assess if a post-treatment (pre-surgery) complete metabolic response by F18-FDG-PET-CT and a blood-only molecular residual disease assay can accurately predict a pCR.

EP.08A LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER - ADJUVANT THERAPY
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.08A.01 Impact of Locoregional Recurrence Versus Distant Metastasis on Survival in Patients with NSCLC after Surgery: A Secondary Analysis of PORT-C RCT

Z. Ma[1], Z. Hui[1], [1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN

Introduction: The therapeutic advantage of postoperative radiation therapy (PORT) for non-small cell lung cancer (NSCLC) has not been shown to benefit overall survival (OS) according to two randomized controlled trials (RCTs), albeit an enhancement in locoregional-free survival was observed. We aimed to evaluate the relative influence of locoregional recurrence (LR) and distant metastasis (DM) on OS for patients with NSCLC after surgery.

Methods: This was a secondary analysis of PORT-C RCT. Patients with pN2 NSCLC undergoing complete resection followed by chemotherapy were included. A dynamic prediction model was developed to evaluate the impact of LR and DM on OS. The endpoint was OS. Age, sex, smoking history, histology, Karnofsky Performance Status, tumor side, T stage, and positive lymph node were baseline factors, whereas LR and DM status were time-dependent covariates.

Results: In total, 364 patients were eligible, including 214 and 150 in the non-PORT and PORT groups, respectively. DM significantly decreased OS in both the non-PORT (odds ratio [OR], 4.74; 95% CI, 2.70-8.30; P<0.01) and PORT (OR, 5.43; 95% CI, 2.56-11.48; P<0.01) groups. LR also significantly impacted OS in the non-PORT (OR, 2.09; 95% CI, 1.12-3.93; P=0.02) and the PORT (OR, 3.44; 95% CI, 1.53-7.75; P<0.01) groups. Multivariate Cox analysis identified the pT stage, positive lymph nodes, and histology as variables correlated with DM. A nomogram was developed to estimate the risk of DM. PORT did not significantly enhance OS in either the low (HR, 1.42; 95% CI, 0.63-3.19, P=0.40) or high-risk (HR, 0.62; 95% CI, 0.35-1.09, P= 0.10) subgroup but in the medium-risk subgroup (HR, 0.20; 95% CI, 0.05-0.86, P=0.02).

Conclusions: DM and LR significantly impacted OS in patients with NSCLC after surgery. DM emerged as the dominant failure pattern, emphasizing more effective control of DM. PORT was beneficial for patients with a medium risk of DM.

EP.08A.02 Adherence to Adjuvant Immunotherapy and Target Therapy Protocols Inpatients with Resected NSCLC: A Meta Analysis

P. Bertoglio[1], F. Gallina[2], D. Marinelli[3], A. Nuccio[4], A. Di Federico[1], F. Ambrosi[5], E. Faccioli[6], R. Ferrara[4], E. Balzani[7], A. Ferro[8], R. Giusti[9], M. Mammana[10], A. Pittaro[11], M. Sepulcri[12], G. Viscardi[13], F. Guerrera[14], [1]IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna/IT,[2]IRCCS Regina Elena National Cancer Institute (IRE), Rome/IT,[3]Sapienza - Università di Roma, Rome/IT,[4]IRCCS San Raffaele Scientific Institute, Milan/IT,[5]Pathology Unit, Maggiore Hospital-AUSL Bologna, Bologna/IT,[6]University of Padova, Padua/IT,[7]University of Turin, Turin/IT,[8]Veneto Institute of Oncology - IRCCS, Padua/IT,[9]Sant'Andrea Hospital, Rome/IT,[10]University of Padua, Padua/IT,[11]Azienda Ospedaliera Universitaria San Luigi Gonzaga, Orbassano/IT,[12]IOV - Istituto Oncologico Veneto IRCCS,, Padua/IT,[13]AORN dei Colli Monaldi, Napoli/IT,[14]Università degli Studi di Torino, Turin/IT

Introduction: Recently, the introduction of immunotherapy (IO) and target therapy with tirosin-Kinase inhibitors (TT) in the treatment of all stages of Non-Small Cell Lung cancer has been radically changing the standards of care. Nevertheless, adherence to post-operative adjuvant treatment protocols has been often limited by patients' performance status after surgery.We aim to verify the adherence to protocols of adjuvant therapy in recent trials using IO or TT.

Methods: A systematic review of PubMed and Embase with meta-analyses was performed. Included studies were prospective clinical trials of postoperative IO or TT alone or in combination with chemotherapy in resected NSCLC. Studies of perioperative therapy were exclude and research cutoff was March 2023. Two authors (P.B. and F.G.) independently and in duplicate screened the abstracts of all publications obtained by the search strategies to identify studies. Primary outcomes were adherence to medical treatment (calculated as omission of therapy rate and incomplete therapy rate) and posttreatment severe adverse events.

Results: We included 7 studies with a total of 2479 patients; 6 studies were phase 3 and one phase 2. The list of all included study is reported in figure 1. All studies were started in the time frame between 2013 and 2018. IO was investigated in three studies, while the remaining 4 studies used TT. Complete omission of adjuvant therapy was found in 1.3% of patients (95% CI 0.8-1.7), while 37.2% (95% CI 35.3-39.1, figure 1) of patients required a reduction of number of cycles originally planned by the protocol. Concurrently, severe adverse events (AEs) were seen in 21.5% of patients (95% CI 19.8-23.1). When we compared IO and TT no significant difference in omission of therapy rate, incomplete therapy rate or severe AEs rate was observed.

Conclusions: The adherence to treatment protocols is a critical point in NSCLC patient's after surgery. Data from the current available literature showed that adjuvant IO or TT therapy is plagued by a high rate of incomplete therapy rate. Nevertheless, when we compared outcomes of IO and TT, we did not observe significant difference in outcomes.The role and the duration of adjuvant therapy should be careful evaluate in the era of IO and TT to reduce AEs and improve completion rate.

EP.08A LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER - ADJUVANT THERAPY
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.08A.03 Real World Outcomes of Adjuvant Atezolizumab in NSCLC: A Single Institution Study

X. Zheng[1], S. Kareff[2], L. Elias[1], Y. Abu[1], J. Lykon[1], N. Villamizar[2], D. Nguyen[2], E. Rodriguez[2], [1]University of Miami, Miami/FL/USA,[2]University of Miami / Sylvester Comprehensive Cancer Center, Miami/FL/USA

Introduction: Adjuvant immunotherapy versus best supportive care after adjuvant chemotherapy has shown disease-free survival (DFS) benefit in patients with resected NSCLC per IMPOWER-010; however, it also has significant associated adverse events. We sought to evaluate the tolerability and effectiveness of adjuvant atezolizumab in a real-world setting.

Methods: We performed a retrospective analysis of patients initiating adjuvant immunotherapy for stage IB-IIIB NSCLC in an NCCN-designated Cancer Center between 2021-2023 treated with 1200 mg or 1680 mg atezolizumab every 3 weeks or 4 weeks, respectively, for one year. We described immune-associated adverse events (irAEs) and DFS.

Results: Thirty-six patients underwent adjuvant immunotherapy with atezolizumab after resection of Stage IB-IIIB NSCLC. 72% (26/36) of patients were able to complete or are continuing to undergo atezolizumab maintenance. 14% of patients (5/36) discontinued therapy due to irAEs while 3% (1/36) of patients discontinued due to disease progression. Grade 3/4 colitis (6% of patients; 2/36) and grade 3/4 pneumonitis (6% of patients; 2/36) were the most common irAEs resulting in early cessation of treatment. There were no Grade 5 irAEs. 80% (29/36) of patients received adjuvant platinum-based chemotherapy (one to four cycles) prior to adjuvant atezolizumab. At time of review, only 19% (7/36) of patients had disease progression after starting adjuvant atezolizumab therapy.

Conclusions: Adjuvant atezolizumab appears well-tolerated in a diverse, real-world population. The toxicity profile and discontinuation rates were similar to that reported in the global IMpower010 study, suggesting good applicability of evidence from this trial to real world context. Further follow-up will be required to assess the ability of adjuvant atezolizumab to promote DFS.

EP.08B LOCAL-REGIONAL NON-SMALL CELL LUNG CANCER - BIOMARKERS FOR NEOADJUVANT
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.08B.01 Heterogeneity of Peripheral Blood Cell Dynamics and Oncologic Outcomes Between LUAD and LUSC Receiving Neoadjuvant Immunochemotherapy

H. Zhou[1], S. Wu[1], C. Cai[1], Y. Lei[1], C. Li[1], L. Huang[2], W. Zhan[1], [1]Guangdong Provincial People's Hospital,Guangdong Academy of Medical Sciences, Guangzhou/CN,[2]Department of Surgery, Competence Center of Thoracic Surgery, Charité Universitätsmedizin Berlin, Berlin/DE

Introduction: Immune checkpoint inhibitors (ICIs)-based neoadjuvant chemotherapy has been approved by the FDA to treat resectable NSCLC with significant benefit over chemotherapy alone. Lung squamous cell carcinoma (LUSC) and adenocarcinoma (LUAD) have distinct biological behaviors and different treatment responses. Studies on of these two pathologic types in the context of neoadjuvant immunotherapy (NAIT) have not yet been explored. Besides, the role of Programmed Cell Death-Ligand 1 (PD-L1) expression and serum tumor markers in this setting is still uncertain, especially for LUSC or LUAD. Therefore, we aimed to evaluate the baseline characteristics and peripheral blood immune cell dynamics in a comparative strategy for these two histologic subtypes.

Methods: This retrospective study collected data from patients with LUAD and LUSC who received NAIT at Guangdong Provincial People's Hospital from May 18, 2019 to December 30, 2023. The oncologic and surgical outcomes were evaluated between LUAD and LUSC groups. In addition to baseline clinical variables such as PD-L1 expression, absolute counts of blood cells in peripheral blood both before and after treatment, as well as the neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR), were calculated and analyzed. These factors, along with their changes, were assessed for impact on pathological complete response (PCR) via univariate and multivariate analysis of logistics regression.

Results: A total of 301 cases (182 LUSC, 119 LUAD) were included. Of these, 111 of 301 (36.9%) patients achieved PCR. No significant differences were found in age, BMI, ECOG, ICIs type and the number of therapy cycles between two groups. LUSC group showed superior PCR rate and less residual tumor cells but higher conversion rate and more extended range of surgical resection, like bilobectomy. Neither PD-L1 expression nor serum markers were associated with PCR in the whole cohort. For LUAD group, only PD-L1 expression (OR=1.019, 95%CI: 1.004-1.033, p=0.013) and smoking status (OR=2.103, 95%CI:1.352-4.484, p=0.013) could independently predict PCR. In contrast, these two factors were less correlated with response for LUSC group. The absolute counts of white blood cell (WBC), platelet and neutrophils after first cycle is significant correlated with PCR, where WBC count is an independently predictor for PCR (OR=0.840, 95%CI: 0.733-0.963, p=0.013).

