Results: Tumor presence significantly impacted ventilation in the corresponding lung ($\chi 2 = 17.74$, $p < 0.001$). Patients with right lung tumors exhibited a 3.82% decrease in right lung ventilation compared to those with left lung tumors (ventilation percentage with right-sided occupancy: 52.74% ± 13.11%, without occupancy: 56.82% ± 12.47%, $p < 0.05$), Similarly, patients with left lung occupancy showed a 4.08% decrease in left lung ventilation percentage compared to those with right lung occupancy (ventilation percentage with left-sided occupancy: 43.19% ± 12.47%, without occupancy: 47.26% ± 13.11%, $p < 0.05$). This trend persisted across adenocarcinoma and squamous cell carcinoma patients (adenocarcinoma: $\chi 2 = 4.81$, $p < 0.05$; squamous cell carcinoma: $\chi 2 = 16.30$, $p < 0.05$). Among 216 patients with survival data, Kaplan-Meier curves revealed that lung ventilation volume and tumor location were not independent predictors of overall survival (lung ventilation volume group HR: 0.910; 95% CI: 0.485-1.706; P = 0.087, tumor location group HR: 1.394; 95% CI: 0.778-2.500; P = 0.262). However, when tumor occupancy was present, patients with greater ventilation on the same side as the tumor exhibited a significantly higher five-year survival rate compared to those with greater ventilation on the opposite side (HR: 0.416; 95% CI: 0.198-0.874; P < 0.05).

Conclusions: This study demonstrates that tumors induce a reduction in ventilation in the corresponding lung, regardless of tumor type. This suggests that local pulmonary ventilation alterations are not solely due to the obstructive effect of tumors themselves. Furthermore, ventilation status surrounding the tumor may impact prognosis, as patients with poorer ventilation on the tumor side have a worse prognosis compared to those without significant ventilation decrease.

EP.08E.06 The Peripheral Bronchial Occlusion or Stenosis after Dumon Y-stenting is Prognostic Factor in Patients with Advanced Lung Cancer

T. Higashiyama, S. Mizuguchi, R. Nakajima, K. Chung, A. Ueno, S. Yamamoto, Osaka City General Hospital, Osaka/JP

Introduction: Dumon Y-stenting for tracheal bifurcation stenosis due to primary advanced lung cancer is useful procedure in relieving patient symptoms and leading to post-stenting chemotherapy and/or radiation therapy. However, we often encounter patients with airway stenosis ranging from the trachea to the orifice of the lobar bronchi or bronchus intermedius, which cannot be wholly covered with a simple Y-stent. We have often customized Y-stent with a small window for right upper bronchus or an additional metallic stent in bronchus intermedius to maintain peripheral bronchus patency. Despite of these efforts, insufficient patency of peripheral bronchus including stenosis or occlusion, lead to obstructive pneumonia, might be affect subsequent therapy for lung cancer. The purpose of this study was to evaluate the poor prognostic factors after Y stenting for bifurcation stenosis in patients with advanced lung cancer.

Methods: From 2012 to 2022, 116 patients who had placed Dumon Y-stent via rigid bronchoscopy under general anesthesia for tracheobronchial stenosis due to primary advanced lung cancer were examined retrospectively. This study involved 82 male and 34 female. The mean age was 67 years (range,30-91). The observation period was 229 days(range,4-1947). A two-week mortality after stenting were observed in 8 patients. In histological type, squamous cell carcinoma in 61, adenocarcinoma in 23, small cell carcinoma in 12, and others in 20 patients. The pre-stenting and post-stenting therapy for lung cancer was performed in 53(46%) and 71(61%) patients, respectively. Simple Y-stent was implanted in 78, Y-stent with small window for right upper bronchus in 9, and Y-stent with metallic stent in 29 patients. To identify prognostic factors, univariate and multivariate analysis were conducted.

Results: The respiratory symptom improved in all patients. The ratio of patients with PS3-4 (ECOG) improved to 17% (n=20/116) after stenting compared to 59% (n=68/116) before stenting. There were 53 patients (46%) of insufficient peripheral bronchial patency after stenting. Univariate analysis showed significantly worse prognosis in post-stenting PS3-4 compared to PS0-2(median survival time:1.8 vs. 4.7months), males (2.6 vs. 7.2), administration of pre-stenting therapy for lung cancer (3.0 vs. 7.0), no post-stenting therapy (1.6 vs. 7.6) and insufficient peripheral bronchial patency (2.3 vs. 7.3), respectively. There were no significant differences in histological type, type and size of Y-stent, and number of stents implanted. Multivariate analysis revealed post-stenting therapy (HR 4.7;2.6-7.7, p<0.001) and insufficient peripheral bronchial patency (HR 1.6;1.0-2.6, p=0.032) were independent prognostic factors. The insufficient peripheral bronchial patency was also significantly correlated with post-stenting chemotherapy and/or radiation therapy for advanced lung cancer.

Conclusions: The insufficient peripheral bronchial patency, such as stenosis or occlusion after Y-stenting was independent prognostic factor affecting the subsequent therapy for advanced lung cancer.

EP.08E.07 Optimal Surveillance Interval and Prediction Models of Short-term Mortality Risk for Elderly Patients (≥70) after Lung Cancer Surgery

X. Li[1], N. Wu[1], D. Chen[1], S. Yan[1], J. Zhang[2], H. Wang[3], Z. Zhonghu He[1], X. Cui[1], Y. Tao[1], W. Yang[1], [1]Peking University Cancer Hospital, Beijing/CN,[2]University of Pittsburgh Medical Center, Pittsburgh/PA/USA,[3]Shanghai Changzheng Hospital, The Second Military Medical University, Shanghai/CN

Introduction: Lung cancer surgery is now commonly adopted on septuagenarians and octogenarians. Due to increased vulnerability to surgery, geriatric patients have higher incidence of postoperative morbidity and mortality than younger counterparts. Thus, optimal surveillance interval and prediction models for mortality after surgery are needed to support decision-making and risk evaluation.

Methods: Clinical data of 989 patients (≥70 years) from Peking University Cancer Hospital (PKUCH) were collected for prediction model development and 16,321 patients were queried from National Cancer Database (NCDB) for external validation. Mortality rates were calculated for legitimate measure of optimal surveillance interval for elderly patients. Logistic regression was used to determine the structure of the prediction models and prediction performances were assessed by discrimination, calibration, and clinical utility. Meanwhile, area under the curve (AUC) of receiver operating characteristic curves and decision curve analysis (DCA) were performed for the assessment.

Results: Short-term mortality showed similar increasing trend from 30 days to 180 days after surgery in PKUCH cohort and NCDB cohort (0.40% and 1.00% within 30 days; 1.03% and 1.32 % within 31-90 days; 2.83% and 1.75% within 91-180 days; For cumulative mortality rates, 1.72% and 2.03% within 90 days, 3.44% and 4.19% within 180 days, respectively). Prediction models for 90-day and 180-day mortality consisted 4 similar predictors (age, gender, tumor diameter and surgery approach, AUC=0.80 and 0.79 in internal validation; AUC=0.71 and 0.69 in external validation). DCA proved the prediction models brought more benefit to elderly patients in clinical practice.

Conclusions: Besides of traditional 30- and 90-days mortality, 180- days mortality was suggested to complement surgical quality surveillance for elderly patients. Optimal performance of prediction models for 90- and 180-day mortality in different ethic cohorts suggest a potentially value of universal application for surgical decision-making in elderly patients. An easy-to-use online prediction model tools can be used at https://ai.dev.linkdoc.com/internal/xueke/lixiang/v2.

EP.08E.08 Local Advanced Lung Cancer: Artificial Intelligence, Complex System Analysis, Simulation of Alive Supersysems for Optimal Management

O. Kshivets, Bagrationovsk Hospital, Bagrationovsk/RU

Introduction: The survival of patients with local advanced of lung cancer (LC) takes several months. Radical operations are extremely complex and remain the prerogative of several top thoracic surgeons of the world. The search of optimal treatment plan for LC patients (LCP) with stage T3-4N0-2M0 was realized. We examined factors in terms of precise prediction of 5-year survival (5YS) of local advanced LCP after complete (R0) combined lobectomies/pneumonectomies (LP).

Methods: We analyzed data of 198 consecutive LCP (age=58.1±8.2 years; tumor size=6.8±2.6 cm) radically operated and monitored in 1985-2024 (m=173, f=25; bi/lobectomies=84, pneumonectomies=114, mediastinal lymph node dissections=198; combined LP with resection of trachea, carina, atrium, aorta, VCS, vena azygos, pericardium, liver, diaphragm, ribs, esophagus=198; only surgery-S=117, adjuvant chemoimmunoradiotherapy-AT=81: CAV/gemzar + cisplatin + thymalin/taktivin + radiotherapy 45-50Gy; T3=137, T4=61; N0=94, N1=44, N2=60, M0=198; G1=42, G2=53, G3=103; squamous=118, adenocarcinoma=65, large cell=15, central=115, peripheral=83. Multivariate Cox modeling, clustering, SEPATH, Monte Carlo, synergetics, bootstrap and neural networks computing were used to determine any significant dependence.

Results: Overall life span (LS) was 1671.7±1721.6 days and cumulative 5YS reached 62.4%, 10 years - 50.4%, 20 years - 44.6%. 94 LCP lived more than 5 years without cancer (LS=2958.6±1723.6 days), 22 - more than 10 years (LS=5571±1841.8 days). 67 LCP died because of LC (LS=471.9±344 days). AT significantly improved 5YS (68% vs. 53.7%) (P=0.028 by log-rank test). Cox modeling displayed that 5YS of LCP significantly depended on: N0-N12, T3-4, blood cell circuit, cell ratio factors (ratio between cancer cells-CC and blood cells subpopulations), LC cell dynamics, recalcification time, heparin tolerance, prothrombin index, protein, AT, procedure type (P=0.000-0.031). Neural networks, genetic algorithm selection and bootstrap simulation revealed relationships between 5YS and N0-12 (rank=1), thrombocytes/CC (rank=2), segmented neutrophils/CC (3), eosinophils/CC (4), erythrocytes/CC (5), healthy cells/CC (6), lymphocytes/CC (7), stick neutrophils/CC (8), leucocytes/CC (9), monocytes/CC (10). Correct prediction of 5YS was 100% by neural networks computing (error=0.000; area under ROC curve=1.0).

Conclusions: 5YS of local advanced non-small cell LCP after combined radical procedures significantly depended on: tumor characteristics, LC cell dynamics, blood cell circuit, cell ratio factors, biochemical factors, hemostasis system, anthropometric data, adjuvant treatment and procedure type. Optimal strategies for local advanced LCP are: 1) availability of very experienced thoracic surgeons because of complexity radical procedures; 2) aggressive en block surgery and adequate lymph node dissection for completeness; 3) precise prediction; 4) AT for LCP with unfavorable prognosis.

EP.08E.09 Safety and Feasibility of Uniportal Robotic Lung Resection

S. Lin[1,2], K. Ma[2], Z. Yu[2], Y. Xu[2], H. Xiao[2], J. Feng[2], L. Fan[2], [1]National Cancer Center, Shenzhen city/CN,[2]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital and Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, Shenzhen City/CN

Introduction: Multi-port robotic-assisted thoracic surgery (RATS) has been comprehensively evaluated for its clinical efficacy through numerous studies. The safety and feasibility of uniportal robotic-assisted thoracoscopic surgery (U-RATS) remain further validated. We have summarized our experience in performing U-RATS via the da Vinci Xi system over the past 4 months.

Methods: Clinical data of 15 non-small cell lung cancer patients who underwent U-RATS at our hospital between November 2023 and February 2024 were reviewed retrospectively. U-RATS was conducted using the da Vinci Surgical Xi system. A utility incision of 4 to 5 cm in the mid-posterior axillary line is made between the 5th intercostal space (Figure 1A-C). Three robotic arms (1, 2, and 3 arms (for left lung resection) or 2, 3, and 4 arms (for right lung resection)) are usually selected during the procedure (Fig. 1D-G).

Results: U-RATS was undertaken in 15 patients (7 males, 46.66%, and 8 females 53.33%), and the median age was 60 years (interquartile range (IQR), 40-69 years). The median BMI of all the patients was 21.7 kg/m2 (IQR, 18.69-26.70 kg/m2). The median forced expiratory volume in 1 second (FEV1) of 90.59% (IQR, 70.95-122.05%) of predicted and median forced vital capacity (FVC) of 93.86% (IQR, 70.70-134.05%) of predicted. Lobectomy was conducted in all patients, including right upper (4/15, 26.66%), right middle (3/15, 20.00%), right lower (3/15, 20.00%), left upper (3/15, 20.00%), and left lower (2/15, 13.33%). The median U-RATS procedural duration was 151 min (IQR, 93-270 min, 162.33 ± 47.26 min), and the median intraoperative blood loss volume was 20 mL (IQR, 15-100 mL, 30.33 ± 22.08 mL) respectively. None of them were converted to thoracotomy and reoperation. The median time interval for chest tube placement and postoperative hospital stay was 4 days (IQR, 3-7 days) and 6 days (IQR, 3-14 days). Postoperative complications included pneumonia (2/15, 13.33%) and atrial fibrillation (1/15, 6.67%) graded as Clavien-Dindo I-II, while none of the patients experienced grade III-IV complications. Based on the TNM staging system, one(6.67%), ten (66.67%), two (13.33%), and two (13.33%) patients were evaluated as pathological stage 0, I, II, and III, respectively. The median number of lymph nodes dissected was 22 (IQR, 10-38), and the median station number dissected was six (IQR, 5-6). No wound infection and postoperative 30-day mortality.

Conclusions: The safety and feasibility of uniportal RATS procedures using the da Vinci Surgical Xi system have been preliminarily validated

Cotarla[11], D. Simmons[12], K. Hsieh[5,11], R.M. Samstein[5], P. Wang[7], R. Veluswamy[1,3,8], [1]Center for Thoracic Oncology, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[2]Department of Radiation Medicine, Westchester Medical Center, Valhalla/NY/USA,[3]Division of Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[4]Division of Pulmonary Medicine, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[5]Department of Radiation Oncology, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[6]Department of Radiology, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[7]Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[8]Institute for Translational Epidemiology, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[9]Department of Thoracic Surgery, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[10]Division of General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York/NY/USA,[11]AstraZeneca, US Medical Affairs, Gaithersburg/MD/USA,[12]AstraZeneca, Oncology Outcomes Research, Gaithersburg/MD/USA

Introduction: Radiation pneumonitis (RP) poses a significant challenge in the management of patients with locally advanced NSCLC undergoing chemoradiation therapy (CRT). In addition to respiratory toxicity, RP complicates decisions related to consolidation immunotherapy. We investigated the role of baseline pulmonary function tests (PFTs) in predicting RP risk by using a novel radiographic score in addition to clinical symptoms.

Methods: Unresectable stage II-III NSCLC patients who underwent CRT (50-70 Gy) without immunotherapy consolidation between 2010 to 2021 at a tertiary hospital in New York were identified. All patients had PFTs within 1 year prior to start of treatment, which included forced vital capacity (FVC), forced expiratory volume in 1 second (FEV1), diffusing capacity (DLCO), total lung capacity (TLC), residual volume (RV), and RV/TLC. Surveillance computer tomography scans for one year after treatment completion were reviewed by a thoracic radiologist for presence of RP and graded accounting for the density (score: 0-2) and extent (score: 0-4) of opacities in each of the five lung lobes (total score: 0-40). RP was defined as radiographic score of ≥ 6 and/or by clinical documentation.

Results: Among 81 eligible patients, the mean age was 68 years old; 46% were white, 58% had stage 3A disease, and 78% and 16% were former and current smokers, respectively. The mean FVC was 83.7±20.8%, mean FEV1 was 72.9±21.1%, mean DLCO was 58.5±16.7%, mean TLC was 5.12±1.08 L, mean RV was 2.21±0.72L, and mean RV/TLC was 43.3±9.3%. We found no correlation between the radiation dose (i.e., v20) and any PFT parameter. 44.4% (n=36) had RP defined as above. Significant differences were observed in the mean DLCO (63.8±17.5% vs. 53.7±14.6%, p=.015) and RV/TLC (40.9±7.4% vs. 45.6±10.3%, p=.035) in patients who developed RP vs. no RP. Baseline DLCO showed a significant positive correlation (r:0.31, p=.015) while RV/TLC demonstrated a significant negative correlation (r:-0.25, p=.035; Table1) with RP. No other PFT parameters were significantly different or correlated between subjects with RP vs. no RP.

Conclusions: Our study demonstrates that increased functional lung volume (i.e., higher DLCO) and lower dead space volume (i.e., decreased RV/TLC) prior to CRT is associated with higher RP risk. These findings may explain prior studies demonstrating smoking as a protective factor for RP, given tobacco users generally have lower DLCO and higher RV/TLC. With the potential of RP impacting consolidation immunotherapy in locally advanced NSCLC patients, prospective evaluation of PFTs to predict RP should be undertaken to prompt closer monitoring.

EP.08F.02 Pifenidone Prophylactic Therapy for Radiation Lung Injury in Patients Who Have Previously Received Immune Checkpoint Inhibitors

G. Han, J. Bi, Y. Li, G. Pi, H. Pi, Y. Li, Hubei Cancer Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN

Introduction: Our previous study found that the incidence of grade ≥2 radiation pneumonitis (RP) was 40% when lung cancer patients previously treated with immune checkpoint inhibitors (ICIs) underwent thoracic radiotherapy (TR). Therefore, we conducted an open-label, single-arm, two-stage, phase II clinical trial to evaluate the efficacy and safety of pirfenidone capsules (TGF-β inhibitor) in preventing RP in lung cancer patients who had previously received ICIs and were given pirfenidone in combination with TR treatment to provide a theoretical basis for future clinical practice.

Methods: lung cancer patients previously treated with ICIs undergoing TR and radiotherapy dose BED(β/ β =10) ≥50.0Gy. The study used a two-stage gen2stage design in R language. Based on the real-world occurrence of grade ≥2 RP of 40% with TR after treatment with ICIs, whereas this trial aimed to reduce the rate of grade ≥2 RP to 25%, β =0.1, β =0.25, the two-stage design was (6/14, 13/41). That is, 14 patients were enrolled in the first phase, and the study was stopped if the number of patients with grade ≥2 RP was ≥6; otherwise, the study entered the second phase, in which an additional 27 patients were enrolled, for a total of 41 patients. If ≥13 patients ultimately developed grade ≥2 RP, the study was considered a failure; otherwise, the study was considered a success. Pirfenidone were started on the first day of TR and dosed as follows 200 mg/dose in week 1, 300 mg/dose in week 2, and 400 mg/dose in weeks 3-12, all 3 times/day. RP grades were categorized by assessing patients in conjunction with their medical history and CT images of the lungs, and defined according to the Common Terminology Criteria for Adverse Events (CTCAE) 5.0.

Results: From 20 March 2023 to 13 October 2023, 14 lung cancer patients were enrolled, including 9 patients with non-small cell lung cancer (NSCLC) and 5 patients with small cell lung cancer (SCLC). The median age was 60 years (range: 42-73), 85.7% were male and 78.6% were receiving PD-1 inhibitors. The median number of previous ICIs cycles was 5 (range: 2-20). The median time between last ICI and start of TR was 27 days (range: 23-184). The median BED(β/ β =10) =60.0Gy (range: 50.3-64.7), the median fractional dose was 2.1Gy (range: 2-2.8), the median PTV=213.7cm3 (range: 120.1-673.7) and the median V20, V5 and Dean were 18.4% (range: 8.3-26.5), 37.0% (range: 18.7-58.1) and 10.0 58.1) and 10.0Gy (range: 4.8-16.4). The median follow-up was 5.9 months (range: 4.2-11.7). A total of 9 (64.3%) patients experienced any grade of RP, including 3 (21.4%) patients with grade ≥2 RP (two grade 2 PRs and one grade 5 PR). Pirfenidone-related adverse events (≤ grade 2) occurred in 7 patients, including six gastrointestinal reactions and one photosensitivity reaction.

Conclusions: The first phase data from this single-arm, open, phase II clinical study demonstrated that pirfenidone can safely and effectively reduce the incidence of grade ≥2 RP in lung cancer patients previously treated with ICIs undergoing TR and the study should enter the second phase (case expansion stage).

EP.08F.03 Efficacy and Safety of Aumolertinib with Radiotherapy in the Treatment of Unresectable Locally Advanced EGFR-Mutant NSCLC: A Phase II Study

X. Meng, L. Kong, K. Zhao, Shandong Cancer Hospital and Institute Shandong First Medical University, Jinan/CN

Introduction: Approximately 30% of patients have advanced to stage III in non-small cell lung cancer (NSCLC) at initial diagnosis. For the patients with stage III unresectable locally advanced NSCLC, the standard treatment is platinum-based concurrent chemoratherapy (cCRT) according to multi-disciplinary team (MDT). However, there are still about 80% patient recurrence within 1-2 year. The PACIFIC study demonstrated the consolidation therapy efficacy and safety of durvalumab after cCRT, but it seems like ineffective for the patients with epidermal growth factor receptor (EGFR) mutation. The POLESTAR and LAURA registered clinical study aim to investigate consolidation therapy efficacy and safety of third generation EGFR tyrosine kinase inhibitors (aumolertinib and Osimertinib) after cCRT. However, some patients cannot tolerate chemotherapy or refuse chemotherapy due to adverse events. A multicenter retrospective REFRACT study demonstrated that combined radiotherapy with tyrosine kinase inhibitor (TKI) are superior than cCRT for stage III NSCLC patients harboring EGFR mutations. Here, we initiate a prospective study named POLESTAR 2 designed to evaluate the efficacy and safety of aumolertinib combined with radiotherapy, which may benefit those unresectable stage III EGFR-mutant NSCLC patients who are intolerant to chemotherapy as a potential chemotherapy-free regimen.

Methods: This is a phase II single-arm clinical trial evaluating the efficacy and safety of aumolertinib combination with radiotherapy in unresectable locally advanced EGFRm NSCLC patients. We plan to accrue 27 patients (One-sample logrank tests, —=0.05, —=0.9, dropout rate 15%) confirmed stage III unresectable EGFRm patients are administrated aumolertinib (110mg, oral once daily), and concurrent radiotherapy (56-66Gy, 1.8-2.0Gy/f) are performed after 8 weeks, follow with aumolertinib after radiotherapy until to disease progression or other criteria for discontinuation. The primary endpoint of efficacy endpoint is PFS (RECIST 1.1) and secondary endpoints are investigators assessed PFS, OS, time to CNS progression, time to distant metastasis (TTDM), objective response rate (ORR), disease control rate (DCR) and during of response (DoR). The safety endpoint: all subjects were observed and recorded for any adverse events that occurred during the clinical trial.

Results: The clinical trial is ongoing.

Conclusions: The clinical trial is ongoing.

Keywords: Locally advanced NSCLC, Aumolertinib, concurrent radiotherapy

EP.08F.04 Development of Learning-Based Predictive Models for Radiation-Induced Atrial Fibrillation in Non-Small Cell Lung Cancer

S.K. Yoo[1], K.H. Kim[1], M. Noh[2], H. Kim[1], H.I. Yoon[1], [1]Yonsei University, Seoul/KR,[2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR

Introduction: Despite advances in radiotherapy, the probability of atrial fibrillation (AF) occurrence still exists. By incorporating patient-specific clinical, dosimetry and diagnostic information, this work developed machine and deep learning-based predictive models for AF following chemoradiotherapy (CRT) for non-small cell lung cancer (NSCLC) with institutional and external datasets. We also investigated patient-specific key influential features associated with cardiac toxicity.

Methods: Institutional and external patient cohorts consisted of 321 and 187 NSCLC datasets who received definitive CRT, including 17 and 6 AF incidences, respectively. The network input features had 159 patient-specific information that incorporated clinical, dosimetry (dose-volume histogram), and diagnostic (coronary artery calcium (CAC) scores) information. The imbalance between AF and non-AF incidences was mitigated by synthetic minority oversampling technique (SMOTE). To handle various types of input features, machine learning-based model adopted an intervention technique in feature selection process that chose a representing feature with the largest weight at each sub-group. Deep learning-based model employed a hybrid architecture that assigned different types of networks to corresponding input paths. The performance of the developed networks was assessed by area under the curve (AUC). The key features were investigated by network coefficients at classifier and an open-source workflow (Captum) for the machine and deep learning-based models.

Results: In the internal validation, the hybrid deep learning model yielded AUC of 0.823, outperforming the machine learning-based algorithm with intervention (AUC of 0.801). The hybrid deep learning-based model produced more consistent performance (AUC of 0.806) than the machine learning model (AUC of 0.776) in the external validation. Importantly, maximum dose to heart and sinoatrial node (SAN) were found to be the key features for both external and internal validations.

Conclusions: The learning-based predictive models showed consistent prediction performance across internal and external cohorts, identifying maximum heart and SAN dose as key features for the incidence of AF.

EP.08F.05 Real World Evidence of Long-Term Safety and Effectiveness of Durvalumab in Unresectable Stage III NSCLC in Japan: AYAME Study

N. Yamamoto[1], H. Kenmotsu[2], Y. Saito[3], K. Ninomiya[4], B. Akdemir[5], S. Uematsu[5], A. Fukui[5], R. Koto[5], M. Fujiwara[5], C. Iwao[5], H. Kitagawa[5], I. Yoshino[6], A. Gemma[3], T. Mitsudomi[7], [1]Wakayama Medical University, Wakayama/JP,[2]Shizuoka Cancer Center, Nagaizumi-cho/JP,[3]Nippon Medical School, Tokyo/JP,[4]Okayama University, Okayama/JP,[5]AstraZeneca K.K., Osaka/JP,[6]International University of Health and Welfare Narita Hospital, Narita/JP,[7]Kindai University, Oska-Sayama/JP

Introduction: Durvalumab is a standard of care as consolidation therapy after concurrent chemoradiation for unresectable stage III non-small cell lung cancer (NSCLC) in Japan. However, the data in the Japanese subgroup of the phase III study (PACIFIC study) are limited. This study aims to assess the long-term safety and effectiveness of durvalumab, including the post-treatment period after completion or discontinuation of durvalumab treatment, in a real-world setting in Japan.

Methods: This is a non-interventional, prospective study. Data are collected for up to 3 years from the start of durvalumab treatment. The primary endpoints are the incidence proportion of interstitial lung disease (ILD) and adverse events of special interest (AESIs, not presented in this report) within 3 years of starting durvalumab; progression-free survival (PFS); and PFS rates at 12 months, 18 months, and 24 months. The secondary endpoints include ILD in patient subset population; overall survival (OS); and OS rates at 24 months and 36 months.

Results: A total of 529 patients were enrolled at 52 sites between July 2019 and December 2020. At the third interim analysis (data cut-off in July 2023), of the 512 patients who received durvalumab treatment after chemoradiotherapy (CRT), 511 were included in the safety analysis population and 495 were included in the effectiveness analysis population. In the safety analysis population, the proportion of patients who completed durvalumab treatment was 41.1%. The incidence of any grade ILD was 74.8% (382/511 patients) in the safety analysis population, and that of grade 1, 2, 3, 4, and 5 ILD was 36.2%, 29.0%, 8.8%, 0%, and 0.8%, respectively. The median number of days to the first onset was 44 days after the first dose of durvalumab. Among 382 patients with ILD, 31.7% (121) discontinued durvalumab treatment, 29.1% (111) experienced durvalumab interruption. Of those, 89.2% (99/111) subsequently resumed the treatment. In addition, 43.7% (167/382) of the patients with ILD received steroid therapy. Of those, 68.3% (114/167) of the patients had the ILD grade 2 and 24.6% (41/167) of the patients had the ILD grade 3. The median PFS in the effectiveness analysis population was 23.5 months (95% confidence interval, 18.2 to 27.2) and the PFS rates at 12 months, 18 months, and 24-month were 62.5%, 54.6%, and 49.6%, respectively. The OS rates at 24-month and 36-month were 75.4% and 64.4%. The final analysis (data cut-off in March 2024), including multivariate analysis of the incidence of ILD, with longer follow-up is to be reported at the World Conference on Lung Cancer 2024.

Conclusions: Based on the interim analysis data obtained so far indicate that real-world durvalumab treatment outcomes are consistent with the Japanese subset in the PACIFIC study. We expect that our findings from the updated results will enhance comprehension of the long-term safety and effectiveness of durvalumab in clinical practice.

EP.08F.06 Concurrent Chemoradiotherapy Followed by Durvalumab for Elderly Patients

A. Yatani[1], N. Katsurada[1], T. Ishihara[1], N. Miwa[2], M. Katsurada[3], Y. Hatakeyama[4], Y. Kawa[5], S. Hori[6], S. Yoshimura[7], M. Tachihara[1], [1]Kobe University Graduate School of Medicine, Kobe, Hyogo/JP,[2]Nishi-Kobe Medical Center, Kobe, Hyogo/JP,[3]Kitaharima Medical Center, Ono, Hyogo/JP,[4]Akashi Medical Center, Akashi, Hyogo/JP,[5]Hyogo Cancer Center, Akashi, Hyogo/JP,[6]Kakogawa Central City Hospital, Kakogawa, Hyogo/JP,[7]Hyogo Prefectural Harima-Himeji General Medical Center, Himeji, Hyogo/JP

Introduction: Consolidation therapy with durvalumab after concurrent chemoradiotherapy (cCRT) for patients with unresectable locally advanced non-small cell lung cancer (LA-NSCLC) has become the standard of care. The PACIFIC-R study has also shown the effectiveness and tolerability of the consolidation therapy in the real world, but there are insufficient data for elderly patients aged above 75 years, especially above 80 years. There are also limited data on the incidence of pneumonitis by age. Here, we conducted a multicenter retrospective study to evaluate the effectiveness and tolerability on elderly patients.

Methods: We evaluated progression free survival (PFS) as the primary endpoint in patients initiated on cCRT for unresectable LA-NSCLC from July, 2018 to March, 2023, and compared among three groups: aged 70 to 74 years, 75 to 79 years, and above 80 years. We also evaluated cCRT completion rate, overall survival (OS), and PFS in carboplatin plus paclitaxel regimen (CP)as the secondary efficacy endpoints, and the rate of initiation and compression of durvalumab, and incidence of pneumonitis as the safety endpoints among the three groups.

Results: 167 patients were included from 6 institutions in Japan. The number of patients was 70 in the group aged 70 to 74 years, 72 in the group aged 75 to 79 years, and 25 in the group aged above 80 years. Patient characteristics in each group was as follows: male 59 (84.3%) / 59 (81.9%) / 19 (76.0%), adenocarcinoma 32 (45.7%) / 36 (50.0%) / 11 (44.0%), and CP regimen in 39 (55.7%) / 61 (84.7%) / 21 (84.0%). The primary endpoint was median PFS of 23.6 / 24.0 / 24.6 months (p-value = 0.97). The secondary efficacy endpoints included cCRT completion rate of 94.3 / 93.1 / 88.0% (p-value = 0.55), median OS of 46.0 / 38.5 / NA months (p-value = 0.30), and median PFS of 24.6 / 26.4 / 17.8 months (p-value = 0.93) in CP regimen. The safety endpoints included: durvalumab initiation rate, 85.7 / 75.0 / 68.0% (p-value = 0.10); durvalumab completion rate, 37.3 / 32.4 / 20.0% (p-value = 0.29); and incidence of pneumonitis during the therapy, 66.7 / 56.6 / 58.8% (p-value = 0.53).

Conclusions: In patients aged above 80 years, consolidation therapy with durvalumab after cCRT is effective, and the completion rate and safety of this therapy are also assured. We will include more patients for further investigation.

EP.08F.07 Induction Immunochemotherapy Before Definitive Chemoradiotherapy for Patients with Stage III Non-Small Cell Lung Cancer

S. Zheng[1], C. Sun[1], H. Zhang[2], B. Dong[1], Z. Hou[1], M. Chen[1], Q. Li[1], [1]Department of Radiation Oncology, State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University Cancer Center, Guangzhou/CN,[2]Department of Radiation Oncology-Hubei Cancer Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/CN

Introduction: Immune checkpoint inhibitors (ICIs) have become the standard consolidation therapy for stage III unresectable non-small cell lung cancer (NSCLC). Whether induction immunochemotherapy can further improve efficacy is unclear. In this study, we used real-world data to explore the possibility of induction immunochemotherapy before definitive chemoradiotherapy (CRT).

Methods: Patients with stage III NSCLC (including postoperative recurrence), who received definitive CRT from 2016 to 2022, were retrospective reviewed. Survival outcomes and the incidence of pneumonia were calculated and compared between patients with induction immunochemotherapy or not.

Results: A total of 156 patients undergoing definitive RCT were analyzed. Among them, 103 patients received induction immunochemotherapy followed by definitive CRT (I-CRT group), and 53 patients received sequential chemoradiotherapy or concurrent chemoradiotherapy (CRT group). The 5-year overall survival (OS) rates were 75.0% in the I-CRT group and 44.4% in the CRT group. The median OS was not reached (NR) and 36.5 months respectively, indicating a significant improvement in survival with the addition of induction immunochemotherapy (P=0.03). However, there were no significant differences between the two groups in median progression-free survival (PFS) (22.4 vs. 13.6 months; P=0.09), locoregional recurrence-free survival (LRFS) (38.0 vs. 36.9 months; P=0.73), and distant metastasis-free survival (DMFS) (37.8 vs. 25.5 months; P=0.14). Multivariate analysis showed that induction immunochemotherapy was an independent favorable prognostic factor for OS (HR 2.89; 95% CI, 1.24-6.75; P=0.01). The incidence of grade 2 or higher pneumonia in the two groups was 37.2% and 29.2%, respectively (P=0.35). Additionally, we found that patients with consolidation ICIs after induction immunochemotherapy had a better OS, with a 4-year OS rate of 90.7% versus 65.5% (P=0.03). Patients undergoing 5-6 cycles of induction immunochemotherapy seemed to have a better outcome compared to those with 3-4 cycles or 1-2 cycles (93.8% vs. 77.4% vs. 60.5%).

Conclusions: For patients with stage III NSCLC receiving definitive CRT, the application of induction immunochemotherapy improves OS without a significant increase of pneumonia in real-world practice. This treatment strategy warrants further research.

EP.08F.08 Safety and Efficacy of Durvalumab Consolidation Therapy after Chemoradiotherapy in NSCLC Patients Positive for Antinuclear Antibodies

A. Tsukaguchi, A. Tamiya, S. Fukuda, Y. Iwahashi, K. Kanaoka, Y. Tanaka, Y. Inagaki, Y. Taniguchi, K. Nakao, T. Kagawa, Y. Matsuda, K. Okishio, Nho Kinki Chuo Chest Medical Center, Sakai City/JP

Introduction: Pneumonitis during durvalumab consolidation therapy after concurrent chemoradiotherapy (CRT) is a major cause of treatment discontinuation and potentially fatal. Identifying biomarkers of pneumonitis is a special concern for oncologists. Although previous studies have revealed the association between serum antinuclear antibody (ANA) levels and the safety and efficacy of immune checkpoint inhibitors in advanced non-small cell lung cancer (NSCLC), there are no reports specific to durvalumab consolidation therapy. In this study, we aimed to investigate the safety and efficacy of durvalumab consolidation therapy after CRT in patients positive for ANA.

Methods: We conducted a single-center retrospective cohort study. We reviewed patients with unresectable NSCLC treated with durvalumab consolidation therapy after CRT between August 2018 and July 2022. Serum ANA titers were assessed before durvalumab initiation and a titer of 1:40 served as the cutoff. We evaluated the association of ANA positivity with the development of treatment-related adverse events (AEs) and survival outcomes.

Results: A total of 80 patients were enrolled in this study. The median age of the patients was 71 years, and 64 patients were male. Thirty-nine patients were positive for ANA. There were no significant differences in the development of each AE, including pneumonitis, between patients positive for ANA and patients negative for ANA. The incidence of pneumonitis of grade 3 to 5 tended to be higher in patients positive for ANA than patients negative for ANA (12.8% vs. 2.4%, p = 0.10). The progression-free survival (PFS) and overall survival (OS) of the patients positive for ANA were significantly shorter than those of the patients negative for ANA (median PFS: 14.9 [95% CI, 6.9-39.3] months and not reached (NR) [95% CI, 15.5-NR], respectively; hazard ratio (HR), 2.42; 95% CI, 1.28-4.60) (median OS: NR [95% CI, 15.8-NR] and NR [95% CI, 41.6-NR], respectively; HR, 2.66; 95% CI, 1.19-5.96). Multivariate analysis using the Cox proportional hazard model revealed that the presence of ANA at pretreatment was an independent predictor of both PFS (HR, 2.23; 95% CI, 1.16-4.29; p = 0.016) and OS (HR, 2.28; 95% CI, 1.01- 5.12; p = 0.046).

Conclusions: ANA positivity was a poor prognostic factor in patients receiving durvalumab consolidation therapy after CRT, which may be due to higher frequency of severe pneumonitis. We recommend careful monitoring for pneumonitis during durvalumab consolidation therapy in patients positive for ANA.

Introduction: Accurate tumor measurement is paramount for evaluating treatment response in non-small cell lung cancer (NSCLC). Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 guidelines are routinely employed by radiologists and oncologists to determine total tumor burden and monitor treatment. However, manual RECIST measurements are time-consuming and subject to inter-observer variability. This study presents evaluated a semi-automated segmentation algorithm, aiming for high correlation with experts' manual annotations of pulmonary lesions.

Methods: Retrospective CT scans obtained at a single time point from 557 stage III and IV NSCLC patients were collected from 4 institutions. For each patient, lung lesions were identified and manually segmented by two or more physicians annotating in consensus. A semi-automated interactive segmentation model ClickSeg was previously developed from ground truth annotations of 1,146 patients) using convolutional neural networks combined with morphological operations tailored for lung tumor characteristics. No patients used in ClickSeg training overlapped with the evaluation cohort of this study. From a users' click point within a lesion, the algorithm delineates tumor boundaries and identifies the longest diameters, conforming to RECIST guidelines. In the case of multiple lesions, the two largest lesions were selected as target lesions of the patient, resulting in 753 lesions. For each patient, the RECIST sum of target lesion diameters (SLD) was calculated and compared between manual and semi-automated annotations. Concordance between SLDs was quantified using the Dice coefficient, Pearson correlation, and intraclass correlation coefficient (ICC).

Results: The full ClickSeg system processed the scans with a mean time of 14.59 seconds (range: 5.04-26.15 seconds) per case, more than 60 times faster than the average manual measurement time of 15 minutes 34 seconds. The median Dice coefficient between the manual and automated segmentations was 0.66. The Pearson correlation coefficient was 0.81 (p<1e-10). The algorithm's SLDs agreed strongly with physician's measurements, achieving an ICC of 0.81 (95% CI: 0.78-0.84, p<1e-10).