Conclusions: Patients receiving NAIT in this real-world study exhibited promising pathological remission rates, especially for LUSC subset. Higher PCR rate was observed in LUAD patients with higher PD-L1 expression whereas higher WBC counts after therapy could predict a less probability of PCR for LUSC patients.

EP.08B.02 The Impact of C-Met Expression on the Immune Microenvironment and Survival in Locally Advanced Non-Small Cell Lung Cancer

Xu, Xu[1], X. Xu[2], Y. Zhu[2], L. Ye[3], Y. Zhang[2], W. Zhang[2], L. Wu[2], C. Wu[2], Y. Xu[2], [1],[2]Shanghai Pulmonary Hospital, Shanghai/CN,[3]Wenzhou Medical University, Hangzhou/CN

Introduction: The c-MET gene is emerging as a crucial therapeutic target owing to its diverse dysregulation in non-small cell lung cancer (NSCLC). Overexpression of the MET gene has been implicated in modulating the tumor immune microenvironment and affecting treatment responses to immunotherapy. This study aims to explore the association between c-MET expression and the immune microenvironment in NSCLC patients treated with radiochemotherapy followed by sequential immunotherapy, along with its clinical implications.

Methods: Clinical information of patients, along with the expression intensity and percentage of c-MET and specific immune microenvironment profile, including CD8, CD68, LAG3, FOXP3, and TIGIT, were collected (Table1) in 60 locally advanced NSCLC patients with radiochemotherapy followed by sequential immunotherapy. Categorical variables were compared using the Chi-square test. Survival curves were computed using the Kaplan-Meier method, and Cox proportional hazard regression was performed to evaluate factors independently associated with overall survival (OS) and progression-free survival (PFS).

Results: This investigation enrolled a cohort of patients diagnosed with NSCLC at Shanghai Pulmonary Hospital who had undergone a combination treatment regimen consisting of chemoradiotherapy and sequential immunotherapy. The median PFS and OS among all enrolled patients were 24.0 months and 34.0 months, respectively. OS was significantly associated with high c-MET expression (P = 0.02) and reduced macrophage (CD68+) infiltration (P = 0.01). PFS was significantly associated with high c-MET expression (P = 0.03). Correlation analysis shows a significant correlation (P = 0.01) between c-MET expression and macrophage (CD68+) infiltration (Figure 1).

Conclusions: Our research has identified expression of c-MET and macrophage (CD68+) infiltration as potential predictors of survival. Moreover, there is a significant correlation between the expression of c-MET and macrophage (CD68+) infiltration. The subsequent intricate mechanisms of interaction between c-MET and macrophage infiltration warrant further exploration.

EP.08B.03 Prognostic Value of Irradiated Cardiac and Metabolic Tumor Volume in Unresected LA-NSCLC Treated with Concurrent Chemo-Radiotherapy.

M.G. Savadkoohi[1,2], A.G. Gouveia[1,2,3], D.A. Ribeiro[1], G. Anagnostopoulos[1], T. Chow[2], O. Ostapiak[2], V. Yordanov[4], G. Hajdok[4], A. Swaminath[1,2], G. Okawara[1,2], J. Wright[1,2], G.R. Pond[1], T.G. Tsakiridis[5], [1]McMaster University, Hamilton/ON/CA,[2]Juravinski Cancer Centre, Hamilton/ON/CA,[3]Latin American Cooperative Oncology Group, Porto Alegre/BR,[4]Walker Family Cancer Center, Niagara Health System, St. Catharines/ON/CA,[5]McMaster University, Hamilton, Ontario, Canada, Hamilton/ON/CA

Introduction: Treatment toxicity and poor survival outcomes highlight an urgent need to identify reliable prognostic markers in unresected locally advanced non-small cell lung cancer (LA-NSCLC). Earlier studies suggested that metabolic tumor volume (MTV) has prognostic value in LA-NSCLC treated with standard-of-care concurrent chemo-radiotherapy (cCRT), while recent work points to the detriment of effect of radiation doses reaching the heart. We compared the prognostic value of 18F-fluoro-deoxy-glucose positron emission tomography (FDG-PET) metabolic parameters [metabolic tumor volume (MTV), total lesion glycolysis (TLG), maximum standardized uptake value (SUVmax)], radiotherapy planning [gross tumor volume (GTV), planning target volume (PTV)] and normal tissue (lung, heart and esophagus) radiotherapy volumes.

Methods: A retrospective analysis of institutional health records (Juravinski and Walker Family Cancer Centers, Ontario, Canada) was pursued to identify patients with unresected stage III (AJCC 7th edition) using brain MRI, CT of the chest, abdomen and pelvic and FDG-PET) and treated with cCRT, between January 2007 and December 2017. Overall survival (OS) data were obtained from local and provincial clinical records. Radiotherapy plans - with fused FDG-PET imaging were pulled from Pinnacle databases, reviewed for tumor and normal tissue volume delineation and subjected to dosimetric data extraction using locally developed algorithms. The MIM-Vista© Encore module was used to evaluate tumor MTV, TLG and SUVmax values using appropriate workflows. OS was estimated using the Kaplan-Meier method. Cox regression was used to explore whether factors were prognostic for OS.

Results: Of 186 consecutive patients who met eligibility criteria, 90 were female and 96 male with a median age of 67. Median OS after completion of cCRT was 36.3 months [95%CI, (28.5-45.4)] and 1-, 2- and 5-year OS rates were 81.6%, 64.0% and 36.7% [95%CI (75.0-86.5), 95%CI (56.4, 72.6) and 95%CI (28.2, 45.1)], respectively. In uni-variable analysis pre-treatment MTV and TLG were prognostic for OS [HR:1.33, 95%CI (1.05-1.68), p=0.018 and HR:1.26, 95%CI (1.03-1.55), p=0.027)] but not SUVmax. The cardiac volume receiving 5-45Gy (cV5 - cV45) and radiotherapy mean heart dose (MHD) were also equally prognostic [HRs:1.28 - 1.42, p=0.044 - 0.002; HR:1.33, 95%CI (1.07, 1.64), p=0.011], respectively. No significant predictive value was found for PTV, GTV, normal lung, and esophagus volumes and radiation doses. Further, combining MTV with MHD did not improve significance.

Conclusions: In this institutional series of well-staged patients with unresected LA-NSCLC, exhibiting contemporary survival outcomes after cCRT, baseline volumes of the tumor with metabolic activity (MTV, TLG) and volumes of heart receiving radiotherapy (cV5-cV45, MHD) illustrate similar prognostic value, in agreement with earlier observations. Recognizing the complexity arising from the typical anatomical distribution of LA-NSCLC, these results suggest that, i) metabolic tumor volume could have greater prognostic value compared to clinical tumor volumes and ii) irradiating the heart may be equally detrimental for survival as tumor burden. Future studies should examine these concepts in larger datasets.

EP.08C.02 Impact of Non-Coplanar Radiation Beam Geometry on Effective Dose to Immune Cells (EDIC) In Stage III NSCLC

B. Hopkins, K. Luca, J. Roper, N. Ridge, N. Sebastian, A.H. Kesarwala, J. Shelton, W. Stokes, S. Tian, Winship Cancer Institute at Emory University, Atlanta/GA/USA

Introduction: Effective dose to immune cells (EDIC) models the effect of radiation on the immune system. Sub-analysis of RTOG 0617 led to the creation of a frequently utilized model measuring EDIC in radiation treatment plans and found EDIC to be an independent prognosticator of survival outcomes in stage III non-small cell lung cancer (NSCLC). Further studies have confirmed the utility of EDIC in prognosticating lymphopenia and survival outcomes in patients treated for stage I-III NSCLC and small cell lung cancer.Despite the prognostic value of EDIC, there have been few studies investigating methods of reducing EDIC in the treatment planning setting. In this study we describe how altered radiation beam geometry can improve EDIC in patients treated with radiation for stage III NSCLC and we model its potential impact on overall survival.

Methods: This single-institution retrospective study included 35 patients treated for stage III NSCLC with definitive chemoradiation in the years 2016 to 2023. All patients received a radiation course of 60Gy in 30 fractions using photon based volumetric modulated arc therapy (VMAT) with coplanar arcs. These clinically delivered plans (CDPs) were replanned using novel non-coplanar oblique arc based VMAT plans (NCPs). These NCPs utilized VMAT arcs with strategic couch rotations limiting entrance dose through the heart. VMAT optimization software and planning objectives remained consistent in replans relative to CDPs. EDIC was calculated for all plans using the Jin model derived from RTOG 0617 sub-analysis which incorporates mean heart dose (MHD), mean lung dose (MLD), and integrated total body dose (ITBD).Two-year overall survival (OS) was modeled for each patients CDP and NCP EDIC values using the previously described Jin model. EDIC, MHD, MLD, ITBD, and two-year OS were compared between CDPs and NCPs using the Wilcoxon signed-rank test.

Results: EDIC and MHD were significantly lower in NCPs relative to CDPs (table 1). MLD was not significantly different between NCPs and CDPs. ITBD numerically improved in NCPs relative to CDPs with a trend towards significance. Modeled two-year OS was significantly improved with NCPs relative to CDPs with a 2.9% projected OS improvement for the cohort.

Conclusions: Using a non-coplanar oblique VMAT beam geometry in radiation planning for the treatment of stage III NSCLC resulted in significant improvement in MHD, EDIC, and modeled two-year OS without significant increase in MLD. Implementing this VMAT planning technique may improve these outcomes and further investigation of the real-world significance of these findings is warranted.

Keywords: Lung, Radiation, EDIC

Table 1	Clinically Delivered Plan	Non-coplanar Replan	p
Mean Heart Dose (Gy)	13.5 (0.8-33.1)	7.2 (0.6-16.7)	<0.00001
Mean Lung Dose (Gy)	15.9 (9.6-20.8)	16.4 (8.7-23.6)	0.17
Integral Total Body Dose (Gy·L)	253 (106-1288)	215 (95-498)	0.06

EP.08C.03 To Construct Multi-Omics Modelfor Predicting Prognosis of Definitive Chemoradiotherapyin Locally Advanced Non-Small Cell Lung Cancer

L. Li[1], X. Song[1], N. Liu[1], T. Zhou[1], S. Yuan[1,2], [1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan/CN,[2]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, Anhui, China., Hefei/CN

Introduction: This study aimed to construct a multi-omics model integrating baseline clinical data, computed tomography (CT) images and genetic information to predict the prognosis of dCRT in locally advanced non-small cell lung cancer (LA-NSCLC) patients.

Methods: The study retrospectively enrolled 105 stage III LA-NSCLC patients who had undergone dCRT. The primary tumor was delineated as a region of interest (ROI) on the CT image using 3D-Slicer, and radiomics features were extracted. The Least Absolute Shrinkage and Selection Operator (LASSO) was employed for dimensionality reduction and selection of features. Genomic information was obtained from the baseline tumor tissue samples. The predictive performance of the model was evaluated by the area under the curve (AUC) of the Receiver operating characteristic (ROC) and the concordance index (C-index).

Results: The median follow-up time was 30.1 months, and the median progression-free survival (PFS) was 10.60 months. Four features were made to construct the radiomics model. Multivariate analysis demonstrated the Rad-score, KEAP1 and MET mutations were independent prognostic factors for PFS. The C-index of radiomics model, genomics model and radiogenomics model all performed well in the training group (0.590 vs. 0.606 vs. 0.663) and the validation group (0.599 vs. 0.594 vs. 0.650).

Conclusions: The radiomics model, genomics model and radiogenomics model can all predict the prognosis of dCRT for LA-NSCLC, and the radiogenomics model maybe superior to other two models.

EP.08D.01 Neoadjuvant Chemoimmunotherapy for Potentially Resectable IIIA/IIIB NSCLC(Neo-Pre-IC): Survival Updates and Predictive Effect of MRD

K. Ma, C. Sun, X. Wang, Y. Xu, G. Shao, Z. Yang, S. Qiu, First Hospital of Jilin University, Changchun/CN

Introduction: Neoadjuvant chemoimmunotherapy for potentially resectable IIIA/IIIB NSCLC significantly improved the pathological remission rate. However, information regarding the long-term survival benefits of neoadjuvant chemoimmunotherapy for potentially resectable IIIA/IIIB NSCLC is limited. Meanwhile, the predictive role of minimal residual disease (MRD) in the prognosis for these patients is not clear.

Methods: This prospective, single-arm, phase 2 clinical trial (NCT04326153) enrolled treatment-naïve patients with 'potentially resectable' IIIA/IIIB NSCLC who were deemed unsuitable for complete (R0) resection upon initial diagnosis. Patients underwent neoadjuvant chemoimmunotherapy (sintilimab combined with nab-paclitaxel and carboplatin) for two to three cycles prior to surgical resection of the lung carcinoma and systematic nodal dissection within 30-45 days. The primary endpoint was the 2-year DFS rate, with secondary endpoints encompassing MPR rate, pCR rate, OS, ORR, downstaging rate, and AEs. Meantime, the tissue samples and blood samples retained before treatment were subjected to NGS sequencing. Plasma ctDNA testing was performed again every six months after surgery to analyze the relationship between ctDNA-MRD and survival.

Results: Between 20 March 2020, and 20 August 2021, 30 patients diagnosed with stage IIIA/IIIB NSCLC were enrolled in the study, and 20 patients underwent complete resection. As of March 31, 2024, the median follow-up time is 46.7 months. The median DFS and OS of the surgical patients is still not achieved. The 2-year DFS rate was 75%, and the 30-month DFS rate was 70%. The 2-year and the 30-month OS rate were both 80%. In 16 patients who underwent secondary plasma ctDNA testing after surgery, 3 patients turned positive and 13 patients were still negative. 2 of 3 MRD positive patients experienced disease recurrence. The two cases of radiological recurrence were found 4.1 and 5.9 months after MRD positive detected, respectively. The MRD negative group benefits more from DFS compared to the MRD positive group. Further survival follow-up is needed to clarify the predictive role of MRD on patient survival.

Conclusions: Neoadjuvant chemoimmunotherapy markedly enhanced the rate of pathological response and 2-year DFS in patients with potentially resectable IIIA/IIIB NSCLC. MRD may serve as a potential predictive biomarker for DFS.

EP.08D.02 Adjuvant Treatment Options after Neoadjuvant Chemotherapy Combined with Immunotherapy and Surgery in Patients with Non-Small Cell Lung Cancer

Y. Li, J. Zhao, Y. Li, Shandong Cancer Hospital and Institute, Jinan/CN

Introduction: A large number of studies have confirmed the place of neoadjuvant immunotherapy combined with chemotherapy (NICT) in patients with non-small cell lung cancer (NSCLC), however, controversy still exists regarding postoperative adjuvant therapy after NICT and surgical treatment. Therefore, this study aimed to explore the continuation of the addition of immunotherapy as adjuvant therapy after NICT and surgical treatment.

Methods: Patients with NSCLC treated with NICT and surgery at our study institution from January 2019 to December 2022 were retrospectively analyzed. Patients were divided into Chemo and Immuno+Chemo groups according to whether the adjuvant therapy after NICT and surgical treatment was chemotherapy or chemotherapy combined with immunotherapy to analyze the disease-free survival (DFS) and overall survival (OS) of the two groups.

Results: A total of 209 patients were enrolled, and compared with the Chemo group, the Immuno+Chemo group had a significant advantage in terms of DFS (1-year DFS 70.8% vs. 94.4%; 2-year DFS 58.4% vs. 69.7 %; P=0.002). There was also a significant advantage in OS (1-year OS 98.5% vs. 100.0%; 2-year OS 77.6% vs. 87.6 %; 3-year OS 64.6% vs. 78.9 %; P=0.034). Among those whose postoperative pathology reached pathological complete remission (pCR), there was no significant difference in DFS and OS between the Chemo and Immuno+Chemo groups, whereas among those whose postoperative pathology reached Non-pCR, compared with the Chemo group, the Immuno+Chemo group had a significant advantage in DFS (1-year DFS was 65.1% VS 90.2%; 2-year DFS was 55.8% VS 69.2 %; P=0.003). Compared with the Chemo group, the Immuno+Chemo group also had a significant advantage in terms of OS (1-year OS 97.7% vs. 100.0%; 2-year OS 72.9% vs. 87.3 %; and 3-year OS 64.8% vs. 76.8 %; P=0.030).

Conclusions: In the real world, patients treated with NICT and surgery can still benefit from immunotherapy after surgery, and chemotherapy combined with immunotherapy is significantly more effective than chemotherapy.

EP.08D.03 Efficacy of Neoadjuvant Immunochemotherapy in the Treatment of Stage III Non-Small-Cell Lung Cancer with Cancer-driven Gene Mutations

J. Liu[1], L. Zhu[2], X. Huang[1], J. Hu[1], [1]the First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN,[2]the First Affiliated Hospital, Zhejiang University School of Medicin, Hangzhou/CN

Introduction: Non-small cell lung cancer (NSCLC) patients with cancer driver gene mutations are mainly treated with targeted therapy. For NSCLC with common cancer-driven gene mutations, neoadjuvant immunochemotherapy modalit is still a field of clinical research attempt and attention. In this study, we explored the efficacy and safety of immunochemotherapy as a neoadjuvant treatment in stage III NSCLC with common cancer-driven gene mutations.

Methods: This retrospective study systematically included stage III NSCLC patients who received neoadjuvant immunochemotherapy with gene testing results (including EGFR, KRAS, BRAF, NRAS, HER2, MET, PIK3CA, ALK, ROS1 and RET). The follow-up period lasted at least 1-year post-surgery or after the patient decided to discontinue treatment. The primary endpoint is the pathological response, while secondary endpoints is objective response rate (ORR), disease-free survival (DFS), overall survival (OS), and adverse events (AEs).

Results: From 2020 to 2022, a total of 34 stage III NSCLC patients were included in this study and were categorized into two groups according to whether there were any cancer-driven gene mutations: mutation group (n=22) and wild type (WT) group (n=12). The rate of major pathological response (MPR) in the WT group was 75.0% and 47.0% in the mutation group (P=0.234). The rate of pathological complete response (pCR) in the WT group was 37.5% and 23.5% in the mutation group (P=0.640). Both groups exhibited a 100% ORR. The 1-year DFS rate in the WT group was 87.5% and 82.4% in the mutation group. The 1-year OS rate in the WT group was 100.0% and 94.1% in the mutation group. No postoperative deaths or grade 3 and 4 AEs were observed.

Conclusions: Neoadjuvant immunochemotherapy for stage III NCSLC patients with cancer-driven gene mutations is feasible and safe with considerable therapeutic effect.

EP.08D.04 Association of Lymph Node Metastatic Patterns and Neoadjuvant Immunochemotherapy Effectiveness in Resectable Non-Small Cell Lung Cancer

Y. Zhou[1], Z. Lin[2], Y. Zheng[3], Y. Lin[1], Z. Zhao[1], D. Liu[2], W. Zhai[1], B. Rao[1], S. Feng[1], H. Long[1], [1]Sun Yat-sen University Cancer Center, Guangzhou/CN,[2]Jiangmen Central Hospital, Jiangmen/CN,[3]Henan Cancer Hospital, Zhengzhou/CN

Introduction: While extensively profiled in the tumor microenvironment, recent studies indicated that tumor-draining lymph nodes (TDLNs) acted as a pivotal organ for anti-tumor immunity and lymph nodes (LNs) metastasis may disrupt the effectiveness of neoadjuvant immunochemotherapy. The objective of this study was to examine the relationship between LNs metastatic patterns and neoadjuvant immunochemotherapy (ICT) effectiveness in resectable non-small cell lung cancer (NSCLC).

Methods: NSCLC patients clinically staged as T1-4N0-2M0 and received ICT followed by surgery were retrospectively reviewed from three institutions. According to the extent of TDLNs (e.g. station 2R/4R for right upper lobe, 7 for right middle lobe, 4L/5/6 for left upper lobe and 7/8/9 for lower lobe tumors), patients were further divided into three groups: uninvolved mediastinal LNs (uiMLNs/cN0-1) group, tumor-draining LNs metastasis (mTDLNs) group and non-draining LNs metastasis (mNDLNs) group. The outcomes were complete pathological response (pCR), major pathological response (MPR) and LN clearance (LN-CR) rates. Multivariable logistic regression was used to evaluate the associations between LNs metastatic patterns and pathological response.