Conclusions: The presented semi-automated lung tumor segmentation model demonstrates high accuracy and substantial time efficiency in deriving quality tumor segmentation and RECIST diameters for NSCLC. These promising results suggest a valuable tool for enhancing consistency and efficiency in tumor size assessment. Future work will explore its ability to distinguish RECIST labels across longitudinal, on-treatment scans, as well as its utility in clinical practice.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.08F.11 Development of Clinical Prediction Model Using Digital Device for ILD in the Stage III NSCLC Patients Treated with Durvalumab

H. Kenmotsu[1], S. Ikeda[2], Y. Sato[3], C. Iwao[4], M. Ogi[4], T. Hirai[4], R. Koto[4], H. Kitagawa[4], N. Yamamoto[5], [1]Shizuoka Cancer Center, Shizuoka/JP,[2]Kanagawa Cardiovascular and Respiratory Center, Kanagawa/JP,[3]AstraZeneca K.K., Osaka/JP,[4]AstraZeneca K.K., Tokyo/JP,[5]Wakayama Medical University, Wakayama/JP

Introduction: Durvalumab serves an important role as a consolidation therapy after chemoradiation therapy (CRT) in patients with unresectable stage III non-small cell lung cancer (NSCLC), but the early detection of interstitial lung disease (ILD) is one of the urgent challenges to prevent treatment discontinuation due to worsened ILD. We aimed to develop a clinical prediction model for the grade 2 or higher ILD in those NSCLC patients, by means of machine-learning analysis on the continuously collected automatic measurements from the wearable device and mobile application.

Methods: This study was a prospective, non-interventional pilot study. We collected the patients' clinical characteristics and outcomes from electronic medical records, physiological data, such as heart rate, respiratory rate and saturation of percutaneous oxygen, from the wearable device, and the number of coughs from the mobile application. The patients were followed up to 6 months after the first dose of durvalumab, or until the start of post-treatment, death, or withdrawal of consent whichever comes first. The primary objective was development of the clinical prediction model for grade 2 or higher ILD. Secondary and exploratory objectives were development of the clinical prediction models for progression disease (PD) and grade 3 or higher ILD, respectively. Eight machine-learning or statistical prediction models were used for each objective, and each performance was evaluated with area under the receiver operating characteristic curve (ROC-AUC).

Results: A total of 145 patients were enrolled in this study from August 2021 and September 2022; 22 patients dropped out before device data acquisition, and 123 patients were included in the analysis set. The median age was 68.0 years, and the mean wearing time of the wearable device, which was used during sleep, was 7.8 hours per day. Among the 123 patients, 40 were diagnosed with grade 2 ILD, 6 with grade 3 or higher ILD (no deaths), and 16 with PD during the follow-up period. For primary objective, the XGBoost had the highest ROC-AUC among the eight predictive models [0.789 (95%CI: 0.724, 0.854)]. For secondary and exploratory objectives, logistic regression developed the prediction models with the highest ROC-AUC [0.713 (95%CI: 0.560, 0.865)] and [0.813 (95%CI: 0.672, 0.954)], respectively. The ROC-AUC decreased when the wearable device data was excluded, and the ROC-AUC was unchanged when the data of cough-counting was excluded.

Conclusions: Our findings suggest that it is possible to construct a clinical predictive model with an accuracy at clinically meaningful level for grade 2 or higher ILD in patients receiving durvalumab after CRT, using patients background information and physiological data collected from a wearable device as a feature by the machine-learning methods.

EP.08F.12 Toxicity and Outcomes by Radio-Sensitizing Chemotherapy Regimen for Unresectable Stage III NSCLC in British Columbia, Canada

M-F. Damours[1], M-H. Denault[2], J. Feng[1], S. Kuang[1], J. Laskin[1], B. Leung[1], S. Sun[1], B. Melosky[1], M. Liu[1], H. Carolan[1], C. Ho[1], [1]BC Cancer Vancouver, Vancouver/BC/CA,[2]Institut Universitaire de Cardiologie et de Pneumologie de Québec, Québec/QC/CA

Introduction: Definitive chemo-radiotherapy (CRT) followed by durvalumab consolidation is the standard of care for the treatment of unresectable stage III non-small cell lung cancer (NSCLC). Platinum and etoposide (PE) every 3 weeks or weekly carboplatin-paclitaxel (CP) are commonly used radio-sensitizing protocols. The risk of toxicities, including radiation and immunotherapy-related pneumonitis, may differ based on the concurrent chemotherapy regimen. This study aimed to (i) compare toxicities associated with the use of different chemotherapy regimens and (ii) evaluate the impact of pneumonitis on patient outcomes.

Methods: Patients treated with concurrent CRT followed by durvalumab consolidation for unresectable stage III NSCLC at BC Cancer, British Columbia, Canada from January 2018 to December 2020 were identified. A retrospective analysis was performed through chart review and the outcomes database to identify various patient, tumor, and treatment factors. Overall survival (OS) was analyzed by the Kaplan-Meier method.

Results: 202 patients with unresectable stage III NSCLC treated with CRT were identified; 111 patients (55%) had stage IIIA disease. The radiosensitizing chemotherapy agents used were cisplatin-etoposide in 82 (41%), carboplatin-etoposide in 49 (24%) and weekly CP in 71 (35%). The most common reason for selecting a carboplatin-based regimen was patient comorbidities (23.3%). The median radiation dose received was 60 Gy (range 50-66) and 202 patients (100%) received at least one dose of durvalumab. CP was better tolerated with a lower incidence of grade 3-4 adverse events, including hematologic and gastrointestinal toxicities, compared to PE regimens. 47 (23%) pneumonitis events were reported (Table 1). Pneumonitis rates were similar with PE and CP and were predominantly low grade (1-2). Events occurred at a median of 49 days after durvalumab initiation (range 0-285). Despite treatment with steroids in 46 patients/47 (97.9%) who developed pneumonitis, 28 patients/47 (60%) were unable to complete one year of durvalumab consolidation due to pneumonitis. Median OS was 58.4 months (95% CI: 45.4-63.9), 45.7 months (30.0-65.9) and 37.1 months (31.1-56.3), for cisplatin-etoposide, carboplatin-etoposide and CP, respectively (p= 0.157). OS did not differ significantly in patients who developed pneumonitis (p=0.256).

Conclusions: CP is associated with a better tolerability profile and fewer high-grade adverse events when compared to PE regimens in patients with stage III NSCLC undergoing CRT. Pneumonitis occurred in 23% of our cohort and negatively impacted treatment completion but did not appear to negatively impact survival. There was no difference in pneumonitis rates and overall survival by radio-sensitizing regimen.

EP.08F.13 Machine Learning Analysis of Cardiac Sub-Structure Dose and Overall Survival of NSCLC Pts Treated with Concurrent Definitive Chemoradiotherapy

T.J. Dilling[1], A. Allen[2], O. Edrich[1], D. Dudas[3], D.H. Lee[2], D. Money[2], G. Eichelberger[2], A. Kumar[2], J.M. Bryant[1], R.J. Cruz-Chamorro[1], E. Keit[1], V. Feygelman[1], E. Scott[1], S.A. Rosenberg[1], I. El Naqa[1], [1]H Lee Moffitt Cancer Center, Tampa/FL/USA,[2]Morsani College of Medicine, Tampa/FL/USA,[3]Czech Technical University in Prague, Prague/CZ

Introduction: We have previously shown that cardiac substructure (CSS) dosimetric parameters (DP) lose significance in linear Cox Proportional Hazards testing after correcting for pt age, PTV volume, and receipt of durvalumab. Here, we perform a nonlinear machine learning (ML) analysis of the impact on overall survival (OS) of dose to 17 different CSS (4 chambers, 4 valves, aorta, superior vena cava, pulmonary artery, SA/AV nodes, and 4 coronary arteries (LAD, circumflex, left/right coronary).

Hypothesis: In LA-NSCLC pts receiving Concurrent Definitive Chemoradiotherapy (CDCRT), dose to individual cardiac substructures is predictive of overall survival (OS)

Methods: We culled consecutive patients with LA- NSLC treated with CD-CRT between 3/2009 and 01/2021 at a multi-site tertiary cancer center from our prospectively maintained database. Pts were excluded if they received sequential therapy, prior lung resection, or had oligometastatic disease. Pts with prior lung SBRT were allowed if prior maximum heart dose was < 1000 cGy. We used open-source software to auto-segment the CSS. In this analysis, we reviewed the DP of minimum/mean doses, D03cc, and gEUD for each CSS and its impact on OS. In this preliminary analysis, we used three ML survival analysis techniques: 1) elastic-net survival regression (ENSR), 2) gradient boosting survival (GBS), and 3) random survival forest (RSF) modeling.

Results: 418 patients met inclusion criteria. 49 (12%) received durvalumab. 56% were male. 74% received IMRT. Prescriptions ranged from 60-70 Gy, with 68% receiving 70 Gy. Median age was 67. Two pts were stage IB, 33 stage 2A/B, and 383 stages IIIA-C (AJCC 8th ed). Patients were divided into training (80%) and testing (20%) cohorts, stratified by year of treatment, to account for any evolution in treatment technique over time, as well as the receipt of durvalumab. Feature importance varied across the models. Pt age, delivered dose (< 6000 cGy vs > 6000 cGy), and ITV and/or PTV volume played a role in all models. However, the specific CSS and DP's varied across the models. ENR focused entirely on clinical features, except for Valve_Mitral_D03cc. The RSF model incorporated a variety of CSS, as well as age, ITV volume, PTV minimum dose, and dose received. Likewise, GBS utilized ITV volume, PTV minimum dose, age, and PTV volume, in addition to various CSS DP's. However, while D0.03cc of A_Aorta and mean A_Cflx dose were important in two of the three models, no single CSS DP played a sole role in all 3 ML models.

Conclusions: This is the largest ML analysis of CSS of which we are aware. In these simple ML models that do not incorporate cardiotoxicity or pt comorbidity, age and tumor volume predominate in determining OS. In ENR, clinical factors predominate, whereas in the other models, various CSS DP's are of greatest importance, though no single one predominated. Additional modeling, incorporating pt comorbidity, cardiotoxicity, and dosiomics into ensemble models, will be presented at the meeting.

EP.08F.14 Outcomes of Durvalumab Consolidation Treatment in Stage III Unresectable NSCLC: A Retrospective Real-World Study

L. Ljubicic[1], L. Bitar[1], F. Seiwerth[1], A. Bacelic-Gabelica[1], D. Srdic[1], S. Badovinac[1], S. Plestina[1], M. Korsic[1], T. Pavic[2], M. Samarzija[1], M. Jakopovic[1], [1]University Hospital Centre ZAgreb, Zagreb/HR,[2]Univeristy Hospital Centre Zagreb, Zagreb/HR

Introduction: The PACIFIC trial established concurrent chemoradiation followed by 12 months of consolidation durvalumab as the standard of care in locally advanced NSCLC, with real-world studies subsequently confirming these findings, the most extensive being the observational PACIFIC-R.

Methods: This retrospective study included ninety-six patients who received concurrent or sequential conventionally fractionated CRT with consolidation durvalumab for unresectable and locally advanced NSCLC between 2018 and 2022. To assess efficacy, we used progression-free survival and overall survival. We employed the Cox regression model to evaluate differences in OS and PFS, considering several key variables such as age, PD-L1 status, histological type, gender, time to durvalumab initiation, and the type of radiation therapy (concurrent vs. sequential).

Results: At the time of analysis, 62 out of 96 patients were alive. The median time to start durvalumab was 39 days. At the median follow-up of 22 months, median PFS was 35 months, with 1- and 2-year PFS rates of 64% and 55% (Figure 1a). The median overall survival was 52 months, accompanied by 1- and 2-year OS rates of 85% and 62% (Figure 1b). Five-year OS rate was 49.6%. Better survival outcomes were observed among patients with PD-L1≥50%, those receiving concurrent chemoradiotherapy, and patients with immune-related adverse events.

Conclusions: Our study demonstrates that our real-world data not only mirrors the outcomes observed in comparable real-world studies but also surpasses those from the PACIFIC trial regarding the survival advantage of durvalumab consolidation therapy.

EP.08F.15 A Retrospective Study of Tislelizumab Combined with Chemotherapy in Patients with Locally Advanced Lung Cancer

J. Zhang, H. Chen, C. Chen, Fujian Medical University Union Hospital, Fuzhou/CN

Introduction: This study aimed to evaluate the downstaging and surgical rates of patients with locally advanced lung cancer treated with tislelizumab combined with chemotherapy through a retrospective collection of real-world data.

Methods: This study was a single-arm, multicenter, retrospective, real-world study. The study mainly includes patients with locally advanced lung cancer who are expected to be unable to achieve radical resection or whose surgery is more difficult and who received at least 2 cycles of tislelizumab combined with chemotherapy from October 1, 2020 to November 30, 2021. Statistically analyze the patients' baseline characteristics, R0 surgical resection rate, major pathological response rate and adverse events, and observe the efficacy and safety of tislelizumab combined with chemotherapy for downstaging and conversion therapy in patients with locally advanced lung cancer.

Results: A total of 65 patients were enrolled, with a median age of 62.0 (57.0-66.0) years, including 62 (95.4%) males and 3 (4.6%) females. Pathological diagnosis of squamous cell carcinoma, adenocarcinoma, squamous cell carcinoma with neuroendocrine differentiation, and malignant epithelial lung cancer accounted for 78.5%, 18.5%, 1.5%, and 1.5% respectively. The clinical stages of the patients were as follows: 26 (40.0%) cases were in stage IIIA, 33 (50.8%) cases were in stage IIIB, and 6 (9.2%) cases were in stage IIIC. There were 30 (46.2%) patients with ECOG PS score of 0. There were 38 (58.5%) patients with smoking history. There were 25 (38.5%) patients who had past medical history.The median treatment cycle of the treatment regimen was 3. The main adverse events related to treatment were lymphocyte count decreased (47.7%), alanine aminotransferase increased (27.7%), aspartate aminotransferase increased (26.2%), anemia (21.5%), neutrophilia granulocyte count decreased (21.5%), hypoalbuminemia (21.5%), white blood cell count decreased (20.0%), and lactate dehydrogenase increased (15.4%).A total of 55 of the 65 patients enrolled underwent surgery. The surgery rate was 84.6% (95%CI: 73.5%-92.4%). All patients who underwent surgery achieved R0 resection after surgery, the R0 resection rate was 100.0% (95%CI: 93.5%-100.0%), and the median surgical interval was 5.7 weeks. Among them, 26 cases achieved pathological complete response after surgery, and the pCR rate was 47.3% (95%CI: 33.7%-61.2%). Among them, 42 cases achieved major pathological response after surgery, and the MPR rate was 76.4% (95%CI: 63.0%-86.8%).

Conclusions: Tislelizumab combined with chemotherapy shows good anti-tumor activity in patients with locally advanced lung cancer, can reduce tumor volume, improve surgical resection rate, has a high pathological complete response rate and is well tolerated. Immunotherapy combined with chemotherapy is one of the new options for downstaging and conversion therapy for patients with locally advanced lung cancer. It can provide surgical opportunities for patients who have no chance of surgery or who have difficulty in surgery, and can increase the rate of radical surgical resection.

EP.08F.16 Re-Irradiation with Chemotherapy with/without Immunotherapy for In-Field Local Recurrence Among Lung Cancer Patients

S. Vannhong, M. Wang, X. Chen, Y. Gong, Division of Thoracic Tumor Multidisciplinary Treatment, Cancer Center and State Key Laboratory of Biotherapy, West China Hospital, Chengdu/CN

Introduction: Radiotherapy is crucial for non-operative locally advanced lung cancer. Normally, a number of patients with in-field recurrent lung cancer after definitive concurrent chemo-radiotherapy (dCCRT) had the possibility of re-irradiation. For these patients, the salvage radio-chemotherapy or radio-chemotherapy followed by immune checkpoint inhibitors (ICIs) treatment still plays an important role in prolong the overall survival for those patients with good performance status. So far, only a few data had been reported.

Methods: Between Sep 2015 and Nov 2022, 83 patients with in-field recurrent non-small cell lung cancer (NSCLC) who had received highly-palliative re-irradiation (50 Gy/25 fractions) were recruited and retrospectively analyzed. Among these patients, 58 patients received re-irradiation combined with chemotherapy (re-RCT), and another 25 patients received re-radiochemotherapy followed by Durvalumab or other drugs (re-RCIT). The chemotherapy regimens were Paclitaxel and Carboplatin/Cisplatin, repeated every 3 weeks. Two to 6 weeks after the re-irradiation and concomitant thermotherapy, the application of ICIs were started according to the NCCN guidelines. Statistical analyses were performed with SPSS 24.0. The chi-square test was used to compare the treatment-related complications between the two groups. Survival time was performed using the Kaplan-Meier method. Log-rank test was applied to compare survival rates. Potential prognostic variables were estimated using multi-variate Cox regression model. The p value was considered statistically significant if less than 0.05.

Results: Generally, the median progression-free survival (PFS) of re-RCT group and re-RCIT group were 5.6 months and 11.4 months respectively (p=0.031). The median overall survival (OS) was 17.9 and 20.2 months in re-RCT and re-RCIT group respectively (p=0.269). There was no significant difference between the 1, 2 and 3 year survival rates in two groups (67.2%, 29.3%, and 19.0% in re-RCT group vs. 72.0%, 32.0% and 28.0% in re-RCIT group) (p>0.05 respectively). Grade 3-4 treatment-related adverse events (TRAEs) and their incidence rates were: treatment-related pneumonitis, 10.3% vs. 16.0% (p=0.365), neutropenia, 77.6% vs. 76.0% (p=0.872), thrombocytopenia, 15.5% vs. 20.0% (P=0.683) and anemia, 8.6% vs. 12.0% (p=0.774). Incidence rates of fetal bronchial bleeding or fracture were 3.4% vs. 4.0% (p=0.817).

Conclusions: Palliative re-irradiation is an effective treatment for patients with locally recurrent NSCLC after the first-course CCRT. Compared with the radio-chemotherapy, the combination of ICIs may significantly improve the short-term survival, but not the overall survival. The TRAEs were clinically acceptable and manageable, including the pneumonitis (radiation-induced or ICIs-induced), but attention of bronchial fracture or bleeding must be emphasized.

EP.08F.18 Survival and Incidence Trends of Non-Small Cell Lung Cancer in Elderly Patients (>75 Years): Insights from SEER Database

N. Aimalla[1], O. Abughanimeh[2], [1]Marshfield Clinic Health System, Marshfield/WI/USA,[2]University of Nebraska Medical Center, Omaha/NE/USA

Introduction: Non-small cell lung cancer (NSCLC) is the most common (85-90%) subtype of lung cancer. Approximately 30-40% of all NSCLC cases occur in individuals aged ≥ 75 years. Our study aims to identify survival, incidence rates, and factors impacting overall survival (OS) in patients aged over 75 years diagnosed with NSCLC.

Methods: We conducted a retrospective cohort analysis utilizing the Surveillance, Epidemiology, and End Results database. Cox proportional regression analysis was used to identify the factors that impact the overall survival (OS). Incidence trends are analyzed over different periods, highlighting changes in survival outcomes and demographic factors.

Results: Between 2000 and 2020, a total of 33,040 cases of NSCLC occurred in patients aged ≥ 75 years. Higher incidence rates are observed among males compared to females (54.74% vs. 45.26%). The incidence trends revealed a significant decrease from 2000 to 2020. Additionally, a higher incidence is noted in patients with lower income levels (< $75,000) (56.28% vs. 43.72%). Over the past five years, there has been a marked improvement in survival rates for patients diagnosed with NSCLC. This is evident from the decreasing hazard ratios (HR) and increasing median survival months associated with the years of diagnosis from 2000 to 2020. Specifically, patients diagnosed between 2015-2020 exhibited the most favorable outcomes, with the highest median survival of 8.33 months. These findings highlight the progress made in NSCLC management and underscore the importance of ongoing advancements in treatment strategies to improve patient outcomes. Among the demographic factors, females, urban residents, higher annual income (> 75,000 $), and married status had better OS outcomes than their counterparts. Among disease stages, localized disease had the best, while regional disease had a better OS than distant disease. Chemotherapy generally shows a protective effect, with lower hazard ratios across all stages. Radiation therapy also demonstrates a protective effect, particularly in localized disease. Surgery appears to have the most significant impact on survival, especially in patients with localized NSCLC, where it is associated with the lowest hazard ratio and highest OS. The incidence rates and OS HRs are shown in Table.

Conclusions: Our study highlights significant advancements in NSCLC management for elderly patients over 75 years. Tailored treatments such as chemotherapy, radiation therapy, and surgery have markedly improved survival rates. Key demographic factors also play crucial roles in shaping patient outcomes. These findings provide valuable insights for optimizing care strategies in this population.

EP.08F.19 Dosimetric Benefits in Adaptive Intensity Modulated Radiotherapy with Sib for Lung Cancer: An Indian Regional Cancer Centers' Early Experience

S.S. DAS[1], A. Ray[1], D.K. Ray[1], B. Pramanik[1], M. Mahawar[1], S. Kundu[1], K. Mazumder[1], S. Mandal[1], S. Mandal[1], S. Bera[1], [1]Chittaaranjan National Cancer Institute, Kolkata/IN

Introduction: Chemoradiation therapy remains the standard of care for inoperable stage III NSCLC.IMRT based SIB technique can deliver a higher dose to the tumor with a relatively lower dose to the CTV. Individual treatment response can cause anatomical changes or tumor shrinkage which causes significant difference between the planned and actual delivered dose. Adaptive radiotherapy (ART) to the changed tumor volume can decrease these geometric discrepancies, thus preventing the surrounding normal tissues from receiving unnecessary high dose.

Methods: 18 patients with histologically proven unresected stage III NSCLC who were treated with one-time scheduled ART using SIB-IMRT technique between July,2023 to December,2023, were included for dosimetric analysis in the study. They were planned for definitive RT with dose prescription of 66 Gy at 2 Gy per fraction to planning gross tumor volume (PGTV=GTV) AND 59.4 Gy at 1.8 Gy per fraction to planning target volume (PTV) in 33 fractions with concurrent regimen of platinum-based doublet chemotherapy. They initially underwent a planning 3 phase (free breathing, deep inspiration and deep expiration) CT simulation scan of 2.5 mm cuts before initiation of treatment (INITIAL SCAN) and also once after delivery of 44 Gy (ADAPTIVE SCAN). KV CBCT was regularly used to monitor tumor shrinkage pattern as well as to correct interfractional geometric displacement during setup. GTV in pre-treatment scan was defined as visible tumors and metastatic lymph nodes which were delineated in all 3 respiratory phases and joined together to generate individual iGTV. CTV included iGTV with a specific 6-8 mm margin in all directions. PGTV (PTV 66) in our study was defined as iGTV and PTV 59.4 was defined as 5 mm extension from CTV in all directions as per institutional protocol. In adaptive scan, PGTV(PTV66) was generated by delineating the visible shrunken tumors and involved positive lymph nodes in all 3 phases of mid treatment scans and later joining it. But in this study, we keep the CTV and PTV59.4 delineation in the adaptive/mid treatment scan same as the pre-treatment scan.To analyse the dose difference from adaptation, the adaptive CT was coregistered(rigid) with the original pre-treatment planning CT to transfer the entire initial 66 Gy plan on adaptive CT - THIS WAS ASSUMED AS NON-ART PLAN(SIMULATED PLAN). On the other hand, ART plan was calculated by combining 22 fractions of previously treated plan with 11 fractions of the new plan. The dosimetric differences of DVHs between 2 were quantitatively evaluated.

Results: Target volume shrinkage was observed in all patients in the adaptive scan.The median GTV/PGTV before initiation of treatment was 213 cubic cm (range:79.3-454.6).But,after 22nd fraction the median GTV/PGTV was 146 cubic cm (range:69.3-201). The absolute value of (I/L lung-PTV) V20,V30 and mean lung dose (MLD) reduced by an average of 1.2%,2.4% and 67 cGy. Same parameters for C/L lung reduced by 2.44%,1.76% and 123.7 cGy respectively. Mean esophagus was reduced by 215.2 cGy. Mean heart dose(MHD) was reduced by an average 96.2 cGy.

Conclusions: • Adaptative replanning to the shrunk tumor can have significant dosimetric benefits to OARs.

EP.08F.20 Stage IIIA Non-Small Cell Lung Cancer (NSCLC): Outcomes by Treatment Strategy

W.P. Carroway[1], S-F. Jiang[2], J. Velotta[2,3], [1]UCSF East Bay, Oakland/CA/USA,[2]Kaiser Permanente, Oakland/CA/USA,[3]University of California San Francisco, San Francisco/CA/USA

Introduction: Current treatment guidelines for Stage IIIA NSCLC from the National Comprehensive Cancer Network (NCCN) are complex and recommend a myriad of options that may or may not include surgery, such as definitive chemoradiation and adjuvant immunotherapy. However, many stage IIIA patients do not undergo definitive chemoradiation and adjuvant immunotherapy as first line therapy due to incomplete mediastinal staging. The purpose of this study was to compare 1, 3, and 5-year overall survival between patients with stage IIIA NSCLC who received definitive chemoradiation +/- immunotherapy versus those who received a multimodal approach involving surgery.

Methods: This is a data-only retrospective multicenter cohort study of patients who were diagnosed with stage IIIA NSCLC at Commission on Cancer (CoC) American College of Surgeons (ACS) accredited hospitals from January 1, 2010 through June 30, 2021. Patients were censored at loss to follow up or study end - 30 June 2023. Overall survival was evaluated as an outcome using Kaplan-Meier analysis between patients received chemoradiotherapy with or without immunotherapy (non-surgical treatment) vs patients received surgery with neoadjuvant or adjuvant chemotherapy/radiation/immunotherapy (surgical treatment). Multivariable Cox proportional hazards regression analyses was conducted to identify independent predictors for overall survival.

Results: A total of 598 patients were identified and included in the study, 281 in the non-surgical treatment group and 317 patients in the surgical group that included neoadjuvant or adjuvant treatment. Age, BMI, CCS, race, and date of diagnosis was similar between group, with a larger proportion of women in the surgical group and higher proportion of tobacco use in the non-surgical treatment group. Shown in Figure 1 is the Kaplan Meier estimate for overall survival. Multivariable Cox Proportional hazards analysis was performed adjusting for age, gender, race, BMI, smoking status and CCS. Overall survival differed significantly between the two groups with average 5-year survival of 52.6% in the surgical treatment group and 30.8% in the non-surgical treatment group. These results are similar to previously published literature and add to the growing body of evidence supporting surgical treatment in appropriate patients with stage IIIAA disease.

Conclusions: There has only been one clinical trial comparing chemoradiation to surgery in stage IIIA NSCLC. The findings included higher progression free survival in the surgical group, as well as improved 5-year overall survival, although these results were published in 2009 before the advent of adjuvant immunotherapy. Our results demonstrate a significant 5-year overall survival of Stage IIIA NSCLC patients who undergo a multimodal treatment approach involving surgery compared to the non-surgical group. This improvement in overall survival provides growing evidence in favor of multimodal surgical treatment in select patients. The treatment plan should come from a multidisciplinary team with an expert thoracic surgeon included who can be a part of the underlying treatment decision for Stage IIIA NSCLC management.

EP.09A.01 Oligoprogression after Local Ablative Treatment for Oligometastatic Non-Small Cell Lung Cancer

N. Steinmann[1], R.S. Werner[1], I. Opitz[1], [1]University Hospital Zurich, Zurich/CH

Introduction: At the initial diagnosis of stage IV non-small cell lung cancer (NSCLC), it is estimated that between 25-50% of patients are in an oligometastatic state with few distant metastases and limited systemic tumor burden. Despite the integration of local ablative therapy into the treatment regimen, local and distant recurrences remain a common challenge in these patients. Analogous to the oligometastatic state, an oligoprogression, is defined as the progression of cancer at a limited number of sites with otherwise controlled disease. We aimed to retrospectively assess the outcomes of patients with oligo- and polyprogression after local ablative treatment including surgical resection of the primary tumor for oligometastatic NSCLC.

Methods: We retrospectively identified 90 patients with synchronous or metachronous oligometastatic NSCLC who underwent local ablative treatment including anatomical lung resection between 2009 - 2023. Oligometastatic disease was defined as ≤5 distant metastases in ≤3 organs. Oligoprogression was defined as progression at ≤3 sites, whereas polyprogression was defined as progression at >3 sites.

Results: Oligoprogression occurred in 41 patients with a median latency of 24 months (95% CI: 7.6 - 40.4 months) and polyprogression occurred in 24 patients with a median latency of 8 months (95% CI: 6.9 - 9.7 months). Median follow-up of the entire cohort was 58 months (95% CI 30.4 - 85.6 months) and in 25 patients, no relapse occurred. Of the 41 oligoprogressive patients, 33 (80.5%) underwent local ablative therapy for progression sites. Among these, 23 (69.7%) were treated with radiotherapy, 5 (15.2%) with surgery, and 5 (15.2%) received both treatments. Upon oligoprogression, systemic therapy was changed in 8 (19.5%) of the patients. Overall survival after initial diagnosis of metastases was significantly longer in patients with oligoprogression when compared to patients with polyprogression (70 months, 95% CI: 43-8 - 96.2 versus 16 months, 95% CI: 3.1 - 28.8, p=0.012). A median overall survival of 134 months (0.0 - 289.0 months) was present in non-progressive patients. Notably, the overall survival difference between non-progressive patients and patients with oligoprogression was not significantly different (p=0.36).

Conclusions: Oligoprogression is the most common pattern of relapse after local ablative treatment in oligometastatic NSCLC. In our patient cohort of oligometastatic patients who underwent local ablative treatment including surgical resection of the primary tumor, overall survival is not significantly different in oligoprogressive and non-progressive patients. These findings suggest that the occurrence of oligoprogression is often not a survival-limiting factor.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.09A.02 Addition of Pulsed Electric Field Ablation to SBRT for Lung Tumors: Effect on Health-related Quality of Life

J.P. Harris, N. Abi-Jaoudeh, C. Boyd, M. Shi, M. Reilly, A. Simon, S. Seyedin, E. Healy, C. McLaren, M. Nagasaka, R. Nabar, A. Chen, University of California, Irvine, Orange/CA/USA

Introduction: A close distance to the proximal bronchial tree and/or mediastinum is associated with higher rates of local recurrence and severe toxicity for lung tumors treated with stereotactic body radiation therapy (SBRT). Electric ablation with pulsed electric fields (PEF) is of interest since it does not disrupt extracellular structures and is thought to be a safer ablative approach for tumors adjacent to major blood vessels or cartilaginous airways. We performed a single-arm clinical trial testing the combination of PEF ablation with single-fraction SBRT. Herein we report health-related quality of life (HRQoL) changes associated with the combination treatment.

Methods: In this prospective trial, adult patients with a metastatic lung tumor of any histology were treated with PEF ablation on day 1 and 12 Gy SBRT between days 8-15. Eligibility included those with 1-3 tumors that were ≤6 cm in size. HRQoL data was collected as a secondary endpoint and included the Functional Assessment of Cancer Therapy-Lung Cancer Subscale (FACT-LCS), FACT-Physical Well-Being (FACT-PWB), FACT-Social/Family Well-Being (FACT-SWB), FACT-Emotional Well-Being (FACT-EWB), and FACT-Functional Well-Being (FACT-FWB). Domain subscales were calculated with a range of 0-28 or 0-24 (FACT-EWB), with higher scores indicating more optimal HRQoL. Surveys were collected at initial screening and at 3 months. Exploratory analysis was conducted to test associations between HRQoL domains and pulmonary function testing (PFT).

Results: Six patients with eight tumors were enrolled and treated between March 2023 and September 2023. All patients completed their course of treatment, and there was no missing HRQoL data. Baseline domain scores were: PWB 25.9 (Std Dev 2.3), SWB 21.0 (Std Dev 6.9), EWB 17.3 (Std Dev 4.7), FWB 21.2 (Std Dev 5.8), and LCS 19.4 (Std Dev 5.3). There were no significant changes in HRQoL domains following IRE and SBRT. At 3 months post-treatment, lower FVC was associated with lower EWB (rho = 0.55, beta = 5.3, p = 0.04) and SWB (rho = 0.58, beta = 2.9, p = 0.01), and lower FEV1 was associated with lower EWB (rho = 0.81, beta = 5.6, p = 0.04) and SWB (rho = 70, beta = 3.0, p = 0.01). A larger decrease in DLCO after treatment was associated with lower FWB (rho = 0.79, beta = 1.3, p = 0.006). Other HRQoL domains were not significantly associated with PFT measurements (p>0.05, for all). Only one patient reported worsened dissatisfaction due to side effects (GP5, "I am bothered by side effects of treatment") and was also the only patient to experience a grade 3 or higher toxicity (grade 3 surgical procedure complication, where the patient whose history included chemoradiation for hypopharyngeal carcinoma experienced laryngeal edema preventing extubation until 1 day post-procedure).

Conclusions: In this prospective trial, treatment of lung metastases with combination PEF ablation and SBRT was well-tolerated. Patient-reported responses from standardized instruments showed no significant treatment-related declines in HRQoL. Exploratory analyses identified associations between worse pulmonary function and a larger decrease in DLCO after treatment with poorer well-being scores.

EP.09A.03 Safety and Efficacyof Cranial Radiotherapy in Combination with Aumolertinibin EGFR-Mutant NSCLC Patients with Brain Metastases

S. Han[1], W. Wang[2], N. Bi[2], [1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, shenzhen/CN,[2]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Beijing/CN

Introduction: Third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), such as osimertinib, has a powerful ability to penetrate the blood-brain barrier and a high potency for controlling brain metastases (BMs) from EGFR-mutant non-small cell lung cancer (NSCLC). However, the safety and efficacy of aumolertinib as first-line therapy combined with cranial radiotherapy in EGFR-mutant NSCLC patients with brain metastases has not been fully investigated.

Methods: Patients with EGFR-mutant NSCLC and BMs and receiving aumolertinib and cranial radiotherapy were retrospectively enrolled. The modality of cranial radiotherapy include whole-brain radiotherapy (WBRT), stereotactic radiotherapy (SRT), hypofractionated stereotactic radiotherapy (HSRT) and simultaneously integrated boost whole-brain radiotherapy (SIB-WBRT). All patients received aumolertinib 110mg orally once daily. Central nervous system objective response rate (CNS ORR) were assessed by RECIST v1.1. Overall survival (OS) after BMs were analyzed using the Kaplan-Meier method.

Results: Of the 16 patients enrolled from 2016 to 2023, including SRT in 2, HSRT in 7, WBRT in 4, SIB-WBRT in 3, median age was 63 years (range, 36-76 years), 62.5% were female. 9 patients have 1 to 3 BM lesions,while 7 patients have more than 3 lesions. The median size of the lesions is 1.2cm (range, 0.7-5.1cm). 87.5% of patients have KPS>70. The median OS after BMs and 1-, 2- and 3- OS rates of 16 patients were 31.3 months, 93.3%, 60.0% and 48.0%. The median OS and 1-, 2- and 3- OS rates of 9 patients treated with local hypofractionated radiotherapy (SRT+HSRT) were 33.2 months, 87.5%, 61.2% and 37.5%. And the median OS and 1-, 2- and 3- OS rates of 7 patients treated with WBRT+SIB-WBRT were 29.7 months, 85.7%, 68.6% and 34.3%, respectively. The CNS ORR was 81.3% (13/16; 95% CI: 65.1-97.1). No grade≥3 cerebral radiation necrosis was observed in these patients.

Conclusions: Aumolertinib showed preliminary safety and efficacy at 110mg once daily as first-line therapy in combination with cranial radiotherapy for EGFR-mutant NSCLC patients with brain metastases.

EP.09A.04 Enhancing Radiotherapy Efficacy for Brain Metastases in Non-Small Cell Lung Cancer Through the Integration of G-CSF and Immunotherapy

X. Gong, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Brain metastases (BMs) significantly contribute to the mortality rate among non-small cell lung cancer (NSCLC) patients. This study evaluates the clinical efficacy of combining G-CSF enhanced whole brain radiotherapy (WBRT) with immunotherapy as a primary strategy for treating BMs in NSCLC patients.

Methods: This retrospective analysis enrolled 117 NSCLC patients with 1-10 intracranial metastatic lesions undergoing first-line WBRT combined with immunotherapy. Patients were divided into two groups: those receiving G-CSF (n=37) and those without G-CSF (n=80). We assessed overall survival (OS), intracranial response, progression-free survival (PFS), intracranial progression-free survival (iPFS), and relief from BM-related symptoms.

Results: The G-CSF group demonstrated a significant improvement in OS compared to the non-G-CSF group (median OS: 14.8 vs. 10.2 months; HR: 0.61, 95% CI: 0.38-0.97, p=0.035, Fig.1a). While not statistically significant, trends toward longer PFS (Median time: 10.4 vs 6.2 months; HR: 0.71, 95% CI: 0.47-1.09, p=0.12, Fig.1b) and iPFS (Median time: 11.9 vs 8.1 months; HR: 0.81, 95% CI: 0.52-1.26, p= 0.35, Fig.1c) were observed in the G-CSF group. The analysis of one-year survival rates further demonstrated G-CSF's potential to significantly impact patient outcomes, showing improvements in OS (51.4% vs. 33.8%, p=0.07), PFS (32.4% vs. 18.8%, p=0.10), and iPFS (45.9% vs. 27.5%, p=0.049). This trend continued into the second year, particularly notable in OS (36.7% vs. 15.7%, p=0.04), while PFS (14.8% vs. 6.2%, p=0.18) and iPFS (21.9% vs. 13.6%, p=0.25) displayed improvements that, although suggestive, did not achieve statistical significance. Notwithstanding, there were no significant differences in intracranial responses between the two groups (p> 0.05). Moreover, a significantly higher rate of symptom relief from BM was noted in the G-CSF group (91.7% vs. 59.5%, p=0.037). Cox regression analyses identified post-treatment absolute lymphocyte count (ALC) > 0.9 × 10^9/L (HR 0.57, 95% CI 0.32-0.99, p = 0.046) and hemoglobin (Hb) > 110g/dL (HR 0.41, 95% CI 0.24-0.71, p = 0.001) as factors significantly associated with improved OS.

Conclusions: The integration of G-CSF with WBRT and immunotherapy as a first-line treatment significantly enhances the therapeutic efficacy for NSCLC patients with BMs, particularly in extending overall survival and alleviating BM-related symptoms. These findings underscore the potential of this combined approach in improving clinical outcomes for this patient population.

EP.09A.05 Consolidative Thoracic Radiotherapy Induced Lymphopenia in Metastatic NSCLC Is Predicted by EDIC and Associated with Poor Clinical Outcomes

K. McComas, R. Whitaker, Vanderbilt University Medical Center, Nashville/TN/USA

Introduction: Immune checkpoint inhibitors (ICI) have led to significantly improved clinical outcomes in localized and metastatic NSCLC. However, a robust response to ICI is predicated on a viable adaptive immune system. The effective radiation dose to immune cells (EDIC) has been shown to be predictive of lymphopenia. Rates of high-grade lymphopenia after chemoradiation can be upwards of 80% and are correlated with a poorer prognosis. Severe radiation-induced lymphopenia has been demonstrated to attenuate the PFS and OS benefit of consolidative durvalumab. Here, we evaluate whether consolidative thoracic radiotherapy with concurrent maintenance ICI is detrimental in the metastatic setting.