Results: A total of 209 patients were included. Of those, 102 (48.8%) were in the uiMLNs group, 67 (32.06%) were in the mTDLNs group and the remaining 40 (19.14%) were in the mNDLNs group. The pCR, MPR and LN-CR rates in the whole cohort were 38.28%, 59.81%, and 74.64%, respectively. Compared with uiMLNs/cN0-1 group, mediastinal LNs metastasis (mMLNs/cN2) group had significantly lower pCR rate in lung squamous cell carcinoma patients (31.03% vs 51.32%, P=0.019, odds ratio [OR]=0.427, 95%CI: 0.209-0.873). In mMLNs/cN2 patients, mNDLNs group had lower pathological response rate in contrast to mTDLNs group (pCR: 7.5% vs 47.76%, P<0.001, OR=0.089, 95%CI: 0.025-0.316; MPR: 22.5% vs 74.63%, P<0.001, OR=0.099, 95%CI: 0.039-0.249; LN-CR: 40% vs 85.07%, P<0.001, OR=0.117, 95%CI: 0.046-0.294; Figure 1A-C). Taking the number of metastatic stations into consideration, patients with multiple-station TDLNs metastasis also had notably higher pCR, MPR and LN-CR rates than those with multiple-station NDLNs metastasis (pCR: 47.83% vs 7.5%, OR=11.306, 95%CI: 2.697-47.387, P<0.001; MPR: 65.22% vs 22.5%, OR=6.458, 95%CI: 2.077-20.082, P<0.001; LN-CR: 82.61% vs 40%, OR=7.125, 95%CI: 2.041-24.871, P=0.01). The pCR, MPR and LN-CR rates had no significantly statistical difference between multiple-station and single-station TDLNs metastasis groups.

Conclusions: Mediastinal LNs metastasis significantly disrupted the neoadjuvant immunochemotherapy effectiveness. In mMLNs/cN2 patients, those with tumor-draining and non-draining LNs metastasis were supposed to have poor pathological response. N-stage classification based on LNs metastatic patterns showed promising potential for neoadjuvant treatment effectiveness prediction in NSCLC.

EP.08D.05 Long Term Follow-up of Two Decades Experience with Neoadyuvant Chemotherapy in Resectable Non Small Cell Lung Cancer

M. Antoñanzas, M. Amman, J.R. Jarabo, C. Aguado de la Rosa, E. Fernández, J-L. González-Larriba, C. Fraile, F. Hernando -Trancho, Hospital Clinico San Carlos, Madrid/ES

Introduction: The addition of neoadjuvant chemotherapy in locally advanced NSCLC has shown 5% absolute improvement in 5-year overall survival (OS). Clinical research indicates a strong correlation between pathological complete response (pCR) and major pathological response (MPR) with survival outcomes, yet long-term data are still required for further validation.

Methods: We retrospectively analyzed patients with stage II and III NSCLC who underwent neoadjuvant chemotherapy and complete tumor resection at Hospital Clínico San Carlos (Spain) between January 1999 and December 2019. We assessed staging, surgery data, relapse patterns, pCR, MPR, event-free survival (EFS), and OS. Log-rank tests and Cox proportional hazards models were used to estimate HR.

Results: 186 patients underwent neoadjuvant therapy. Initial staging included 20 with stage II disease and 166 with stage III disease, of which 91 were N2 positive, including 46 with multistation N2 involvement. Lobectomy, bilobectomy, and pneumonectomy rates were 64.5%, 7.5%, and 27.9% respectively. pCR was observed in 22 patients (11.8%), while MPR was observed in 37 patients (19.9%). Among the 98 patients experiencing relapse, 69 had distant relapses (36.2% in the central nervous system), and 29 were local relapses. Carboplatin plus paclitaxel was the preferred chemotherapy regimen (62.4%)We conducted statistical analyses of EFS and OS comparing patients achieving pCR versus those who did not, and patients achieving MPR versus those who did not. In the pCR scenario, estimated OS rates at 2, 5 and 10 years were 90.9%,72.2% and 45% in the pCR group, and 69.8%, 44.3% and 29% in the non-pCR group (HR 0.45, 95% CI 0.26-0.79 p < 0.001). Similarly, EFS results were statistically significant (p < 0.002) with 85.7% at 2 and 5 years and 70.7% at 10 years in the pCR group, and 53.4%, 40.4% and 33% in the non-pCR group, respectively (HR 0.27 95% CI 0.11- 0.62).EFS at 2, 5 and 10 years were 88.9%, 83.1% and 69% in the MPR group, and 48.4% and 35.5% 25 in the non-MPR group. OS rates at 2, 5 and 10 years were 94.6%, 78.4% and 55% in the MPR group, and 66.4%, 39.5% and 24.1% in the non-MPR (HR 0.40, 95% CI 0.25-0.63 p < 0.001). Figure 1.

Conclusions: In our patient cohort, achieving pCR or MPR correlated with improved EFS and OS compared to non-histological responder groups. This strong association, coupled with a lengthy follow-up period, underscores the importance of implementing immune-based neoadjuvant strategies to enhance pathological response for long-term survival.

Keywords: Neoadyuvant chemotherapy, pCR MPR, Long term survival

EP.08D.06 Neoadjuvant Chemoimmunotherapy Does Not Increase Postoperative Morbidity of Pneumonectomy in NSCLC Patients: A Multi-Center Psmanalysis

Z. Li[1], W. He[2], [1]Shanghai Pulmonary Hospital, Shanghai/CN,[2]Shanghai Pulmonary Hospital, Shanghai/CN

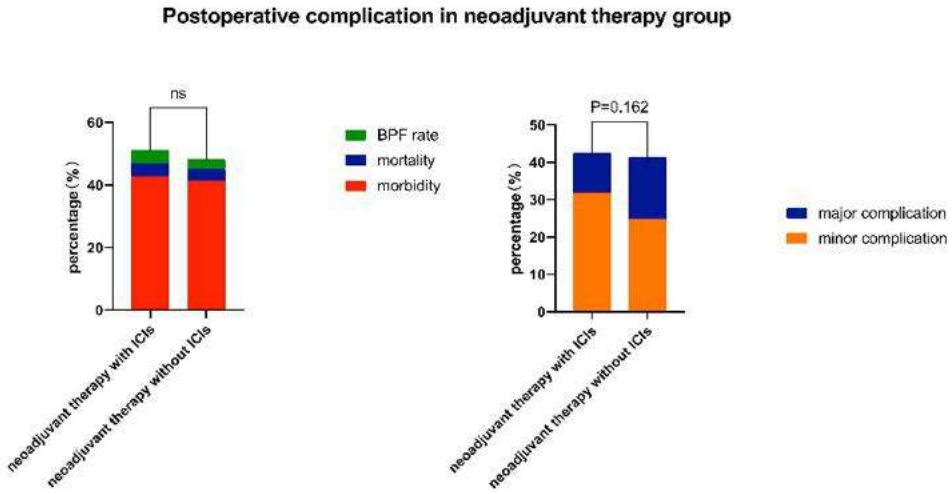
Introduction: The feasibility and efficacy of PN for locally advanced NSCLC after preoperative induction therapy especially with ICIs are uncertain and its indications after neoadjuvant therapy remain controversial.

Methods: A total of 1187 patients who underwent pneumonectomy for non-small-cell lung cancer were retrospectively analyzed from three hospitals in China, including 209 patients who received neoadjuvant therapy and 978 patients who did not. Propensity-score matching (PSM) was adopted to create a balanced cohort of 174 paired cases. The logistic regression was used in this study. The primary endpoint was the postoperative morbidity.

Results: In the unmatched cohort, univariable logistic regression analysis showed that FEV1, extended pneumonectomy, and intraoperative transfusion were risk factors for postoperative complications, and multivariable logistic regression analysis showed FEV1 (odds ratio [OR], 1.487; P=0.019) and extended pneumonectomy (OR, 1.499; P=0.007) were independent risk factors. The neoadjuvant group had larger tumors (4.7±2.2 vs. 3.9±1.9cm, P<0.001; cT4: 36.3% vs. 19.1%, P<0.001), had a greater rate of N2 metastases (64.5% vs. 33.3%, P<0.001), and were at a more advanced clinical TNM stage (stage III: 89.4% vs. 58.6%, P<0.001). However, no significant difference in postoperative morbidity was observed between the two groups before and after PSM (43.5% vs. 42.9%, P=0.975; 49.4% vs. 41.9%, P=0.162). The complete pathologic response of chemoimmunotherapy was significantly superior to chemotherapy alone (27.7% vs. 2.0%, P<0.001), and no significant difference in postoperative morbidity was noted in different neoadjuvant therapy modalities.

Conclusions: After neoadjuvant therapy with ICIs, pneumonectomy can be safely performed in selected patients without increased postoperative morbidity.

Keywords: pneumonectomy, non-small cell lung cancer, Neoadjuvant chemoimmunotherapy



EP.08D.07 Pathological Response to Neoadjuvant Tislelizumab Plus Chemotherapy in Potentially Resectable Stage IIIB NSCLC

T. Wang[1,2], P-L. Wang[3], Y-X. Song[4], H. Chen[5,6], L. Li[1], Y. Wang[4], L-R. Ding[3], X-J. Huang[3], B. Zheng[5,6], J-R. Zhang[5,6], J-W. Liu[1,2], D-X. Zhu[1,2], L. Tian[1,2], L-L. Jiang[7], P. Zhou[7], M-G. Su[8], D. Pu[1,2], R. Jiang[1,2], K-L. Huang[1,2], Y-S. Wang#[9], C. Chen#[4], Q-H. Zhou#[10, 11] Department of Thoracic Surgery, West China Hospital, Sichuan University, Cheng du/CN,[22] Lung Cancer Center, West China Hospital, Sichuan University, Cheng du/CN,[33] Department of Respiratory and Critical Care Medicine, The Second Affiliated Hospital of Zhejiang University School of Medicine, Hang zhou/CN,[44] Department of Thoracic Surgery, The Affiliated Hospital of Zunyi Medical University, Zunyi/CN,[55] Key Laboratory of Cardio-Thoracic Surgery, Fujian Medical University, Fujian Province University, Fuzhou/CN,[66] Department of Thoracic Surgery, Fujian Medical University Union Hospita, Fuzhou/CN,[77] Pathologic Department, West China Hospital, Sichuan University, Cheng du/CN,[88] Department of Nuclear Medicine, West China Hospital, Sichuan University, Cheng du/CN,[99] Division of Thoracic Tumor Multimodality Treatment, Cancer Center, West China Hospital, Cheng du/CN,[102] Lung Cancer Center, West China Hospital, Sichuan University, Zunyi/CN*

Introduction: In patients with resectable stage II-IIIA non-small cell lung cancer (NSCLC), neoadjuvant tislelizumab plus chemotherapy showed clinically meaningful improvements in major pathological response (MPR) and pathological complete response (pCR) rates compared to chemotherapy alone. However, the clinical benefit of neoadjuvant tislelizumab plus chemotherapy for potentially resectable stage IIIB NSCLC remains to be determined. This exploratory analysis retrospectively evaluated the pathological response of neoadjuvant tislelizumab plus chemotherapy for patients with potentially resectable stage IIIB NSCLC.