Methods: A retrospective review of patients with metastatic NSCLC treated at our institution from 2022 to 2024 was performed. Six patients with stage IV NSCLC were identified that were treated with upfront chemoimmunotherapy with at least stable disease on early surveillance imaging. Patients subsequently underwent consolidative thoracic radiation (3-4 Gy/fraction to total doses of 45-60 Gy) with continuation of concurrent maintenance ICI. 4 of 6 patients also underwent concurrent SBRT to additional metastatic sites (2 adrenal, 1 lung and 1 thoracic spine). Degree of lymphopenia, EDIC, and oncologic outcomes were evaluated.

Results: Median follow-up was 218 days, with absolute lymphocyte count collected prior to, during and at approximately 1, 4, and 6 weeks after radiotherapy. Four patients had grade 3-4 lymphopenia, three of whom progressed prior to 100 days (the fourth patient had only limited follow-up of less than 1 month). Two patients had grade 1 lymphopenia, one of whom has not progressed and the other who progressed at 494 days and remains alive at greater than 18 months. EDIC was associated with decreased lymphocyte count and higher grade toxicity with lower observed EDIC in patients with G1 lymphopenia (median = 5.1 Gy) compared to those with G3+ lymphopenia (median = 6.2 Gy).

Conclusions: Addition of consolidative radiotherapy to SOC maintenance systemic therapy in patients with limited metastatic NSCLC has previously failed to demonstrate improved outcomes in the phase 2 study NRG LU-002. We postulate that the failure of this larger study could at least be partially explained by the impact of RT on systemic immune function. In this small cohort we demonstrate that lymphopenia from hypofractionated consolidative radiation to the thorax with ICI is associated with poor prognoses in patients with metastatic NSCLC. Short-course, ablative radiation utilizing smaller treatment volumes, lower total radiation doses and more conformal plans may improve outcomes of consolidative radiation by reducing the risk of lymphopenia and preventing immune exhaustion. Further exploration into altered fractionation schedules could lead to improved oncologic outcomes.

EP.09A.06 Assessment of Treatment Outcomes and Chest Wall Toxicity Following Stereotactic Body Radiotherapy for Lung Nodules Adjacent to the Pleura

S. Oz, O. Bascik, S. Duru Birgi, Y. Arslan, A. Kayi Cangir, S. Akyurek, Ankara University, Ankara/TR

Introduction: Stereotactic Body Radiotherapy (SBRT) has emerged as an efficacious approach for early-stage lung cancer and locally effective treatment for oligometastatic-oligoprogressive lung lesions. While SBRT demonstrates a favorable safety profile with minimal toxicity in current literature, its application to lesions proximal to the pleura may lead to chest wall toxicities such as chest wall pain and rib fracture. This study aims to evaluate treatment outcomes and chest wall toxicity following SBRT administered to lung nodules adjacent to the pleura.

Methods: A retrospective analysis was conducted on 70 patients (comprising 74 lesions) who underwent SBRT with 4D respiratory monitoring for lung nodules proximal to the pleura at our center between July 2020 and April 2023. Dose prescription was based on the planning target volume (PTV), excluding volumes intersecting with the ribs. Data collection and analysis were performed using SPSS v23.0, and toxicity rating was assessed in accordance with CTCAE v5.0.

Results: The median age of the patients was 68.5 years (range: 40-86 years). Karnofsky performance score was 80 and above in 81% of patients (n=57). The median volume of the internal Gross Tumor Volume (iGTV) and PTV were 6 cc(range: 1-70 cc) and 22 cc (range: 3-125 cc). Treatment was administered over a median of 5 fractions (range: 4-8) with a total dose of 50 Gy (range: 50-65 Gy). The median Biologically Effective Dose with an alpha/beta ratio of 10 (BED10) was 112.5 Gy (range: 100-150 Gy). The median volume of PTV intersecting with the chest wall was 1.5 cc (range: 1-12 cc). Median chest wall D0.1cc was 55 Gy (range: 22-73 Gy), median V30 was 10 cc (range: 0-61 cc), and median maximum dose to the rib was 40 Gy (range: 22-62 Gy). Following a median follow-up of 21 months (range: 3-43 months) post-treatment, the 2-year local control rate was 92%. While no grade 2 or higher side effects were observed, grade 1 chest wall toxicity was reported in 8% of patients (n=6). One case of grade 1 rib fracture was documented 21 months after SBRT, with a rib maximum dose of 39.8 Gy, treated in 4 fractions. Notably, this patient had a history of breast cancer and prior chest wall irradiation on the same side.

Conclusions: With a dose definition for SBRT in lesions adjacent to the pleura, which subtracts intersecting rib volumes from the PTV, effective treatment outcomes were achieved with minimal toxicity, thereby preserving local control.

EP.09A.07 Prognostic Factors for Advanced Invasive Mucinous Adenocarcinoma of the Lung with Emphasis on the Treatment Modalities

S.H. Kim, J.S. Eom, M-H. Kim, Pusan National University Hospital, Busan/KR

Introduction: Invasive mucinous adenocarcinoma (IMA) of the lung represents a rare subtype of lung adenocarcinoma with limited understanding regarding its prognosis, particularly in advanced stages. This study aimed to assess the prognosis of advanced IMA, focusing on treatment modalities.

Methods: A retrospective analysis was conducted on 33 patients diagnosed with advanced-stage IMA or who progressed after curative treatment between 2011 and 2021 at a single center. Overall survival (OS) and progression-free survival (PFS) were the primary and secondary outcomes, respectively, calculated from the date of advanced IMA diagnosis.

Results: The cohort included 13 patients diagnosed at an initial advanced stage and 20 patients who progressed after curative treatment. Treatment modalities included local ablative therapy (LAT) in 13 patients (39.4%), conventional chemotherapy in 24 patients (72.7%), targeted therapy in 7 patients (21.2%), and immunotherapy in 13 patients (39.4%). Median OS was 32.0 months (95% CI, 2.9-61.0), with LAT significantly associated with improved OS compared to non-LAT treatment (not reached vs. 11.3 months, p=0.001). However, OS did not significantly differ based on conventional chemotherapy (p=0.396), targeted therapy (p=0.655), or immunotherapy (p=0.992). On multivariate analysis, LAT remained an independent prognostic factor for OS (HR 0.125; 95% CI, 0.026-0.608; p=0.01). Regarding PFS, there were no significant differences based on treatment modalities. Multivariate analysis identified high body mass index as an independent prognostic factor for progression (HR 0.885; 95% CI, 0.768-0.990; p=0.043).

Conclusions: Our findings suggest that LAT may confer a favorable survival outcome in advanced IMA patients, although it did not significantly impact cancer progression. Further studies are warranted to validate these results and explore additional prognostic factors.

EP09A.08 Assessment of MR-Guided Single-Fraction SABR/SBRT of Peripheral Lung Tumors: Dosimetric and Clinical Outcomes - A Prospective Study

S. Hering[1], J. Hofmaier[1], S. Marschner[1], N-S. Schmidt-Hegemann[1], V. da Silva Mendes[1], G. Landry[1], M. Niyazi[2], A. Tufman[1], N. Reinmuth[3], C. Belka[1], S. Corradini[1], C. Eze[1], [1]University Hospital LMU Munich, Munich/DE,[2]University of Tübingen, Tübingen/DE,[3]Asklepios Lung Clinic Munich-Gauting, Gauting/DE

Introduction: The aim of this study was to evaluate the clinical and dosimetric outcomes of online MR-guided single-fraction stereotactic ablative radiotherapy (SABR) and assess acute changes in pulmonary function tests (PFTs), inflammatory markers, and patient-reported quality of life (QoL).

Methods: Patients with inoperable primary lung cancer ≤2 cm or with ≤3 lung metastases ≤3 cm were included in this monocentric prospective study. Patient and treatment characteristics are depicted in the Table. Patients underwent MR-guided single-fraction SABR. Treatement involved delivery of 28 Gy or 30 Gy prescribed to the 80% isodose line, with real-time intrafractional tumor tracking using online 2D cine MRI and respiratory gating. The primary endpoints of the study encompassed local control (LC) and overall survival (OS), while secondary endpoints included acute toxicity (CTCAE v. 5.0), changes in PFTs, inflammatory markers and QoL.

Results: Between October 2020 and October 2022, 29 patients with 33 lung tumors were prospectively enrolled. At a median follow-up of 19.2 months (range: 15.9 - 22.5 months), 1-/2-year LC and OS rates were 96.6% (95% CI: 89.9 - 100.0%)/78.2% (95% CI: 56.8 - 99.6%) and 89.5% (95% CI: 78.3 - 100.0%)/76.1% (95% CI: 59.0 - 93.2%), respectively. Four local failures were observed, three in patients with colorectal carcinoma lung metastases (CRLM) and one in a patient with Ewing sarcoma lung metastasis. Median PTV coverage by the prescribed dose (PTV VPD) was 98.3% (range: 91.9 - 101.7%; compared to PTV VPD of the baseline plans); 4/33 (12.1%) plans were reoptimized, and no CTCAE grade ≥3 side effects were observed. While there was a slight reduction in Forced expiratory volume in 1 second (l) by a median of 4.0% (p = 0.022, range: -23.7 - 66.7%) other PFT parameters remained stable. The neutrophil-to-lymphocyte ratio increased by a median of 8.3% (p = 0.017, range: -100.0 - 207.4%) while serum c-reactive protein and albumin remained stable. Patient-reported QoL did not exhibit significant changes.

Conclusions: MR-guided single-fraction SABR emerges as a safe and effective treatment option for peripheral lung tumors demonstrating encouraging clinical outcomes. This study underscores the potential for dose-escalation in CRLM and offers novel insights into acute changes in lung function, systemic inflammation, and QoL within this context.

EP.09B.01 Closing the Gap: Moving Toward Equitable Care in Surgical Management of Stage IV Lung Disease

S.A. Ries[1], Y. Qing[1], R. Sun[1], J. Mitchell[2], M. Eisenberg[1], K. Mitchell[1], R. Mehran[1], D. Rice[1], J. Roth[1], S. Swisher[1], A. Vaporciyan[1], S. Swisher[1], W. Hofstetter[1], R. Rajaram[1], M.A. Antonoff[1], [1]MD Anderson Cancer Center, Houston/TX/USA,[2]Howard University Hospital, Washington/DC/USA

Introduction: Despite evolving paradigms in the management of lung cancer, disparities continue to permeate various facets of patient care. We aimed to characterize the relationship between demographic characteristics and likelihood of undergoing lung surgery in stage IV NSCLC. Further, we sought to explore whether any disparities in receipt of surgery changed over time.

Methods: Using the National Cancer Database, we retrospectively reviewed patients diagnosed with clinical stage IV NSCLC from 2004-2019. Patients were categorized into surgical and nonsurgical groups. Comparisons of demographic, clinical, and outcomes variables were made between groups using Wilcoxon rank-sum test for continuous variables and Fisher's exact test for categorical variables. A multivariable logistic regression model (MVA) was used to assess determinants of receiving surgery. Log-rank test was used to compare overall survival (OS) between groups. Comparative subgroup analyses were performed for patients diagnosed in the years from 2004-2009 versus 2014-2019.

Results: Our cohort was comprised of 137,302 patients, including 2,089 (1.5%) who underwent lung resection as local consolidative therapy (surgical group). Sex distribution within the surgical group was even (1,067 women, 51%). Most patients in the surgical group were between the ages of 61-80 years old (67%, n=1,410), White (89%, n=1864]), and insured (98%, n=2051. Patients who did not receive surgery were more frequently older (p<0.001), non-White (p<0.001), uninsured (p<0.001), and had lower income (p=0.003). After adjusting for clinical T and N, age, and Charleson-Deyo score, we found that non-White, uninsured, and lower income patients remained substantially less likely to receive surgery. Surgical patients had longer OS (median 30.5 months; 95% CI, 28.1-34.3) compared to non-surgical (median 6.0 months; 95% CI 5.9-6.1, p<0.0001, Figure). From 2004 to 2009, the trends mirrored those observed over the entire 15-year span, indicating a lower likelihood of surgery for non-White, uninsured, and lower income patients after adjusting for clinical factors. However, importantly, in subgroup analysis of the last 5 years, no significant differences were observed in terms of race or insurance during this period.

Conclusions: We identified concerning disparities in terms of which patients are offered surgical LCT for stage IV NSCLC. Patients who were non-White, uninsured, and low income were less likely to receive lung surgery, with negative impact on subsequent survival. Notably, comparative data over time suggests that ongoing efforts to address healthcare inequities are making an impact. It is imperative that we persist in addressing inequities in care, thereby ensuring improved outcomes for all patients.

EP.09B.02 Performing Lung Resection Simultaneously with Cardiac Valve Surgery is Safe and Economical

W-Z. Zhong, Z. Chen, H. Guo, J. Lin, Y. Wu, Guangdong Provincial People's Hospital, Guangzhou/CN

Introduction: A pulmonary tumor is occasionally detected on a chest computed tomography (CT) scan before cardiovascular surgery. In this study we evaluate the safety of performing both lung resection and heart valve surgery simultaneously in one anesthesia, and the advantages of simultaneous surgery from the perspectives of economy and patient experience.

Methods: From January 2018 to January 2023,48 pulmonary tumor is occasionally detected on a chest computed tomography scan before cardiovascular surgery with a median age of 59.8 years. We prioritize recommendation of simultaneous cardiopulmonary surgery, with 31 patients choosing it and 17 patients choosing sequential surgery because the unknown risks. Both groups of patients signed informed consent forms before the surgery. We recorded the patient's intraoperative condition, perioperative data, and total cost for subsequent comparative analysis. The median follow-up time was 3.2 years. The surgical process for the simultaneous cardiopulmonary surgery is as follows: 1. Thoracoscopic wedge resection of the lung and frozen biopsy; 2. Start extracorporeal circulation and perform valve surgery; 3. Resume heartbeat after valve surgery; 4. Confirm pathological malignancy and decide whether to expand to lobectomy 5. Indwelling drainage tubes in the pericardium and chest cavity, completing the chest closure surgery.

Results: No perioperative death occurred in both groups. Pathological examination revealed that in simultaneous surgery group with the clinical stages of 1A in 29 (93.5%) patients, 2A in one patient and 2B in one patient. ALL of the sequential surgery group clinical staging was stage 1A. Among them, 40 patients received the radical pulmonary resection subsequently, whereas 8 patients were unable to receive it due to their poor cardiopulmonary function. Kaplan-Meier analysis of patients with the 3-year survival rate (OS) and lung cancer revealed progression-free survival (PFS) rate were 96.2% and 93.8%, respectively in simultaneous group.94.1% and 94.1% in sequential group. The average hospitalization cost for the simultaneous group is 238,112 RMB, while the average for the sequential group is 307,076 RMB.

Conclusions: Simultaneous pneumonectomy and cardiac valve surgery is a safe and economical method that can reduce anesthesia episodes, accelerate recovery, save costs, shorten waiting time, and reduce patient stress.

Keywords: lung resection, cardiac valve surge, safe and economical

EP.09B.03 Salvage Surgery Following Inductiontherapy for Advanced ALK-Positive NSCLC: Pathological Response and Surgical Outcomes

J-Y. Ding[1,2], C. Zhang[1,2,3], H-Z. Hong[1,2], Z-B. Qiu[1,2,3], Y-F. Qi[1,2], H-J. Li[1,2,3], Y-L. Wu[1,2], W-Z. Zhong[1,2,3], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China., Guangzhou/CN,[2]Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN,[3]School of Medicine, South China University of Technology, Guangzhou, China., Guangzhou/CN

Introduction: ALK-TKIs have dramatically changed clinical outcomes in patients with advanced ALK-positive non-small cell lung cancer (NSCLC). However, the persistent challenge of residual tumor presence remains significant. salvage surgery could be a therapeutic option. We aimed to describe the characteristics and outcomes of patients undergoing salvage surgery after targeted therapy for locally-advanced or metastatic ALK-positive NSCLC.

Methods: We retrospectively collected patients diagnosed with stage IIIA-IVB ALK-positive NSCLC at Guangdong Provincial People's Hospital between January 2016 and March 2024, and those were eligible who underwent pulmonary surgical resection after disease control with targeted therapy. Unidimensional measurements as defined by Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 were used in this study. Progress-free survival (PFS) defined as the duration from initial treatment to recurrence or metastasis and were estimated using the Kaplan-Meier method.

Results: A total of 79 patients were consecutively collected, consisting of 51 cases of stage III and 28 cases of stage IV. The median age at diagnosis was 47 years (interquartile range (IQR), 39-55 years), and the majority of patients(n=45,56.9%) were women. The median interval from treatment initiation to surgery was 155 days, with 1 patient achieved complete response (CR), 63 patients achieved partial response (PR) and 15 patients maintained stable disease (SD). Surgical procedures included pneumonectomy in 1.2% of patients, lobectomy in 68.4%, and sublobar resection in 30.4%. 8 patients required conversion to open thoracotomy during surgery. Pathological complete response and major pathological response, defined as 0% and <10% viable tumor cell in the resected tumor bed, respectively, were observed in 29.1% and 69.6% of cases. The median progress-free survival (PFS) time was 37 months. The common recurrence pattern was distant metastases (including 11 intracranial metastases and 2 bone metastases), 5 patients had both intrathoracic recurrence and distant metastases and 5 patients had intrathoracic metastases only.

Conclusions: Target therapy have revolutionized the paradigm of therapy advanced NSCLC with impressive pathological response and promising long-term results. In highly selected ALK-rearranged advanced cases, salvage surgery may have a role.

EP.09B.04 Neoadjuvant Chemo-Immunotherapy Followed by Radical Surgery for Synchronous Oligometastatic Non-Small Cell Lung Cancer

F.T. Gallina, F. Fusco, F.L. Cecere, R. Tajè, D. Forcella, L. Landi, G. Minuti, S. Buglioni, P. Visca, E. Melis, F. Facciolo, F. Cappuzzo, IRCCS Regina Elena National Cancer Institute, Rome/IT

Introduction: Synchronous oligometastatic NSCLC patients represent a category without a standard therapeutic approach. However, in selected oligometastatic patients, a radical treatment with curative intent seems to offer a good prognosis. Our retrospective analysis aims to analyze the feasibility of the radical multimodality treatment including chemo-immunotherapy in this specific subset of population.

Methods: The study was designed as a single-center, retrospective analysis of patients with synchronous oligometastatic NSCLC undergoing neoadjuvant treatment with platinum-based chemotherapy associated to immunotherapy followed by radical surgery between May 2020 and June 2023. The neoadjuvant treatment included immunotherapy (pembrolizumab or nivolumab) combined with platinum-based chemotherapy. Tumor response was assessed via CT scans, PET-CT and systematic mediastinal minimally invasive staging with EBUS-TBNA.

Results: From January 2020 to June 2023 a total of 11 patients underwent multimodality treatment for synchronous oligometastatic NSCLC. Median age at the diagnosis was 62 (4 - 71). A history of smoking was reported in all patients. Only one patient had a squamous cell histology. A PD-L1 > 50% expression was found in 3 patients. Six patients at the preoperative staging were cN2, of which 4 patients were classified as single-station cN2 after the minimally invasive mediastinal staging. All patients underwent 3 or 4 cycles of chemo-immunotherapy without any III or IV grade of toxicities related to the treatment. All the patients showed a R0 resection after primary tumor surgery. The most frequent site of metastasis was brain (nr=4) and contralateral lung (nr=4). Metastasectomy was performed in 10 patients. One patient with single, 5mm, brain metastasis showed a complete radiological response after neoadjuvant treatment. pCR was reported in 6 patients (54.5%). Five patients underwent adjuvant immunotherapy after surgical resection. After a medium follow up of 16.5 months, all the patients were alive without recurrence.

Conclusions: Neoadjuvant chemo-immunotherapy and radical surgical treatment seems to be safe and feasible in selected synchronous oligometastatic NSCLC with encouraging mid-term outcomes.

EP.09B.05 The Role of Pulmonary Metastasectomy (PM) For Non-Primary Lung Cancer: Umbrella Review of Meta-Analyses

W. Woo[1], B. Park[2], A. Ahadi[1], L.I-y. Chung[1], C.M. Jung[1], A. Bharat[1], Y.K. Chae[1], [1]Northwestern University Feinberg School of Medicine, Chicago/IL/USA,[2]University of Missouri-Kansas City School of Medicine, Kansas City/MO/USA

Introduction: The lungs are the most common metastatic area for many cancers. Due to heterogeneous characteristics of primary cancers, the efficacy of pulmonary metastasectomy (PM) in non-primary lung cancers has not been investigated other than colorectal cancers. Furthermore, conducting robust trials in this field are difficult to undertake due to the diverse nature of primary cancers and associated therapeutic approaches. This study aims to investigate the clinical outcomes of PM for non-primary lung cancer by synthesizing existing literature.

Methods: A systematic search for meta-analyses on PM for non-primary lung cancers was conducted, encompassing publications up to January 3, 2024. The analysis included seven primary cancer types: renal cell, breast, adrenocortical, head and neck cancers, melanoma, germ cell tumors, and sarcoma. Primary outcomes, overall survival, and recurrence rates post-PM were assessed using random-effect models to account for study heterogeneity. Subgroup analysis categorized the survival rates based on primary cancer types, and a proportion meta-analysis was performed for comparison.

Results: This study included 16 systematic-review articles and 101 individual studies, involving 10,277 patients who underwent PM for non-primary lung cancer. Patients had a mean age of 48.0 [95% CI 43.9-52.0] years, with 68.4% [95% CI 65.0-71.7] being male. About half of the patients (47.1% [95% CI 40.8-53.5] presented with multiple metastatic lesions, and 26.6% had bilateral involvement of lung. Sublobar resection was mostly performed (82%), and complete R0 resection achieved in 87.2% [95% CI 83.0-90.8]. The pooled 5-year overall survival (OS) rate post-PM was 41.2% [95% CI, 37.1-45.4%], with specific rates for each primary cancer type listed in Table 1. Patients with germ cell tumors demonstrated significantly higher survival rate than other cancers ($p<0.05$), while patients with melanoma exhibited the poorest outcome ($p<0.05$). During follow-up, 57.6% [95% CI 46.4-68.1] had recurrence; 48% of them had intrathoracic-only recurrence and 52% had extra-thoracic recurrence.

Conclusions: This study underscores the survival benefits associated with PM. Overall survival rates following PM do not significantly differ based on primary cancer types, except for germ cell tumors and melanoma. Additionally, the recurrence rates are comparable to those observed in stage 4 advanced cancers. These findings highlight the importance of recognizing and incorporating PM into clinical practice when appropriate.

EP.11A.01 Evaluation of Six Clinical Prognostic Scores in NSCLC Patients Undergoing First Line Chemoimmunotherapy

Y. Wang, J. Sun, L. Wang, L. Feng, Z. Fan, J. Han, X. Zhang, X. Zhou, D. Li, H. Jin, J. Liu, J. Zuo, The Fourth Hospital of Hebei Medical University, Shijiazhuang/CN

Introduction: Chemoimmunotherapy (CIT) has become the standard of first-line treatment for advanced non-small cell lung cancer (NSCLC) with negative driver genes. The study aimed to evaluate the effectiveness of six prognostic scores for predicting the outcomes to first-line CIT in NSCLC patients.

Methods: NSCLC patients receiving first-line chemoimmunotherapy were included. The prognostic scores evaluated were the Royal Marsden Hospital (RMH), MD Anderson Cancer Center (MDACC), MDACC + Neutrophil-to-Lymphocyte Ratio (NLR), MD Anderson Immune Checkpoint Inhibitor (MDA-ICI) scores, Lung Immune Prognostic Index (LIPI), and Gustave Roussy Immune Score (GRIm). Survival outcomes were estimated using the Kaplan-Meier method, and the prognostic value of these scores was assessed with Cox proportional hazards model.

Results: A cohort of 298 NSCLC patients was analyzed. The median overall survival (mOS) of patients receiving first-line CIT was 36.5 months (95% CI: NR-NR), and the median progression-free survival (mPFS) was 14.5 months (95% CI: 11.9-17.1). nivariate analysis showed that older age (≥ 65), poor performance status (PS≥1), and having more than two metastatic sites were correlated with worse OS (P<0.05). Similarly, the presence of bone, lung, and liver metastases, and more than two metastatic sites were associated with worse PFS(P<0.05). Multivariate analysis showed that PS≥1, bone metastases, and more than two metastatic sites as independent predictors of poor OS (P<0.05). Moreover, having more than two metastatic sites was an poor independent prognostic factor for PFS(P<0.05). Evaluation of the six prognostic scores revealed that the differences in mOS between high- and low-risk groups were statistically significant for RMH, MDACC, MDACC+NLR, and GRIm scores (RMH high- vs. low-risk mOS 20.6 months vs. NR, P=0.026; MDACC 14.0 vs. 34.6 months vs. NR, P=0.003; MDACC+NLR 34.6 vs. 36.5months, P=0.028; GRIm 15.8 vs. 36.5months, P=0.032). Similarly, high-risk patients had significantly shorter mPFS in three of the scoring systems (RMH high-risk vs. low-risk mPFS 8.7 vs. 15.3 months, P = 0.052; MDACC 8.4 vs. 11.2 vs.17.0 months, P = 0.021; MDACC+NLR 11.7 vs. 17.7 months, P = 0.009).

Conclusions: RMH and MDACC scoring systems can more accurately predict the efficacy and prognosis of NSCLC patients treated with first-line chemoimmunotherapy. These findings support the use of these scoring systems by clinicians to inform treatment planning and decision-making.

EP.11A.02 Pretreatment Plasma sCD14 as a Prognostic Indicator in aNSLC Patients Undergoing Immunotherapy

L. Dai[1], G. Fan[3], T. Xie[3], L. Tang[3], S. Yuankai[3], X. Han[4], [1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN,[3]Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN,[4]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN

Introduction: CD14+CD16-HLA-DRhi monocytes have been identified as robust prognostic indicators in metastatic melanoma patients undergoing immune-checkpoint blockade. However, the prognostic potential of secretory CD14 (sCD14) in plasma remains unexplored in advanced non-small-cell lung cancer (aNSCLC) patients receiving immunotherapy.

Methods: We collected 149 pretreatment plasma samples from aNSCLC patients undergoing anti-PD1 therapy at Cancer Hospital, Chinese Academy of Medical Sciences (CHCAMS) between 2016 and 2023. Using flow cytometry, we screened 41 cytokines to identify predictive markers distinguishing durable clinical benefit (DCB) from non-durable clinical benefit (NDB) patients (n = 40). An independent cohort (n = 109) validated candidate cytokines, and the prognostic value of sCD14 was confirmed through bulk-RNA sequencing (n = 16 and 27). Single-cell transcriptomic analysis compared signaling pathway enrichment between CD14+ and CD14- monocytes.

Results: Eight predictive cytokines (IL-17A, EGF, TNFR1, GFAP, CCL27, CCL5, CHI3L1, and CD14) were selected and validated, achieving baseline cytokine predictive efficacy with AUCs of 0.865, 0.755, 0.705, 0.726, 0.875, 0.749, 0.749, and 0.84. sCD14 exhibited significant prognostic value in progression-free survival ($p < 0.05$) in the validation cohort, with higher baseline sCD14 levels correlating with superior survival. CD14 expression was further validated in bulk-RNA seq datasets (GSE126044 and GSE135222) showing prognostic significance ($p < 0.05$). Comparative analysis of CD14 expression across 49 cell types revealed its enrichment in monocytes, with CD14-positive monocytes displaying elevated PDL1 (CD274) expression ($p = 0.014$, FC = 1.89) and enrichment in signaling pathways including INFLAMMATORY_RESPONSE, GLYCOLYSIS, and IL6_JAK_STAT3_SIGNALING.

Conclusions: This study identifies sCD14 as a potential biomarker for monitoring aNSCLC patients undergoing immunotherapy, with sCD14 emerging as a potent prognostic indicator. Additionally, CD14+ monocytes demonstrate enhanced PDL1 expression, suggesting their potential role in modulating immunotherapy response.

Keywords: immunotherapy, CD14, prognostic marker

EP.11A.03 Anti-PD-1 Therapy Plus Denosumab in Advanced Non-Small Cell Lung Cancer with Bone Metastases: A Single-Centre, Retrospective Study in China

J. Zhou, J. Qu, N. Liu, Q. Shen, J. Zheng, Y. Li, J. Zhou, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou/CN

Introduction: Basic studies and clinical studies have demonstrated that bone metastases may affect the efficacy of immunotherapy and concomitant anti-programmed cell death protein 1 (anti-PD-1) therapy and denosumab treatment can improve clinical outcomes of non-small cell lung cancer (NSCLC) patients with bone metastasis. However, limited data are available among Chinese patients, and the effect of this treatment combination on bone metastases has not been adequately studied.

Methods: This single-centre, retrospective study analysed NSCLC patients with bone metastases who received first-line anti-PD1-therapy and concomitant denosumab treatment between March 2021 and June 2022. Bone lesion response was evaluated using a novel quantitative method based on single photon emission computed tomography/computed tomography scans.

Results: 66 patients were included in the final analysis, the median follow-up was 20.08 months (range: 1.00, 46.43). The overall response rate was 36.4% (95% CI: 24.9%-49.1%), with 24 (36.4%) patients having partial response. The median progression-free survival (PFS) was 7.67 months (95%CI:6.20-12.80) and median overall survival(OS) was 20.40 months (95%CI:16.80,28.50). The OS rate (95% CI) was 96.9% (92.7%-100.0%) at 6 months and 79.7% (70.4%-90.2%) at 12 months. Out of 33 bone lesions identified, 28 had improved uptake values between consecutive bone scans (mean change in region-of-interest ratio: -32.7%±19.2%). 16 patients had decreased ROI ratios for all of their focal sites, the ORR of the 16 patients was 50.0% (95% CI: 24.7%-75.4%), the median PFS was 13.28 months (95% CI: 95%CI:7.47,NR), the median OS was 25.8 months (95% CI: 14.30,NR), the OS rate (95% CI) was 93.8 % (82.6%-100.0%) at 12 months.

Conclusions: This study provided further support for the concomitant use of anti-PD-1 therapy and denosumab in NSCLC patients with bone metastases. The novel, quantitative assessment method explored in this study may help inform a new, practical method for bone lesion assessment.

Keywords: NSCLC, denosumab, Anti-PD-1 therapy

EP.11A.04 Patterns of Failure and Subsequent Treatment after Progression on First-Line Immunotherapy Monotherapy in Advanced NSCLC

J-Y. Deng[1,2], M-Y. Yang[1], X-R. Yang[1], C-R. Xu[2], Q. Zhou[2], [1]School of Medicine, South China University of Technology, Guangzhou/CN,[2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN

Introduction: Immune checkpoint inhibitors (ICIs) became the recommended first-line therapy for advanced NSCLC without driver gene mutation, but the data about failure pattern of first-line ICIs monotherapy was lacking and the optimal strategy for subsequent treatment remained controversial.

Methods: Patients with advanced NSCLC and receiving first-line ICIs monotherapy at Guangdong Lung Cancer Institute between December 2017 and October 2021 were identified from an electronic database. The progressive sites were recorded to analyze the patterns of failure. Overall survival (OS) was compared between different regimens.

Results: A total of 121 patients receiving first-line ICIs monotherapy were identified, among whom 65 patients with available imaging at diagnosis as well as progressive disease were included in the patterns of failure analysis, and 50 patients with recorded second-line treatment were included in the subsequent treatment patterns analysis. For those with new lesions, progression frequently occurred in the liver (32.0%), LNs (16.0%), and bone (16.0%). As for those with failure in the existing lesions, the most common sites of progression were the liver (77.8%), lung parenchyma (62.5%), and pleura (50%). About 56.9% of patients showed oligoprogression, while the others had progression in more than 3 sites. Isolated oligoprogression occurs most often in the lung parenchyma and intracranial lesions, and more than half of these patients still received immunotherapy after local treatment, with a 2.5-year OS rate of 51.4%. The frequency of anti-angiogenesis therapy, chemotherapy, and immunotherapy used in the second-line therapy was 38.0%, 56%, and 74%, respectively. The application of anti-angiogenesis therapy could significantly prolong the OS (median: unreached vs. 13.5 months, P = 0.025). For those with progression in the liver, the application of anti-angiogenesis therapy could also prolong the OS (unreached vs 6.3 months, P = 0.067). Besides, the median OS of those with immunotherapy in the second-line setting was 21.3 months, which was numerically longer than those without immunotherapy (6.8 months, P = 0.089)

Conclusions: The liver was the most common site of progression on first-line ICIs monotherapy. Anti-angiogenesis-based therapy might be an optimal therapeutic regimen for a second-line setting. Isolated oligoprogressive patients might still benefit from immunotherapy after local treatment.

EP.11A.05 Use of Immune Checkpoint Inhibitors in Advanced NSCLC Cases with Very Poor ECOG-PS: A Real World Experience.

P.K. Singh, A. Ahuja, J. Grover, G. Arya, Pt BDS Post Graduate Institute of Medical Sciences, Rohtak/IN

Introduction: Approximately 50% non-small cell lung cancer (NSCLC) patients present with Eastern—cooperative-oncology-group performance status (ECOG-PS) ≥2. Chronic-obstructive-pulmonary-disease (COPD) and coronary-artery-disease (CAD) frequently contribute towards poor PS. Such cases are frequently excluded from the clinical trials, therefore leading to a dearth of safety or effectiveness data for ICI in this specific population. Due to poor PS, chemotherapy is often ruled out, leading to limited management options. Here we are presenting our experience of using immune checkpoint inhibitors (ICI) in patients with PS 3/4.

Methods: Data of all cases treated with ICI from the thoracic oncology clinic was retrieved from September 2022 to March 2024. Inclusion criteria were NSCLC with stage IIIB or higher and ECOG-PS 3 or 4. Demographic and clinical data was collected, coded and analysed. Progression-free survival (PFS) and overall survival (OS) were calculated.

Results: Out of 101 cases, data of 24 patients was retrieved and analysed. Majority subjects were males (83.3%), smokers (79.2%), with COPD (62.5%), squamous histology (66.7%), stage IVA (45.8%), and PDL1 between 1-49% (41.7%). Disease burden contributed to poor PS in majority of subjects (45.8%) followed by comorbidities (37.5%). Mean age was 61.75±10.2 years. ECOG at the time of ICI initiation was 3 in 83.3% and most had previously received one (45.8%) or two (33.3%) lines of therapy. Nivolumab (70.8%) and atezolizumab (29.2%) were the two ICIs used. 20.8% had brain metastasis at the time of ICI initiation and 41.7% had history of prior radiotherapy treatment (any site). Over a median follow-up of 20 weeks, 14 (58.3%) progressed and (33.3%) died. Three patients experienced hypothyroidism, one had pneumonitis and one patient had Grade 3 transaminitis. Median PFS was 24 (IQR 8-40) weeks, whereas median OS was 44 (IQR 24-64) weeks. Best response was Partial Remission in 25%, whereas Stable Disease was achieved in 45.8%. Neither PFS nor OS was significantly different among the groups stratified according to stage, histology, ECOG, type of ICI used, comorbidities, line of therapy or PDL1 Status. Of the 14 progressed, ICI was continued beyond progression in 10. An improvement in ECOG-PS of minimum one unit, was documented in 8 subjects. Quality of life data was not collected.

Conclusions: ICI remain a viable treatment option in patients of advanced NSCLC with very poor ECOG-PS. The relative safety of ICI over chemotherapy may provide an additional tool to Best Supportive Care treatment recommendation for this specific subgroup.

EP.11A.06 Somatic Gene Changes Associated with Response to Immune Checkpoint Inhibitors in Non-Small Cell Lung Cancer

A.G. Pachimatla[1], S. Kalvapudi[1], S. Bawek[2], Y. Vedire[1], P. Jain[1], S. Yendamuri[1], S. Patnaik[1], [1]Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA,[2]University of Buffalo, Buffalo/NY/USA

Introduction: While immune checkpoint inhibitors (ICI) have altered the paradigm for treating lung cancer, the long-lasting benefit of ICI therapy remains limited to too few of those who receive it. We examined if somatic changes in genes influence ICI response.

Methods: Response to ICI according to RECIST 1.1 guideline and tumor gene changes were noted from CT imaging, pathology, and other clinical records of 550 primary non-small cell lung cancer patients who received ≥ three doses of ICI within six months at our institution during 2015-23.

Results: Tumors of 277 patients had somatic changes in 1-46 genes (median = 3) as per FoundationOne or OmniSeq tests for 22-368 genes (median = 67) performed before or within 30 days of ICI treatment. Of the total 1,654 changes affecting 340 genes, 1,410 were protein-coding (272 patients), 166 copy loss (72), 35 copy gain (42), 13 fusion (seven), and 1 splicing (one). The fraction of tested genes that had changes was greater in non-Caucasians compared to Caucasians (median 7% vs. 5%, Wilcoxon p=0.041), and in PDL1-low compared to PDL1-high tumors (6% vs. 4%, p = 0.049), but not significantly associated with age, sex, race, smoking status, BMI, cancer histology, or ICI response (partial/complete or not) or adverse events. Among the 72 genes that were tested in > 100 patients, the prevalence of somatic change (0.4%-59%) was highest for TP53 (59%), KRAS (40%), CDKN2A (21%), APC (14%), and ATM (13%). Among the 28 genes (Figure) that were changed in ≥ 10 patients, ICI response was less likely for those with changes in NF1 (21/24 vs. 170/250, p=0.047), SMAD1 (21/24 vs. 170/250, 0.047), and TSC1 (10/10 vs. 146/217, 0.03), but not the other genes, including KRAS (70/111 vs. 121/165, 0.07), STK11 (19/30 vs. 173/247, 0.50), and TP53 (108/163 vs. 84/115, 0.20). In the PDL1-low group (n=138), significant associations with lack of response were noted for NF1 (12/12 vs. 91/125, 0.04) and STK11 (12/21 vs. 91/117, 0.045). For the PDL1-high group (n=118), somatic change in only TSC2 was associated with a lack of response (0/4 vs. 51/79, 0.02). Patients with variation in both KRAS and TP53 were 1.7 times more likely to respond to ICI than others (22/47 vs. 63/229, p=0.009).

Conclusions: KRAS, NF1, STK11, TP53, and TSC1/2 genes may be of high relevance to identify NSCLC patients who are more likely to respond to ICI and to understand the biology of such responsiveness.

EP.11A.07 Immunotherapy in Metastatic Pulmonary Lymphoepithelioma-Like Carcinoma

C.Y.R. Ho, K.M. Cheung, J.C.H. Chow, H.H.Y. Yiu, Queen Elizabeth Hospital, Hong Kong/HK

Introduction: Pulmonary lymphoepithelioma-like carcinoma (pLELC) is a rare subtype of non-small cell lung cancer. With the increasingly dominant role of PD1/PDL-1 checkpoint inhibitor in the treatment landscape of NSCLC, chemotherapy remained the current mainstay approach of systemic treatment for pLELC due to the under-representation of pLELC in major NSCLC IO trials. A body of efficacy data of immunotherapy (IO) in pLELC needs to be accumulated.

Methods: A single tertiary-institution cohort study was conducted to include all patients with recurrent or metastatic pulmonary pLELC in 2010-2023 who received IO in an institutional cancer registry. Patient demographics and clinical characteristics were described and analyzed. Progression-free survival (PFS) and overall survival (OS) were estimated by the Kaplan-Meier method. Comparison of the survival end points were made using the log-rank test.

Results: Two-hundred pLELC patients were identified in database. Twenty-six patients received IO (M=6, F=20), median age was 65 (range 40-80), with 21 (80.3%) were non-smokers. Eight patients underwent IO in 1st line and 18 patients in 2nd line or beyond. PD-L1 tumor proportional score (TPS) were >/= 50% in 23% of patients. None of them had targetable driver mutation of EGFR, ALK and ROS-1. The immunotherapy used in 1st line were mainly pembrolizumab(pembrolizumab =7, atezolizumab = 1). Only 2 patients were given IO-chemotherapy combination. In 2nd line and beyond, 11 patients used nivolumab and 7 used atezolizumab. The response rate was 15.4% and the median PFS for immunotherapy used in 1st line and 2nd line or beyond was 8.63 and 3.50 months respectively. The median OS for immunotherapy used in 1st line and 2nd line or beyond was 26.3 and 8.23 months. An exploratory analysis in subsequent line patients shows trend towards longer median PFS and OS for patients receiving atezolizumab than nivolumab (mPFS 7.73 vs 3.50 months, p=0.231; mOS 22.2 vs 8.00 months, p=0.114). There was 1 patient (3%) complicated with G3 dermatitis.

Conclusions: The observed mPFS and mOS in our cohort of pLELC treated with immunotherapy were numerically similar to those observed in major NSCLC trials, including KEYNOTE-024, Checkmate 057 and OAK. As driver mutation was rarely seen in pLELC, IO monotherapy or combination could become the mainstream treatment as in NSCLC lacking driver mutation.

EP.11A.08 Real-World Comparative Effectiveness in Advanced NSCLC and High PD-L1 with 1L Immune Checkpoint Inhibitors ± Chemotherapy

M.L. Hsu[1], Q. Xia[2], S. Aggarwal[2], E. Nkhoma[2], D. R[2], T. Hager[2], R. Quek[2], J. Feliciano[3], [1]University Hospitals, Cleveland/OH/USA,[2]Regeneron Pharmaceuticals, Inc., Tarrytown/NY/USA,[3]Johns Hopkins Bayview Medical Center, Baltimore/MD/USA

Introduction: Immune checkpoint inhibitors (ICIs) ± chemotherapy is currently the recommended treatment for patients with advanced NSCLC (aNSCLC) and programmed cell death-ligand 1 (PD-L1) ≥50%. The objective of the study was to compare real-world clinical outcomes among patients with aNSCLC and PD-L1 ≥50% treated with ICI monotherapy or in combination with chemotherapy in the first-line (1L) setting.

Methods: The ConcertAI Oncology Database was used to identify patients in the United States with aNSCLC with PD-L1 ≥50% prior to initiating 1L ICI+chemotherapy or ICI monotherapy up to 30 days post-treatment between May 2017 and February 2023. We characterized real-world (rw) response rate (rwRR), overall survival (rwOS), progression-free survival (rwPFS), time to discontinuation (rwTTD), and time to next treatment (rwTTNT). Time-to-event outcomes were assessed using Kaplan-Meier methods after applying inverse probability of treatment weighting (IPTW). Differences in outcomes across patients initiating ICI+chemotherapy or ICI monotherapy were assessed using Cox regression with IPTW to adjust for potential key confounders, including clinical and demographic characteristics; unbalanced covariates were added to the Cox model. Statistical significance was interpreted using 95% CIs.

Results: We identified 1,384 eligible patients, of whom 65% initiated ICI monotherapy and 32% started ICI+chemotherapy. The mean age was 70 years (SD: 9.5) and 51.4% of patients were male; most had adenocarcinoma (63.0%) or squamous cell carcinoma (22.5%). After performing IPTW, key confounding variables were generally well balanced between the ICI monotherapy and ICI+chemotherapy groups. The rwRR was 48.1% (95% CI: 42.4-53.8%) and 39.4% (95% CI: 35.7-43.2%) among patients initiating ICI with and without chemotherapy, respectively, yielding an adjusted odds ratio for response of 1.42 (95% CI: 1.08-1.89). The median rwOS was 19.3 months (95% CI: 15.7-24.4) and 15.9 months (95% CI: 13.5-19.1) among patients who received ICI with and without chemotherapy, respectively, yielding an adjusted hazard ratio (aHR) for death of 0.85 (95% CI: 0.72-1.01). Additionally, ICI+chemotherapy was associated with longer rwPFS with an aHR for disease progression or death of 0.54 (95% CI: 0.42-0.69). No differences were observed in rwTTD and rwTTNT across the 2 groups. See Figure 1 for results.

Conclusions: We observed significantly higher rwRR and rwPFS among patients who received ICI+chemotherapy compared with ICI monotherapy. No significant differences in the rwOS, rwTTD, and rwTTNT between patients on ICI+chemotherapy and ICI monotherapy were observed. Further research is needed to understand patient characteristics associated with benefit from each treatment modality.

EP.11A.09 Predictive Role of BMI and Inflammation Markers in Immunotherapy (ICI) For HIV Associated Lung Cancer

A.E. Cali Daylan[1], J. Song[2], S.Y. Kim[3], E. Lin[4], L. Deng[5], M. Ginsberg[6], B. Halmos[1], H. Cheng[1], [1]Montefiore Einstein Comprehensive Cancer Center, Bronx/NY/USA,[2]Jacobi Medical Center, Bronx/NY/USA,[3]Yale School of Medicine, New Haven/CT/USA,[4]Providence Health, Portland/OR/USA,[5]University of Washington, Seattle/WA/USA,[6]Albert Einstein College of Medicine, Bronx/NY/USA

Introduction: Historical exclusion of HIV patients(pts) from ICI trials limits data on predictive markers which may differ from HIV negative counterparts due to altered immune activation and inflammation. Inflammation markers are implicated as predictive in ICI treated solid tumors with various optimal cut offs. Here, we study the predictive role of and the optimal cut off for inflammation markers in HIV associated lung cancer treated with ICI.

Methods: Baseline characteristics and survival outcomes for 53 pts with HIV associated advanced lung cancer diagnosed between 2011-2023 treated with ICIs in first or subsequent lines were analyzed. Receiver operator characteristics curve was employed to determine ideal cut offs for systemic inflammation index (SII = neutrophils (N) /lymphocytes (L) x platelets (P)), monocyte-lymphocyte ratio (MLR) and PLR. The optimal cut offs were 874 for SII, 0.6 for MLR, 295 for PLR. Cox regression analysis was conducted to assess the association of body mass index (BMI), NLR, SII, MLR and PLR with overall survival (OS).

Results: 32 pts received ICIs; 21 pts received chemotherapy (CT) exclusively. The baseline characteristics of age, gender, stage, histology, race/ethnicity and ECOG performance status (PS) were balanced. The median age was 57 and 61 years, with 67% and 66% self-identifying as non-Hispanic Black and 29% and 25% as Hispanic in the CT and ICI groups, respectively. The median follow up was 12 months. 84% had HIV viral load < 200 copies/mL, and 86% had median CD4 count > 200 cells/μL. Median PD-L1 TPS (22c3) was 1, the objective response rate was 27% with a disease control rate of 59% in the ICI group. Low BMI and poor ECOG PS were strongly associated with shorter OS and high SII was associated with longer OS in the ICI cohort in univariate and multivariate analyses controlling for age and gender. In comparison, only high MLR and PLR were associated with longer OS in the entire cohort. PD-L1 TPS and CD4 count were not associated with OS in the ICI cohort.

Conclusions: Our study focusing on HIV associated lung cancer reveals that BMI and SII are strongly associated with survival outcomes exclusively in the ICI treated cohort. Given the lack of correlation between PD-L1 expression and clinical outcomes, better predictive biomarkers are necessary. Addition of inflammation markers identified in this study, when validated in larger studies, may assist in refined prediction of survival in ICI treated HIV associated lung cancer.

EP.11A.10 Chronological and Biological Age as a Response Factor to Immune Checkpoint Inhibitors in Advanced Non-Small Cell Lung Cancer

G. Suay[1], A. Ortiz-Gracia[1], C. Rodrigo[2], J. Linares[1], J-C. Garcia-Cañaveras[2], A. Armero[2], F. Aparisi[2], A. Lahoz[1], O. Juan-Vidal[1], [1]University and Polytechnic La Fe Hospital, Valencia/ES,[2]Health Research Institute Hospital La Fe, Valencia/ES

Introduction: Immune checkpoint inhibitors (ICIs) have radically changed the prognosis of patients with non-small cell lung cancer (NSCLC) by increasing the overall survival (OS). However, some doubts exist regarding special populations such as elder patients, which show less benefit to different ICIs in different subgroup analyses of approbatory trials. It has been suggested that this may be a consequence of immunosenescence. However, the elder population was underrepresented in those trials, and there is scarce real-world data.

Methods: Our study aimed to retrospectively analyze the baseline characteristics and overall survival (OS) according to age in patients with advanced NSCLC who received first-line ICIs. Patients were treated in a tertiary reference Hospital in Spain from January 2016 to December 2024. The cohort was also stratified based on the number of comorbidities as a surrogate marker of biological age.

Results: 247 patients with advanced NSCLC, candidates to ICIs, were included into the study (Table 1). No statistically significant difference in median OS was observed when comparing patients with <70 years old and patients with ≥70 years old (18 vs 15 months; p=0.270) (Figure 1A). The analysis of median OS stratified by comorbidities (as a surrogate of biological age) showed statistically significant differences in patients who had 0-2 comorbidities, compared with patients who had ≥3 comorbidities (28 months vs 13 months; HR= 0.697; p=0,04) (Figure 1B).

Conclusions: Our study shows that there are no statistically significant differences in OS stratified by chronological age. However, when considering the number of comorbidities as a surrogate of biological age, median OS was worse in patients who had ≥3 comorbidities. Biological age might be a key factor regarding response to ICIs treatment. Further research should be done to better understand the immunosenescence process, and to personalize treatments to each patient.

EP.11A.11 Application of Circulating Tumor Cell (CTC) PD-L1 Detection in the Evaluation of Therapeutic Efficacy in Advanced NSCLC: A Retrospective Study

Y. Deng[1], Y. Huang[2], S. Cai[1], Z. Yu[1], X. Guo[1], [1]Shenzhen Cancer Hospital, Shenzhen/CN,[2]Cellomics shenzhen, Shenzhen/CN

Introduction: PD-L1 shows a dynamic expression profile during therapies. It is affected by intratumoral heterogeneity, leading to different responses to immune checkpoint inhibitors (ICIs), but the invasiveness and risks of tissue biopsy make longitudinal sampling challenging and almost unfeasible. Our study aims to analyze the consistency between CTC PD-L1 liquid biopsy and pathological tissue PD-L1, to explore whether the CTC PD-L1 can screen the beneficiaries of immunotherapy, and to assess the predictive value of CTC on treatment response and prognosis.

Methods: Sixty-four patients newly diagnosed with advanced-stage NSCLC who undergo PD-L1 immunohistochemical detection were recruited in our institute from February 2022 to April 2024. CTCs were captured and identified from the peripheral blood of enrolled patients through the microfluidic chip-based CTC screening platform CTC100. CTC and CTC PD-L1 expression were dynamically evaluated at baseline, on treatment, and disease progression.

Results: CTCs and PD-L1(+) CTCs were detected in 57/64 (89%) and 44/57 (77.2%) patients at baseline. The mean and median values of baseline CTCs were 10 and 7, respectively. Thirty-one of 51 patients (60.8%) with available immunohistochemistry (IHC) PD-L1 results presented positive PD-L1 expression (TPS>1%). Among the 47 comparable samples, the overall coincidence rate of PD-L1 status between the tissue sample and CTC was 70.2%, with a positive concordance rate of 93.1% and a negative concordance rate of 33.3%. The positive predictive value (PPV) and negative predictive value (NPV) of CTC PD-L1 were 69.2% and 75%, respectively. In the current incomplete clinical follow-up, we obtained preliminary results worth further exploration. We found that the disease control rate was lower for patients with high CTC levels (Figure1A), and patients with CTC PD-L1 positive expression at baseline have no less response to immunotherapy than those with tissue PD-L1 positive expression (Figure1B).

Conclusions: CTC PD-L1 has a high consistency with immunohistochemical PD-L1. Detection of PD-L1 expression on CTC before treatment is an alternative approach to help therapy decisions. Serial biopsies of CTC may enable treatment response monitoring on immunotherapy.

EP.11A.12 Real-World Treatment Patterns and Clinical Outcomes Following Chemotherapy and Anti-PD-(L)1 In Non-Small Cell Lung Cancer

V. Velcheti[1], J. Moore[2], H. Wang[2], X. Zhu[2], Y. Samyshkin[3], T. Ward[3], A. Christensen[4], C. Solem[5], [1]NYU Langone Perlmutter Cancer Center, New York/NY/USA,[2]GSK, Collegeville/PA/USA,[3]GSK, Brentford/GB,[4]GSK, Lakeville/MN/USA,[5]GSK, Bethesda/MD/USA

Introduction: Effective treatment options for advanced/metastatic non-small cell lung cancer (NSCLC) are limited, especially for those with progression after platinum-based chemotherapy (PBC) and an anti-programmed cell death 1 protein (PD-1) or ligand 1 (PD-L1) regimen. We report real-world treatment options and associated outcomes, including time to treatment discontinuation (TTD), progression-free survival (PFS), and overall survival (OS) in US patients who previously received PBC and anti-PD-(L)1 regimens.

Methods: This study used data from the nationwide Flatiron Health electronic health record-derived deidentified database. Patients were aged ≥18 years with an initial diagnosis of advanced/metastatic NSCLC and an ECOG performance status of 0 or 1 who had received PBC and anti-PD-(L)1 therapy in 1 (in combination) or 2 (in sequence) lines and initiated ≥1 subsequent treatment between 2018 and 2023. The index date was the start date of subsequent treatment (defined as the index regimen). Patients were followed up until death or last available data through June 30, 2023. Patient characteristics, treatment patterns, and outcomes were analyzed in the overall patient group and according to initial treatment (cohort 1: first-line PBC + anti-PD-(L)1; cohort 2a: first-line PBC and second-line anti-PD-(L)1; or cohort 2b: first-line anti-PD-(L)1 and second-line PBC). Subgroup analyses were stratified by index regimen, without adjustment for differences between groups. TTD, PFS, and OS were estimated using Kaplan-Meier methods.

Results: A total of 1793 patients were included: 73.5% in cohort 1, 22.5% in cohort 2a, and 4.1% in cohort 2b. Median follow-up from index date was 7.8 (range, 0.0-65.0) months. A broad range of treatments were used after PBC and anti-PD-(L)1 regimens; among all patients, the most common were docetaxel + ramucirumab and docetaxel monotherapy (Table 1). Median TTD, PFS, and OS were similar across cohorts. Compared with outcomes in the overall population, median TTD (2.63 [95% CI, 2.10-3.02] months), PFS (4.17 [3.61-4.57] months), and OS (7.89 [7.10-8.71] months) were shorter in patients who received chemotherapy monotherapy as index therapy, including docetaxel and gemcitabine monotherapies. Median TTD (5.59 [4.40-8.77] months), PFS (8.71 [5.88-12.85] months), and OS (26.97 [20.37-31.74] months) were longer in those receiving index immuno-oncology monotherapy.

Conclusions: Short median TTD, PFS, and OS underscore a significant unmet need among patients previously treated with PBC and anti-PD-(L)1, particularly among those subsequently treated with chemotherapy monotherapy. Further investigation of novel modalities to extend survival, including immuno-oncology combinations, is warranted in this patient population.

EP.11A.13 Efficacy and Safety of Immune-Checkpoint Inhibitors in Advanced NSCLC Patients with Rare Mutation after Developing Targeted Therapy Resistance

W. Zhang[1], Y. Li[1], H. Jiang[1], D. Wang[1], B. Liu[1], F. Qian[1], B. Zhang[1], Y. Zhang[1], R. Li[2], W. Ma[2], B. Han[1], Y. Lou[1], [1]Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/CN,[2]Department of Clinical Research Center, Shanghai Chest Hospital, Shanghai/CN

Introduction: Efficacy and safety of Immune-checkpoint inhibitor (ICI) in patients with non-small cell lung cancer (NSCLC) harboring rare molecular alterations after developing targeted therapy resistance remain poorly elucidated.

Methods: We retrospectively collected the statistics of NSCLC patients carrying rare oncogenic driver mutations who treated at Shanghai Chest Hospital between June 1st, 2018 and December 31th 2022. Progression-free survival (PFS) and overall survival (OS) were utilized to evaluate the outcomes of this study.

Results: A total of 375 patients were included. Up to July 15th 2023,the median follow-up time was 25.1 months (IQR, 6.2-63.6 months). The molecular alterations involved EGFR rare mutation (n=141, 37.6%), ALK rearrangement (n=107, 28.5%), ROS1 rearrangement (n=86, 22.9%), MET amplification or exon 14 mutation (n=27, 7.2%), BRAF V600E mutation (n=14, 3.7%). Survival analysis indicated that when exclude patients with ALK rearrangement, patients treated with immunotherapy in the post-line had better overall survival (OS) and Progression-free survival (PFS) compared with those treated with other treatments (median OS, 31.3 vs. 23.5 months, P<0.001; median PFS, 4.9 vs. 9.2 months, P<0.001)(Figure 1 and Figure 2). What's more, high level PD-L1 expression status can not demonstrate better PFS in patients received immunotherapy after developing targeted therapy acquired resistance. From 375 patients with available data, 33 (8.8%) had grade 3-5 irAEs, including 21 (5.6%) of grade 3,11(2.9%) of grade 4, and 1 of grade 5 (0.3%, endocrine di-sorder).

Conclusions: Our study implies that immune checkpoint inhibitor-based treatment may provide more favorable survival for these patients than other treatments, while patients with ALK rearrangement seems to benefit more from targeted therapy in post-line. The recording of significant (grades3 and 4) irAE was optional. What's more, PD-L1 expression status was not associated with the prognosis of these patients.

EP.11A.14 Impact of Immune-Related Adverse Event Severity on Overall Survival in Patients Receiving PD-1/L1 Therapy, with a Focus on Combination Regimens

M. Sugai, Y. Amino, K. Miyadera, R. Tsugitomi, R. Ariyasu, K. Uchibori, S. Kitazono, N. Yanagitani, M. Nishio, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo/JP

Introduction: Anti-PD-1/L1 antibody (PD-1/L1) plays a crucial role in the treatment of non-small cell lung cancer (NSCLC) lacking driver mutations, with combination therapies involving chemotherapy (CT) and/or anti-CTLA4 antibody (CTLA) becoming standard. While these treatments may lead to immune-related adverse events (irAEs), studies have demonstrated a link between irAEs and treatment efficacy. However, the impact of severe irAEs on the overall survival (OS) of patients undergoing PD-1/L1 therapy, particularly in combination regimens, remains underexplored.

Methods: We conducted a retrospective analysis of patients diagnosed with advanced or recurrent NSCLC who received PD-1/L1 therapy, including PD-1/L1 alone, PD-1/L1 with CT, and PD-1/L1 with CTLA ± CT between January 2018 and December 2022. Toxicity was assessed using CTCAE version 5.0, categorizing irAE severity into two groups: severe (Grade 3-5) and mild (Grade 1-2). We assessed the association between irAEs and OS using Kaplan-Meier analysis and the log-rank test was used to compare survival curves. Significant differences were defined by p values < 0.05.

Results: Of the 256 enrolled patients, 59 (23%) experienced severe irAEs, 88 (34%) had mild irAEs, and 109 (43%) had no irAEs. The median OS for patients with mild irAEs was significantly longer than for those with no irAEs (33.6 months; 95% CI, 24.6-40.3 vs. 16.6 months; 95% CI, 12.3-23.6, P=0.0146). Conversely, patients with severe irAEs had a shorter median OS (13.3 months; 95% CI, 9.0-21.4) compared to those with no irAEs. The relationship between irAE severity and OS by regimen is presented in the table.

Conclusions: Whether in PD-1/L1 monotherapy or combination therapy, patients with mild irAEs exhibited longer OS, while patients with severe irAEs showed either no significant difference or shorter OS compared to those with no irAEs.

EP.11A.15 NSCLC-ClustOpt: A Semi-Supervised Optimized Clustering to Stratify Patients with NSCLC on Immune Checkpoint Blockers Therapy

F. Paoloni[1], F. Pecci[1], G. Bruschi[2], E. Tola[3], A. Sbrollini[2], T. Galassi[1], A. Borgheresi[3], V. Cognigni[1], L. Cantini[4], K.S. Saini[4], L. Santamaria[5], M. Gualtieri[1], V. Lunerti[1], M. Di Pietro Paolo[1], P. Mazzanti[1], V. Agostinelli[1], A. Agostini[3], G. Mentrasti[1], A. Giovagnoni[3], L. Burattini[2], R. Berardi[1], [1]Department of Medical Oncology, Università Politecnica delle Marche, AOU delle Marche, Ancona/IT,[2]Department of Information Engineering, Università Politecnica delle Marche (UNIVPM), Ancona, Italy, Ancona/IT,[3]Department of Clinical, Special, and Dental Sciences (DISCO), Università Politecnica delle Marche (UNIVPM). Department of Radiological Sciences, Azienda Ospedaliero Universitaria delle Marche, Ancona/IT,[4]Fortrea Inc., Durham/NC/USA,[5]Università Politecnica delle Marche (UNIVPM), Faculty of Medicine and Surgery, Ancona/IT

Introduction: Immune checkpoint inhibitors (ICIs) have improved the clinical outcomes of patients affected by advanced non-oncogene addicted non-small cell lung cancer (NSCLC). The aim of our study is to develop a semi-supervised optimized K-means clustering algorithm (ClustOpt) to prognostically stratify patients with advanced NSCLC treated with ICIs based on baseline features.

Methods: Data extraction involved, retrospectively, patients with advanced NSCLC treated with ICIs at Department of Medical Oncology, Ancona. Baseline body mass composition (BC) was assessed through computed tomography (CT) scan at L3 level, abstracting subcutaneous and visceral fat and muscle mass indicators. Moreover, baseline clinicopathologic features, nutritional status through The Controlling Nutritional Status (CONUT) score, and comorbidities were collected. A semi-supervised clustering analysis (ClustOpt) was employed to identify two groups of patients with different outcomes in terms of progression-free survival (PFS) and overall survival (OS). Then, we assessed whether these two groups had different BC phenotype. ClustOpt was implemented by optimizing the initial centroid's position with Particle Swarm Optimization algorithm. The cost function used for optimization is the time warp distance between the survival curves associated to the 2 generated clusters. The model was developed in Python on-cloud using the Google Colab service.

Results: A total of 50 patients with complete baseline data available were included in the final analysis. The two generated clusters of patients were cluster 1 (n=22) and cluster 2 (n=28) (Table).

The two clusters detained different clinical outcomes: median PFS was 24.4 months for cluster 1 and 7.1 months for cluster 2 (HR 0.38, 95%CI 0.18-0.75, p=0.01), and median OS was 41.8 months for cluster 1 and 13.3 months for cluster 2 (HR 0.43, 95%CI 0.21-0.89, p=0.02). After that, we investigated whether these two prognostically different clusters had differences in terms of BC phenotype assessed by CT scan at baseline. Compared to patients in cluster 2, patients in cluster 1 showed higher median lean psoas muscle area (1449.2 versus 1025, p=0.003), higher median psoas muscle index (7.2 versus 5.2, p=0.004) and lower median intramuscular adipose tissue content (-0.2 versus -0.1, p=0.04).

Conclusions: By using easy to obtain and reproducible baseline clinicopathologic features, employing semi-supervised clustering, we were able to stratify patients with advanced NSCLC in two groups with different prognosis in terms of PFS and OS, under ICIs. Moreover, we showed that also BC phenotype was different in the two groups, with better muscle mass indicators in the group with longer survival.

EP.11A.16 Infusion Timing of ICI Monotherapy in Patients with Advanced NSCLC: A Single Institution-Retrospective Study

R. Tagawa[1], S. Takemoto[1], H. Gyotoku[1], H. Taniguchi[2], M. Matsuo[1], H. Tomono[1], K. Akagi[1], S. Ono[1], F. Hayashi[1], T. Fukuda[1], H. Mukae[1], [1]Nagasaki University Hospital, Nagasaki City/JP,[2]Nagasaki University Hospital,, Nagasaki City/JP

Introduction: The prognosis of non-small cell lung cancer (NSCLC) patients is still reported to be poor. Immune checkpoint inhibitors (ICIs) has caused a paradigm shift in the treatment of NSCLC, but its efficacy is limited. It is necessary to enhance the efficacy of ICI treatment. Recently, several studies suggested that infusion timing of ICI affected the efficacy. In this study, we investigated the association between clinical outcomes and infusion timing of immune checkpoint inhibitor monotherapy in patients with advanced NSCLC.

Methods: Patients who received at least 4 ICI monotherapy in any line between 2016 and 2022. The study population was split into two groups according to the timing of the initial 4 ICI infusions. Early group was defined as patients received 2 to 4 infusions starting before 11:45am and non-early group was defined as except for early group. Progression-free survival (PFS) and overall survival (OS) were analyzed according to each group.

Results: Eighty-five consecutive patients who received ICI monotherapy were screened and 50 patients were received at least 4 ICI monotherapy. Non-early group included 17 patients and early group included 33 patients. Although there was no significant difference about characteristics in the two groups, early group tended to contain more PS 0, more pretreatment, more adenocarcinoma and more women. PFS tended to be better in early group than non-early group (median PFS: 11 months vs 6.5 months, HR: 0.74(95%CI, 0.32-1.33). OS tended to be also better in early group than non-early group (median OS: 39.3 months vs 15.9 months, HR: 0.62(95%CI, 0.24-1.41).

Conclusions: Although there was no significant difference due to lack of power, there was a trend toward better PFS and OS in early group. It was suggested that ICI should be administered in the morning. Prospective intervention study is needed.

EP.11A.17 Efficacy and Influencing Clinical Factors of Tislelizumab Combined with Chemotherapy Plus Bone-Targeted Agents for NSCLC Bone Metastasis

Y. Wang, X. Zhang, S. Xu, Department of Medical Oncology,The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou/CN

Introduction: About one-third of advanced non-small cell lung cancer patients still experience bone metastasis. Bone-related events can affect quality of life and the efficacy of metastatic NSCLC patients remained to be improved according to bone metastatic status. This study was aimed to evaluate the efficacy and influencing clinical factors of tislelizumab combined with chemotherapy plus bone-targeted agents as first-line therapy for NSCLC patients with bone metastasis.

Methods: This study prospectively recruited 29 eligible untreated NSCLC patients with bone metastasis. These patients received 4-6 cycles of tislelizumab combined with chemotherapy plus one of bone-targeted agents like denosumab, Ibandronate, followed by tislelizumab plus bone-targeted agents maintenance therapy until progression. The primary endpoints include progression free survival, object response rate, disease control rate by RECIST1.1. The secondary endpoints include overall survival, safety outcomes and influencing clinical factors etc.

Results: As of Mar 2024, 29 pts with stage IV NSCLC with bone metastasis were included by a median age of 65 (range 55-78) years, and 80% males. The median PFS of total population was 9.6 months, the overall ORR and DCR were 65.5 %, and 86.2%, respectively. For the influencing clinical factors, we found that PLR(the ratio of platelet -to-lymphocyte)≥200 was associated with significantly lower PFS(p=0.086), however, the NLR(the ratio of neutrophil-to-lymphocyte)≤5 was associated with a trend for longer PFS(p = 0.240). For the safety outcomes, mild immune-related AEs such as rash, pruritus,hypothyroidism, pneumonitis were experienced and none ≥3irAE occurred.

Conclusions: This study demonstrated that tislelizumab combined with platinum-based chemotherapy plus bone-targeted agents is a promising option in the first line therapy for advanced NSCLC patients with bone metastasis and baseline levels of NLR and PLR were important and associated with PFS outcomes of immunotherapy.

EP.11A.18 LUMINATE 101-Maccabi: Real-World Study of Treatment Patterns and Clinical Outcomes in Patients with Mnsclc in an Israeli HMO

J. Bar[1,2], S.S. Moser[3], A. Zer Kuch[4], N. Passwell[5], M. Hoshen[3], H. Alhasani[5], A. Virani[5], N. Daaboul[6], Q. Xu[5], S. Gazit[3], [1]Institute of Oncology, Sheba Medical Center, Ramat Gan/IL,[2]Faculty of Medicine, Tel Aviv University, Tel Aviv-Yafo/IL,[3]KSM Institute for Research and Innovation, Maccabi Healthcare Services, Tel Aviv-Yafo/IL,[4]Rambam Health Care Campus, Haifa/IL,[5]AbbVie Inc., North Chicago/IL/USA,[6]Integrated Cancer Center, Charles-Le-Moyne Hospital, Université de Sherbrooke, Quebec/QC/CA

Introduction: Most patients with non-small cell lung cancer (NSCLC) progress on first-line (1L) treatment, including those treated with immunotherapy (e.g., programmed death receptor 1 and programmed death-ligand 1 [PD(L)1] inhibitors). Limited effective therapies are available in second-line (2L)+, presenting an unmet need. The LUMINATE-101-Maccabi study assessed the treatment landscape and outcomes in patients with epidermal growth factor receptor wild-type (EGFR-WT), nonsquamous metastatic NSCLC (mNSCLC) in an Israeli Health Maintenance Organization (HMO).

Methods: This retrospective cohort study used the de-identified Maccabi Healthcare Services Israel electronic database to assess adult patients with EGFR-WT or unknown type, nonsquamous mNSCLC (≥2 NSCLC diagnosis codes) who initiated 1L treatment between 01 January 2017 and 31 December 2020. Patient characteristics and treatment patterns from 1L to 2L were evaluated using descriptive statistics. Time-to-event analysis for time on treatment (ToT), time to next treatment or death (TTNTD), progression-free survival (PFS), and overall survival (OS) from 2L treatment initiation were assessed using Kaplan-Meier analysis. Data were collected until December 2022 to allow ≥24 months follow-up.

Results: Of 886 patients with EGFR-WT nonsquamous mNSCLC who initiated 1L treatment, 176 (20%) subsequently received 2L treatment. At 2L treatment initiation, median age was 67 (61-74) years, 34% were female, and 93% had adenocarcinoma. ECOG performance status at 1L treatment initiation was 0-1 in 52% of patients. Demographics stratified by 1L and 2L treatment were similar, except patients who received 1L platinum-doublet chemotherapy and 2L PD(L)1 combination were younger (median age: 60 [52-61] years). Median ToT, TTNTD, PFS, and OS from 2L treatment initiation for the various 1L to 2L treatment sequences are shown in the Table. The most common 1L to 2L treatment sequences were platinum-doublet chemotherapy to PD(L)1 monotherapy, and PD(L)1 monotherapy to pemetrexed. Most 1L to 2L sequence subgroups demonstrated poor outcomes, except for two groups (platinum-doublet chemotherapy to chemotherapy, and PD(L)1 monotherapy to PD(L)1 combination), which were relatively small (N=8 and N=5, respectively). Among subgroups with >20 patients, PD(L)1 monotherapy to pemetrexed demonstrated numerically better outcomes than platinum-doublet chemotherapy to PD(L)1 monotherapy. Third-line treatment was initiated in 31% of patients.

Conclusions: In this real-world study, almost half of patients received 1L platinum-doublet chemotherapy and switched to PD(L)1 monotherapy in 2L. Docetaxel, the currently recommended 2L treatment and standard-of-care in clinical trials was not commonly used in this cohort. Clinical outcomes were generally poor at 2L treatment, highlighting the unmet need for more effective treatment options following progression on 1L.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11A.19 Efficacy and Outcomes of Immunotherapy-Based Treatments in EGFR-Mutant Non-Small Cell Lung Cancer

I-T. Chen[1,2], H-C. Huang[1,2], C-L. Chiang[1,2], C-I. Shen[1,2], Y-H. Tseng[1,2], Y-M. Chen[1,2], Y-H. Luo[1,2], [1]Taipei Veterans General Hospital, Taipei/TW,[2]National Yang Ming Chiao Tung University, Taipei/TW

Introduction: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are approved for first-line treatment for EGFR-mutant metastatic non-small cell lung cancer (NSCLC); however, most patients ultimately experience tumor progression. The optimal immunotherapy (IO)-based treatment strategies to improve survival outcomes, along with the optimal timing for such an approach in EGFR-mutant NSCLC after failure of EGFR-TKIs, continues to be a subject of ongoing debate.

Methods: A retrospective analysis of outcomes for patients with EGFR-mutant NSCLC who underwent IO alone or IO combined with chemotherapy (C/T) as subsequent treatment after disease progression was conducted. Data were collected from January 2014 to December 2022 at Taipei Veterans General Hospital. The Kaplan-Meier method was utilized to evaluate overall survival (OS) and time to treatment failure (TTF). The Cox proportional hazard model was employed to examine the relationship between clinical characteristics and survival outcomes.

Results: This study enrolled a total 107 patients with advanced EGFR-mutant NSCLC, all of whom had received treatment with first- or second-generation EGFR-TKIs. The IO alone group comprised 33 cases, while the group receiving IO combined with C/T (IO+C/T) included 74 cases. The median number of prior treatment lines before starting immunotherapy was 2. The IO+C/T group exhibited a trend toward longer OS and TTF than IO alone group (OS: 20 vs. 16 months, p=0.74; TTF: 4 vs. 2 months, p=0.71). The multivariate analysis showed that patients who underwent more than 4 lines of treatment before IO-based treatment demonstrated poorer OS (hazard ratio [HR] 2.26, 95% confidence interval [CI] 1.17-4.37, p=0.01) and TTF (HR 1.89, 95% CI 1.12-3.21, p=0.02) compared to those with fewer than 4 lines of treatment .The HRs for OS were 4.91 (95% CI 2.11-11.46) for patients receiving more than 4 lines of treatment and 2.04 (95% CI 0.99-4.19) for those undergoing 2-4 lines of treatment before IO-based therapy, in comparison to patients who received 0-1 lines of treatment (p<0.01), suggesting that initiating IO-based treatment earlier can significantly reduce the risk of death. In patients with EGFR L858R mutation, the multivariate also showed that patients receiving more than 4 lines of treatment before IO-based treatment had higher risk of treatment failure (HR 2.52, 95% CI 1.01-6.26).

Conclusions: This study highlights the advantages of incorporating IO-based therapies early in the treatment regimen for patients with advanced EGFR-mutant NSCLC after failure of EGFR-TKIs. IO+C/T tended to yield better survival than IO alone. Furthermore, the detrimental effects of undergoing numerous prior treatments before starting IO-based therapy emphasize the critical need to commence such treatments early.

EP.11A.20 Incidence and Outcomes of Adrenal Oligoprogression in Metastatic Lung Cancer During Immunotherapy

B.V. Miyamura, F.C. Maluf, F.M. Silva, G.M. Andriatte, I.Q. Castro, L.S. Bugalho, L.O.M. Koch, V.A.R. Sousa, O. Smaletz, G. Schvartsman, Hospital Israelita Albert Einstein, Sao Paulo/BR

Introduction: Lung cancer presents as stage IV disease at diagnosis in around 70% of patients with small cell lung carcinoma and 30-40% with non-small cell lung carcinoma. One of the most common sites of metastasis is the adrenal gland. Significant advances in treatment have occurred with the use of immunotherapy when there are not actionable mutations. However, treatment response can be heterogeneous in different metastatic sites, which may be related to tumor microenvironment. Some studies have demonstrated response heterogeneity in the adrenal gland, suggesting that it may serve as a sanctuary for metastasis after immunotherapy use, possibly related to the glandular microenvironment, corticosteroid production, and T-lymphocyte inactivation. This study aims to evaluate the incidence of adrenal oligoprogression in metastatic lung cancer after immunotherapy treatment and its impact on overall survival.

Methods: A retrospective analysis of medical record data from Hospital Israelita Albert Einstein and Hospital Municipal Vila Santa Catarina was conducted from 2017 to 2022 to evaluate patients diagnosed with lung cancer who received immune checkpoint inhibitors. The primary objective of the study was to assess the incidence of adrenal oligoprogression during immunotherapy. Secondary objectives included overall survival (OS) of patients with adrenal oligoprogression and association with baseline characteristic by Cox regression method. Imaging examinations were assessed before the start and after the completion of immunotherapy. Survival curves were plotted utilizing the Kaplan-Meyer method.

Results: We queried data from 159 patients with metastatic NSCLC and SCLC who received anti-PD-1 either as monotherapy or in combination with chemotherapy. We included 37 patients with adrenal metastasis either before and/or during immunotherapy treatment. Mean age was 65 years and 70% were male. The median OS of the entire cohort was 36.1 months (95% CI 18.1 - 54.1). Twenty-nine patients (78%) had any disease progression, with 24 (65%) of patients having adrenal progression (with or without progression at other sites). Adrenal oligoprogression was observed in 9 patients (24.3%), of whom 7 underwent stereotactic body radiation therapy. In the 37-patient cohort, there was no other site of oligoprogression besides the adrenal gland. The OS was numerically longer in patients with adrenal oligoprogression, but statistical significance was not achieved due to the small sample size.

Conclusions: Adrenal oligoprogression may occur in a significant portion of patient with metastatic lung cancer. The adrenal gland may represent a sanctuary site of disease resistance to immunotherapy and deserves further research to validate our finding and elucidate the underlying mechanisms involved.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11A.21 Target Switching as an Effective Second-Line Strategy for Refractory Metastatic NSCLC

W.Y. Aung[1], M. Locke[1], L. Hou[2], A. Sood[2], C-S. Lee[3], N. Seetharamu[1], [1]R.J. Zuckerberg Cancer Center, New Hyde Park/NY/USA,[2]Northshore University Hospital at Northwell Health, Manhasset/NY/USA,[3]St. John's University College of Pharmacy and Health Sciences, Jamaica/NY/USA

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of metastatic non-small cell lung cancer (NSCLC) without actionable mutations, providing durable response in certain patients. Nonetheless, patients who progress on ICI face limited second-line treatment options, primarily cytotoxic chemotherapy or investigational treatments. Often, factors such as performance status or personal preference preclude these options. The strategy of switching the checkpoint target from the receptor to ligand (or vice-versa) following disease progression or adverse events has not been explored in clinical trials. This study evaluated the efficacy of this strategy, with or without chemotherapy, in NSCLC patients who experienced disease progression or adverse events on 1st ICI.