Methods: Between August 2020 and January 2024, 75 patients with potentially resectable stage IIIB NSCLC from 4 centers (West China Hospital, Sichuan University; Fujian Medical University; Fujian Province University; The Second Affiliated Hospital of Zhejiang University of Medicine Affiliated Hospital of Zunyi Medical University) were included in this retrospective study. All patients received 2-4 cycles of neoadjuvant tislelizumab plus chemotherapy (nab-paclitaxel/pemetrexed and cisplatin/carboplatin) followed by surgery and optional adjuvant therapy. The primary endpoint was MPR. Secondary endpoints included R0 resection rate, pCR, tumor downstaging, as well as objective response rate (ORR) and disease control rate (DCR) per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1.

Results: Of the 75 patients, the median age was 57.0 years (range, 46.0-73.0). The majority of patients were male (74/75, 98.7%). As of January 14, 2024, 64 patients (85.3%; 95% CI, 75.3%-92.4%) completed the planned neoadjuvant therapy and underwent successful R0 resection, while 11 patients declined or were not suitable for surgery . 47(73.4,60.91-83.7)of 64 patients had an MPR, and 28 (43.7%; 95% CI, 32.4%-56.7%) had a pCR. Tumor downstaging occurred in 84.37% (54/64) of patients. The ORR and DCR were 81.3% (95% CI, 70. 7%-89.4%) and 98.7% (95% CI, 92.79%-100.0%), respectively.Table 1: Efficacy results of included patients (N=75)

Conclusions: Tislelizumab in combination with chemotherapy as neoadjuvant therapy demonstrated promising antitumor activity for potentially resectable stage IIIB NSCLC with high rates of MPR and pCR.

EP.08D.08 Aumolertinib as Neoadjuvant Therapy for EGFR M+ NSCLC: A Subcohort Analysis of PURPOSE Trial Data Updated

Y.Y. Wang[1], Z.T. Gu[1], F.C. Bao[1], T. Mao[1], C.Y. Ji[1], J. Wang[2], Y.R. Cai[2], B. Li[2], W.T. Fang[1], [1]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai/CN,[2]Burning Rock Biotech, Guangzhou/CN

Introduction: Recently, promising results with neoadjuvant targeted therapy and immunotherapy have been seen in resectable non-small cell lung cancer (NSCLC). Aumolertinib, a 3rd generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), has been proven to be highly effective for postoperative and advanced NSCLC with EGFR mutations. The primary data has been published (WCLC 2023 EP07.05-17). Here, we update the data of aumolertinib as neoadjuvant treatment for resectable EGFRm+ NSCLC from the PURPOSE trial.

Methods: The PURPOSE trial is an open-label, prospective, phase II, umbrella study of precise neoadjuvant therapy for patients with stage II-IIIB resectable NSCLC. Eligible patients with EGFR 19del were given aumolertinib 110mg QD for 9 weeks followed by surgery, as one of the six cohorts in the PURPOSE trial. The primary endpoint was objective response rate (ORR). The secondary endpoints were major pathologic response (MPR) rate, pathological complete response (pCR) rate, event-free survival (EFS) and overall survival (OS).

Results: Up to March 26, 2024, 9 patients have completed the neoadjuvant treatment and received radical surgery. The median follow-up time were 12 months. 6 patients were females and 3 patients were males, 8 patients were lung adenocarcinoma and 1 was squamous cell carcinoma, 2 patients were stage II and 7 patients were stage III, 2 patients were N1 and 7 patients were N2. Remarkably, the ORR was 100%. Serious adverse event was not observed. All patients achieved R0 resection, 8 patients received VATS lobectomy (88.9%) and 1 underwent open bi-lobectomy. Importantly, 2 patients achieved pCR (pCR rate 22.2%, including one squamous cell carcinoma) and 1 achieved MPR (MPR rate 33.3%). 3 patients had pathological response (Tumor residual <50%). 3 patients pN2 and 6 patients pN0. The rate of N1 and N2 mediastinal lymph node downstage was 100% and 57.1%, respectively. After surgery, 7 patients received aumolertinib maintenance therapy and 2 patients received 4 cycles of chemotherapy combination with aumolertinib maintenance therapy. No intraoperative and postoperative complication was occurred. MRD detection were performed in all patients, MRD was detected before the treatment of aumolertinib neoadjuvant therapy and surgery, 3 months, 6 months, and 1 year after surgery. 5 patients completed MRD detection at 1 year, 4 patients completed MRD detection at 6 months after surgery. 7 patients were MRD positive and 2 patients were MRD negative before the treatment of aumolertinib neoadjuavant therapy, and later MRD were negative in all patients.

Conclusions: The subcohort analysis from the PURPOSE study has illustrated that aumolertinib as neoadjuvant therapy is effective and feasible for locally advanced EGFR 19del NSCLCs. The rest results of this study will be released in the future. Clinical trial information: ChiCTR2100053021

EP.08D.09 Efficacy and Safety of Neoadjuvant Tislelizumab Plus Chemotherapy for the Treatment of Non-Small Cell Lung Cancer: a Pooled Analysis

Y-B. Lin[1], L-R. Ding[2], P-L. Wang[2], J. Hu[3], J-Z. Shan[4], X-Y. Cheng[5], Q-H. Zhou[6], Y-S. Wang[6], D-Q. Sun[7], H. Chen[8], H. Long[1], [1]Sun Yat-Sen University Cancer Center, Guangzhou/CN, [2]The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou/CN, [3]The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou/CN, [4]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN, [5]First Affiliated Hospital Guangzhou Medical University, Guangzhou/CN, [6]West China Hospital, Sichuan University, Chengdu/CN, [7]Tianjin Chest Hospital of Tianjin University, Tianjin/CN, [8]Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: Although various effective Immune checkpoint inhibitors for the neoadjuvant treatment of non-small cell lung cancer (NSCLC) improved MPR/pCR rate, the optimal regimen remains controversial. Previous studies revealed that PD-1 inhibitor tislelizumab had extensive antitumor activities. However, the majority of studies on neoadjuvant tislelizumab in NSCLC are non-randomized controlled trials with small sample sizes, different treatment modes and uncontrolled statistical analysis. Here, this meta-analysis aims to evaluate the efficacy and safety of neoadjuvant tislelizumab plus chemotherapy in patients with NSCLC.

Methods: We performed a systematic literature review of trials reporting outcomes of neoadjuvant tislelizumab-based therapy on PubMed, Embase and the proceedings of the most relevant international conferences before December 2023. Eligibility criteria: Animal experiments, cell research, reviews, meta-analyses, duplicates, case report or letters were not in consideration; studies with less than 10 patients were excluded. The study was registered on the International Platform of Registered Systematic Review and Meta-analysis Protocols (INPLASY202430114). The statistical analysis was performed using R version 4.1.2 statistical computing software.

Results: A total of 9 studies with 280 patients were included in the meta-analysis. For neoadjuvant tislelizumab plus chemotherapy in NSCLC pts, the pooled pCR and MPR rate was 0.40 (95% CI 0.33-0.46) and 0.65 (95% CI 0.59-0.71) respectively, with an ORR 0.76 (95% CI 0.68-0.83). R0 resection rate was 1.0 (95% CI 0.98-1). The pooled incidence of all grade TRAEs was 0.89 (95% CI 0.69-1.00), and that of >= grade 3 TRAEs was 0.17 (95% CI 0.05-0.33).

Conclusions: According to our analysis, reliable efficacy and safety of neoadjuvant tislelizumab plus chemotherapy for NSCLC were demonstrated across multiple clinical trials.

EP.08D.10 Outcome after Preoperative Chemoradiotherapy for Non-Small Cell Lung Cancer with Chest Wall Invasion

Y. Koike, K. Aokage, M. Tada, T. Miyoshi, K. Tane, J. Samejima, M. Tsuboi, National Cancer Center Hospital East, Chiba/JP

Introduction: Multimodality treatment including anatomic lung resection and chest wall resection is recommended for patients with chest wall-invasive non-small cell lung cancer (NSCLC). Surgery after chemoradiotherapy (CRT) for chest wall invasive cancer has been reported to be safe and effective. On the other hand, there are few reports showing the outcomes of preoperative treatment for chest wall invasive cancer, excluding SST. We will clarify the outcomes of preoperative CRT for NSCLC with chest wall invasion at our institution.

Methods: From 2000-2020, Seventy patients who underwent lobectomy or more for chest wall invasive cancer (NSCLC) with rib involvement on CT images were included in this study. The clinicopathological characteristics between the two groups, 20 patients in the preoperative CRT group and 50 patients in the upfront surgery (UFS) group, were clarified, and the 3- and 5-year OS, RFS prognosis, recurrence format, and cause of death were comparatively analyzed.

Results: The preoperative CRT group was more likely to be younger and cN0 with good PS and fewer serious postoperative complications than the UFS group. Five patients (25%) in the preoperative CRT group had pathologic complete response; 13 patients (25%) in the UFS group received postoperative adjuvant therapy. About 15% of patients in both groups were not curative. Median follow-up was 33.7 months. 3/5-year OS was 74/53% in the preoperative CRT group and 41/37% in the UFS group (HR=0.51, p=0.05). 3/5-year RFS was 63/42% in the preoperative CRT group and 30/28% in the UFS group (HR=0.49, p=0.04). As for recurrence, there was 1 (5%)/8 (16%) chest wall margin recurrence, 4 (20%)/23 (46%) distant recurrence, and 5 (20%)/27 (54%) lung cancer deaths.

Conclusions: The preoperative CRT group had a better prognosis than the UFS group. Future prospective studies examining the efficacy and safety of preoperative CRT (±ICI) for chest wall invasive cancer excluding SST need to be considered.

EP.08D.11 Redefining Prognosis in NSCLC after Neoadjuvant Immunotherapy: The Predictive Power of Pathologic Response and Lymph Node Status

Y. Xu, H. Liu, Peking Union Medical College Hospital, Beijing/CN

Introduction: This study evaluates the predictive value of pathologic response and lymph node status on progression-free survival (PFS) in patients with non-small cell lung cancer (NSCLC) undergoing neoadjuvant immunotherapy.