Methods: In this single-center, IRB-approved retrospective study, we analyzed outcomes of NSCLC patients from June 2015 to December 2022 who were treated with PD-1 followed by PD-L1 inhibitor (or vice-versa) after disease progression or adverse events. We evaluated progression free survival (PFS) from start of the initial ICI and subsequent ICI to disease progression or death. Patients who were alive without disease progression or had an adverse event before disease progression were censored at their last follow-up or at time of adverse event, respectively. Multivariable cox-proportional hazard model examined factors associated with PFS on 2nd ICI.

Results: In our cohort of 45 patients (49% female and 51% male), the majority of 87% (39/45) switched to a 2nd ICI after disease progression on 1st ICI. The remaining 13% (6/45) switched due to adverse event on 1st ICI. Median PFS on 1st ICI was 5.6 months (95% CI: 4.7-12.1). Median PFS on 2nd ICI was 4.9 months (95% CI: 2.5-10.8) which extended to 8.9 months (95% CI: 4.9-25) in patients who tolerated the 1st ICI beyond the first 8 months without disease progression (n=16). The median overall survival was 24.4 months (95% CI: 16.9-33.6). Among 34 patients who received a PD-1 inhibitor followed by PD-L1 inhibitor, the median PFS was 5.0 months (95% CI: 2.5-8.9). Conversely, in 11 patients who received a PD-L1 inhibitor followed by a PD-1 inhibitor, the median PFS was 2.6 months (95% CI: 2.4-11). In the multivariable cox proportional hazards model, no significant difference was observed in PFS based on PFS on 1st ICI (p=0.09), PD-L1 tumor proportion score (p=0.27), or target of 2nd ICI (p=0.43). However, combination therapy with chemotherapy was associated with a worse PFS (HR 3.31, 95% CI: 1.54-7.13).

Conclusions: Switching the ICI target from PD-1 to PD-L1 (or vice-versa) following disease progression offers benefit in refractory metastatic NSCLC, with a median PFS comparable to that of single agent chemotherapy. Although PFS on initial ICI or target of 2nd ICI did not significantly impact outcomes, adding chemotherapy to second-line ICI was associated with worse outcome. These findings highlight the potential benefits of switching target as a viable strategy for those with disease progression or adverse events while cautioning against use of chemotherapy in this context.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11A.22 Comparing Outcomes and Adverse Events in Lung Cancer Immunotherapy: The Impact of Smoking Status

M. Zafar[1], M. Arnous[1], N. Nwankwo[1], A. Reddy[2], [1]Arkansas College of Osteopathic Medicine, Mercy Hospital Fort Smith, Fort Smith/AR/USA,[2]Mercy Hospital Fort Smith, Department of Oncology, Fort Smith/AR/USA

Introduction: Lung cancer remains the leading cause of cancer-related death worldwide. Despite advances in early detection and treatment, the prognosis for patients with advanced-stage lung cancer continues to be poor. Checkpoint inhibitor therapy commonly termed immunotherapy is the corner stone of treatment in patients with early and advanced lung cancer patients. In some studies immunotherapy was found to have a better outcome in NSCLC patients with a smoking history compared to non-smokers. We conducted a retrospective analysis in our patients to identify the correlation between smoking and patient outcomes and adverse events.

Methods: We reviewed and analyzed data on all patients with lung cancer diagnoses who were treated with immunotherapy from January 2020 to December 2022 (approximately two years). We performed a retrospective chart analysis on patients who received immunotherapy for lung cancer. Data collected included age, race, smoking status, causes for early discontinuation, immunotherapy-related adverse events (not including thyroid dysfunction), and corticosteroid use.

Results: During our study timeline, a total of 122 eligible patients were included in the analysis. The average age of the patients is approximately 72 years (38 to 94 years old). Most patients were Caucasian (n=113), three patients were African American, and six patients belonged to other races. With regards to immunotherapy drugs, most patients were on pembrolizumab (n=59), followed by atezolizumab (n=30), durvalumab (n=29), and nivolumab (n=4). A total of 81 patients (66%) had discontinued treatment earlier than planned, and early discontinuation rates for immunotherapy were significantly higher in current smokers compared to former or never smokers (60 % vs. 49%), with the most common reason for early discontinuation being progression of disease or hospice transition (56%). Other reasons for early discontinuation included immunotherapy adverse effects, death, and non-compliance. A total of 31 patients had adverse effects documented explicitly as related to immunotherapy, and the most common was severe fatigue (6 patients), followed by dermatitis (5 patients). Other adverse events included anemia, nausea, colitis, cytopenia, pneumonitis, hepatitis, arthralgia, and neuropathy in the order of their frequency. Systemic corticosteroids were used in 16 patients for immunotherapy-related adverse effects, and the remaining patients either received topical steroids or drug discontinuation alone. An additional eight patients were identified to be using topical steroids without any documentation of dermatological adverse effects. In our analysis, we also observed that a significantly higher percentage of patients (77 %) with immunotherapy adverse effects were former, or non-smokers compared to current smokers.

Conclusions: From our retrospective study, we observed that a significant proportion of patients on immunotherapy for lung cancer discontinue treatment due to disease progression, and the rates of disease progression are much higher in current smokers. This observation argues against previous reports of better clinical responses in smokers receiving immunotherapy. The interesting observation in our study is that patients who are active smokers tend to have a lesser number of immunotherapy-related adverse events compared to past smokers and non-smokers. We also identified a proportion of patients using topical steroids without any documentation of dermatitis, likely underreporting dermatological immune-related side effects.

Introduction: Schemes involving immune checkpoint inhibitors (ICI) have revolutionized first-line treatment for Advanced NSCLC without driver mutations regardless of PD-L1 expression. However, selecting the optimal treatment for the subgroup of patients without PD-L1 expression poses a challenge due to the heterogeneity of benefits observed in clinical trials and the lack of real-world data in this subgroup. In turn, due to the high cost of these therapies, their indication is not authorized by some health providers in developing countries. This study aims to demonstrate the effectiveness of different approved ICI schemes versus chemotherapy (CT) alone in the subgroup PD-L1 negative patients in the real-world context in Argentina.

Methods: Retrospective cohort study including patients with advanced NSCLC PD-L1 negative (<1% by IHC), without driver mutations (negative test for EGFR and ALK), treated at the first line with ICI or CT from 2017 to December 2023 from 22 Argentinian centers. Progression-free survival (PFS), overall survival (OS), and overall response rate (ORR) outcomes were compared between those treated with ICI schemes versus CT in the first line.

Results: 218 patients were analyzed. Median age 65 (59-74), male gender 126 (57%), previous or active tobacco use 187 (88%), adenocarcinomas 181 (82%). Treated with ICI 151 (69%) and 67 (31%) with CT.IO schemes: CT + Pembrolizumab 125 (82%), Ipilimumab + Nivolumab 12 (7.9%), CT + Ipilimumab + Nivolumab 11 (7.3%), CT + Atezolizumab + Bevacizumab 3 (2%). At the data cut/off, the median follow-up was 20.8 months. The median PFS was 10 in the ICI group vs 7.2 months in the CT group log-rank P: 0.003 Cox Regression HR 0.61 (0.43-0.85) P: 0.004 . The 12-month OS was 71% in the ICI group vs 69% in the CT group. The ORR was 47% in the ICI group vs 25% in CT P: 0.04. Grade 3 immune-related adverse events occurred in 8.7% of patients.

Conclusions: Our study in advanced PD-L1 negative NSCLC patients demonstrated the effectiveness of ICI in the real-world context. The results showed statistically significant improvements in PFS and ORR. The frequency of grade 3 adverse events were similar to those reported in clinical trials. Longer follow-up is needed to evaluate the benefits of OS.

Introduction: Immunochemotherapy is the standard of care for NSCLC patients with PD-L1 expression < 50%. However, early disease progression is observed in some cases. Prediction of this scenario would be useful.

Methods: We analysed a group of 303 patients with NSCLC (CS IV). OS and PFS were estimated using Kaplan-Meier estimator and Cox model. For morphological parameters, we explored functional forms and cut-off points to optimize concordance in exploratory OS analysis. The final model including factors significant in univariate analysis was used to develop predictive scoring (Table 1).

Results: After the median of follow-up 10.52 months in the entire cohort mPFS was 13.1 months (95%CI 11.4-15.3) and mOS - 16.3 months (95%CI 1.3-20.3). The mPFS within the prognostic groups groups were - respectively- 19.5, 13 and 5.8 months (p<0.001; Fig.1), with the percentage of patients without disease progression after 12 months estimated at 69%, 45.1% and 25.8% (p<0.001). The mOS were NR, 14.5 and 5.8 months (p<0.001;Fig.2), with the percentage of patients alive after 12 months - 81.2%, 60.2% and 20.4% (p<0.001).

Conclusions: The efficacy of immunochemotherapy in the real-world population is variable. CLIPI-LC is a useful tool to stratify patients according to their baseline clinical parameters.

EP.11A.25 Consensus on Maintenance Therapy after a First-Line Pembrolizumab-Containing Regimen in Advanced/metastatic NSCLC

U. Tapan[1], M. Shah[2], K.F. Bell[2], A. Liao[3], H. Yang[4], S. Lee[4], L. Korrapati[5], N. Reinmuth[6], [1]Section of Hematology & Medical Oncology, Boston University Chobanian & Avedisian School of Medicine, and Boston Medical Center, Boston/MA/USA,[2]GSK, Collegeville/PA/USA,[3]GSK, Zug/CH,[4]Analysis Group, Boston/MA/USA,[5]Analysis Group, San Francisco/CA/USA,[6]Thoracic Oncology Department, Asklepios Lung Clinics Munich-Gauting, Gauting/DE

Introduction: First-line (1L) maintenance therapy (1LMT) treatment guidelines are inconsistent for patients with advanced/metastatic non-small cell lung cancer (a/mNSCLC) who have completed a 1L induction pembrolizumab-containing regimen. This study used a Delphi method to reach consensus on 1LMT recommendations for patients with a/mNSCLC without actionable genomic alterations.

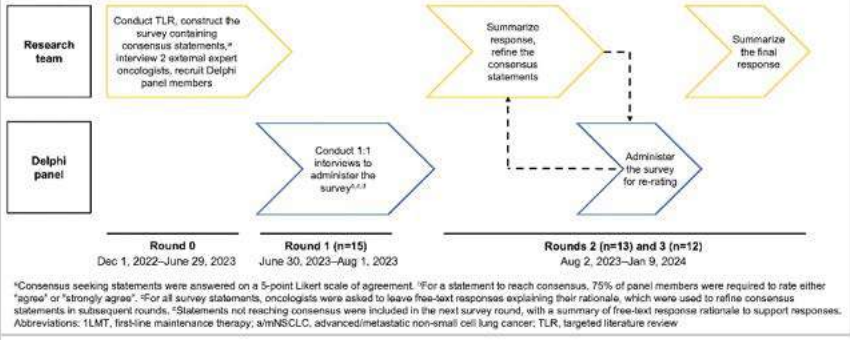
Methods: A literature review and input from two clinical experts (UT, NR) were used to develop consensus statements related to 1LMT. Using an iterative Delphi method, the survey was administered over three rounds between June 30, 2023, and January 9, 2024, (Figure) to a panel of oncologists actively treating patients with a/mNSCLC in France, Germany, the UK, and the US. In each round, updates to the survey were based on aggregated results from the prior round.

Results: Participating oncologists (round 1, n=15; round 2, n=13; round 3, n=12) concurred that 1LMT should be considered for patients with a/mNSCLC who achieved a response or stable disease after 4-6 cycles of 1L pembrolizumab-containing induction. The panel's recommended 1LMT varied by 1L induction treatment, programmed death-ligand 1 (PD-L1) level, and Eastern Cooperative Oncology Group performance status (ECOG PS; Table). When considering 1LMT duration, the panel agreed on factors to consider (toxicity/side effects, patient preference, ECOG PS, and disease progression). If 1LMT pembrolizumab was used (as monotherapy or with pemetrexed), oncologists agreed it should be used for up to 2 years, as long as it was tolerated (including induction and 1LMT duration); the panel did not agree on a preferred pemetrexed duration.

Conclusions: In this study, panel oncologists concurred on a 1LMT strategy, but differed on recommended 1LMT when PD-L1 levels were <50% and on preferred pemetrexed duration. Given a lack of 1LMT treatment guidelines for patients with a/mNSCLC without actionable genomic alterations, these results provide useful recommendations for treating physicians.

Keywords: first-line maintenance therapy, metastatic NSCLC, treatment recommendations

Figure. Delphi method used to reach consensus on 1LMT recommendations for a/mNSCLC



[a]Consensus seeking statements were answered on a 5-point Likert scale of agreement. [b]For a statement to reach consensus, 75% of panel members were required to rate either "agree" or "strongly agree". [c]For all survey statements, oncologists were asked to leave free-text responses explaining their rationale, which were used to refine consensus statements in subsequent rounds. [d]Statements not reaching consensus were included in the next survey round, with a summary of free-text response rationale to support responses.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11A.26 Evaluating Efficacy and Safety of Nivolumab in Pretreated NSCLC Patients: Insights from Real-World Data

L. Bitar, F. Seiwerth, L. Ljubicic, A. Bacelic-Gabelica, D. Srdic, M. Korsic, S. Plestina, S. Badovinac, M. Samarzija, M. Jakopovic, University Hospital Centre ZAgreb, Zagreb/HR

Introduction: Over the past years, the treatment strategies for metastatic NSCLC have changed. Three anti-PD-(L)1 agents, nivolumab, pembrolizumab, and atezolizumab, have been approved as a second-line treatment. Since the introduction of the first immunotherapy as a second-line treatment for non-small cell lung cancer (NSCLC) in 2014, nivolumab has demonstrated superior efficacy compared to docetaxel, particularly in advanced squamous and nonsquamous NSCLC with a median overall survival (mOS) of 12.2 months for nonsquamous and 9.2 months for squamous NSCLC.

Methods: We performed a retrospective, real-world, non-interventional cohort study of all patients with metastatic or recurrent non-small cell lung cancer treated with nivolumab monotherapy for second-line or later-line treatments in University Hospital Center Zagreb, Department for Pulmonary Diseases. In total, 105 patients diagnosed with non-small-cell lung cancer after progression on standard chemotherapy were included. The program started in March 2017 and the last patient was enrolled in October 2017. The patients were observed for disease progression and death until November 1st 2023. The primary objective of this study was to evaluate the safety and effectiveness of nivolumab.

Results: Median follow-up time was 79.9 months (35.8-87.6) for PFS and 82.4 months (81.6-87.6) for OS. Despite previous treatment modalities, mOS was 15.9 months (95% CI 10.6-20.3). The median PFS was 7.07 months (95% CI 5.57-9.9). Therapy was primarily applied in the second and third lines (n=67; 64.4%), but even up to the seventh line (n=2; 1.9%). Mean number of applied nivolumab doses was 17 (1-69). Side effects were observed in 22 patients (20.9%), leading to treatment discontinuation in 16 patients (15.2%). The most common side-effect was pneumonitis in 7 patients (6.7%), followed by endocrine disorders (n=4; 3.8%) and rash (n=4; 3.8%), then gastrointestinal (n=3; 2.9%), myositis (n=3, 2.9%) and hepatitis (n=1; 0.9%). Patients who developed side effects had significantly longer mPFS than the ones who didn't (13.2 vs 6.1 months; 95% CI 4.77-9.07 vs 9-35.83; p=0.007).

Conclusions: This study represents the real-world experience with nivolumab. Although our patients were heavily pretreated, there was a clear survival benefit of nivolumab treatment compared to available extensive clinical trial data. We observed that the development of side effects was a significant factor in better overall survival and progression-free survival.

EP.11A.27 Real-Life Study of Patients with Unresectable Stage III Non-Small Cell Lung Cancer Treated with Chemoradiotherapy Followed by Durvalumab.

M. Tuller, G. Buela, Y. Ferreira, A. Antivero, L. Lupinacci, L. Basbus, Hospital Italiano de Buenos Aires, CABA/AR

Introduction: There is limited evidence in our setting regarding durvalumab in patients with unresectable stage III non-small cell lung cancer (NSCLC)

Methods: Retrospective cohort study of NSCLC patients who underwent durvalumab within a closed cohort of affiliates to the private healthcare system of the Hospital Italiano de Buenos Aires. Relapse-free survival (DFS) and overall survival (OS) were evaluated.

Results: Twenty-two patients were analyzed, median age 66 years IQR 63 to 71, 95% (21) PS 0 - 1. Eighty-two percent (18) were smokers, 82% (18) had adenocarcinomas, with a prevalence of molecular testing of 82% (18), of which 44% (8) were PD-L1 negative, and 33% (6) had PD-L1 greater than 50%. Ten percent (2) experienced serious immune-mediated toxicities, one patient developed G4 pneumonitis and another Guillain-Barre syndrome. With a median follow-up of 22 months, 36% (8) of patients experienced relapse, while 76% were disease-free at 12 months after completing durvalumab treatment. The value of PD-L1 was not associated with the probability of recurrence or relapse-free survival (HR 1,1 IC95 0,99-1,02 p= 0,3 Cox Regression Model). The median relapse-free survival was not reached; of the 8 relapsed patients, 50% (4) received second-line treatment with docetaxel-based chemotherapy regimens, and 5 died, with median post-relapse overall survival of less than 6 months.

Conclusions: Encouraging results are observed in terms of relapse-free survival and treatment response. Despite limited evidence in our region, the majority of patients treated with durvalumab experienced prolonged relapse-free survival.

EP.11A.28 Efficacy and Safety of Penpulimab-Containing Regimens for Advanced Malignant Solid Tumors That Have Failed Immunotherapy: A Real World Study.

J. Zhou, C. Xu, L. Zhang, C. Ma, First Affiliated Hospital of Soochow University, Suzhou/CN

Introduction: Immuno-checkpoint inhibitors(ICI) have shown good anti-tumor efficacy and survival benefits in a variety of solid tumors, such lung cancer, gastric cancer(GC), esophageal cancer (EC), head and neck squamous carcinoma (HNSCC) and nasopharyngeal cancer(NPC). ICI have rewritten the guidelines for multiple tumor types. However, there are still a large number of patients who are ineffective or initially effective after use ICI, and subsequently develop ICI resistance. For this patients, how we choose further treatment is currently uncertain clinically. Some studies suggest that even if the treatment of PD - (L) 1 is ineffective or progresses, it can still bring a certain degree of benefit to re-challenge with other target ICI. This study was to evaluate the efficacy and safety of the patients with advanced malignant solid tumors with the regimen of penpulimab (PD1 antibody).

Methods: This is a non-interventive registration study. Eligible participants must be ≥ 18 years old and have proven malignant tumors that are ineffective, fail for immunotherapy and have no other standard treatment. Patients were treated with penpulimab alone or in combination with chemotherapy or anti-angiogenic agents until progression or unacceptable toxicity. The primary endpoint is objective response rate (ORR). Secondary endpoints were disease control rate (DCR), progression free survival (PFS), overall survival (OS) and safety.

Results: Form Sep 2021 to Feb 2024, 26 patients(median age 59.9 years, male 65.4%)were recruited, including 7 pts with NSCLC, 4 pts with HNSCC, 3 pts with NPC, 3 pts with Intestinal cancer, 3 pts with GC and 6 with other tumor types. Among all, 1 chieved PR and 22 achieved SD, the DCR was 88.5% (23/26). The median treatment duration was 9.5 cycles and the median PFS was 9.1 months. Among the 7 pts with NSCLC, the DCR was 85.7% (6/7) (See the table below for details). Treatment-related adverse events (TRAEs) of grade 3 were observed in 5 (17.9%) of the 28 patients. The most common TRAEs were decreasedanemia (57.7%, 15/26), lymphocyte count(53.4%, 14/26), hypoalbuminemia (42.3%, 11/26), increased thyrotropin (34.6%, 9/26), hypercholesterolemia (26.9%, 7/26), albuminuria(19.2%, 5/26).

Conclusions: Penpulimab-containing regimens for advanced malignant solid tumors that have failed ICI have shown significant efficacy and a favorable safety profile. More specific studies are needed to confirm these results.

Introduction: Immune checkpoint inhibitors (ICIs) have transformed the management of advanced malignancies, notably non-small cell lung cancer (NSCLC). However, ICIs can induce immune-related adverse events (irAEs) necessitating biomarker identification for irAE detection and monitoring.

Methods: A comprehensive search of PubMed, Embase, Web of Science, and Google Scholar until April 2024 was conducted. English-language studies relevant to the research objective were included while excluding case reports, editorials, conference abstracts, reviews, and studies combining ICIs with other therapies. Statistical analyses were performed using Review Manager software, and bias assessment was conducted using the Newcastle Ottawa Scale. Subgroup analyses were performed for CRP and pneumonitis/interstitial lung disease (ILD) association, as well as pretreatment and post-treatment CRP levels and pneumonitis risk

Results: Six eligible studies were identified. Subgroup analysis indicated no significant difference in pneumonitis risk between high and low CRP levels (OR: 1.66; 95% CI: 0.77-3.56; p = 0.20). However, high pretreatment CRP was associated with increased pneumonitis risk (OR: 3.43; 95% CI: 1.07-11.02; p = 0.04). Conversely, no significant ILD risk increment was observed with higher pretreatment CRP levels (OR: 1.07; 95% CI: 0.96-1.18; p = 0.22).

Conclusions: Elevated pretreatment CRP levels are linked to pneumonitis development, underscoring its potential as a predictive biomarker. However, further research is warranted to validate this finding. Additionally, higher CRP levels post-ICI therapy initiation may not correlate with pneumonitis. Similarly, no association was found between pretreatment CRP levels and ILD development.

EP.11B.01 Machine Learning-Based Clinical Model for Predicting Thromboembolism in Lung Cancer after Immunotherapy

M. Zhao, Shanghai Pulmonary Hospital, Tongji University, Shanghai/CN

Introduction: The unpredictable thromboembolism events (TEs) remains important in lung cancer patients (LCP) treated with immune checkpoint inhibitors (ICIs), since TEs significantly increased after immunotherapy and associated with adverse survival.

Methods: LCP treated with ICIs were retrospectively reviewed from two clinical centers, and combination of 5 feature selection methods and 5 machine learning (ML) algorithms were compared by area-under-curve (AUC) to identify the final ML model. The performance of the final model was compared with existed VTE-risk score (Khorana, Padua, PROTECHT, ONKOTEV, COMPASS-CAT score), and decision-curve-analysis (DCA) and net-reclassification-improvement-analysis (NRI) applied to assess clinical utility. Shapley-Additive-exPlanation (SHAP) method was used for feature importance ranking and explaining the final model.

Results: Of all 2300 LCP, 1610 were randomly splitted as training set, 345 as validation, and 345 as test set, separately. The model established by logistic regression with 22 features selected by Lasso performed best with a highest AUC of 0.692, and was selected as the final model. The Lasso-Logistic-model outperformed existed VTE-risk scores in TEs risk evaluation ($p<0.050$ for all), and the high-TEs-risk group identified by this model was significantly associated with higher cumulative incidence of TEs (12.3%, $p=0.006$). The positive association between high-risk and adverse survival were found in all LCP, regardless of whether combined with chemotherapy, and especially in stage IV LCP ($p<0.001$ for all). The better net benefits derived by the Lasso-Logistic-model were further verified by DCA and NRI analysis. SHAP analysis revealed that D-Dimer level and ECOG status had the largest impact on TEs risk prediction, which were consistent with traditional statistical analyses.

Conclusions: The established ML model outperformed validated VTE-risk scores for predicting TEs risk, and highly relevant to adverse survival in LCP initiating ICIs, which might assist in selecting LCP who would benefit from thromboprophylaxis.

EP.11B.02 Correlation Analysis of Peripheral Blood Cell Immune Phenotype with Prognosis of Immunotherapy in Advanced Non-Small Cell Lung Cancer

N. Wang[1], M. Tian[1], X. Song[2], [1]Shanxi Medical University, Taiyuan/CN,[2]Shanxi Provincial Cancer Hospital;Cancer Hospital of Chinese Academy of Medical Sciences Shanxi Hospital;Affiliated Cancer Hospital of Shanxi Medical University, Taiyuan/CN

Introduction: Tumor immune microenvironment plays an important role in tumor immunity, which determines the efficacy of immunotherapy largely.This study aims to was to explore the prognostic value of dynamic changes of different lymphocyte immunophenotypes and serological inflammatory cell markers based on peripheral blood immune microenvironment, as well as PD-L1 expression level and gene mutation based on tissue level in aNSCLC(advanced NSCLC)immunotherapy. Moreover, immune adverse events were collected during immunotherapy in aNSCLC patients.

Methods: From the "CAPTRA-Lung" database, 190 patients with aNSCLC in Shanxi Cancer Hospital from January 2020 to May 2023 were prospectively collected. The patients were further divided into response group (CR, PR) and non-response group (SD, PD).Using flow cytometry to dynamically monitor the distribution of different lymphocyte subsets. NLR, PLR, LMR, SII, SIRI, PNI, ALI and dNLR in peripheral blood and the immune adverse events during immunotherapy were also collected.The follow-up deadline was February 1, 2024.

Results: All patients of median progression-free survival is 11.13 months[95%CI:9.553-12.714], and ORR,DCR are respectively 64.2% and 87.4%.In 106 patients tested PD-L1, the PFS of PD-L1< 1% subgroup is significantly shorter than that of 1-49% PD-L1subgroup (p=0.004) and PD-L1 ≥ 50% subgroup (p < 0.001), but it's not significantly between 1-49% PD-L1 subgroup and PD-L1 ≥ 50% subgroup (p= 0.079).In 133 patients genetic testing, the common types of mutation include KRAS mutation, TP53 mutation, STK11 mutation, ERBB2 insertion mutation, SMARCA4 mutation and so on. The results of survival analysis showed the PFS of KRAS mutation patients have significantly longer PFS than wild-type patients (mPFS:16.27m vs 10.53m, HR:0.6400, 95%CI:0.4287-0.9556, p=0.042). Although the PFS of TP53 positive patients is longer, no statistical correlation is found (p=0.470). According to flow cytometry data, the proportion of CD45+CD3+T cell, CD3+CD8+T cell, CD45+CD3-CD16+CD56+NK cell and CD45+CD4+CD25HICD127LOWTregs cell increase significantly after 3 cycles immunotherapy. Similarly, it's found that these lymphocyte subsets in the response group increased significantly after immunotherapy, but this phenomenon is not observed in the non-response group. CD45+CD3-CD19+B cell have different degrees of significant increase in response group and non-response group .In the patients with detection PD-L1, CD3+CD4+T cells and CD45+CD4+CD25HICD127LOW Tregs cells have statistical differences among two subgroups (50% as threshold), and CD3+CD4+T cells has statistical correlation among three subgroups (1%,50% as threshold).The proportion of baseline CD45+CD4+CD25HICD127LOWTregs cells in patients with KRAS mutation positive was higher with no significant difference (p > 0.05) .Multivariate analysis showed that NLR, dNLR and BMI are risk factors for PFS,but LMR is related to long-term survival. Moreover, it is found that the occurrence of irAEs is in relation to longer PFS (mPFS:13.73m vs 9.73m,HR:1.373,95%CI:0.996-1.895,p<0.001).

Conclusions: This study shows that the lymphocyte immunophenotype and serological inflammatory cell markers in peripheral blood can reflect the changes of tumor immune microenvironment and have the potential to serve as biomarkers for immunotherapy in aNSCLC. Exploring the PD-L1 level,gene changes can provide more predictive value for immunotherapy.And the survival time of irAEs was longer.

EP.11B.03 Body Mass Index and Genetic Association in Durable Responders to Immunotherapy in Metastatic Non-Small Cell Lung Cancer

S. Wang[1], E. Miao[2], D. Alicea[2], P. Ch'en[2], H. Cheng[1], M. Lee[1], [1]Montefiore Medical Center/Albert Einstein Medical College, the Bronx/NY/USA,[2]Albert Einstein College of Medicine, the Bronx/NY/USA

Introduction: Immunotherapy has revolutionized the management of metastatic non-small cell lung cancer (NSCLC), leading to durable responses in many patients. Preclinical studies suggested obesity might be associated with upregulation of PD-L1 expression and improved response to immune checkpoint blockade. However, there is limited literature exploring the genomic features in different body mass index (BMI) groups and their association with response to immune checkpoint inhibitors (ICI) in NSCLC.

Methods: We conducted a retrospective analysis of patients with metastatic NSCLC diagnosed 1/2017 to 12/2021, who received first or subsequent lines of ICIs. Patients were divided into durable responders (DR) with time on treatment (TOT) ≥ 18 months, and non-durable responders (NDR) with TOT < 18 months. Demographic, clinical and genomic information were collected and compared between the two cohorts, including age, sex, race, smoking status, ECOG performance status (PS), BMI, histology, presence of brain metastasis, presence of immune-related adverse events (iAEs), PD-L1 score, genetic test, type and line of ICI, and chemotherapy use. Chi-squared test and Fisher's exact test were used to analyze categorical variables, while ANOVA and Mann-Whitney were conducted for continuous variables. Multivariate analysis was conducted using logistic regression and included variables that were considered relevant in univariable analysis.

Results: Among 324 identified patients with a median follow up of 13.3 months, the median age was 66 years, with 54.3% being male. There were 67 patients in the DR group, while NDR group had 257 patients. No racial/ethnicity differences were noted in our diverse patient population between DR and NDR groups. Multivariate analysis revealed that an ECOG PS < 2 (OR 0.26, 95% CI 0.12-0.54; P=0.00) and BMI ≥ 25 (OR 0.52, 95% CI 0.29-0.94, p=0.03) were associated with durable response outcome. Overall, there was a significantly lower incidence of STK11 mutations in the DR group compared to the NDR group (2.7% vs. 14.5%, P=0.048). Moreover, subgroup analysis examining genomic testing within stratified BMI and ECOG groups revealed that among patients with BMI < 25, SMARCA4 mutations were significantly more common compared to those with BMI ≥25 (7.8% vs. 0, P=0.02).

Conclusions: Our study demonstrated that in metastatic NSCLC patients treated with ICIs, better ECOG performance status and being overweight or obese were associated with durable responses. Additionally, there were notable genomic associations in overweight/obese patients and in durable responders. Future prospective studies are warranted to further explore genetic features and their implications in durable responders to immunotherapy.

EP.11B.04 Differential Durable Responses in Intrathoracic Versus Overall Lesions of Non-Small Cell Lung Cancer Treated with Immunotherapy

S. Lee[1,2], J. Lee[1,2], M. Yadav[1], W.Y. Kim[1], M.J.A. Chuchuca[1], T. Um[1], L.I-Y. Chung[1], Y.K. Chae[1], [1]Feinberg School Of Medicine, Northwestern University, Chicago/IL/USA,[2]Kyungpook National Univeristy, Daegu/KR

Introduction: Tumor response to immunotherapy in non-small cell lung cancer (NSCLC) in intrathoracic versus extrathoracic lesions may differ due to tumor heterogeneity. This study assesses the concordance of intrathoracic versus overall lesion response and identifies clinical factors linked to durable response in NSCLC patients treated with immunotherapy.

Methods: This study analyzed 78 NSCLC patients with both intrathoracic and extrathoracic lesions receiving first-line immunotherapy. Clinical response was evaluated by RECIST v1.1. Durable response was defined as patients achieving complete response (CR), partial response (PR), or stable disease (SD) for ≥24 weeks. Clinical benefit rate (CBR) was defined as percentage of durable responders.

Results: Patients had a median age of 65.0 (range, 37-99) years, with a male-to-female ratio of 1.69 [male (n=29); female (n=49)]. Baseline metastases included brain (n=34, 43.6%); bone (n=25, 32.1%); and liver (n=17, 21.8%). Median duration of immunotherapy was 4.84 (range, 0.2-55.3) months.

Among durable responders (n=27, 34.6%), the median progression-free survival (PFS) and overall survival (OS) were 14.3 (range, 9.0-19.6) and 35.7 (range, 19.4-52.1) months, while those in non-durable responders (n=51, 65.4%) were 2.7 (range, 1.0-4.4) and 10.5 (range, 6.9-14.0) months, respectively (PFS: p<0.001; OS: p<0.001). For intrathoracic durable responders (n=29, 37.2%), the median PFS and OS were 12.2 (range, 7.5-16.9) and 30.7 (range, 13.6-47.8) months, while those in non-durable responders (n=49, 62.8%) were 3.8 (range, 2.6-5.0) and 9.4 (range, 4.9-13.8) months, respectively (PFS: p=0.02; OS: p=0.002).

The concordance of tumor response between overall and intrathoracic lesions only was 80.8% (63/78). The changes were as follows: one PD to CR, three PRs and two PDs to SDs, five SDs and two PDs to PRs, two SDs to PDs. Tumor responses of overall lesions were PR (n=11, 14.1%), SD (n=42, 53.9%), and PD (n=25, 32.1%) with a CBR of 34.6%. Tumor responses of intrathoracic lesions only were CR (n=1, 1.3%), PR (n=15, 19.2%), SD (n=40, 51.3%), and PD (n=22, 28.2%) with a CBR of 37.2%.

Median duration of treatment in both overall and intrathoracic were 11.0 months and 8.3 months (p-value 0.003 and 0.05, respectively). Lower baseline platelet count (<400K) was associated with intrathoracic durable response (p=0.03). TMB, PD-L1 status, or treatment regimen were not significantly different between durable responders and non-responders.

Conclusions: Concordance of response rate between intrathoracic only vs. overall lesions in NSCLC patients was 80.8%. Intrathoracic response evaluation showed higher rates of durable response (37.2% vs 34.6%). Lower baseline platelet count was linked with intrathoracic durable response.

Keywords: Durable response, intrathoracic versus overall lesions, NSCLC

EP.11B.05 The Differential Effect of Radiation, IL39, and the Combination on Expression of HLA Molecules

K. D'mello[1], E. Kaser[1], C. Hu[1], M. Lequio[2], Z. Zhu[2], Z. Hunzeker[2], A. Heslin[2], H. Xiao[2], Q. Bai[2], M. Wakefield[2], Y. Fang[2,3], [1]UT Health Science Center at San Antonio, San Antonio/TX/USA,[2]University of Missouri, Columbia/MO/USA,[3]Des Moines University, Des Moines/IA/USA

Introduction: Lung cancer is the leading cause of cancer death amongst men and women in the US, and it is one of the leading causes of cancer death in the world. Currently, lung cancer treatments include chemotherapy, radiation, and immunologic therapy. More research has focused on improving radiation and immunologic therapies to specifically target the cancer cells and not subject the body to systemic treatment and side effects. IL-39 is a newly studied signaling molecule with potential implications on the development and progression of cancer. HLA-DQA, HLA-DQB, and HLA-DPA molecules confer anti-tumor effects against various other types of cancer, and thus upregulation would imply potential therapeutic benefit against lung cancer. CD74 is a proinflammatory molecule that supports proliferation of cancer cells. Blocking CD74 and its negative effects would be a significant finding for combating lung cancer. Il-39 and radiation inhibit cancer growth by modulating proliferative, anti-proliferative, pro-apoptotic, and anti-apoptotic molecules. This study aims to view the interaction between IL-39 and radiation on MHC class 2 molecules HLA-DQA, HLA-DQB, and HLA-DPA on the expression and proliferation of lung cancer cells. The experiment also studies the interaction of radiation plus IL-39 and its effects on CD74.

Methods: A549 adenocarcinoma lung cancer cells were treated with three different combinations: radiation, IL-39, or IL-39 plus radiation. RT-PCR was utilized to measure the expression of co-stimulatory molecules in A549 lung cancer cells.

Results: Radiation alone increased the expression of HLA-DQA in lung cancer cells compared to the control. IL-39 treated lung cancer cells increased the expression of HLA-DQA, HLA-DQB, and HLA-DPA compared to the control. Radiation plus IL-39 increased the expression of HLA-DQA. Surprisingly, the combination of radiation plus IL-39 also decreased the expression of CD74.

Conclusions: Radiation, IL-39, and the combination of the two demonstrated different effects on HLA molecules and CD74. While both radiation alone and IL-39 were able to upregulate certain HLA molecules, their combination had the additional benefit of decreasing CD74. This result implies there is potential benefit of the combined treatment, and can encourage further immunotherapy research on IL-39 alone and in combination with radiation.

EP.11B.06 The Impact of Body Mass Index on Immune-Related Adverse Events and Outcomes in Patients with Lung Cancer: A Real-World Study

X. Hu, A. Gurinovich, S. Pan, Y.V. Salei, J.H. Lin, A.M. Rodday, S.K. Parsons, Tufts Medical Center, Boston/MA/USA

Introduction: Immune checkpoint inhibitors (ICIs) have dramatically advanced the treatment landscape of lung cancer. Body mass index (BMI) is a widely used body size measurement and high BMI has been a proven risk factor for multiple malignancies. Obesity is considered a chronic inflammatory state and may influence ICI safety and efficacy by changing T cell functions. This study sought to examine the association between baseline BMI on immune-related adverse events (irAE) and outcomes in patients with lung cancer treated with ICIs.

Methods: Patients with pathology-confirmed lung cancer, newly started on ICIs between 10/01/2018 and 09/30/2021 were retrospectively identified from the Tufts Medical Center cancer registry and pharmacy records. Patient characteristics were extracted from the electronic health record; any irAEs occurring within 12 months after ICI initiation were identified. BMI was categorized into high BMI (>=25 kg/m2) and low BMI (<25 kg/m2). Mann-Whitney U test and Chi-square test were used to compare baseline information. Logistic regression was used to assess the impact of BMI on irAEs. Log-rank test and multivariable Cox regression were performed to assess the impact of BMI on progression-free survival (PFS) and overall survival (OS).

Results: A total of 125 patients were included with a median age of 70 years (range: 50-88), of whom 68 (54.4%) were males, 104 (80.8%) had non-small cell lung cancer, and virtually all (98%) had advanced stages (stage III+IV). Pembrolizumab was the most often used ICI agent (67.2%). When comparing high (N=66) and low BMI (N=59) groups, more Whites (92.4% vs 71.2%, p=0.002), and fewer prior infections 3 months before ICI initiation were observed in the high BMI group (4.5% vs 18.6%, p=0.021). In total 50 irAEs occurred in 39 individuals with the most common irAEs being endocrinopathies (34%) followed by pneumonitis (20%). With multivariable logistic regressions adjusting for age and histology, there were no significant associations between BMI and the occurrence of any irAE (Odd ratio [OR]: 0.942, 95%CI [0.413, 2.125], p=0.885). In contrast, high BMI was marginally associated with the development of endocrinopathies (OR: 2.920, 95%CI [0.879, 11.659], p=0.096], but not with pneumonitis (OR: 0.890, 95%CI [0.233, 3.412], p=0.862). In the advanced-stage patients, there were no differences with regards to PFS (p=0.240) or OS (p=0.530) by log-rank test between the two BMI groups. After adjusting for age, stage, and histology, high BMI showed trends of a superior PFS (Hazard ratio [HR]: 0.689, 95% CI [0.428, 1.107], p=0.123), but unfavorable OS (HR: 1.134, 95% CI [0.637, 2.019], p=0.668), although these results were not statistically significant.

Conclusions: Our findings suggested that in lung cancer patients treated with ICIs, BMI was not significantly associated with the occurrence of any irAEs, but overweight or obese patients were more likely to develop endocrinopathies. The width of the confidence interval suggests that the study may not have been adequately powered to detect this relationship. Baseline BMI was found to have no significant impact on the efficacy of ICIs in lung cancer. Future studies with larger sample sizes are warranted to validate these findings.

EPB.07 Choline Metabolism Reprogramming Mediates an Immunosuppressive Microenvironment in Non-Small Cell Lung Cancer

B. Xiao[1], G. LI[2], T. Zhou[1], Y. Huang[1], [1]Sun yat-sen university cancer center, Guangzhou/CN,[2]Nanfang Hospital, Southern Medical University, Guangzhou/CN

Introduction: Lung cancer is a prevalent malignancy globally, and immunotherapy has revolutionized its treatment. However, resistance to immunotherapy remains a challenge. Abnormal cholinesterase (ChE) activity and choline metabolism are associated with tumor oncogenesis, progression, and poor prognosis in multiple cancers. Yet, the precise mechanism underlying the relationship between ChE, choline metabolism and tumor immune microenvironment in lung cancer, and the response and resistance of immunotherapy still unclear.

Methods: Firstly, 277 advanced non-small cell lung cancer (NSCLC) patients receiving first-line immunotherapy in Sun Yat-sen University Cancer Center were enrolled in the study. Pretreatment and the alteration of ChE after 2 courses of immunotherapy and survival outcomes were collected. Kaplan-Meier survival and cox regression analysis were performed, and nomogram was conducted to identify the prognostic and predicted values. Secondly, choline metabolism-related genes were screened using Cox regression, and a prognostic model was constructed. Functional enrichment analysis and immune microenvironment analysis were also conducted. Lastly, to gain further insights into potential mechanisms, single-cell analysis was performed.

Results: Firstly, baseline high level ChE and the elevation of ChE after immunotherapy were significantly associated with better survival outcomes for advanced NSCLC. Constructed nomogram based on the significant variables from the multivariate Cox analysis performed well in discrimination and calibration. Secondly, 4 choline metabolism-related genes (MTHFD1, PDGFB, PIK3R3, CHKB) were screened and developed a risk signature that was found to be related to a poorer prognosis. Further analysis revealed that the choline metabolism-related genes signature was associated with immunosuppressive tumor microenvironment, immune escape and metabolic reprogramming. scRNA-seq showed that MTHFD1 was specifically distributed in tumor-associated macrophages (TAMs), mediating functional heterogeneity and the differentiation of macrophages, which may potentially impact endothelial cell proliferation and tumor angiogenesis.

Conclusions: Our study highlights the discovery of cholinesterase (ChE) as a prognostic marker in advanced NSCLC, suggesting its potential for identifying patients who may benefit from immunotherapy. Additionally, we developed a prognostic signature based on choline metabolism-related genes, revealing the correlation with the immunosuppressive microenvironment and uncovering the role of MTHFD1 in macrophage differentiation and endothelial cell proliferation, providing insights into the intricate workings of choline metabolism in NSCLC pathogenesis.

EP.11C.01 Treatment Options for Tumor Progression after Initial Immunotherapy in Advanced Non-Small Cell Lung Cancer: A Real-World Study

Y. Li, J. Zhao, Y. Li, Shandong Cancer Hospital and Institute, Jinan/CN

Introduction: Whether to continue administering immunotherapy to patients with advanced non-small cell lung cancer (NSCLC) who have experienced tumor progression remains controversial after immunotherapy. The aims were to explore survival outcomes after further immunotherapy post-progression and to determine the optimal combination therapy in such cases.

Methods: A total of 507 patients with NSCLC who underwent immunotherapy and experienced tumor progression were retrospectively divided into Immuno-combination and No-immuno groups according to whether additional combination therapy involving immunotherapy was administered post-progression. Progression-free survival (PFS) and overall survival (OS) outcomes were evaluated. Subgroup analyses were performed according to the different treatment regimens of patients in the Immuno-combination group.

Results: Superior PFS outcomes were observed in the Immuno-combination group compared with those in the No-immuno group (3-month PFS: 51.0% vs. 83.9%; 6-month PFS: 24.8% vs. 60.7 %; and 12-month PFS: 6.5% vs. 24.2 %, respectively; P<0.001). Similar intergroup differences were observed for OS outcomes (6-month OS: 73.1% vs. 97.2%; 12-month OS: 22.4% vs. 69.7 %; and 18-month OS: 6.2% vs. 40.4%, respectively; P<0.001). Superior PFS outcomes were observed in the Immuno+Antiangiogenic group than in the Immuno+Chemo group ((3-month PFS: 78.5% vs. 90.6%; 6-month PFS: 51.6% vs. 71.7%; and 12-month PFS: 21.9% vs. 27.1%, respectively; P=0.005). Similar differences in OS were observed between those same subgroups ((6-month OS: 97.4% vs 96.9%; 12-month OS: 63.5% vs 77.1%; and 18-month OS: 33.7% vs 48.4%, respectively; P=0.003).

Conclusions: Patients with NSCLC experiencing tumor progression post-immunotherapy can still benefit from further treatment, with immunotherapy combined with antiangiogenic therapy being the most efficacious option.

Keywords: non-small cell lung cancer, immunotherapy, antiangiogenic therapy

EP.11C METASTATIC NON-SMALL CELL LUNG CANCER - IMMUNOTHERAPY - IMMUNORESISTANCE
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11C.02 Role of Immune-Related Adverse Events (irAEs) and Albumin in Non-Small-Cell Lung Cancer (NSCLC)

S. Bawek[1], S. Kalvapudi[2], Y. Vedire[2], A. Pachimatla[2], P. Jain[2], S. Yendamuri[2], [1]University at Buffalo, Buffalo/NY/USA,[2]Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA

Introduction: Immune checkpoint inhibitors (ICIs) are used to treat advanced non-small cell lung cancer (NSCLC), but they can cause toxicities known as immune-related adverse events (irAEs), potentially disrupting treatment. We aimed to analyze the characteristics of NSCLC patients who are more likely to develop irAEs in a single-center cohort and assess the effects of irAE history on progression-free survival (PFS).

Methods: We retrospectively reviewed NSCLC patients treated with at least 3 doses of immunotherapy between 2015-2023. Data on patient age, sex, smoking history, histology, type of ICI regimen, BMI, and baseline albumin were collected. History of irAE was determined through clinical chart review. Patient response was assessed using Recist 1.1 coding and chart review to determine progression-free survival (PFS). Group differences were assessed using t-tests/chi-square tests, and Cox proportional hazards modeling was utilized to evaluate univariate and multivariable PFS.

Results: The study included 480 patients (245 female, 235 male). The median age was 66 years old (interquartile range (IQR): 59-73), with the majority (87.7%) being Caucasian and non-current smokers (56.7%). The median baseline albumin level was 4 (IQR: 3.7-4.3). There were 89 out of 480 patients (18.5%) who experienced treatment-limiting irAEs, with pneumonitis being the most common (4.2%). IrAEs were more prevalent in females compared to males (22% vs. 15%, p=0.044), non-current smokers vs. current smokers (22% vs. 14 %, p=0.033), patients with BMI >=30 vs. BMI <30 (24% vs. 16%, p=0.039), and those receiving only immunotherapy vs. chemoimmunotherapy (22% vs. 15%, p=0.048). Univariate analysis indicated significantly better PFS for patients with a history of irAEs (Hazard Ratio [HR]=0.534; 95% Confidence Interval [CI]=0.383-0.746, p=<0.001) and tending to show benefit with higher albumin levels (HR=0.72; 95% CI 0.538-0.962, p=0.026) (Figure 1). Multivariate analysis including all collected variables confirmed a significant correlation of PFS with a history of irAEs on immunotherapy (HR=0.57; 95% CI=0.406-0.799, p=0.001) and showed a benefit of PFS with increased albumin levels (HR=0.747; 95% CI=0.588-1, p=0.05).

Conclusions: We demonstrate that irAE's were associated with certain patient characteristics, including sex, smoking status, BMI and treatment regimen. Furthermore, a history of irAEs and higher baseline albumin levels were independently correlated with improved progression-free survival, suggesting their potential as prognostic factors in NSCLC patients undergoing immunotherapy.

Keywords: Non-Small-Cell Lung Cancer, irAE, Albumin

EP.11C.03 Anlotinib Combined with Immune Checkpoint Inhibitor May Benifit Advanced Smarca4-Deficient Thoracic Tumor Patients in First Line

Y. Lou[1], R. Li[1], B. Liu[1], Y. Li[1], D. Wang[1], W. Zhang[1], B. Han[1], F. Qian[1], Y. Zhang[1], B. Zhang[1], L. Zhang[1], W. Ma[1], [1]Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/CN

Introduction: The first-line treatment strategy of patients with advanced SMARCA4-deficient tumors is inconclusive. Although previous studies have shown immunotherapy to be effective, the efficacy and safety of different ICIs combination treatment strategies have not been explored in detail.

Methods: We collected the clinical and pathological information of 55 patients with SMARCA4-dNSCLC and SMARCA4-dUT, after which we evaluated and analyzed the clinicopathological characteristics and survival status of the patients.

Results: The patients were mainly male smokers with a mean age of 66 years old(range:46-81 years old). Histologically, non small cell lung cancer(NSCLC) accounts for the majority(n=40, 72.7%), and only a small proportion of patients carried high PD-L1 expression status(n=3, 5.4%). Additionally,concomitant mutation genes such as TP53,STK11,and KRAS were observed. Survival analysis demonstrated that the progression-free survival(PFS) of patients who received anlotinib in combinnation with immunotherapy was superior to that of patients who received chemotherapy in combination with immunotherapy as a first-line treatment(not reach vs.8.63m, p=0.05)(Figure1). Overall survival(OS) was significantly longer in patients who received first-line immnotherapy compared to those who receive first-line immunotherapy or no immunotherapy(21.67m vs. 8.80m, p=0.027)(Figure2).

Conclusions: SMARCA4-deficient thoracic tumor has unique clinicopathologic features and worse prognosis, and immue checkpoint inhibitors combined with anlotinib may be a better treatment for first-line.

Keywords: SMARCA4-defcient thoracic tumor, Immune Checkpoint Inhibitor, Anlotinib

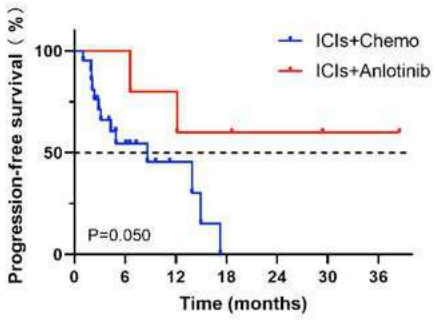

Figure1. PFS in patients treated with Chemotherapy+ICIs versus ICIs+Anlotinib

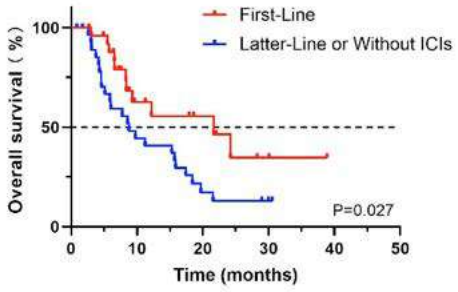

Figure2. OS in patients treated with immunotherapy for first-line versus latter-line or without immunotherapy.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11C.04 Retrospective Evaluation of Biomarkers (KRAS, TP53, STK11, KEAP1, POLE, PIK3CA, ARID1A) In Patients with NSCLC IV

J. Roeper[1], M. Falk[2], S. Schatz[2], L. Heukamp[2], F. Griesinger[3], [1]Universitätsklinik Innere Medizin-Onkologie, Oldenburg/DE,[2]HPH Hamburg, Hamburg/DE,[3]Universitätsklinik Innere Medizin-Onkologie AG Prof. Frank Griesinger, Oldenburg/DE

Introduction: Immunotherapies targeting the Programmed Cell Death-1 receptor (PD-1) and its ligand (PD-L1) have led to significantly higher survival rates in patients with metastatic non-small cell lung cancer (mNSCLC). Nevertheless, a high proportion of patients with mNSCLC do not respond to immunotherapy. The detection of PD-L1 expression as a predictive biomarker can indicate which patients are likely to benefit from immunotherapy. However, PD-L1 expression alone does not always correlate with response. In order to optimize the treatment of patients with mNSCLC, additional biomarkers for response and resistance to immunotherapy mono or in combination with chemotherapy are needed.Therefore, the influence of the following mutations KRAS, STK11, KEAP1, TP53, PIK3CA, ARID1A and POLE on PFS and OS in patients with mNSCLC receiving immunotherapy as monotherapy or in combination with chemotherapy will be investigated.

Methods: In retrospective study a total of 505 PD-L1 positive mNSCLC patients were analyzed for the following mutations: KRAS, STK11, KEAP1, TP53, PIK3CA, ARID1A and POLE. The patients were first diagnosed between 2018 and 2022 in a cancer center in northern Germany. Clinical data including sex, age, smoking status, as well as PD-L1 score was captured. Detailed information on the course of treatment and the patient survival will be presented at the conference.

Results: Median age of the 505 patients was 65 years (36-88 years) and 59% (298/505) of them were male. Most of the patients had an ECOG status of 0 or 1 (77%; 389/505) and 89% of them were current or ex heavy smoker (450/505). PD-L1 groups are distributed as follows: 36% (182/505) of the patients had a PD-L1 <1% expression, 25% (127/505) of the patients had a PD-L1 1-49% expression and 39% (196/505) of the patients a PD-L1 ≥50% expression. Overall, a TP53 mutation was detected in 59% (241/409) of patients, a STK11 mutation in 23% (83/359), a KEAP1 mutation in 29% (138/354), a POLE mutation in 15% (31/202), an ARID1A mutation in 13% (27/202), a PIK3CA mutation in 9% (34/374) and a KRAS mutation in 30% (114/379) of patients.

Conclusions: Initial descriptive analysis has shown the distribution of the various biomarkers in a PD-L1 positive patient setting. OS and PFS will be calculated from the start of immunotherapy or immunotherapy in combination with chemotherapy and correlated with the various biomarkers. In addition, an adjusted Cox regression will be performed at the conference to assess the predictive value of the various biomarkers.

EP.11D.01 A Phase II Study of Cadonilimab Plus Chemotherapy as First-Line Treatment for PD-L1-Negative Advanced Non-Small Cell Lung Cancer:LungCadX

L. Wang, C. Su, Shanghai Pulmonary Hospital & Thoracic Cancer Institute, Shanghai/CN

Introduction: Immunotherapy against non-small-cell lung cancer (NSCLC) with PD-L1-negative remains an unmet need. Many phase III clinical trials had demonstrated that the 12-month PFS rate in PD-L1 negative populations was significantly lower compared to PD-L1 positive populations. Cadonilimab is a bispecific antibody that simultaneously targets programmed cell death receptor-1 and cytotoxic T lymphocyte-associated antigen-4. In this study, we aimed to assess the efficacy and safety of cadonilimab combined with chemotherapy for the first-line treatment of PD-L1-negative advanced NSCLC.

Methods: LungCadX (ChiCTR2300071681) is a multi-center, open-label, single-arm, investigator initiated, phase II study. Patients received 4 cycles cadonilimab 10 mg/kg every three weeks (Q3W) plus chemotherapy, followed by cadonilimab maintenance therapy. The chemotherapy was determined by the investigators. The primary endpoint was the 12-month PFS rate by investigator assessment per RECIST 1.1. Secondary endpoints included PFS, OS, ORR,DoR,DCR, and the safety. Exploratory objective was to assess blood/tumor/urine/faeces tissue for potential biomarkers. Adverse events will be monitored throughout the trial and graded according to the CTCAE v5.0.

Keywords: NSCLC, PD-L1 negative, PD-1/CTLA-4 bispecific antibody

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11D.02 An Investigator-Initiated Phase II Study of Combination Treatment of Nivolumab and TM5614, A PAI-1 Inhibitor for Previously Treated NSCLC

T. Masuda[1], T. Hirata[1], T. Sakamoto[2], Y. Tsubata[3], E. Ichihara[4], T. Kozuki[5], H. Shoda[6], E. Fukagawa[1], T. Yoshida[1], M. Fukutani[1], K. Tsuji-Takayama[1], Y. Orihashi[1], N. Hattori[1], [1]Hiroshima University Hospital, Hiroshima/JP,[2]Tottori University, Yonago/JP,[3]Shimane University Faculty of Medicine, Izumo/JP,[4]Okayama University Hospital, Okayama/JP,[5]National Hospital Organization Shikoku Cancer Center, Matsuyama/JP,[6]Hiroshima City Hiroshima Citizens Hospital, Hiroshima/JP

Introduction: There is no established standard 3rd line treatment for patients with advanced non-small cell lung cancer (NSCLC). Although cytotoxic chemotherapeutic agents that are not used as 1st or 2nd line treatment are administrated as 3rd line treatment, their anti-tumor efficacy is insufficient. Anti-programmed death ligand-1 (PD-L1)/programmed death-1 (PD1) treatment is more effective and less toxic than chemotherapy in anti-PD-L1/PD-1 treatment-naïve patients with NSCLC. Therefore, anti-PD-L1/PD-1 therapy is considered an appropriate 3rd line treatment. However, the anti-tumor efficacy is limited in patients previously treated with anti-PD-L1/PD-1 antibody. Today, new drugs are needed to increase the efficacy of anti-PD-L1/PD-1 antibodies.

Methods: This open-label, single-arm, investigator-initiated phase II study is designed to evaluate combination treatment of nivolumab and TM5614, a plasminogen activator inhibitor (PAI)-1 inhibitor as 3rd or more line treatment in NSCLC patients who underwent standard treatment. The primary endpoint is the objective response rate and the secondary endpoints are progression-free survival, overall survival, duration of response and safety. The study protocol conformed to the ethical principles outlined in the Declaration of Helsinki. All patients will provide written informed consent prior to enrollment.

Results: This study is registered to Japan Registry of Clinical Trials with number: jRCT2061230039 (19/July/2023). Recruitment began in September 2023 and is expected to continue for approximately three years. As of April 2024, 13 subjects have been enrolled.

Conclusions: Currently, there is no standard 3rd line treatment for advanced NSCLC, and we hope that the findings of this study will facilitate more effective treatments in this setting.

EP.11E.01 Immune-Related Myasthenia Gravis in Patients with NSCLC: A Case Series

Y-Y.C. Kang[1,2], M-H. Lin[1], C-Y. Wang[1], C-H. Hsu[1], Y-C. Jiang[1], C-F. Chen[1], [1]Kaohsiung Veterans General Hospital, Kaohsiung/TW,[2]Kaohsiung Medical University, Kaohsiung/TW

Introduction: Immune checkpoint inhibitors (ICIs) enhance immune response, offering clinical benefits but also increasing the risk of immune-related adverse events (irAEs). These irAEs stem from off-target inflammatory and autoimmune responses, including the induction or exacerbation of myasthenia gravis (MG). Immune-related MG (irMG) is rare (0.5% of all irAEs) and presents with acute onset and rapid progression. IrMG carries a significantly higher mortality rate than classic MG (28-30% vs. 6%), where most patients present with mild disease (classes I and II), primarily due to respiratory failure. The immunobiology of irMG remains poorly understood, and its distinct features from classic MG pose challenges for optimal diagnosis and treatment. Here, we present a series of irMG cases.

Methods: Patients with NSCLC who developed irMG after receiving at least one dose of ICI were monitored at a single center in Taiwan. The study analyzed immunotherapy cycles, time to irMG onset, diagnostic results, MG symptoms and severity, management strategies, and patient outcomes.

Results: Three stage IV NSCLC patients are presented: two female, none with smoking history, autoimmunity, or driver gene alterations. All had high expression of programmed death-ligand 1 (PD-L1) and received first-line platinum-based chemotherapy. Patients 1 and 3 (100% and 98% PD-L1 expression) developed irMG rapidly after starting pembrolizumab; Patient 2 developed MG only after pembrolizumab cessation due to disease progression and a subsequent switch to gemcitabine. Immunotherapy was discontinued for Patients 1 and 2 upon MG onset due to rapid progression, but continued for Patient 3 as MG symptoms regressed. All patients shared ptosis as a symptom. The two deceased patients (Patients 1 and 2) also experienced elevated troponin, general weakness, muscle discomfort, dyspnea, and concurrent irAEs. Acetylcholine receptor antibodies were positive in Patients 1 and 3; Patient 2, with negative antibodies, had positive repetitive nerve stimulation results. All received glucocorticoids and pyridostigmine as initial treatment. The deceased patients had class V MG; they underwent plasmapheresis, mechanical ventilation, and extensive supportive care, but still succumbed to irMG. Patient 3 (class I) experienced milder, ongoing MG symptoms despite treatment.

Conclusions: High PD-L1 expression correlated with severe irMG in this series. Prompt, aggressive therapy (e.g., plasmapheresis, intravenous immunoglobulin) is crucial for severe irMG, alongside standard treatments like glucocorticoids and pyridostigmine.

EP.11E.02 Intrapleural Plus Systemic Tislelizumab Injection Combined Chemotherapy as Second-Line Treatment in a Case of RET Gene Fusion-Positive Lung Adenocarcinoma Presenting Refractory Malignant Pleural Effusion

C. Chen, The First Affiliated Hospital of Soochow University, Soochow/CN

Introduction: RET fusions were discovered in non-small cell lung cancer (NSCLC) and the efficacy of RET-targeted treatment in these patients has been previously established. However, patients with required resistance to RET-TKIs have limited treatment options.

Methods: We present a case of 55-year-old male who was diagnosed with stage IV NSCLC harboring RET fusion and PS >4 who treated with Pralsetini achieved an excellent clinical benefit initiated at the midmonth of November 2021. The patient continued to tolerate Pralsetini without any further notable toxicities.However, the patient again developed a progressive malignant pleural effusion along with a progression of pulmonary nodule in July 2023. The therapy was initiated in late September 2023 and consisted of Pemetrexed 500 mg/m2 and Tislelizumab 200mg. We then exploited intrapleural Tislelizumab 100mg injection as an adjunctive therapy alongside all systemic treatments.

Results: The patient tolerated the administration of intrapleural Tislelizumab injection well and did not have any clinical signs of side effects or toxicities at first follow-up. Also, we conducted a CT follow-up examination, which revealed comprehensive therapeutic response of the NSCLC to this therapy, together with regressed aforementioned pleural effusion. As the patient consistently showed good therapy tolerance, additional cycles of chemo-immunotherapy were administered with unchanged dosage.

Conclusions: This case contributes to propose intrapleural immunotherapy as a feasible treatment option and intrapleural PD-1inhibitor bridging to systemic immunotherapy may represent a promising approach in NSCLC treatment. As with other potential applications of immunotherapy, immune biomarkers need to be better understood to aid in selection of this therapy.

EP.11E.03 Therapeutic Efficacy of Immunotherapy and Chemotherapy in Metastatic Nuclear Protein in Testis Carcinoma with NUTM1::NSD3 Mutation Originating from the Bronchus: A Case Report

S. Yang, H. Pan, W. Han, J. Chen, Y. Chen, C. Zheng, The First Affiliated Hospital, Zhejiang University School of Medicin, Hangzhou/CN

Introduction: Nuclear protein in testis carcinoma (NC) is an exceedingly rare subtype of poorly differentiated thoracic cancers, characterized by a fusion oncogene between nuclear testis antigen and an epigenetic reader. Among these fusion mutations, NUTM1::NSD3 represents the third most common variant in NC, crucial for maintaining proliferation in NC cells in vitro. The overall survival of metastatic NC is typically limited, with reported median OS of 12 months. While there have been isolated reports of NC patients responding to immunotherapy, the efficacy of combining chemotherapy with immunotherapy remains uncertain. Here, we present a case of metastatic NC harboring the NUTM1::NSD3 mutation, demonstrating a partial response to first-line treatment with immunotherapy and chemotherapy.

Methods: Clinical data were obtained from the First Affiliated Hospital, Zhejiang University School of Medicine. Tumor, para-tumor, and normal lung tissues were collected during surgery for genomic analysis using the Novaseq-SE50 platform. Structural variation prediction was performed using Delly 2 after quality control.

Results: The patient, a 34-year-old male with a 10 pack-year smoking history, presented with a 5-month history of cough. PET-CT(Fig. 1a-b) and CT(Fig. 1c-d) scans revealed cT4N2M0 (stage IIIB) lung cancer. Diagnosis of NC was confirmed by immunohistochemistry and FISH(Fig. 2c-d) in November 2023. Initial treatment comprised a combination of albumin-bound paclitaxel, carboplatin, and Tislelizumab. After 3 cycles of neoadjuvant therapy, significant tumor shrinkage was observed(Fig. 1e-f). Subsequent R0 resection(Fig. 2a-b) yielded a pathological stage of ypT1bN2M0 (stage IIIA). Whole-genome sequencing identified the fusion mutation of NUTM1 and NSD3. The patient has survived for 6 months since diagnosis with no signs of recurrence or metastasis during follow-up.

Conclusions: This case highlights the potential therapeutic benefit of combining immunotherapy and chemotherapy as first-line treatment for metastatic NUTM1::NSD3 NC. Our findings suggest that immunotherapy may confer clinical benefits for NC patients with specific mutation profiles.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.11E.04 Low-Dose Nivolumab in Advanced NSCLC; Light at the End of the Tunnel

A. Alaga, K. Jeyabalan, A.A. Rushdan, Hospital Sultanah Bahiyah, Alor Setar/MY

Introduction: Immune checkpoint inhibitors (ICIs) have radically changed the treatment and outcomes of numerous types of cancer, including NSCLC. Nivolumab (anti-PD-ligand 1 [PD-L1]) is approved by the Food and Drug Administration (FDA) for use in metastatic non-small cell lung carcinoma (NSCLC). Nivolumab is used at 3 mg/kg or in fixed doses of 240 mg every 2 weeks. However, it has resulted in 'financial toxicity' of NSCLC treatment in many parts of the world. Data from Phase I studies that used multiple-dose levels suggest that, in general, response does not decrease with a decrease in doses. This study evaluated the efficacy of low-dose nivolumab as a salvage therapy for advanced NSCLC in Malaysia to address financial toxicity.

Methods: Outcomes of patients with advanced NSCLC treated with nivolumab as salvage therapy in the respiratory department of Hospital Sultanah Bahiyah from December 2022 until March 2024 were retrospectively analysed. Patients who could not afford standard nivolumab treatment received low-dose nivolumab (40 mg fixed dose every 2 weeks) until disease progressed. The epidemiology of patients and treatment outcomes (progression free survival - PFS) were analysed.

Results: In total, six patients received low-dose nivolumab. PD-L1 positivity was observed in one (16.7%) patient. 3 of them were male and 3 of them were female, with a median age of 53. Out of the 6 patients, 2 of them received nivolumab as a 2nd-line treatment, 3 as 3rd-line treatment, and 1 as a 4th-line treatment. On average, nine cycles of nivolumab were given to each patient, with a maximum of 20 cycles of nivolumab given to one patient. The mean PFS was documented as 18.4 weeks. There were no immune-related adverse events noticed in patients, except one of them developed an exacerbation of underlying psoriasis.

Conclusions: Low-dose nivolumab can be effective in advanced NSCLC and can be an option to reduce financial toxicity. The efficacy of low-dose nivolumab is comparable with minimal adverse events.

EP.11E.05 Outpatient Treatment Strategies for Grade 3-4 Immune-Mediated Hepatitis in Patients with Lung Cancer

A. Cardeña-Gutiérrez, P. Rodríguez-Hernáez, I.A. Castellano-Carneiro, A. Rosa-Díaz, C. Dorta-Pérez, M. Gutiérrez-Gordo, A. Herrero-Márquez, A. Arencibia, K. Medina-Sánchez, Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife/ES

Introduction: The escalating use of immune checkpoint inhibitors in clinical oncology has led to a surge in immune-related adverse events. Among these, immune-mediated hepatitis ranks as the third most common (5-15%). Current guidelines advocate corticosteroids (1-2 mg/kg/day) as first-line therapy, yet corticosteroid pulse therapy offers efficacy with reduced toxicity in other scenarios, such as lupus nephritis. Despite this, a subset of patients remains refractory. Further immunosuppressive intervention with mycophenolate mofetil (MMF) achieves resolution in over 80% of cases. Optimal dosing, duration, and cessation protocols remain challenging.

Methods: This report highlights three cases of grade 3-4 asymptomatic immune-mediated hepatitis managed with outpatient corticosteroid pulse therapy. Patient data were reviewed confidentially and anonymized for presentation.

Results: Patient A: 60-year-old women diagnosed in May 2023 from stage IV small-cell lung cancer (SCLC). Carboplatin + Etoposide + Atezolizumab. Partial response after 4 cycles. Maintenance Atezolizumab for 10 cycles, until asymptomatic grade 3 hepatitis was diagnosed. Outpatient management with methylprednisolone 250 mg iv for 3 days in day-hospital, and 30 mg/day of oral prednisone after bolus. Tapering dose of prednisone until suspension. Partial response without treatment and no corticosteroid-toxicity appeared. Patient B: 62-year-old women diagnosed in June 2021 from stage IV SCLC. Carboplatin + Etoposide + Atezolizumab. Complete response after 6 cycles. Maintenance Atezolizumab for 36 cycles until grade 4 hepatitis was diagnosed. Methylprednisolone 250mg x3, and 60mg/day of prednisone after bolus until achieving grade 1. Upturn to grade 3. MMF 1000 mg/12h for corticosteroid-refractory hepatitis until liver function normalized. MMF stopped. New upturn solved by reintroducing MMF. Tapering dose of MMF ongoing. Complete response without treatment and no corticosteroid-toxicity. Patient C: 62-year-old man diagnosed in May 2022 from stage IVB lung adenocarcinoma. Carboplatin+ Pemetrexed+ Pembrolizumab every 21 days. Partial response after 4 cycles. Maintenance therapy for 16 months until grade 3 hepatitis was diagnosed. Methylprednisolone 250mg x3, 30mg/day of prednisone after bolus, and tapering dose afterwards. Corticosteroid-refractory hepatitis that require MMF 1000/12 h, achieving normalization of liver function without toxicity. Partial response maintained.

Conclusions: Corticosteroid pulse therapy presents as a less toxic alternative to standard corticosteroid regimens, even for grade 3-4 toxicities, as evidenced by our case series in lung cancer patients. This approach facilitates expedited immunosuppressive escalation for steroid-refractory immune-mediated toxicities, particularly immune-related hepatitis, where MMF emerges as a preferred adjunct. Further research is essential to elucidate optimal dosing and cessation protocols for immunosuppressive therapy.

EP.11E.06 "Down-Stage" To Thoracic Surgery after Neoadjuvant Immunochemotherapy

N. Zou, H. Pan, Y. Tian, H. Zhu, Shanghai Chest hospital, Shanghai/CN

Introduction: A 59-year-old male who smoked two packs of cigarettes per day for an average of 35 years was diagnosed with right upper lobe lung cancer (3.1*2.3*2cm) after a CT scan. The initial presentation included chronic cough accompanied by bloody sputum for over one month. PET/CT indicated primary central lung cancer and lymph node (LN) metastasis accompanied by distal atelectasis without distant or brain tumor invasion. Pathological examination revealed squamous cell carcinoma and hilar LN metastasis by EBUS-TBNA. PD-1 expression was more than 40%. No other gene mutations were detected. The bronchoscope found a neoplasm at the beginning of the right superior bronchia, and intermediate bronchus was suspected to be invaded (figure 1A). The diagnosis was c-T2aN1M0, stage IIb. Patient 's BMI was 22 (58kg/163cm), fev1% was 88% (2.5/2.82 L) and left ventricular ejection fraction was 66%.

Methods: Based on multidisciplinary team's assessment of the disease, if treated directly by surgery, the patient needed to undergo sleeve resection of the right upper lobe and resection of the intermediate bronchus. Concurrently, the bronchus of the middle lobe and lower lobe needed to be anastomotic to the right main bronchus respectively. Even pneumonectomy was under consideration. For less postoperative complications and better quality of life, two-cycle of neoadjuvant therapy completed 33 days before the surgery. Each cycle included 500mg carboplatin, 400mg albumin paclitaxel, and 200mg Sintilimab. The patient was expected to undergo a right upper lobectomy and systematic LN dissection. The adjuvant therapy with the same therapeutic schedule as neoadjuvant therapy would be applied.

Results: The patient was estimated as PR according to the rechecked bronchoscope and CT scan which showed the tumor decreased (2.5*1.5*1cm) (figure 1B). No side effects were recorded during medication. Intraoperative cryopathology showed a negative margin. Paraffin wax pathology resulted in less than 10% of tumor remaining, no residual tumor in LN, squamous cell carcinoma infiltrating bronchial mucosa. The pathological diagnosis was yp-T1N0M0 (MPR), stage Ia. The perioperative outcome was as follows: blood loss less than 100ml, 121 minutes of operating time, 180ml of pleural fluid volume, 3 days of chest tube duration, and 8 days of postoperative hospital stay, with no recorded postoperative complications. During the next 7 months of follow-up, no recurrence or metastasis was found.

Conclusions: Neoadjuvant therapy may have potential to simplify surgical treatment, which means down-stage to thoracic surgery, but benefit patients with the same oncology effect, negative margin, and better perioperative outcome.

Keywords: lung cancer, neoadjuvant therapy, thoracic surgery

EP.12A.01 Preclinical Characterization of a Potent, Selective, Brain-Penetrant Inhibitor of Osimertinib-Resistant EGFR Variants

K. Amberg-Johnson, J. Xu, H. Izadi, R. Kannan, S. Ellery, S. Kurhade, A. Verras, J. Guo, B. Jean, M. Svensson, P. Hsiao, E. Evangelista, Z. Liu, J. Bell, A. Futran, K. Akinsanya, K.K. Jensen, Schrodinger, New York/NY/USA

Introduction: Mutations in the epidermal growth factor receptor (EGFR) gene are found in approximately 15-40% of non-small cell lung cancer (NSCLC). Classical EGFR activating mutations, characterized by a short in-frame deletion in Exon 19 ("Del19") or the L858R missense mutation, lead to ligand-independent EGFR activation that drives mitogenic signaling. Third generation, irreversible tyrosine kinase inhibitors (TKIs) such as osimertinib, have become the standard of care and are used in first-line treatment of NSCLC with EGFR classical mutations. After first-line treatment with osimertinib, approximately 8% of patients relapse with an EGFR on-target mutation, C797S, which blocks covalent binding of third generation TKIs to EGFR. For these patients, there is an unmet need for next-generation EGFR TKIs with: (1) strong potency on EGFR variants containing C797S, (2) selectivity over EGFR wild-type (WT) to mitigate the cutaneous adverse events associated with EGFR WT inhibition, and (3) sufficient brain penetration to address brain metastasis.

Methods: Leveraging in silico physics-based techniques such as Free Energy Perturbation (FEP+), we have identified a potent, selective, and brain-penetrant EGFR inhibitor. We tested our compounds in biochemical assays for EGFR mutants and EGFR WT to measure potency, and evaluated cellular activity in vitro with phospho-EGFR target engagement assays and proliferation assays in cells expressing several EGFR variants. We measured anti-tumor activity of our lead compounds in vivo using tumor xenograft models. To quantify our EGFR WT selectivity in vivo, we compared phospho-EGFR inhibition in tumor xenografts with that in mouse skin.

Results: We have developed an orally-bioavailable, potent, selective, brain-penetrant inhibitor that is active against the C797S resistance mutation while sparing EGFR WT. Biochemical and cellular assays revealed nanomolar potency on EGFR Del19 and EGFR L858R, as well as the osimertinib-resistant mutants EGFR Del19/C797S and EGFR L858R/C797S. Our inhibitor demonstrated EGFR WT selectivity in vitro that is comparable to osimertinib using various cellular models of EGFR WT activity as well as human keratinocytes. In rodents, we observed brain penetration (Kpu,u > 0.3). Oral dosing led to tumor regression in multiple tumor xenograft models at well-tolerated doses that were correlated with tumor phospho-EGFR levels. The doses showing anti-tumor activity spared inhibition of mouse skin phospho-EGFR, which may lead to a therapeutic window that minimizes the cutaneous adverse effects of EGFR WT inhibition.

Conclusions: We have identified and optimized an orally-bioavailable, potent, selective, brain-penetrant EGFR inhibitor. Due to its potency on EGFR mutants with the C797S resistance mutation and the unmet medical need in that population, the preclinical package supports the development of this inhibitor in NSCLC patients that have progressed on osimertinib with a C797S resistance mutation.

EP.12A.02 What is the Optimal First-Line Regimen for EGFR-Mutated Advanced Non-Small Cell Lung Cancer: A Network Meta-Analysis

W. Zhang, Z. Guo, L. Ye, Z. Chen, K. Xu, X. Liu, Y. Liu, H. Wang, L. Zhao, W. Zhao, Y. He, Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Regimens based on epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are the first-line and standard of care for patients with advanced EGFR-mutated non-small cell lung cancer (NSCLC). There are currently various TKI-based regimens available, and it can be challenging for clinicians to determine the most effective and safe option due to the lack of direct comparisons between these regimens. In this study, we conducted a network meta-analysis (NMA) comparing the efficacy and safety of distinct regimens to determine the optimal regimen for patients with EGFR-mutated NSCLC, thereby facilitating clinical decision-making.

Methods: The PubMed, Embase, Cochrane Library databases and international conference databases were comprehensively searched from their inception to 02 November 2023 for collecting data regarding efficacy and safety from eligible randomized controlled trials (RCTs). Following literature screening and data extraction, a NMA was conducted to compare the efficacy and safety among 21 regimens with a random-effects consistency model in a Bayesian framework using a Markov Chain Monte Carlo simulation technique within the GEMTC package.

Results: A total of 35 RCTs were included, of which 25 were phase III trials and 10 were phase II trials, involving 9718 individuals and 21 regimens. The primary study endpoint across all studies was progression-free survival (PFS). Compared with other interventions, combination therapies based on third-generation TKIs, especially osimertinib plus ramucirumab (OSI_RAM), showed the most favorable PFS prolongation in overall patients (Figure A). Consistently, subgroup analyses showed that third-generation TKIs-based combination regimens were superior to other regimens in most prespecified subgroups with distinct clinicopathological characteristics (Figure A). In terms of overall survival, despite the combination regimens based on third-generation TKIs also showing relatively superior outcomes, erlotinib plus chemotherapy and gefitinib plus chemotherapy were ranked more favorably (Figure B). In terms of safety profile, combination therapies based on third-generation TKIs did not significantly increase the incidence of grade 3 or higher adverse events compared with other regimens.