Methods: We conducted a retrospective analysis of 143 patients with potentially resectable NSCLC who underwent neoadjuvant immunotherapy followed by surgical resection. Data on pathologic response, lymph node involvement, and clinical outcomes were collected and analyzed. Kaplan-Meier analysis and Cox regression were used to evaluate the association between these factors and PFS.

Results: Both major pathological response (MPR) and complete pathological response (CPR) were significantly associated with improved PFS (p<0.01), with no statistical difference observed between them (p=0.15). Lymph node involvement adversely affected PFS (p<0.01). A novel risk stratification based on pathologic response and nodal status effectively distinguished prognosis (3-year PFS: 98.9%, 78.9%, 53.3%). Adjuvant immunotherapy did not demonstrate a clear benefit for PFS (p=0.62). Gender (p=0.02) and total pneumonectomy (p=0.04) emerged as prognostic factors.

Conclusions: MPR and CPR confer similar survival benefits in NSCLC after neoadjuvant immunotherapy. Lymph node status significantly influences prognosis. The proposed risk stratification provides a valuable tool for personalized management.

EP.08D.12 Comparision of Neoadjuvant Chemoimmunotherapy and Chemotherapy for Potentially Resectable Stage IIIA/B NSCLC

K. Ma, Y. Xu, X. Chen, Y. Wang, X. Zhao, First Hospital of Jilin University, Changchun/CN

Introduction: Currently, the treatment of stage III non-small-cell lung cancer (NSCLC) remains a significant challenge. It has been reported that the 5-year survival rate following surgery in patients with stage III NSCLC is only 13-36%. However, patients who received neoadjuvant chemoimmunotherapy could improve pathological response and downstaging of the tumor compared to neoadjuvant chemotherapy alone. However, most of these studies are single-armed trials with small sample sizes. Consequently, this study aimed to compare the real-world efficacy and safety of neoadjuvant chemoimmunotherapy to chemotherapy alone in patients with potentially resectable stage III NSCLC.

Methods: We retrospectively analyzed patients with newly diagnosed stage III NSCLC in our institution during 2018-2023. A total of 71 patients were finally selected including 46 patients in the neoadjuvant chemoimmunotherapy group and 25 patients in the neoadjuvant chemotherapy group. All patients were followed up to collect perioperative pathology and clinical data. SPSS 27.0 was used for statistics.

Results: Patients who received perioperative chemoimmunotherapy had significantly longer disease-free survival (DFS) (median DFS: NR vs. 15 months; hazard ratio [HR]=0.186, 95CI: 0.073-0.479, p=0.001). Patients who received neoadjuvant chemoimmunotherapy performed better overall survival (OS) (p=0.193). The objective response rate (ORR) in the combination group was higher compared with that of the chemotherapy group (73.9% vs. 60.0%), but without statistical significance (P = 0.123). The major pathological response (MPR) and pathological complete response (pCR) were significantly higher in the neoadjuvant chemoimmunotherapy group than in the neoadjuvant chemotherapy group (65.9% vs. 16.7%, 36.4% vs. 8.3%, respectively; P < 0.05). In subgroup analyses by pathological response, patients with a MPR had better DFS (P = 0.016) and OS (P = 0.032) than those with incomplete pathological response. We have also found that neoadjuvant chemoimmunotherapy was more effective in nodal downstaging (61.4% vs. 41.7%, p = 0.039). Although the incidence of all grades adverse events was higher in the neoadjuvant chemoimmunotherapy group than in the neoadjuvant chemotherapy group (80.4% vs. 64.0%), and the incidence of grade 3 and above adverse events was 10.9% (5 cases) and 8.0% (2 cases) respectively, none of these reached statistically significance.

Conclusions: Overall, neoadjuvant chemoimmunotherapy is effective and safe in potentially resectable stage IIIA/B NSCLC. Compared with chemotherapy alone, neoadjuvant chemoimmunotherapy provides a significant improvement in pathological response and DFS without increasing the incidence of adverse events.

Keywords: Non-small cell lung cancer, Neoadjuvant chemoimmunotherapy, Potentially resectable

EP.08D.13 Macrophage Polarization States Predicting the Efficacy of Neoadjuvantchemoimmunotherapyin Resectable or Potentially Resectable NSCLC

Z. Xu[1,2], K. Shao[1], Y. Li[1], J. Ying[1], T. Xie[1], P. Xing[1], J. Li[1], [1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN,[2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN

Introduction: Neoadjuvant chemoimmunotherapy has been proved beneficial for resectable or potentially resectable non-small cell lung cancer (NSCLC) in the neoadjuvant setting, while the predictive and prognostic biomarkers are still under investigation. This study aims to reveal the predictive role of macrophage polarization states in tumor microenvironment for patients who underwent neoadjuvant chemoimmunotherapy.

Methods: This study included stage I-IIIB resectable or potentially resectable NSCLC who required neoadjuvant therapy of immune checkpoint inhibitors combining with standard chemotherapy after assessment by surgeons. We classified patients into pathological response (MPR) group and non-MPR group, according to the pathological remission rate, defined by at least 90% tumor necrosis in the resected tissue. Multiple immunofluorescence (mIF) assay was performed for macrophage detection. The detected biomarker molecules included CD68, IRF5, CD86, CD206, CD163, panCK, and DAPI. The DAPI was a fluorescent dye that binds strongly to DNA and was used for preliminary identification of all cells. The panCK was a pan-cytokeratin marker used to identify lung cancer cells. The CD68 was a pan-macrophage marker. The CD86/IRF5 served as indicators of M1 macrophage polarization, while the CD163/CD206 served as indicators of M2 macrophage polarization. The relationship between the macrophage characteristics at baseline and the pathological responses was analyzed.

Results: A total of 14 samples from patients who had received 2-3 cycles of neoadjuvant chemoimmunotherapy followed by radical surgery was included for mIF analysis, with 7 cases in MPR group, and another 7 cases in non-MPR group. The distribution and characteristics of macrophage cells in one sample was shown in Fig A. As characterized by a pro-tumoral activity and the production of immune-suppressive cytokines, M2-polarized macrophages in both groups had relatively higher density than M1-polarized macrophages, characterized by having anti-tumoral activity and producing pro-inflammatory cytokines, shown in Fig B. In MRP group, the median number of M2 and M1 macrophages were 48/mm2 (range 18-376) and 16/mm2 (range 2-163), respectively (P=0.848); in non-MPR group, the median number of M2 and M1 macrophages were 181/mm2 (range 4-260) and 21/mm2 (range 3-71), respectively (P=0.949), shown in Fig C. However, the difference value in the density of M1-M2 macrophages was less than in MPR group than in non-MPR group (median difference value of 25/mm2 and 152 16/mm2, respectively).

Conclusions: Baseline M1/M2-polarized macrophages level may be related to the pathological reponses, therefore the detection of macrophage polarization states is potential in predicting the efficacy of neoadjuvant chemoimmunotherapy in resectable or potentially resectable NSCLC.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.08D.14 Long-Term Prognosis of Patients Undergoing Trimodality Therapy for Locally Advanced Non-Small-Cell Lung Cancer

K. Okada[1], K. Suzawa[1], T. Ryuko[1], Y. Tomioka[1], S. Tanaka[1], K. Shien[1], K. Miyoshi[1], M. Okazaki[1], S. Sugimoto[2], E. Suzuki[2], J. Soh[3], S. Toyooka[2], [1]Okayama university hospital, Okayama-shi/JP,[2]Okayma university hospital, Okayama-shi/JP,[3]Osaka metropolitan university hospital, Osaka-shi/JP

Introduction: Induction chemoradiotherapy (CRT) followed by surgery (trimodality therapy) is a therapeutic option for locally advanced non-small-cell lung cancer (NSCLC). In this study, we conducted a single-center retrospective analysis of the long-term prognosis of patients undergoing trimodality therapy for locally advanced NSCLC.

Methods: Patients treated with trimodality therapy between January 1999 and December 2021 were retrospectively analyzed. Overall survival (OS) and recurrence-free survival (RFS) were calculated from the initiation of induction CRT until death from any cause or the last follow-up for OS, and until confirmed recurrence at a local or distant site or death from any cause for RFS. Univariate analysis of OS and RFS was performed using the Kaplan-Meier method with the log-rank test. Multivariate analysis was conducted using the Cox proportional hazards model.

Results: A total of 206 patients underwent trimodality therapy. The median age at the time of surgery was 64.5 (range, 31-79), and 160 patients were male. The 7th edition of the TNM classification was used for disease staging, with clinical stages including II (n = 24), III (n = 178), and IV (n = 4). Tumor histology included adenocarcinoma (n = 120), squamous cell carcinoma (n = 77), or others (n = 9). The median radiation dose was 46 Gy, and 201 patients received platinum doublets. One hundred seventy-six patients completed the planned CRT, and 35 patients underwent more than lobectomy, while one patient underwent exploratory thoracoscopy solely due to pleural dissemination. Downstaging was achieved in 153 patients (74.3%), and 69 patients (33.5%) achieved a pathological complete response (pCR). Postoperative complications included pneumonia (n = 28), radiation pneumonitis (n = 32), bronchopleural fistula (n = 9), and 17 patients underwent reoperation. Adjuvant chemotherapy was administered to 92 patients (45.1%), and 89 patients (43.2%) developed recurrence. The median follow-up was 11.08 years (Kaplan-Meier estimate). Excluding the patient with pleural dissemination, the 3-, 5-, and 10-year OS rates were 77.8%, 68.2%, and 51.8%, respectively, and the 3- and 5-year RFS rates were 57.2% and 51.5%, respectively. Multivariate analysis showed that a history of other malignancy (P = 0.006), lower lobe tumors (P = 0.009), non-pCR (P = 0.004), and reoperation (P = 0.003) correlated with a worse prognosis. In non-recurrence patients, more than lobectomy (P = 0.02) and postoperative pneumonia (P = 0.04) were independent poor prognostic factors. It is considered that preserving lung function and preventing postoperative complications are important not only for short-term prognosis but also for long-term outcomes.

Conclusions: This study demonstrated the long-term prognosis of patients undergoing trimodality therapy for locally advanced NSCLC. Trimodality therapy is a feasible therapeutic option.