Conclusions: Combination regimens based on third-generation TKIs, especially OSI_RAM, showed superior efficacy compared with third-generation TKIs monotherapy or other regimens as first-line therapy in EGFR-mutated advanced NSCLC, along with an acceptable safety profile. Our study concluded that combination regimens based on third-generation TKIs (OSI_RAM, OSI plus chemotherapy, OSI plus bevacizumab, amivantamab plus lazertinib and aumolertinib plus apatinib) could be the new and clinically preferable first-line, standard of care for EGFR-mutated advanced NSCLC.

Keywords: epidermal growth factor receptor, non-small cell lung cancer, network meta-analysis

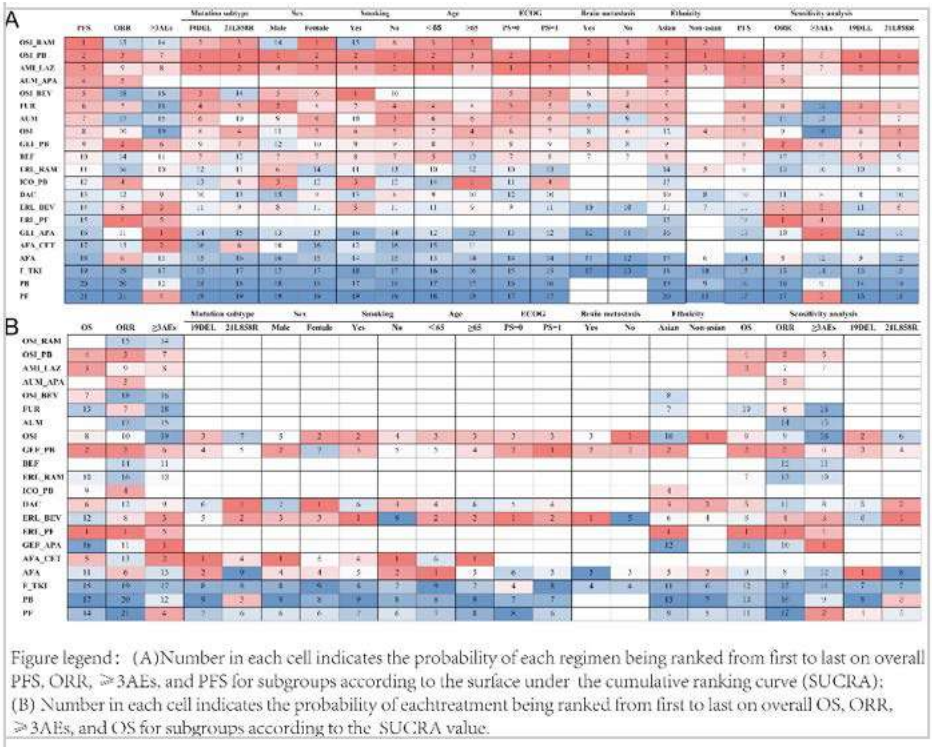

Figure legend: (A)Number in each cell indicates the probability of each regimen being ranked from first to last on overall PFS, ORR, ≥3AEs, and PFS for subgroups according to the surface under the cumulative ranking curve (SUCRA); (B) Number in each cell indicates the probability of eachtreatment being ranked from first to last on overall OS, ORR, ≥3AEs, and OS for subgroups according to the SUCRA value.

EP.12A.03 Overall Survival after Treatment with First-Line Osimertinib for EGFR-Mutant Advanced NSCLC in the US

J.K. Sabari[1], H.A. Yu[2], P. Mahadevia[3], Y. Liu[4], L. Demirdjian[5], A.A. Sultan[4], Y.H. Chen[4], X. Wang[6], A. Passaro[7], [1]Perlmutter Cancer Center, New York University Langone Health, New York/NY/USA,[2]Memorial Sloan Kettering Cancer Center, New York/NY/USA,[3]Janssen Research & Development, Raritan/NJ/USA,[4]Department of Global Real-World Evidence, Janssen Global Services LLC, Raritan/NJ/USA,[5]Janssen US Data Sciences, San Diego/CA/USA,[6]Department of Janssen Data Science, Titusville/NJ/USA,[7]European Institute of Oncology IRCCS, Milan/IT

Introduction: Osimertinib is approved for first-line treatment of EGFR-mutated advanced non-small cell lung cancer (NSCLC). In the FLAURA study, median overall survival (OS) was 38.6 months and 2-year landmark OS was 74%. We assessed OS following first-line osimertinib using real-world data from large longitudinal US oncology databases.

Methods: This retrospective cohort study used electronic medical records from ConcertAI, Flatiron, and COTA. Patients with newly-diagnosed advanced/metastatic disease with exon 19 deletions or exon 21 L858R substitutions who initiated first-line osimertinib monotherapy between 18-Apr-2018 and 31-Oct-2022 were eligible. Patients were followed up until death, loss to follow-up, or 31-Oct-2023. Mortality data were captured from multiple sources from each database, ensuring completeness. OS was estimated using the Kaplan-Meier method.

Results: 432 patients from ConcertAI, 636 from Flatiron, and 234 from COTA were included (Table). Median age ranged from 68-71 years, 67%-70% were female, ECOG score of 0-1 in 49%-70%, and 34%-39% had CNS metastases.

The 24-month survival rate (95% CI) was 57% (53-63) in ConcertAI, 57% (53-61) in Flatiron, and 60% (53-67) in COTA (Figure) with corresponding median OS of 27.7, 28.8, and 29.2 months, respectively. Among patients with ECOG 0 or 1, the median OS was 30.7, 30 and 29.1 months, respectively. Between 26%-32% of patients died prior to 2nd line-of-therapy. Older age, CNS metastases, liver metastases, TP53 comutations, exon 21 L858R, and ECOG ≥2 were associated with higher mortality and shorter median OS. A pooled analysis including additional subgroups is underway.

Conclusions: We observed that real-world OS for osimertinib is lower than observed in clinical trial settings. Between one quarter and one third of patients die prior to receiving 2nd line-of-therapy. These results highlight the pressing need for innovative treatments to improve survival.

EP.12A.04 Patterns of Osimertinib Dose-Reduction and Impact on Outcomes in EGFR-Mutation Positive Non-Small Cell Lung Cancer

L. Ramagiri[11], S. Farid[2], S. Zhao[2], M. Li[2], B. To[2], N. Amirmokhtari[2], L. Wei[2], R. Memmott[2], A. Alahmadi[2], K. He[2], J. Kaufman[2], L. Roof[2], P. Shields[2], D.P. Carbone[2], G.A. Otterson[2], C.J. Presley[1], D.H. Owen[2], [1]The Ohio State Univeristy, Columbus/OH/USA,[2]The Ohio State University, Columbus/OH/USA

Introduction: EGFR mutations are the most common targetable driver mutations found in lung adenocarcinoma. EGFR exon 19 deletion and exon 21 L858R mutations account for ~ 85% of the somatic EGFR alterations and predict sensitivity to EGFR tyrosine kinase inhibitor (TKI). Third generation TKI, osimertinib, has shown overall survival benefit and superior CNS activity compared to earlier generation TKIs in patients with treatment naive EGFR positive NSCLC. The impact of dose reductions/modifications on outcomes including CNS disease in real world setting has not been well characterized.

Methods: This was a retrospective study including 94 patients with NSCLC harboring classical EGFR mutations who received osimertinib therapy between 10/1/2017-10/31/2023 at the Ohio State University. Medical records were extracted via chart review and data was collected in REDCap. Demographics and clinical characteristics were summarized using descriptive statistics and compared between patients with and without dose reduction using Kruskal-Wallis test (continuous outcomes) and Fisher's exact test (categorical outcomes). Kaplan-Meier survival analysis was used to assess the survival outcomes. All statistical analysis was done in SAS 9.4

Results: Median age of 94 patients at diagnosis was 66.9 years (range 37-89). Our cohort included 64.9% females and 35.1% males, majority (77%) of patients were white, 10% Asian, 5.1% were African Americans, 3% other/unknown. All patients received first-line osimertinib. Twenty patients (21.5%) underwent dose reduction at any time during treatment. Median time to first dose reduction was 4.8 months (IQR: 0.6-34.5). Fatigue (25%), diarrhea (25%) and nausea (20%) were the most common reasons for dose reductions. Other causes included rash (15%), thrombocytopenia (10%), anemia (5%) and pneumonitis (5%). Median time on treatment with osimertinib was 8.3 months (IQR: 3.2-20.0) in patients who underwent dose reduction versus 9.2 months (IQR: 0.8-40.7) in patients without. CNS progression was seen in 57.1% of patients who underwent dose reduction compared to 31% without dose reduction (p=0.217). Median overall survival (OS) for the entire cohort was 26.7 months (95% CI: 20.73, 34.79). There was no significant difference in OS between patients who underwent dose reduction and those who did not. Patients who required dose reduction were older (mean age: 71.3 years) than those who did not require dose reduction (mean age: 65.2 years, p=0.03). There was no significant association between sex and dose reduction (p=0.2687). There was no significant association between race and dose reduction (p=0.07).

Conclusions: In our cohort, older patients more frequently required dose reduction with osimertinib therapy. Outcomes for patients with and without dose modifications were overall similar. Patients with dose reduction experienced higher rates of CNS progression, though this was not statistically significant in our study.

EP.12A.05 Evaluation of the Role of VAF/cellularity as Proxy of Gene Aberration in EGFR Mutated Advanced NSCLC During Osimertinib

M. Brambilla[1,2], D. Lorenzini[3,4], G. Nardo[1], M. Occhipinti[1,5], G. Mazzoli[1], T. Beninato[1], L. Mazzeo[1,6], R. Leporati[1], S. Manglaviti[1], D. Miliziano[1], G. Di Liberti[1], C. Giani[1], A.D. Dumitrascu[1], T. Serra Cassano[1], A. Prelaj[1,6], C. Proto[1], M. Ganzinelli[1], F. de Braud[1,4], G. Lo Russo[1], [1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan/IT,[2]The Open University, Milton Keynes/GB,[3]Fondazione IRCCS Istituto Nazionale Tumori, Milan/IT,[4]University of Milan, Milan/IT,[5]Sapienza University of Rome, Rome/IT,[6]Polytechnic University of Milan, Milan/IT

Introduction: The efficacy of Osimertinib in EGFR mutated advanced non-small cell lung cancer (aNSCLC) is associated to type of EGFR mutations (EGFRm) and line of treatment. Recently, through the use of Next Generation Sequencing analysis (NGS), we have gained access to information regarding not only type of mutation but also clonality and genetic aberrancy that could help in identifying diversity of response to targeted treatments. We have previously demonstrated that variant allele frequency (VAF), as a proxy of clonality, did not impact in efficacy of Osimertinib as first line treatment in aNSCLC harbouring common EGFRm. We aimed to test if VAF/cellularity ratio (VAF/cell) could be better than VAF in highlighting differences in efficacy during Osimertinib treatment.

Methods: We retrospectively collected data of 84 aNSCLC harbouring a common EGFRm (Ex19dels or Ex21 L858R) treated with at least one cycle of first-line Osi from January 2019 to March 2023 at Fondazione IRCCS Istituto Nazionale Tumori of Milan. NGS analyses were performed at baseline using three different panels (evaluating respectively: Custom panel 7 genes, Hotspot Panel 50 genes, Oncomine Cancer Assay plus DNA 500 genes). Patients were divided into two subgroups according to median (medHigh vs medLow) VAF/cell. Moreover, a subgroup analyses according 3rd quartile (3QVAF/cell) cutoff (3QHigh vs 3QLow) was performed, postulating that an increase VAF/cell ratio may be a surrogate of large genomic aberration or amplification involving EGFR. Median progression free survival (mPFS) differences between subgroups were analysed. Survivals were estimated through Kaplan-Meier method and compared by Cox-proportional Hazard model.

Results: In our cohort, VAF/cell has a positive skewed distribution with mVAF/cell 0,74 and 3QVAF/cell 1,13. With a median follow up of 24,8 months (mo), mPFS in the overall population was 20,9 mo (0.95CI 15-31,1). No differences in mPFS were found according to panel used (p=0.5) and mVAF/cell (HR 0,7, p=0.25: medHigh 26,4 mo, 0.95CI 16-54,5 vs medLow 20,3 mo, 0.95CI 11,9-37,4). Intriguingly, a trend toward a worse PFS was seen if patients were divided according 3QVAF/cell cutoff (HR 1,83, p=0.09: 3QLow 13,5 mo, 0.95CI 11,7-NA vs 3QHigh 23,3 mo, 0.95CI 16-42).

Conclusions: Our study suggests that EGFRm VAF/cell may represent a more reliable surrogate than tumour clonality, as it may be able to highlight genomic imbalance involving EGFR. In particular, a higher VAF/cell ratio may represent a proxy of tumours with aberration involving EGFR, such as loss of heterozygosity or copy number gain, that could give worse outcome during Osimertinib treatment.

EP.12A.06 Diarylheptanoid 35d Overcomes EGFR TKI Resistance by Inducing EGFR Degradation in EGFR-Mutant Lung Adenocarcinoma

X. Hong[1], P-C. Lee[2], [1]Harbin Medical University Cancer Hospital, Harbin/CN,[2]China Medical University, Taichung/TW

Introduction: EGFR-mutant lung adenocarcinomas (LUAD) patients often respond to EGFR tyrosine kinase inhibitors (TKIs) initially, but eventually develop resistance to TKIs. The switch of EGFR downstream signaling from TKI-insensitive to TKI-insensitive is a critical mechanism driving resistance to TKIs. Identification of potential therapies to target EGFR effectively is a potential strategy to treat TKI-resistant LUADs.

Methods: EGFR mutant TKI-sensitive and multiple TKI-resistant LUAD cells were investigated to examine the effects of 35d and Osimertinib in vitro and vivo. Global transcriptome analysis by RNA-sequencing was used to explore the specific mechanisms in TKI-resistant cells treated with 35d. Body weight monitoring and histology morphology analysis of multiple tissues form the mice bearing TKI-resistant tumors were performed to examine the long-term safety of the Osimertinib-35d combination treatment. Correlation between HSPA1B expression and survival in LUAD patients was performed based on the east Asia cohort of LUAD obtained from OncoSG.

Results: Diarylheptanoid 35d effectively suppressed EGFR protein expression, killed multiple TKI-resistant LUAD cells in vitro, and suppressed tumor growth of EGFR-mutant LUAD xenografts with variant TKI-resistant mechanisms including EGFR C797S mutations in vivo. Furthermore, our data showed that combination of 35d significantly inhibits tumor re-progression on Osimertinib and prolongs mice survival. Mechanically, 35d triggers hsp70-mediated lysosomal pathway through transcriptional activation of several components in the pathway, such as HSPA1B, to induce EGFR protein degradation. Clinical significance analysis in LUAD showed that higher HSPA1B expression in LUAD tumors associated with longer survival of EGFR-mutant TKI-treated patients.

Conclusions: Collectively, our results suggest that 35d as a promising lead compound to suppress EGFR expression and provide important insights into the development of combination therapies for TKI-resistant LUADs, which could have translational potential for the treatment of this deadly disease.

EP.12A.07 Restoring Expression of Tumor Suppressor PTEN by Engineered Circular RNA Enhances Osimertinib Sensitivity in Non-Small Cell Lung Cancer

H. Li[1], Z. Liu[2], J. Cai[2], S. Chen[2], M. Qiu[2,3,4], [1]Peking University People's Hospital, Beijing/CN,[2]Peking University Peoples' Hospital, Beijing/CN,[3]Peking University, Beijing/CN,[4]Peking University People's Hospital, Beijing/CN

Introduction: The tumor suppressor PTEN directly inhibits PI3K/AKT pathway, which is con activated in lung cancer cells with oncogenic mutations of EGFR, but loss expression of PTEN protein is common in lung cancer. It is hypothesized that restoring PTEN expression may be a therapeutic strategy for Osimertinib-resistant lung cancer.

Methods: Circular RNAs (circRNAs) are covalently closed single-stranded RNAs that are resistant to exonuclease-mediated degradation. Compared with linear mRNA, circular RNA is more stable and efficient as translate templates, thus circRNA has been considered as "the next generation" of mRNA. By splicing CVB3 IRES into 2 parts, we developed a new Group I permuted intron-exon (PIE) self-splicing system (named NeoAna) for in vitro circRNA synthesis. Then, a microfluid system was established to synthesize lipid nanoparticles for circRNA delivery. Osimertinib-resistant HCC827 and PC9 cells were used for in vivo and in vivo experiments.

Results: First, we established the NeoAna system to synthesize circRNA transcripts in vitro without extra sequences in final products. CircRNA engineered by NeoAna system has minimized immunogenicity, enhanced stability, and longer protein translation duration. A circRNA template (cPTEN_NeoAna) was synthesized with to restore PTEN protein expression. Indeed, cPTEN_NeoAna significantly decreased proliferation of Osimertinib-resistant lung cancer cells and induced apoptosis. In mice bearing xenograft tumor of Osimertinib-resistant cells, intratumor delivery of cPTEN_NeoAna plus Osimertinib significantly reduced tumor growth and tumor volume compared with Osimertinib only. In addition, cPTEN_NeoAna is slightly superior to PTEN circular RNA synthesized with conventional PIE system or m1ψ-PTEN in enhancing Osimertinib sensitivity both in vitro and in vivo. Mechanically, in addition to inhibition of PI3K-AKT pathway, restoring PTEN expression in Osimertinib-resistant cells also decreased KRAS protein expression. cPTEN_NeoAna also increases the sensitivity of Osimertinib by decreasing AKR1C2 expression and increasing intracellular ROS levels in Osimertinib-resistant cells.

Conclusions: Overall, the NeoAna provides an alternative circRNA platform for RNA medicine and restoring PTEN expression could be a promising strategy to overcome EGFR-TKI resistance.

EP.12A.08 Furmonertinib as First-Line Therapy for Chinese Patients with EGFR Mutation-positive NSCLC: A Real-World Study

N.n. Yan, S. Guo, S. Huang, H. Zhang, X. Li, The First Affiliated Hospital of Zhengzhou University, Zhengzhou/CN

Introduction: Furmonertinib is the standard treatment option in the first-line setting for locally advanced or metastatic non-small cell lung cancer (NSCLC) with sensitive epidermal growth factor receptor (EGFR) mutations in China. However, there is limited real-world data available.

Methods: We conducted a retrospective study at a single center, analyzing a cohort of 72 NSCLC patients who tested positive for EGFR mutations and were treated with Furmonertinib as their initial therapy between August 2022 and March 2024. The primary endpoint was progression-free survival (PFS), with secondary endpoints including objective response rate (ORR), overall survival (OS), and safety profile.

Results: The median follow-up was 14.7 months (95% confidence interval [CI], 14.3-15.1). The ORR was 77.8% (95%CI, 67.9 - 87.6). The intracranial ORR was 84.6% (95%CI, 69.8-99.5). The median PFS was 19.9 months (95%CI, 14.4 - 25.4). mPFS for patients without brain metastases was not reached, and mPFS for patients with brain metastases was 16.7 months (95%CI, 14.7 - 18.6). Univariate analysis found that age (<65 years vs ≥65 years, P=0.031), smoking status (yes vs no. P=0.042), liver metastases (No vs Yes, P=0.000) and ECOG score (0/1 vs 2, P=0.000) were associated with a poor prognosis. However, multivariate analysis indicated a potential trend towards extended PFS in patients younger than 65 years (p=0.055, HR 0.42, 95%CI, 0.17-1.02), although the p-value was only marginally significant. Adverse events were noted in 24 patients who received furmonertinib as a first-line treatment. Diarrhea (8.3%) (6/72), anemia (12.5%) (9/72), and liver injury (9.7%) (7/72) were the most frequently reported adverse events. Grage 3 or above were found in 5.6% (4/72) patients.

Conclusions: In a real-world setting, Furmonertinib appears to be a favorable treatment option for EGFR mutation-positive NSCLC patients. The manageable nature of adverse events further supports its use in clinical practice.

Keywords: NSCLC, EGFR, Furmonertinib

EP.12A.09 Oligoprogression and Osimertinib Continuation Post-progression in Patients with EGFR-Mutations.

V. Mai, J. Lee, L. Zhan, M.C. Brown, K. Balaratnam, K. Khan, S. Cheng, S. Barghout, F. Al-Agha, R. Raptis, K. Kuang, L. Eng, A.G. Sacher, P.A. Bradbury, N.B. Leighl, M. Cabanero, R. Hsu, P. Pal, M.S. Tsao, F.A. Shepherd, W. Xu, G. Liu, University Health Network, Toronto/ON/CA

Introduction: Treatment post-progression is commonly observed with many tyrosine kinase inhibitors (TKI) for non-small cell lung cancer. We evaluated the outcomes of patients on osimertinib who were treated versus not treated post-progression, stratified on whether there was oligoprogression versus systemic (non-oligo)-progression.

Methods: Patients at Princess Margaret Cancer Centre (Toronto; CARMA-BROS NCT:04151342) diagnosed from December, 2011 to June, 2021 with classical EGFR mutations who failed osimertinib (after any line) were analyzed for their clinico-demographic data, sites of progression, subsequent treatments and outcomes. Oligoprogression was defined as having five or fewer sites of progression in a maximum of two organs, all identified within 60 days of the first progression on osimertinib.

Results: Of 127 patients progressing on osimertinib, 31% received first-line; remainder as subsequent-line; 4% had clinical progression only; 54% met radiological definition of oligoprogression, of which 59% continued osimertinib post-progression for at least 60 days; amongst all patients having oligoprogression, there was a median of 4.6 (95%CI:1.4-7.1) months continuing osimertinib from first date of progression. In contrast, among the 43% who had systemic (non-oligo)-progression, only 35% continued osimertinib post-progression for at least 60 days; the median time on osmertinib post-progression amongst all patients with systemic progression was 1.1 (95% CI:0.5-2.0) months. Among patients evaluable post-progression, Kaplan-Meier curves from date of progression to time of osmertinib discontinuation are presented in Figure. Only 24% had molecular testing at osimertinib-progression, with 53% with secondary mutations, 4% neuroendocrine-transformed, and 4% sarcomatoid-transformed. Almost half (48%) received no subsequent therapy post-osimertinib: older patients ($p<0.001$) and those with poorer performance status at time of osimertinib-progression ($p=0.01$) were less likely to receive subsequent therapy. Increasing age was also associated with worse performance status ($p=0.06$). Those not receiving subsequent therapy had a median OS of only 0.3 (95% 0-0.8) months, of which half had died while still on osimertinib; those receiving subsequent therapy had a median OS of 8.2 (95%CI 6.0-11.4) months. Among those receiving subsequent therapy, 73% received chemotherapy, 20% received TKI/trial, and 8% received immunotherapy-based treatments. Lung/pleura, bone and brain were the most common sites of progression with osimertinib.

Conclusions: Osimertinib treatment post-progression provided benefit (median 4.6 months) in patients with EGFR-mutations in the oligoprogression setting, but not when there is systemic progression. However, almost half the patients received no subsequent therapy, particularly older patients and those with poor performance status, thus identifying an unmet need for osimertinib replacements and in the post-osimertinib setting.

EP.12A.10 Multi-Omics Uncovers Signatures Associated with Resistance to Osimertinib in EGFR-Mutant Non-Small Cell Lung Cancer Patients

E-B. Braune[1], I.J. Zwicky Eide[2], O. Grundberg[1], L. De Petris[1], O.T. Brustugun[2], S. Ekman[1], P. Hydbring[1], [1]Karolinska Institutet, Stockholm/SE,[2]University of Oslo, Oslo/NO

Introduction: Targeted therapy with tyrosine kinase inhibitors (TKIs) against Epidermal Growth Factor Receptor (EGFR) is part of clinical routine for around 10-15% of advanced non-small cell lung cancer (NSCLC) patients with tumors harboring activating mutations in the kinase domain of EGFR. Osimertinib is a third-generation EGFR TKI displaying potency to both activating kinase domain EGFR mutations and the T790M gatekeeper mutation. Osimertinib is approved by the FDA and EMA for usage in the first-line setting to NSCLC patients with EGFR activating mutations regardless of presence of T790M. Despite improved clinical response following osimertinib treatment compared to treatment with first-generation EGFR TKIs, resistance is inevitable. Intriguingly, a significant fraction of resistant cases following osimertinib treatment cannot be linked to additional genetic aberrations. Here we analyzed if circulating RNAs, including mRNAs and microRNAs, as well as circulating proteins could provide clues of molecular factors associated with acquired resistance to osimertinib.

Methods: Plasma was collected at baseline and progression of disease using paired samples from 20 patients enrolled in the multicenter phase II study First-line treatment with osimertinib in EGFR-mutated non-small cell lung cancer (FIOL). Plasma was centrifuged at 16000g followed by exosomal RNA extraction using Qiagen exoRNeasy Midi kit according to manufacturers' instructions. Total RNA was subjected to paired-end 150 Illumina sequencing (mRNA-seq, lncRNA-seq) or single-end 50 Illumina sequencing (microRNA-seq). For systematic protein analysis, plasma was subjected to the SomaLogic SomaScan 7K Assay Kit.

Results: Systematic transcriptome profiling revealed hundreds of differentially expressed mRNA transcripts, adjusted p-value <0.05, while only 13 microRNAs and 21 proteins displayed differential expression using an identical statistical cutoff. Interestingly, 20 out of 21 differentially expressed proteins were upregulated at disease progression while 12 out of 13 differentially expressed microRNAs were downregulated at disease progression. Baseline samples clustered in a distinct manner compared to samples from disease progression when using mRNAs and lncRNAs as input. We are currently investigating the therapeutic impact of modulating the expression of top-candidate RNAs and proteins in cell lines with acquired resistance to osimertinib. Additional data will be presented at the meeting.

Conclusions: Our study demonstrates the usage of circulating RNAs and proteins from plasma to unveil resistance signatures to the third-generation TKI osimertinib. Furthermore, it highlights the involvement of multiple RNAs and proteins of potential functional impact in osimertinib-refractory NSCLC patients.

Keywords: Non-small cell lung cancer, Osimertinib, Resistance

EP.12A.11 Effect of Antibiotic Exposure on the Efficacy of EGFR TKIs in Patients with Advanced EGFR Mutation-Positive Non-Small Cell Lung Cancer (NSCLC)

B. Pengnoraphat, S. Saichaemchan, T. Thambamroong, J. Phavirunsiri, K. Peechatanan, N. Prasongsook, Phramongkutklao Hospital, Bangkok/TH

Introduction: Infections are often associated with clinical deterioration of advanced NSCLC. Most antibiotics induce dysbiosis in the gut microbiome affecting immune homeostasis and deregulating metabolism. The effect of antibiotic use on the efficacy and toxicity of EGFR-TKIs should be explored.

Methods: This study was a historical cohort design. Data analysis was performed on patients with advanced EGFR mutation-positive NSCLC treated with the first line of EGFR TKIs at Phramongkutklao Hospital, Bangkok, Thailand. The primary endpoint was progression-free survival (PFS). The secondary endpoints were overall survival (OS), objective response rate (ORR), and treatment-related toxicity. Statistical analysis was performed with univariate tests, and multivariate models to evaluate the differences.

Results: A total of 189 eligible patients were enrolled. Twenty-nine of 189 patients (15.3%) were in the antibiotic use group (group A), and one hundred sixty of 189 patients (84.6%) were in the no antibiotic use group (group B). The median PFS of patients in group A, and patients in group B were 5.9 months (95%CI 3.68-8.25), and 11 months (95%CI 9.54-12.46) (p-value=0.005), respectively. The median OS of patients in group A, and group B were 9.3 months (95%CI 5.17-13.49), and 23 months (95%CI 17.74-28.26) (p-value=0.015). The objective response rate of patients in group A, and group B were 35.7%, and 61.29% (p-value=0.012). On multivariate analysis, antibiotic use was independently associated with shorter OS. Patients in group A had a statistically significant increased incidence of transaminitis compared with patients in group B (10.34% vs 1.88%, p-value=0.04).

Conclusions: Antibiotic use independently decreased both PFS and OS. The antibiotic use could be an independent predictor of shorter clinical outcomes (including PFS, OS, and ORR), and higher incidence of mild-grade transaminitis in patients with advanced EGFR mutation-positive NSCLC treated with first-line EGFR TKIs.

Keywords: EGFR TKIs, Antibiotic use, Advanced NSCLC

EP.12A.12 Lazertinib as Second-Line or Greater Treatment is More Effective in Patients who Showed Extended Response to Prior TKI in Advanced NSCLC

C.D. Yeo[1], L. Jeong Uk[2], [1]Eunypyeong St. Mary's Hospital, Seoul/KR,[2]Yeoido St. Mary's Hospital, Seoul/KR

Introduction: Lazertinib is an oral, third-generation EGFR-TKI, and it specifically targets the EGFR T790M mutation along with activating mutations Ex19del and L858R. More real-world data are needed to evaluate its efficacy and safety in treating locally advanced and metastatic non-small cell lung cancer (NSCLC) following prior EGFR TKI treatment.

Methods: This multicenter retrospective study was conducted at seven university hospitals affiliated to Catholic Medical Center (CMC) in Korea. A clinical data warehouse (CDW) platform was used to access and extract information.

Results: Total of 48 patients were assessed. The majority were female (75%) and diagnosed with adenocarcinoma (95.8%). Patients had exon 19 deletion in 56.3 and L858R mutation in 41.7%. The median progression-free survival (PFS) was 15.4 months. At 6, 12, and 18 months, PFS rates were 79.1%, 53.6%, and 27.3%, respectively. When PFS was analyzed by prior TKI duration (<18 months vs >18months), significant differences were noted at the 6 and 9-month marks (P=0.013 and P=0.010, respectively). In multivariate analyses for PFS, only prior TKI duration and ECOG score showed statistical significance (P=0.026 and P=0.049, respectively). In multivariate analysis for OS, ECOG score showed statistical significance (P=0.006). Among 48 patients, 34 (70.8%) experienced adverse events (AEs) related to lazertinib. The most frequent AEs were skin reaction (29.8%), diarrhea (21.3%), and peripheral neuropathy (20.8%).

Conclusions: The results suggest that lazertinib is effective in 2nd or more line settings, with tolerable safety profile. More patients' data are necessary to find possible prognostic markers associated with outcomes of the patients.

EP.12A.13 CRISPR with Double Mismatch Guide RNA Enhances Detection EGFR Mutation in Circulating Cell-Free DNA of Lung Cancer Patients

B. Chang[1], S. Kang[2], W. Hwang[3], J.K. Hur[4], [1]Kyung Hee University Hospital at Gangdong, School of Medicine, Kyung Hee University Seoul, Seoul/KR,[2]Graduate School of Biomedical Science and Engineering, Hanyang University, Seoul/KR,[3]Hanyang Institute of Bioscience and Biotechnology, Hanyang University, Seoul/KR,[4]Department of Genetics, College of Medicine, Hanyang University, Seoul/KR

Introduction: Many efforts have been made to detect the pathogenic mutated DNA from cell-free circulating DNA (cfDNA) in blood, which is less invasive and more practical than tissue biopsy that requires complicated surgical procedures. But detection of mutated DNA in blood by high throughput sequencing is hampered by their sparsity.

Methods: In this study, we have developed a highly sensitive system that can amplify rare mutated DNA in a patient's blood to the extent enough to make a reliable detection by selectively removing normal DNA using CRISPR/Cas12a, called as the CRISPR/Cas12a amplification system. Using CRISPR/Cas12a amplification system, we sought to detect EGFR L858R and exon 19 deleted mutation, known as biomarkers related to NSCLC, in cfDNA of 48 patients with non-small cell lung cancer (NSCLC).

Results: As a result, we successfully verified that our amplification method could detect mutated DNA in all 7 L858R positive samples and 6 of 11 exon 19 deletion positive samples previously diagnosed from tissue biopsy. It showed that our method can be utilized to prevent unreliable diagnosis.

Conclusions: In conclusion, our CRISPR/Cas12a amplification system was proved to be a robust validation tool for detection of EGFR mutations from cell-free DNA and suggested that this technique can be applied to various genetic diseases.

Reungwetwattana[1,2], V. Sriuranpong[2,3], [1]Division of Medical Oncology, Department of Medicine, Faculty of Medicine Ramathibodi hospital, Mahidol university, Bangkok/TH,[2]Thai Lung Cancer Group (TLCG), Thai Society of Clinical Oncology (TSCO), Bangkok/TH,[3]Department of Internal Medicine, Faculty of Medicine, Chulalongkorn University and the King Chulalongkorn Memorial Hospital, Bangkok/TH,[4]Sriphat Medical center, Faculty of Medicine, Chiang Mai University, Chiang Mai/TH,[5]Department of Medicine, Faculty of Medicine Ramathibodi hospital, Mahidol university, Bangkok/TH,[6]Oncology Unit, Department of Medicine, Rajavithi Hospital, College of Medicine, Rangsit University, Bangkok/TH,[7]Department of Medicine, Faculty of Medicine, Pharmongkutklao College of Medicine and The Pharmongkutklao Hospital, Bangkok/TH,[8]Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok/TH,[9]Nursing affairs, Faculty of Medicine Ramathibodi hospital, Mahidol university, Bangkok/TH

Introduction: Osimertinib is the only available third-generation EGFR-TKI in Thailand. Only Civil Servant Medical Benefits Scheme (CSMBS) patients could reimburse osimertinib as the second- or later-line treatment for T790M-mutant patients. Universal Coverage (UC) and Social Security Scheme (SSS) patients have to pay out of pocket. We aimed to explore the utility and outcomes of osimertinib usage in real-world basis from multi-university-based centers in Thailand.

Methods: EGFR-mutant (EGFRm) advanced lung cancer patients received any lines of osimertinib treatment during 2015-2023 were enrolled from 5 university-based hospital. Medical records were reviewed. Overall survival (OS) and progression-free survival (PFS) were estimated by Kaplan-Meier method.

Results: Total of 483 patients were included. Only 81 patients (17%) received osimertinib as first-line (1L) treatment while 54% received as the second-line (2L) treatment to overcome T790M. Liquid biopsy was a major technique (67.4%) for T790M detection. Seventy percent of patients were female with median age of 66 and were non-smokers (70%). Most patients could reimburse osimertinib under CSMBS (55%) and self-pay (45%). At a median follow-up time of 17.4 months, there was statistically significant difference in PFS between 1L-treated patients at 25.3 months and 2L-treated patients at 11 months [HR=2.3, 95% CI (1.65-3.19), P<0.001] (Figure 1A). However, sequencing of osimertinib treatment did not significant affect the OS (P=0.792). The overall-response rate (ORR) was significantly higher in the 1L-treated patients compared to 2L or later-treated patients (74% vs 50%, P <0.001). In both 1L and 2L-treated settings, dose-reduction/interruption occurred 19% and did have significantly longer OS compared to no dose-reduction/interruption patients (Figure1B). Brain metastases at baseline were found at 37% for 1L-treated patients and 32% for 2L-treated patients, both groups of patients had only 10% CNS progression. Self-pay/Insurance and CSMBS/State enterprise patients had significantly longer OS compared to UC patients. Eighteen percent of patients had adverse events which were mostly grade 1-2. Only 3 patients had grade 3 pneumonitis which led to stop treatment.

Conclusions: This real-world study showed osimertinib's efficacy in survival, ORR, CNS control, and tolerability in both 1L and 2L to later-line treatment in Thai population. Dose-reduction and dose-interruption did not lower the treatment efficacy. Our study showed early initiation of treatment is associated with better outcomes, but if the patients could reimburse the drug in all healthcare schemes as the 2L or later-line of treatment, this will be very useful for a lot of patients in Thailand whom could not access to the drugs.

EP.12A.15 ACTN4 as a Predictive Biomarker for Osimertinib Efficacy in EGFR Mutant Non-Small Cell Lung Cancer

T. Tozuka[1], R. Noro[1], Y. Naito[2], N. Miura[2], S. Kunugi[3], K. Honda[2,4], M. Seike[1], [1]Department of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo/JP,[2]Department of Bioregulation, Institute for Advanced Medical Sciences, Nippon Medical School, Tokyo/JP,[3]Department of Analytic Human Pathology, Nippon Medical School, Tokyo/JP,[4]Department of Bioregulation, Graduate School of Medicine, Nippon Medical School, Tokyo/JP

Introduction: Actinin-4 (ACTN4) is an actin-bundling protein involved in cancer invasion and metastasis. This study aimed to evaluate the potential of ACTN4 expression as a predictive biomarker for osimertinib efficacy in EGFR mutant non-small cell lung cancer (EGFR-mt NSCLC).

Methods: We retrospectively analyzed 63 patients with EGFR-mt NSCLC treated with osimertinib as a first-line therapy at Nippon Medical School from August 2018 to October 2021. Immunohistochemistry staining of tumor tissues before the initiation of osimertinib administration was performed. Patients were categorized as ACTN4-positive (ACTN4(+)) if ≥30% of tumor cells were ACTN4-positive, and ACTN4-negative (ACTN4(-)) if <30%. We compared progression-free survival (PFS) and overall survival (OS) between these groups, employing the Inverse Probability of Treatment Weighting (IPTW) method to adjust for background characteristics.

Results: Among 63 patients (median age, 73 [34-89] years; female, 41; ECOG PS 0-1, 52; adenocarcinoma, 63; EGFR 19del/L858R/uncommon, 32/24/7), 33 patients were classified in ACTN4(+) group and 30 patients were classified in ACTN4(-) group. The IPTW-adjusted OS of patients in the ACTN4(+) group was significantly shorter than that of patients in the ACTN4(-) group (median, 33.7 [95% CI, 24.2-NR] months versus 50.7 [95% CI, 49.7-NR] months; HR, 2.76 [95% CI, 1.02-7.45]; p = 0.037). The IPTW-adjusted PFS of patients in the ACTN4(+) group was significantly shorter than that of patients in the ACTN4(-) group (median, 12.3 [95% CI, 5.3-15.6] months versus 16.9 [95% CI, 13.3-22.3] months; HR, 1.87 [95% CI, 1.01-3.48]; p = 0.035).

Conclusions: IPTW analysis revealed that ACTN4 expression was a useful biomarker for identifying patients with poor efficacy of osimertinib. ACTN4 expression may be a predictive biomarker for the poor efficacy of osimertinib in EGFR-mt NSCLC. Based on ACTN4 expression in tumors, the development of treatments for EGFR-mt NSCLC may be considered.

EP.12A.16 High-Dose Aumolertinib Combined Intrathecal Chemotherapy for the Treatment of EGFR-Mutated NSCLC with Leptomeningeal Metastasis

W. Wang, M. Zhong, Chongqing University Three Gorges Hospital, Chongqing/CN

Introduction: Leptomeningeal metastases (LMs), the spread of tumor cells into the leptomeninges and CSF, had a poor prognosis and limited treatment efficacy in advanced NSCLC with a median survival limited to 3 months. Due to the different sites of invasion, the manifestations of LM are complex and diverse, and lack of specificity. Meningeal irritation, intracranial hypertension, cranial nerve damage and even spinal cord injury are common manifestations. The incidence of LMs was reported approximately 9.4% in epidermal growth factor receptor (EGFR) mutation patients. Several therapeutic options had been applied to manage LMs. Some studies had shown that high-dose of third-generation EGFR-TKIs can significantly prolong PFS to 8.6 months. Implement intrathecal chemotherapy has also shown positive effects.