EP.08D.15 Radical Surgery after Induction Therapy for Initially Unresectable Stage III Non-small Cell Lung Cancer

Y. Yan, Z. Niu, C. Li, Y. Cao, X. Chen, F. Luo, R. Jin, H. Li, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China, Shanghai/CN

Introduction: Treatments for stage III non-small cell lung cancer (NSCLC) is controversial. Surgical resection is primarily recommended for T1-3 diseases with single station and non-bulky N2, while other stage III NSCLC are determined initially unresectable. Previous studies have shown that selective surgery after induction therapy could bring potential benefits for these patients. However, it requires strict operation indications and patient screening. This single-arm, prospective study evaluated the safety and feasibility of surgery after induction therapy for initially unresectable stage III NSCLC patients (NCT04945928).

Methods: Patients with initially unresectable stage III NSCLC who received induction therapy and evaluated operable for radical resection were included and underwent surgery. The primary endpoint is perioperative morbidity. The lymph nodes count, R0 resection rate, operation time, blood loss, operative complications, postoperative hospital stay, 30-day mortality, complete pathological remission rate (pCR) the rate of major pathological remission (MPR), one-year overall survival (OS), and one-year disease-free survival (DFS) were secondary outcomes.

Results: From August, 2021 to January, 2024, 30 patients were included (Figure 1A). Most of the patients received immunochemotherapy (23/30, 76.7%), others received chemotherapy (4/30, 13.3%) and targeted therapy (4/30, 13.3%) as induction therapy. The R0 resection rate was 93.3%. Ten out of 30 patients (33.3%) experienced post-operative morbidity with details shown in Figure 1B. No in-hospital mortality was observed, but one patient died 30-90 days after the surgery. MPR and pCR were achieved in 20 (20/30, 66.7%) and 9 (9/39, 30%), respectively (Figure 1C). The rate of one-year DFS was 87.5%, and one-year OS was 96.7% (Figure 1D-E).

Conclusions: Surgery after induction therapy was safe and feasible for initially unresectable stage III NSCLC patients, with acceptable surgical-related morbidity, MPR/pCR rate, and 1-year DFS/OS.

EP.08D.16 Neoadjuvant Chemoimmunotherapy in the Treatment of Stage III Non-Small Cell Lung Cancer: A Single-Center Initial Results.

A. Allakhverdiev, P. Akhmedov, S. Smolin, The Loginov Moscow Clinical Scientific Center, Moscow/RU

Introduction: Neoadjuvant immunotherapy combined with chemotherapy has demonstrated high efficacy in the treatment of patients with locally advanced non-small cell lung cancer. However, there is still not much data on the surgical feasibility as well as on the tumor response. We have analyzed our personal experience of using chemoimmunotherapy in combination therapy of patients with stage III NSCLC.

Methods: Patients with stage III resectable locally advanced NSCLC treated with neoadjuvant chemoimmunotherapy followed by surgery at The Loginov Moscow Medical Scientific Center from 2023 to 2024 were retrospectively included. Patients with activating mutations were not included in our study. Surgical, therapeutic and morphological outcomes were assessed.

Results: A total of 22 stage III locally advanced non-small cell cancer carcinoma patients were included in our study. All patients received 3 cycles of neoadjuvant chemoimmunotherapy with a subsequent assessment of the treatment response. The objective radiological response rate was 90.9% among all patients: complete response in 4 patients (18.2%), partial response in 16 patients (72.7%), and stable disease was achieved in 2 patients (9.1%). All patients underwent surgical treatment. A totally minimally invasive surgical treatment was successfully completed in 4 cases (18.2%). 7 patients (31.8%) received lobectomy with lymph node dissection, 3 patients (13.6%) underwent sleeve lobectomy with lymph node dissection, bilobectomy with lymph node dissection was performed in 4 cases (18.2%), 2 patients (9.1%) received pneumonectomy with carinal resection and both right and left pneumonectomy were performed in 6 patients (27.3%). A reduction in the volume of surgery was achieved in 7 patients (31.8%). All surgeries were performed in full and there was no residual tumor (R0). Complete pathological response was found in 8 patients (36.4%), in 13 cases (59.1%) major pathological response was achieved and only in 1 patient (4.5%) there was no pathological response. There were no significant therapeutic complications in postoperative period and no 30- or 90-day mortalities.

Conclusions: Surgical treatment after chemoimmunotherapy for resectable stage III NSCLC is feasible and safe. Moreover, neoadjuvant chemoimmunotherapy leads to a significant pathological response. This study has limitations, such as lack of PD-L1 scores and short follow-up period and further research is needed to analyze these data.

EP.08D.17 Long-Term Survival Outcomes of Surgery after Neoadjuvant TKI for Locally Advanced Lung Adenocarcinoma Harboring Driver Gene Mutations

M. Aoki, G. Kamimura, S. Morizono, T. Tokunaga, A.H. Takeda, K. Maeda, T. Nagata, K. Ueda, Kagoshima University School of Medicine, Kagoshima/JP

Introduction: The optimal treatment for locally advanced non-small cell, including stage IIIA, remains controversial. In addition, tyrosine kinase inhibitors (TKIs) have been shown to be effective in lung adenocarcinomas with driver gene mutations, and the usefulness of surgery for lesions that remain after TKI treatment has been reported.

Methods: Between January 2016 and December 2018, ten patients with stage III lung adenocarcinoma harboring driver gene mutations were treated with TKI (EGFR-Exon19 deletion, n=5; EGFR-L858R point mutation, n=3; EGFR-L861Q point mutation, n=1; EML4-ALK rearrangement, n=1). With the exception of one patient who refused surgery, nine patients received two courses of platinum doublets and underwent surgery. Postoperatively, two to four courses of platinum doublet were added in six cases, and TKI was restarted in four cases.

Results: In all cases, the therapeutic effect of TKI was greater than a partial response (according to RECIST), and radical surgery was performed in nine cases, excluding one patient who refused surgery. Although residual cancer cells were histologically observed in the EGFR gene mutation-positive case, the expression of the EGFR-T790M point mutation was not observed. A complete pathological response was observed in the EML4-ALK rearrangement case. No major postoperative complications due to surgery were observed. One patient who refused surgery continued to receive Osimertinib for 30.1 months, but died 33.5 months after the initiation of treatment. Of the patients who underwent surgery, three were alive without recurrence, but six had distant metastases, including five with brain metastases. Among the cases in which TKI therapy was not restarted postoperatively, brain metastases were observed in three patients and lung metastasis was observed in one patient. In two of the cases in which TKI therapy was restarted, brain metastasis recurrence was observed 47.4 months after the administration of Erlotinib and 6.6 months after the administration of afatinib. In two cases who were not able to receive any adjuvant therapy, recurrence of brain metastasis was observed in the early postoperative period. At present, a median observation period of 77.2 months has passed since the initiation of treatment, and seven of the nine patients who underwent surgery are still alive.

Conclusions: We report the long-term survival outcomes of ten patients with stage III lung adenocarcinoma harboring driver gene mutations who received TKIs as neoadjuvant therapy. The treatment was feasible, and radical surgery was performed without major complications. Eight of the nine patients who underwent surgery survived for more than five years from the initiation of treatment, suggesting the usefulness of this treatment. It is difficult to completely cure EGFR mutation-positive cases with drug therapy alone, and radical surgery is desirable at some point. In addition, pretreatment radiological imaging showed locally advanced lung cancer, but a high rate of distant metastasis, mainly brain metastasis, was observed after surgery. This suggests the need for additional postoperative treatment, including TKI therapy.

EP.08E.01 Comparison of CT Findings Between Staple Line Granuloma and Recurrent Tumor after Sub-Lobar Resection for Lung Cancer and Pulmonary Metastasis.

T. An, Y.K. Cha, T.J. Kim, J. Lee, Samsung Medical Center, Seoul/KR

Introduction: The use of autonomous suture devices increased with the rise of thoracoscopic surgery in the treatment of lung cancer and the formation of staple line granuloma has been reported. Staple line granuloma is known to be more frequent in sub-lobar resection. Distinguishing between a recurrent tumor and staple line granuloma is clinically important. However, previous studies only included few cases of staple line granuloma. This study aimed to find CT imaging feature for differentiating staple line granuloma from recurrent tumor, especially in the case of sub-lobar resection for lung cancer and pulmonary metastasis.

Methods: A cross-sectional retrospective analysis was conducted on consecutive 57 patients, with pathologic confirmed staple line granulomas (n=21) and recurrent tumors (n=36), who underwent sub-lobar resection for lung cancer or pulmonary metastasis from 1 April 1995 to 1 May 2022. Three independent radiologists interpreted CT parameters as follows: lesion size, enhancement, internal low density, staple line abutting length, air-bronchogram, growth pattern (one side contact or radial), margin, satellite nodule, preserved vascular or lobular margin, and mediastinal or hilar lymph node enlargement. We compared CT parameters between staple line granuloma and recurrent tumor groups and analyzed univariate and multivariate logistic regression. We assessed inter-reader reliability for significant CT imaging features.

Results: For the reader 1, radial growth pattern (OR=0.014), enhancement (OR=0.943), internal low density (OR=21.000), air-bronchogram (OR=0.059), preserved vascular or lobular margin (OR=13.000) and satellite nodule (OR=31.818) were significant in univariate analysis ($p < 0.01$), while only radial growth pattern (OR=0.046) and air-bronchogram (OR=0.055) were significant in multivariate analysis ($p<0.05$). For the reader 2, internal low density (OR=24.700), air-bronchogram (OR=0.067), preserved vascular or lobular margin (OR=12.750) and satellite nodule (OR=21.538) were significant in univariate analysis but only internal low density (OR=14.142), air-bronchogram (OR=0.015) and preserved vascular or lobular margin (OR=21.019) were significant in multivariate analysis. For the reader 3, margin (smooth vs. lobulated; OR=0.123), internal low density (OR=47.5), air-bronchogram (OR=0.053), preserved vascular or lobular margin (OR=8.250) and satellite nodule (OR=31.818) were significant in univariate analysis, while only internal low density (OR=158.891) and air-bronchogram (OR=0.002) significant in multivariate analysis. Inter-reader reliability was good to almost perfect (weighted kappa=0.648-0.953).

Conclusions: If suspicious lesion is detected at suture margin after sub-lobar resection, the presence of internal low density and preserved vascular or lobular margin on CT may suggest possibility of staple line granuloma. Whereas, if the air-bronchogram or radial growth pattern is accompanied, recurrent tumor should be considered.

Keywords: lung cancer, sub-lobar resection, staple line granuloma

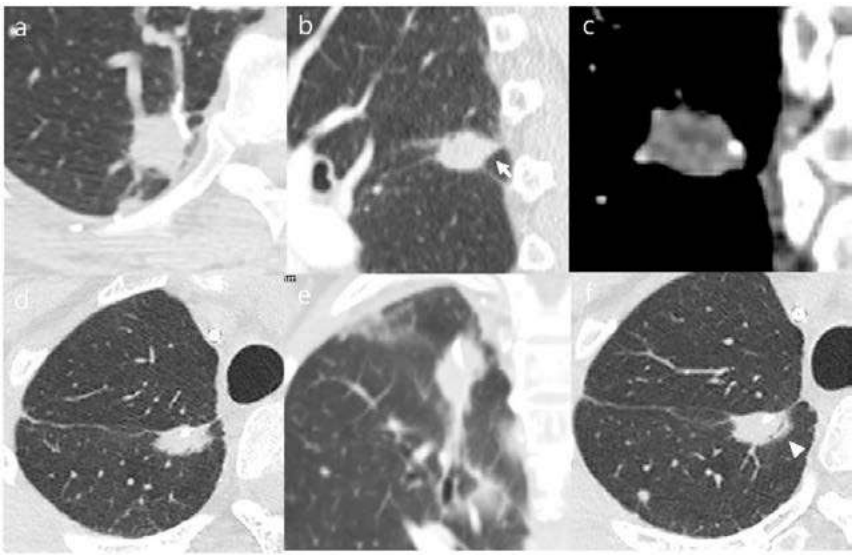

Figure 1. Representative CT image of staple line granuloma (a-c) and tumor recurrence (d-f).

Axial scan (a) with lung window setting shows staple line granuloma with one-side abutting growth pattern at staple line. Sagittal scan (b) shows preserved lobular margin (arrow) and coronal scan (c) shows internal low density of staple line granuloma. Axial (d) and coronal (e) scan with lung window setting shows recurrent tumor with radial growth pattern around the staple line. Same nodule at different slice section, axial scan with lung window setting (f) shows air-bronchogram (arrowhead).

EP.08E.02 Long Term Impact of IASLC Uncertain Resection (Run) Definition in Surgically Resected pN2 Non-Small Cell Lung Cancer

P. Bertoglio[1], V. Aprile[2], F. Lococo[3], F. Antonacci[1], M. Chiappetta[3], D. Nachira[3], J. Brandolini[1], A. Lenzini[2], M. Lucchi[2], S. Margaritora[3], P. Solli[1], [1]IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna/IT,[2]Pisa University Hospital, Pisa/IT,[3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome/IT

Introduction: In 2019 IASLC better defined surgical radicality for Non-Small Cell Lung Cancer (NSCLC) introducing the concept of uncertain resection (Run) in addition to R0, R1 and R2. Briefly, in case of pathological N2 patients, the presence of metastasis in the highest lymph-node resected and/or a lymphadenectomy below guidelines' standards should be defined as Run.The aim of this study is to analyze the long-term impact of Run in a cohort of surgically treated pN2 NSCLC.

Methods: We prospectively collected all consecutive surgically resected pathological N2 patients from three high-volume institutions between 2016 and 2021. All preoperative, intraoperative and long-term postoperative data were collected and analyzed. Patients with incomplete follow-up information were excluded.

Results: Among 155 patients, mean age was 67.2 years (range 38-90) and 61 (39.4%) were female. Neoadjuvant was administered to 35 patients (22.6%) and 116 (74.8%) received a lobectomy. A pathological single N2 station involvement was identified in 98 patients (63.2%) and 97 patients (62.6%) had a concomitant N1 involvement. R0 resection was seen 83 patients (53.5%) and the remaining 72 (46.5%) were classified as Run. Adjuvant therapy was administered to 99 patients. At follow up, recurrence occurred in 94 cases (60.6%) and 45 were loco-regional. Patients with a single N2 station involvement had a better overall survival (OS) compared to multiple stations, but it was not significant (p=0.163). Patients with R0 resection had a significant better OS compared to Run patients (p<0.001, figure 1) and a better disease-free survival (DFS, p<0.001). Run patients had a significant higher recurrence rate (p=0.002), but no difference in recurrence site (loco-regional or distant) was found between R0 and Run (p=0.544). Run patients exhibited a worse OS and DFS also in the subgroup of patients who received adjuvant therapy (p=0.010 and p=0.016 respectively). At multivariable analysis age (p=0.029, HR 1.036 95% CI 1.004-1.007), no adjuvant therapy (p=0.038, HR 1.902 95% CI 1.037-3.486) and Run (p=0.024, HR 1.910 95% CI 1.088-3.351) were independent prognostic factors for a worse OS.

Conclusions: In our cohort of resected pN2 NSCLC, patients with older age and no adjuvant therapy had worse long-term outcomes. Moreover, uncertain resection was significantly related to worse OS and DFS compared to R0 patients; this significant difference was confirmed in the subgroup of patients who received adjuvant therapy. Our data suggest that Run population might require a more careful and tailored postoperative management given their higher risk of recurrence and mortality.

EP.08E.03 Clinical Characteristics and Outcomes in Resectable Stage III ALK-Positive Non-Small Cell Lung Cancer: A Multicenter Real-World Cohort Study

F. Tan[1], Y. Jiang[2], J. Duan[3,4], N. Bi[2], J. He[1], [1]Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN,[2]Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/CN,[3]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing/CN,[4]Department of Respiratory Medicine,Shanxi Province Cancer Hospital/ Shanxi Hospital Affiliated to Cancer Hospital, Chinese Academy of Medical Sciences/Cancer Hospital Affiliated to Shanxi Medical University, Taiyuan/CN

Introduction: Resectable stage III non-small cell lung cancer (NSCLC) needs multimodal therapy, particularly for patients harboring driver gene mutations. Nonetheless, data concerning resectable stage III ALK-positive NSCLC are limited.

Methods: This study was a multicenter real-world cohort study to examine clinical characteristics and outcomes among patients with resectable stage III ALK-positive NSCLC. Cox proportional hazards analysis was utilized to assess the impact of risk factors on clinical outcomes.

Results: Out of the 133 enrolled patients, the median age were 52.6 (19-75), 80 (59.7%) were female, and 98 (73.7%) were never-smokers. After a follow-up with 53.13 months, the 5-year overall survival (OS), 5-year progression-free survival (PFS), median OS, and median PFS were 74.8%, 14.6%, not reached, and 20.8 months, respectively. 94 (70.1%) patients relapsed, and 74 (55.2%) patients had distant metastasis, including 26 (19.4%) with brain metastasis, 16 (11.9%) with bone metastasis, and 15 (19.4%) with lung metastasis. Salvage ALK TIKs after disease progression significantly improved the OS (5-year OS, 72.5% vs. 95.4%, P = 0.015). 15 patients were treated with surgery and upfront ALK TKIs. Upfront ALK TKIs significantly prolonged median PFS (mPFS, NA vs. 17.8 months, P < 0.0001), while OS data were immature (5-year OS, 100.0% vs. 73.1%, P = 0.015). Histological type emerged as an independent prognostic factor for poorer OS (univariate Cox regression analysis: HR = 3.36, P = 0.049; multivariate Cox regression analysis: HR = 3.47, P = 0.049).

Conclusions: Patients with resectable stage III ALK-positive NSCLC are at high risk for relapse, with distant metastasis being the predominant pattern of failure. Salvage ALK TKIs can confer relatively prolonged survival for these patients. Combining surgery with upfront ALK TKIs represents a promising therapeutic strategy.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.08E.04 Not all pN1 Are the Same: Stations 12-14 Involvement, an Independent Prognostic Factor of Better Survival

S. Ricciardi, S. Treggiari, S. Mantovani, M.O. Jaus, G. Cardillo, San Camillo Forlanini Hospital, Rome/IT

Introduction: The nodal status is still considered one of the most important prognosticators as well as crucial to establish the optimal treatment strategy for resectable NSCLC. The latest IX edition of lung TNM include only one change in N2 descriptors, but several changing proposals are under evaluation along with the role of different metastatic N1 stations (Hilar/Interlobar 10/11, Peripheral 12-14). The aim of our study was to analyse the impact of different lymph node location on overall survival (OS) and Disease-Free Survival (DFS).

Methods: A retrospective analysis of 104 patients (68% male, mean age 67 years) who underwent an anatomical resection (segmentectomy or lobectomy) and a systematic lymph node dissection for T1/T3 single station N1-N2 NSCLC (VIII TNM edition) adenocarcinoma or squamous cell carcinoma between 2013 and 2023 in a single centre, was conducted. Patients with >2 metastatic lymph nodes, who underwent induction therapies or extended/incomplete resections were excluded. All patients were divided into three groups: pN1(12-14), pN1(10-11) and pN2a1("skip N2", N2 positive node without N1 involvement). OS, DFS and risk factors of pN1(12-14), pN1(10-11) and pN2a1 were analysed

Results: An overall mean number of 11 (±5.8) lymph nodes were resected: 5.1 (±3.1) from the hilum and 6,2 (±4,1) from the mediastinum. The median lymph node ratio was 0,16. After grouping all cases according to N+ location we observed: 23 pN1(12-14) (22%), 35 pN1(10-11) (34%) and 46 pN2a1(44%). With a median follow up of 40 months, the median OS and DFS were 36 and 28 months respectively. pN1(12-14) had a significant better OS (p=0,005) and DFS (p=0,016) when compared with the other two groups. 5-year OS and 5-year DFS for pN1(12-14), pN1(10-11), pN2a1 were 91%, 31%, 41% and 85%, 25%, 40% respectively. At univariate analysis pN1(12-14) was confirmed a good prognosticator for both OS (p=0,019) and DFS (p=0,012).

Conclusions: Our data underlined the importance of peripheral N1 lymph node. Patients with metastasis in station 12-14 lymph nodes have a significant better prognosis compared both to other pN1 and pN2a1 groups

EP.08E.05 The Presence of NSCLC Results in Diminished Ventilation in the Affected Lung

K. Yu[1,2], [1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN,[2]National Clinical Research Center for Respiratory Disease, Guangzhou/CN

Introduction: Pulmonary tumors have long been associated with hypoxic environments, yet the reciprocal relationship between tumors and local ventilation remains underexplored. Ventilation-perfusion scintigraphy (VPS) has emerged as a valuable tool for assessing pulmonary function and regional ventilation-perfusion status. This study aims to utilize VPS to investigate the impact of tumors on surrounding ventilation and understand how the oxygen environment influences tumor survival.

Methods: 365 patients diagnosed with non-small cell lung cancer with a single lesion were enrolled. Lesion characteristics (including size, location, specific pathological subtypes), VPS results, and survival data were collected. Statistical analyses including chi-square, t-tests, and Kaplan-Meier survival analysis were employed to assess the influence of tumor location on pulmonary ventilation and overall survival rate.