Methods: We report five first-line or treated L858R EGFR-mutated patients (pts) with LMs, with a median age of 56 years, who are mostly female (80%). The most common co-mutations were TP53 and DNMT3A, and 2 pts were combined with T790M mutations. All pts received third-generation EGFR-TKI Aumolertinib (165mg orally once daily) combined intrathecal pemetrexed chemotherapy (Ommaya reservoir). Pemetrexed was performed in different doses depending on the individual patient's tolerance. In the initial stage (cycles 2-4), 2 pts were given 30 mg (administered on days 1 and 8) once every 3 weeks (group A); 2 pts were given 30mg D1 q3W (group B:); 1 pt was given 10mg D1, 8, 15 q3W (group C). All pts received 30mg q4W as maintenance therapy.

Results: As of March 20, 2024, the median treatment duration was 10 months. Objective response rate (ORR) and disease control rate (DCR) were 60% and 100%, respectively. The intracranial ORR was 100%. It is noteworthy that the median ECOG PS was 3 before treatment and decreased to 1 after combination therapy. LM-related symptoms improved significantly in all pts after 3 weeks of treatment. After 6 weeks combination treatment, the brain MRI of all pts showed a significant decrease in LM lesions; and the lesion of 1 patient (group A) intracranial complete response (CR) with the continuation of treatment. In our long-term follow-up of 1 patient (group A), CEA levels in CSF and blood were observed to be positively correlated with remission, while cfDNA levels in CSF and blood showed irregular fluctuations. All pts reported ≥1 treatment-related AEs (TRAEs), most of the AEs were related to chemotherapy. 2 pts had grade 3 TRAE, and none had grade 4 TRAE. Leukopenia, anemia, serum creatinine increase, dizziness, nausea, vomiting, and decreased appetite were the most common AEs.

Conclusions: Our case series demonstrated that aumolertinib(165mg) combined Ommaya reservoir intrathecal chemotherapy had a positive efficacy on LMs from NSCLC, which has rapid and long remission period of LM lesions. Overall, high-dose aumolertinib showed controllable toxic side effects, and significant improvement ECOG PS of pts. The case series provide a feasible strategy for clinical treatment decision, the long-term follow-up data and large sample prospective studies are required for further validation.

EP.12A.17 Impact of Osimertinib and Cranial Therapy on EGFR-Mutated Lung Cancer with Brain Metastasis: A Single-institution Retrospective Study

J. Lee, R. Luke, C.A. Garcia, Weill Cornell Medicine / New York Presbyterian Hospital, New York/NY/USA

Introduction: The third-generation tyrosine kinase inhibitor (TKI), Osimertinib, has demonstrated exceptional CNS activity in the FLAURA study. Multiple first-line treatment options are available for EGFRmt NSCLC, including TKI therapy at 80 mg orally daily with or without initial cranial local therapy (CLT). Failure pattern analyses revealed that 51.8% of patients not receiving initial CLT developed their first progressive disease in the brain, and 59.0% of cranial progression occurred solely at the original sites. This suggests the potential clinical importance of initial CLT. The Bloom study further showed that Osimertinib, administered at 160 mg once daily, exhibited significant therapeutic effectiveness in the CNS and a manageable safety profile for EGFRm NSCLC patients with leptomeningeal disease.

Methods: This retrospective study aims to delineate the clinical characteristics, treatment modalities, and survival outcomes of EGFRmt NSCLC patients with CNS disease, treated with front-line Osimertinib, with or without initial CLT. We evaluated patients diagnosed with EGFR mt NSCLC with CNS disease at the time of diagnosis at a single academic institution (2004-2023).

Results: Our study evaluated 58 patients with EGFRmt NSCLC and CNS disease. Most were female (75%, 43/58) and nearly half were self-identified Asians (47%, 27/58). Majority (88%, 51/58) were diagnosed at Stage IV, with 88% (45/51) having brain metastasis. 81% (47/58) patients received Osimertinib alone for brain metastasis, and 14% (8/58) concurrently underwent first-line radiation (five SRS, two whole brain radiation, one SBRT). Among those who developed brain metastasis post-first-line treatment, the average duration to brain metastasis was 775 days (25.5 months, range 10-60 months). After progression on first-line treatment, 54 patients were evaluated: eight had a complete response (CR), 35 had a partial response (PR), five had stable disease (SD), and four had progressive disease, with two showing a mixed response. The median response time was 8.8 months (range 0.9-44.8 months). After CNS disease progression on first-line treatment, 26 patients received further treatment: 15/26 received EGFR TKI alone (most at 160mg dose), two received combination EGFR TKI with radiation, two received EGFR TKI with chemo and radiation, and one received EGFR TKI with chemotherapy.

Conclusions: The findings from our study indicate that the majority of patients with EGFRmt NSCLC and CNS disease are females, self-identified as Asian, diagnosed at Stage IV with brain metastasis. Osimertinib, often combined with first-line radiation, appears to be a common treatment for brain metastasis in these patients. Following first-line treatment with Osimertinib, a considerable number of patients show either complete or partial response, suggesting the potential efficacy of the treatment. However, for patients with progressive disease, the response time varies significantly. Upon progression of CNS disease after first-line treatment, EGFR TKI, especially at a 160mg dose, is the most commonly employed therapy in our cohort. Some patients also receive combination treatments involving radiation and chemotherapy. Overall, our study highlights the predominance of EGFRmt NSCLC with CNS disease in females and the potential effectiveness of treatments like Osimertinib. However, further research is needed to optimize treatment strategies, particularly for patients with progressive disease.

EP.12A.18 Afatinib vs. Osimertinib as First-Line Treatment for Metastatic Non-Small Cell Lung Cancer Harboring EGFR Mutations

T.T.A. Hoang[1], T.T.T. Nguyen[1], C.T.M. Pham[1], H.Q. Dong[2], K.T. Nguyen[1], [1]Ho Chi Minh City Oncology Hospital, Ho Chi Minh City/VN,[2]University of Medicine and Pharmacy, Ho Chi Minh City/VN

Introduction: The optimal treatment approach for advanced non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (EGFR)-mutant remains the matter of debate. Currently, osimertinib is the preferred treatment of choice in the first-line setting, however, in Vietnam, the accessibility is limited due to high treatment cost and lack of reimbursement. On the other hand, the lastest real world studies of afatinib in Vietnam and other Asian countries has provided evidence of durable survival benefit and manageable toxicity profile thank to flexible dose adjustment approach. Given the lack of head-to-head comparison between these two EGFR TKIs, this study aimed at comparing the survival outcomes and safety of patients with metastatic NSCLC harboring EGFR mutations treated with osimertinib or afatinib in the first-line setting.

Methods: Patients with advanced and recurrent non-small cell lung cancer who harbored EGFR mutations given either osimertinib or afatinib as first-line therapy from January 2018 to December 2022 were retrospectively recruited and analyzed. The primary endpoint of the study was the time on treatment (TOT). Two secondary endpoints included overall survival and tolerability.

Results: There was a total of 156 patients enrolled in this study. The afatinib cohort included 84 patients, whereas 72 patients received osimertinib. With median follow-up time of 16.5 months in osimertinib group and 24.3 months in afatinib group, there was no significant difference on the time on treatment between two cohorts (median: 18.6 (95% CI: 13.5-23.6) vs 16.1 (95% CI: 14.7-17.5) months, p value = 0.79). Patients with Del19 had the median TOT of 15.7 months in the afatinib group and 15.6 months in the osimertinib group (p value = 0.99), Among those with L858R, the median TOT was 19.0 months and 18.6 months in the cohort treated with afatinib and osimertinib, respectively (p value = 0.60). On the brain metastases status, osimertinib seemed not provide significant survival benefit over afatinib (p value = 0.87). There was no between-group difference according to gender, age, and smoking status. At the data cut-off, overall survival was immature. The survival rate at 12 months was 88% and 82% in those treated with afatinib and osimertinib, respectively. Both afatinib and osimertinib have manageable toxicity profile with low tolerability-related discontinuation rate (2.4% vs 1.4%, respectively).

Conclusions: In this single-center real-world retrospective study, osimertinib failed to demonstrate the superiority of survival outcome over afatinib in the first-line setting. These findings warrant larger prospective studies to establish the optimal treatment sequence for Asian patients with EGFR mutant NSCLC.

EP.12A.19 Race May Affect Survival in 1L Patients with Metastatic Non-Small Cell Lung Cancer (mNSLC) Onegfr-Targeted Therapy

A. Barsouk[1], O. Elghawy[1], G. Yang[1], A. Heidlauf[2], C. Yu[2], L. Wang[3], K. Goel[2], L. Rushkin[2], A. Huang[2], L. Sun[1], A. Singh[1], R.B. Cohen[1], C. Aggarwal[1], M. Marmarelis[1], C. Langer[1], [1]Hospital of the University of Pennsylvania, Philadelphia/PA/USA,[2]University of Pennsylvania School of Medicine, Philadelphia/PA/USA,[3]Perelman School of Medicine, Philadelphia/PA/USA

Introduction: Black Americans with EGFR-mutated mNSCLC exhibit inferior survival in limited retrospective analyses. East Asians are more likely to develop EGFR-mutated mNSCLC; trials suggest superior efficacy of erlotinib and osimertinib among East Asian patients vs. other races. Limited data are available on racial disparities in survival with EGFR TKI use.

Methods: We performed a single-institution retrospective analysis of patients (pts) with EGFR-mt mNSCLC treated between 2007 and 2023 with a 1L EGFR TKI. Pts on clinical trials were excluded. Baseline demographics, disease characteristics, treatment history, and clinical outcomes were abstracted from the electronic medical record. Baseline characteristics were compared using independent sample t-tests and chi-square analyses. Median PFS and OS were compared using Kaplan-Meier log-rank analysis and multivariable Cox linear regression. P-values <0.05 were considered statistically significant.

Results: Among 355 treatment-naïve mNSCLC pts with EGFR mutations, median age at diagnosis was 63y, 65.1% were female, 251 (70.7%) White, 60 (16.9%) Asian, and 37 (10.4%) Black. 52.1% of pts received osimertinib, 33.5% erlotinib, 13.0% afatinib, and 1.4% gefitinib. Among erlotinib pts (n=110), mPFS was significantly poorer for Black pts (10m[95%CI:5-15]) compared to White (17m[13-21];p=0.009) or Asian pts (20m[15-26];p=0.025), independent of age or sex. Among osimertinib pts (n=169), mPFS trended inferior for Black (9m[7-11]) compared to White (16m[12-20];p=0.192) or Asian pts (17m[11-23];p=0.251). mOS for erlotinib trended superior for Asian (64m[27-82]) compared to Black (34[3-65]; p=0.223) or White pts (31m[24-38];p=0.264). Likewise, mOS for osimertinib trended superior for Asian (39m[21-49]) compared to Black (24m[13-38];p=0.154) or White pts (38m [15-43];p=0.179). White pts were the only race to show mPFS improvement on osimertinib (33m[13-21]) vs erlotinib (22m[12-20];p=0.033).

Conclusions: In a single US institution, Black patients had shorter PFS on erlotinib and trended towards shorter PFS on osimertinib compared to White or Asian patients. Asian patients trended towards superior OS on both TKIs.

EP.12A.20 EGFR Inhibitors Combined with Intrathoracic Perfusion Manages Malignant Pleural Effusion in EGFR-Mutated Metastatic Lung Adenocarcinoma

W. Huang, S. Liao, X. Lei, Z. Chen, K. Xu, Y-F. Wang, Q. Zhou, J. Liu, Sichuan University West China Hospital, Chengdu/CN

Introduction: Malignant pleural effusion (MPE) is a conventional complication for metastatic lung carcinoma with poor prognosis and noteworthy clinical symptoms. Epidermal growth factor receptor (EGFR) inhibitors were standard medical treatment for those with specific EGFR mutations and proved effective in primary tumors rather than some metastatic sites. FLAURA2 study has showed the potential of first-line chemotherapy combined with Osimertinib in reducing the risk of disease progressing and death. We aimed to retrospectively assess the safety and efficacy of EGFR inhibitors combined with first-line intrathoracic perfusion for EGFR-mutated stage IV lung adenocarcinoma.

Methods: Patients diagnosed with histologically confirmed stage IV lung adenocarcinoma with EGFR 19-del or L858R mutations in Lung Cancer Center, West China Hospital of Sichuan University from January 2013 to December 2019 were identified, among which were detected malignant pleural effusion by chest computed tomography or thoracic ultrasound. All the patients received next generation sequencing or quantitative real-time polymerase chain reaction to identify the targeted gene mutations. They received Gefitinib, Erlotinib, or Osimertinib plus platinum-based intrathoracic perfusion or tyrosine kinase inhibitor monotherapy. Objective response, safety and patient-derived comfort assessment were analyzed.

Results: A total of 31 patients were included in the study with a median age of 52 years (range, 49-85 years), in which 16 (51.6%) were males, and 16 (51.6%) were stage IVA. As for genetic mutation subtypes, 14 (45.2%) of them were found EGFR 19-del mutation, 16 (51.6%) were found EGFR L858R mutation, and one (3.2%) were EGFR T790M mutation. Thirteen patients (41.9%) received tyrosine kinase inhibitor and platinum-based intrathoracic perfusion. The median overall survival was 19 months (range, 3-41 months) versus 45 months (range, 17-86months) for monotherapy and combined treatment, respectively, and combined treatment was associated with favored prognosis (HR=0.017; 95%CI, 0.04-0.84; P=0.030; Figure 1).

Conclusions: Tyrosine kinase inhibitor plus first-line intrathoracic chemotherapy perfusion would manage the disease progression patterns and improve the prognosis of stage IV lung adenocarcinoma with EGFR sensitive mutations. Efficacy, safe outcomes and patient-derived comfort assessment in a large cohort would be presented subsequently.

EP.12A.21 Nimotuzumab Plus Chemotherapy in the Posterior Line Therapy of EGFR-TKIs Resistant Lung Adenocarcinoma: A Case Series Study

K. Lu, M. Zhang, Q. Wang, A. Sun, Y. Xiang, J. Liu, Jiangsu Province Hospital, Nanjing/CN

Introduction: There is a paucity of effective therapy options for patients with epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) resistant lung adenocarcinoma. Here, we report a case series study to assess the efficacy and safety of nimotuzumab combined with chemotherapy, a humanized anti-EGFR monoclonal antibody, in lung adenocarcinoma with EGFR-TKIs resistance.

Methods: We collected nimotuzumab plus chemotherapy in patients with metastatic, stage IV, EGFR-mutated, posterior line therapy (one patient was secondary line therapy) failed, EGFR-TKIs resistant lung adenocarcinoma. Patients received chemotherapy with nimotuzumab (600 mg every three weeks). The primary endpoint was overall survival (OS). Progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), and safety were used as secondary endpoints. Efficacy was evaluated by RECIST 1.1. Safety was classified by CTCAE version 5.0 and performed based on descriptive analysis.

Results: Between Nov, 2018 and Dec, 2023, 19 patients were collected, with a median follow-up of 14.52 months (95% CI: 9.76-21.49). The median age was 61.0 years (range: 42.0-79.0). There was one patient treated with second-line treatment, and others with third-line and above treatment (Table). Nimotuzumab plus chemotherapy showed favorable survival outcomes in OS (1-year OS: 64.2%, 95% CI: 36.2-82.4; 2-year OS: 55%, 95% CI: 26.6-76.4) and PFS (1-year PFS: 33.4%, 95% CI: 13.7-54.7). The median PFS was 4.44 months (95% CI: 3.25-12.39). An ORR was noted in 26.3% (95% CI: 9.1-51.2) patients, and the DCR was 89.5% (95% CI: 66.9-98.7). All patients were treated with nimotuzumab for 2-13 treatment cycles, of which 3 patients who still receive nimotuzumab now. The most common Grade 3-4 treatment-related adverse events (TRAEs) were myelosuppression (21.05%), nausea (5.26%), vomiting (5.26%), gastrointestinal reaction (5.26%), neutropenia (15.79%), leukopenia (21.05%), and thrombopenia (10.53%). No Grade 3-4 nimotuzumab-related AEs were observed.

Conclusions: The encouraging efficacy and tolerable toxicity results support further clinic study of nimotuzumab as a potential alternative treatment for patients with EGFR-TKIs resistant lung adenocarcinoma.

EP.12A.22 Aumolertinib with Chemotherapy as First-Line Treatment in Patients with EGFR-Mutated Advanced NSCLC: A Real-World Study

J. Xu, J. Li, X. Liu, Y. Jiang, R. Guo, The First Affiliated Hospital of Nanjing Medical University, Nanjing/CN

Introduction: Aumolertinib, a third-generation EGFR-tyrosine kinase inhibitor (TKI), has shown efficacy in EGFR-mutated (EGFRm) NSCLC. The FLAURA2 study revealed that first-line osimertinib combined with platinum-pemetrexed chemotherapy significantly improves progression-free survival (PFS) over osimertinib monotherapy. Given aumolertinib's superior efficacy and safety profile, we explored whether adding platinum-pemetrexed chemotherapy could further enhance PFS while maintaining an excellent safety profile.

Methods: This real-world study enrolled patients with advanced EGFR-mutated NSCLC (exon 19 deletion or L858R mutation) who had not received prior treatment for advanced disease. Patients were treated with aumolertinib (110mg once daily) and platinum-pemetrexed chemotherapy (every 3 weeks for 4 cycles), followed by maintenance pemetrexed and aumolertinib. The primary endpoints were PFS. Overall survival (OS), objective response rate (ORR), disease control rate (DCR) and safety were also assessed.

Results: A total of 94 patients were retrospectively enrolled and evaluated. The median age was 62.5 years, and the distribution of EGFR exon 19 deletion / L858R mutation was 54.2%/45.8%. At the data cutoff (March 27, 2024), the median follow-up was 15.8 months. The combination of aumolertinib and chemotherapy yielded a median PFS of 30.5 months. Notably, patients with the 19 deletion exhibited a significantly prolonged PFS compared to those with L858R mutation (median not reached vs. 19.2 months; p=0.027). Furthermore, there was a significantly improvement in PFS among patients with central nervous system (CNS) metastasis compared to those without CNS metastasis (p=0.011). OS has not been reached, with 1-, 2-, and 3-year OS rates of 100%, 84%, and 76.9%, respectively, showing a trend towards improvement compared to data from the FLAURA2 study. Objective response (complete or partial) was observed in 78% of patients, and DCR was 100%. The incidence of all-grade adverse events (AEs) was 90.4% (85/94),with Grade ≥ 3 AEs occurring in 34.0% (32/94) of patients (Table 1). A total of 3.2% (3/94) of patients discontinued treatment due to AEs. The most frequent Grade ≥ 3 AEs were neutropenia (9.6%) and thrombocytopenia (8.5%). No Grade ≥ 3 gastrointestinal disorders, skin toxicity, or fatigue were reported.

Conclusions: This study presents the first report of PFS outcomes for initial treatment with aumolertinib and chemotherapy in patients with EGFR-mutated advanced NSCLC. Aumolertinib combined with chemotherapy appears to be safer compared to the findings in the FLAURA2 study. This study proposes a safer and feasible option for the first-line treatment of EGFR-mutated advanced NSCLC.

EP.12A METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - EGFR
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12A.23 PD-L1 Induced Resistance to EGFR-TKIs in Lung Adenocarcinoma

G. Yi[1,2], X. Zhang[1], S. Li[3], L. Liu[1], P. Yuan[1], Z. Yang[1], [1]The Second Affiliated Hospital of Chongqing Medical University, Chongqing/CN,[2]The Third Hospital of Mianyang (Sichuan Mental Health Center), Mianyang/CN,[3]Geneplus-Beijing, Beijing/CN

Introduction: In advanced Non-Small Cell Lung Cancer (NSCLC), concurrent PD-L1-positive and activating epidermal growth factor receptor (EGFR) mutations often lead to limited efficacy with EGFR-tyrosine kinase inhibitors (EGFR-TKIs), and the underlying mechanism remains unidentified.

Methods: We enrolled 103 EGFR-mutant LUAD patients across three centers, assessed PD-L1 expression, and conducted next-generation sequencing (NGS) for gene mutation analysis. We also expanded the enrollment to include EGFR-mutant patients treated with either EGFR-TKIs alone or in combination with chemotherapy as first-line therapy and evaluated progression-free survival (PFS) following different treatment strategies.

Results: Our data showed that SMO and MET gene amplification, biological processes, and signaling pathways associated with DNA recombination, cell cycle transition, and abnormal phosphorylation were significantly concentrated in the PD-L1 ≥1% than PD-L1<1% group. Clonal RARA and PIK3CA alterations were observed more frequently observed than PD-L1≥1%. On the contrary, the TP53 subclonal mutation accounted for the majority. EGFR-TKI combined with chemotherapy (TKI+C) overcame primary resistance, prolonging median PFS by 9.8 months, with no significant difference compared to PD-L1<1%.

Conclusions: This study presents the molecular mechanism of PD-L1-induced primary resistance to EGFR-TKI, while EGFR-TKI combined with chemotherapy may suggest a potential shift in the current first-line treatment approach.

EP.12A.24 Prognostic Value of Functional Subtype Classification of Co-Occurring TP53 Mutations in Patients with EGFR-Mutant NSCLC Treated with TKI

D. Chukkalore, A. Pemmaraju, C-S. Lee, N. Seetharamu, Northwell Heath Cancer Institute, New Hyde Park/NY/USA

Introduction: Patients with non-small cell lung cancer NSCLC harboring epidermal growth factor receptor (EGFR) mutations represent a distinct subgroup that can benefit from targeted therapy with tyrosine kinase inhibitors (TKIs). However, the co-occurrence of TP53 mutations in EGFR-mutant NSCLC has been associated with poorer clinical outcomes, including shorter progression-free survival (PFS) and overall survival (OS) rates. Understanding the prognostic value of TP53 mutations, particularly in relation to their functional subtype classification, is crucial for optimizing treatment strategies in this patient population.

Methods: This retrospective study which was reviewed by institutional IRB and granted exempt status included patients diagnosed with sensitive EGFR mutation-positive NSCLC who were treated with first- or second-generation TKI therapy between 2013 and 2017. Patient demographics, treatment details, and molecular characteristics, including EGFR and concurrent TP53 mutation status, were collected. TP53 mutations were classified as pathogenic or non-pathogenic/unknown based on current literature. Treatment response rates and PFS were compared between TP53 mutant and wild-type groups, as well as among subgroups with pathogenic TP53 mutations. Statistical analyses were performed using chi-square tests, one-way ANOVA, and Kaplan-Meier curves.

Results: Of the included patients (n=73), those with TP53 mutations (n=31) were younger (median age 61.6 years) compared to TP53 wild-type patients (n=42, median age 72 years). Although demographic differences were noted, only age reached statistical significance (p = 0.003669). While numerical differences in treatment response rates and PFS were observed between TP53 mutant and wild-type groups, these were not statistically significant (fig 1A). However, the subgroup analysis revealed that patients with known pathogenic TP53 mutations (n=17) had significantly lower PFS (8.9 months) compared to TP53 wild-type patients (11.6 months) (p=0.0057) (fig 1B).

Conclusions: Our results suggests that while there are no significant differences in treatment response rates and PFS between TP53 mutant and wild-type NSCLC patients overall, the presence of pathogenic TP53 mutations may serve as a prognostic factor for shorter PFS in EGFR-mutant NSCLC patients treated with TKIs. Further research is needed to understand the underlying mechanisms and explore personalized treatment approaches based on individual molecular profiles. This study underscores the importance of ongoing efforts to improve outcomes for patients with EGFR-mutant NSCLC, particularly those harboring co-occurring TP53 mutations.

Keywords: NSCLC, TKI, TP53

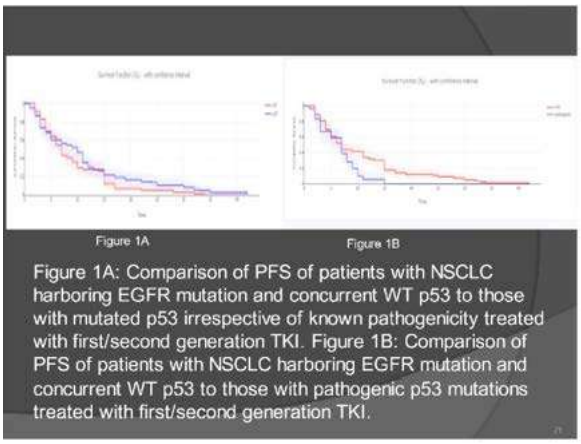

Figure 1A: Comparison of PFS of patients with NSCLC harboring EGFR mutation and concurrent WT p53 to those with mutated p53 irrespective of known pathogenicity treated with first/second generation TKI. SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12A.25 Concurrent RB1/TP53 Alterations in Targetable EGFR-Mutant Lung Adenocarcinoma Imply Aggressive Treatment

Y. Li[1], Y. Zhang[2], R. Zhang[2], X. Nie[2], [1]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology,, Wuhan [430022], Hubei,/CN,[2]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan [430022], Hubei/CN

Introduction: Concurrent RB transcriptional corepressor 1 (RB1)/tumor protein p53 (TP53) alterations in EGFR-mutant lung adenocarcinomas are at unique risk of histologic transformation and define inferior clinical outcomes. Whether those patients would benefit more from EGFR-tyrosine kinase inhibitor combined with other therapy remains unknown. The aim of this study was to investigate clinicopathological characteristics, compound mutation, and prognosis of patients with EGFR-mutant lung adenocarcinoma harboring concurrent RB1/TP53 alterations.

Methods: 76 patients with EGFR-mutant lung adenocarcinomas carrying contaminant RB1/TP53 mutations identified by next-generation sequencing from 2020 to 2023 were enrolled in current study. For patients with early-stage EGFR-mutant lung adenocarcinoma,19 patients who had received adjuvant EGFR-tyrosine kinase inhibitor were compared to 6 patients who had received adjuvant chemotherapy alone. For patients with advanced EGFR-mutant lung adenocarcinoma, 23 patients who had received combined first-line EGFR-tyrosine kinase inhibitor and other treatments were compared to 15 patients who had received first-line EGFR-tyrosine kinase inhibitor alone. Disease-free survival, time to first-line treatment discontinuation, overall survival, clinicopathological characteristics and genomic alterations were evaluated.

Results: Among 76 patients with lung adenocarcinoma, there were 45 females (59.21%) with the median age of 57.28 ± 9.59 years. There were 21 patients in clinical stage I, 6 patients in stage II, 4 patients in stage IIIB and IIIC, and 45 patients in stage IV. Lobectomy is the commonest surgical procedure in early-stage lung adenocarcinoma (stage I-II, 23/27, 85.19%). Amplification of the MYC gene is the commonest compound mutation (11/76, 14.47%) with the median copy number of 4.1(range: 2.9 - 13.9). The median disease-free survival (mDFS) and 95% confidence interval (CI) of patients with early-stage lung adenocarcinoma receiving adjuvant targeted therapy were 5 (2.562 to 7.438) months, while 9 (1.799 to 16.201) months for patients with adjuvant chemotherapy (p = 0.354). 23 patients with advanced lung adenocarcinoma received first-line EGFR-tyrosine kinase inhibitor alone, while 15 patients received combined EGFR-tyrosine kinase inhibitor with other therapy including chemotherapy (10 cases), anti-angiogenesis therapy (2 cases) and chemotherapy plus anti-angiogenesis therapy (3 cases). The median progression-free survival (mPFS) and 95% confidence interval (CI) of those patients receiving combined targeted therapy were 14 (8.336 to 19.664) months, while 7 (2.658 to 11.342) months for patients receiving targeted therapy alone (p = 0.037). The median overall survival (mOS) and 95% confidence interval (CI) of patients with advanced lung adenocarcinoma received receiving first-line combined targeted therapy were 28 (12.423 to 43.577) months, while 21 (16.830 to 25.170) months for patients with targeted therapy alone (p = 0.123).

Conclusions: Patients with advanced EGFR-mutant lung adenocarcinoma harboring concurrent RB1/TP53 alterations benefit more from the compound treatment comprising EGFR-tyrosine kinase inhibitor and other therapy.

Keywords: EGFR, RB1/TP53, lung adenocarcinoma

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12A.26 Overall Survival of Advanced Non-Small Cell Lung Cancer Treated with First-Line Afatinib: A Multicenter Real-World Study in Vietnam

C.T.M. Pham[1], M.C. Truong[2], T.A. Do[2], P.C. Pham[3], H.T.T. Nguyen[2], K.T. Nguyen[1], T.T.A. Hoang[1], A.T. Le[4], H.D.T. Vuong[4], T.D.N. Nguyen[5], K.V. Dang[6], O.T. Nguyen[6], P.V. Luan[7], H.M. Nguyen[7], T.T.H. Vo[3], K.H. Do[2], T.H. Vu[2], H.T.T. Nguyen[2], T.V. Pham[3], H.L. Trinh[8], G.H. Nguyen[9], P.T.B. Nguyen[2], [1]Ho Chi Minh City Oncology Hospital, Ho Chi Minh city/VN,[2]Vietnam National Cancer Hospital, Hanoi/VN,[3]Bach Mai Hospital, Hanoi, Hanoi/VN,[4]Cho Ray Hospital, Ho Chi Minh city/VN,[5]Thong Nhat Hospital, Ho Chi Minh city/VN,[6]National Lung Hospital, Hanoi/VN,[7108] Military Central Hospital, Hanoi/VN,[8]Hanoi Medical University, Hanoi/VN,[9]Hanoi Oncology Hospital, Hanoi/VN

Introduction: Afatinib, a second-generation tyrosine kinase inhibitor (TKI), has been approved for the treatment of non-small cell lung cancer (NSCLC) harboring epidermal growth factor receptor (EGFR) mutations in Vietnam since 2018. The previous largest multicenter study of first-line afatinib in Vietnamese NSCLC patients indicated that the median time-to-treatment failure was 16.7 months, but the overall survival (OS) data were not mature at that time. Here, we briefly present the updated OS data from the same cohort.

Methods: We retrospectively reviewed data from patients with EGFR-mutant NSCLC who were treated with first-line afatinib between April 2018 and June 2022 in nine cancer centers in Vietnam. Eligibility criteria included advanced NSCLC (inoperable stages IIIB-IIIC, recurrences, and stage IV), initial treatment with afatinib, and specific EGFR mutations (excluding de novo T790M mutations). A starting dose of afatinib ranging from 20 mg to 40 mg was determined by physicians and adjusted based on tolerability. Post-afatinib treatment strategies were guided by T790M mutation status, performance status, site of progression, and patient preferences. The OS was estimated using the Kaplan-Meier method, with univariate and multivariate analyses performed to identify prognostic factors.

Results: Out of 343 patients treated with first-line afatinib, EGFR exon 19 deletions (Del19) were detected in 46.9% of patients, L858R mutations in 26.3%, and other uncommon EGFR mutations, including compound mutations, in 26.8%. Brain metastases at baseline were present in 25.4% of patients. The predominant starting dose of afatinib was 30 mg (58.6%), followed by 40 mg (39.9%) and 20 mg (1.5%). Subsequent treatments post-afatinib failure included osimertinib (31.2%), doublet platinum-based chemotherapy with or without immunotherapy (24.6%), single-agent chemotherapy (5.4%), and best supportive care (31.5%), with 7.3% of treatments unknown. After a median follow-up of 36.8 months, 61.2% of the patients experienced events, with a median OS (mOS) of 31.1 months (95% CI: 29.4-32.9). Patients who received osimertinib after first-line afatinib had a mOS of 37.5 months. The mOS for patients with uncommon mutations was lower compared to those with the Del19 mutation (27.6 vs. 31.7 months, p=0.022) and the L858R mutation (27.6 vs. 35.2 months, p=0.040), using the Hochberg adjustment method. The mOS did not significantly differ between patients with and without brain metastases (31.5 vs. 29.9 months, p=0.130), between starting dose subgroups (40 mg vs. <40 mg: 32.6 vs. 30.0 months, p = 0.133), or based on the tolerance dose (40 mg vs. <40 mg: 31.5 vs. 30.6 months, p = 0.942). Multivariate analyses identified uncommon mutations, a poor performance status (PS score ≥2), and current smoking as adverse prognostic factors for OS.

Conclusions: The OS observed in patients treated with first-line afatinib in Vietnam was encouraging. In this real-world setting, the effectiveness of first-line afatinib treatment was evident across various patient subgroups, including those with or without brain metastases, those with common and uncommon mutations, and those receiving different starting doses.

Keywords: Overall survival, Vietnam, Afatinib

EP.12A.27 Targeting DDR Pathway Activates the TBK1-NF?B P65 Axis and Enhances the Killing Effect of CD8+ T Cells

G. Li, C. Xuan, D. Zhong, L. Zhang, Tianjin Medical University General Hospital, Tianjin/CN

Introduction: Deficiencies in DDR signaling pathways have been linked to improved responses to immunotherapy. This study seeks to explore whether inhibiting the key mediator of DDR pathways, ATR, could enhance the function of CD8+ T cells and elucidate its underlying mechanism.

Methods: The CD8+ T cell-killing experiment was conducted in vitro to assess the effectiveness of ATR inhibitors. RNA Sequencing analysis was then performed to identify the regulatory mechanism following ATR inhibition. Subsequent investigations involved Western blotting, RT-qPCR, and immunofluorescence assays were utilized to evaluate the inflammatory signaling pathway in relation to the RNA sequencing results. Flow cytometry and ELISA were employed to detect downstream targets such as surface MHC-I expression and chemokine molecules within the network, in order to confirm our hypotheses.

Results: The ATR inhibitor (VX970) had been demonstrated to increase the cytotoxic impact of CD8+ T cells on tumor cells. RNA-seq analysis indicated the enrichment of pathways associated with inflammatory responses, along with pathways related to TNFκ signaling via NFκB. Accumulation of cytosolic dsDNA and increased κH2AX protein expression had been found, suggesting important roles of DNA damage in triggering inflammatory responses following ATR inhibition. Further increases in phospho-TBK1 (p-TBK1) and p-NFκB p65 proteins were observed as RNA-seq analysis indicated. Activated NF-κB then entered the nucleus and initiated the transcriptional response involving CCL2 and CCL20 to exert significant anti-tumor effects. Furthermore, the upregulation of active forms could enhance the expression of MHC-I molecules via TAP1 presentation, which partially explained the reason ATR inhibition could induce the recruitment of CD8+ T cells.

Conclusions: Targeting the DDR pathway results in the accumulation of stimulated CD8+ T cells, possibly through increased MHC-I surface expression and upregulation of CCL2 and CCL20. This accumulation may be attributed to the presence of cytosolic DNA and activation of the TBK1-NFκB/p65 signaling pathway. Ultimately, these mechanisms could enhance the efficiency of immunotherapy.

Keywords: ATR, immunotherapy, CD8+T cell

EP.12A.28 Overall Survival in a U.S. Asian Population with EGFR-Mutated Stage IV NSCLC Treated with Any Generation of TKIs as First-Line Treatment

Y. Liu, Z. Ma, A. Moreira, A. Chachoua, V. Velcheti, S. Lau, S. Punekar, J. Sabari, E. Shum, New York University Langone Health, New York/NY/USA

Introduction: Osimeritinib, a 3rd-generation EGFR tyrosine kinase inhibitor (TKI), was approved as first-line (1L) treatment for metastatic non-small-cell lung cancer (NSCLC) with EGFR mutations (ex19del or L858R) in 2018. This approval was based on the FLAURA trial, which showed improved progression-free survival and overall survival (OS) of 1L osimertinib compared to 1st-generation TKIs. Despite this, subgroup analyses revealed no OS difference in Asian or L858R patients. Observational studies such as GioTag and UpSwinG showed better median OS in Asian ex19del patients on sequential afatinib and osimeritinib treatment, prompting the question of whether sequencing treatment may also benefit L858R patients. We conducted this analysis of real-world outcomes in U.S. Asian patients with EGFR mutated NSCLC treated with 1L osimertinib, 1st- or 2nd- generation TKIs (TKIs-only), or sequential 1st- or 2nd- generation TKI followed by osimertinib (sequential-TKI-osi). This abstract was accepted by ASCO 2024 for online publication only.

Methods: We conducted a single-institution IRB-approved retrospective study at NYU, including Asian patients diagnosed with stage IV NSCLC with EGFR ex19del or L858R, who received any generation of TKIs from 1/1/2010 to 1/1/2024. We compared 3-year OS based on treatment groups, excluding patients with less than 3 years of follow-up. The analysis utilized the Cox proportional-hazards model to calculate hazard ratios (HR) and P values of OS. Survival curves were estimated using the Kaplan-Meier method. The log-rank tests were used to assess survival differences between treatment groups. Additionally, a multivariable Cox proportional-hazards model explored the association between patients' survival time and multiple predictor variables.

Results: We analyzed 139 cases: 103 (74%) females, 68 (49%) L858R, 113 (81%) never smokers, with age range of 31-96 years. The analysis revealed no significant difference in the OS among L858R patients who received TKIs-only (p=0.83) or sequential-TKI-osi (p=0.90), compared to 1L osimertinib (median OS not reached in all three groups). However, in ex19del patients, TKIs-only (HR 0.31, 95% CI 0.13-0.76) and sequential-TKI-osi (HR 0.30, 95% CI 0.11-0.85) treatments showed superior OS compared to 1L osimertinib, with a median OS of 24.7 months in 1L osimertinib vs. not reached in the other two treatments. Among all predictor variables (treatment, age, sex, EGFR subtypes, and smoking status), only age had a significant but small impact on OS (HR 1.03, 95% CI 1.01-1.06).

Conclusions: Our real-world analysis revealed that Asian stage IV NSCLC patients with L858R treated with 1L osimertinib had a similar 3-year OS compared to those treated with TKIs-only and sequential-TKI-osi. Whereas, 1L osimertinib was inferior to both treatments in OS for ex19del patients. This finding may be unique and significant in Asian ex19del patients, though our analysis is limited by the small cohort of a retrospective study. Larger cohorts from retrospective studies and real-world data sets are needed to investigate the response of Asian ex19del patients to either 1L osimertinib, and now the recently approved FLAURA2 1L regimen of Osimertinib and chemotherapy, while underlining the need for novel treatment options for L858R patients.

EP.12A METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - EGFR
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12A.29 Characteristics of Osimertinib Non-Responders vs Responders in EGFR Mutated Lung Cancer

A. Reyes, S. Sampath, R. Muddasani, M. Afkhami, A. Amini, V. Villaflor, R. Salgia, A. Rock, X. Li, E. Massarelli, City of Hope Comprehensive Cancer Center, Duarte/CA/USA

Introduction: Since the early 2000s the treatment options for Non-Small Cell Lung Cancer (NSCLC) have increased after the discovery of targetable 'driver mutations'. From the landmark FLAURA trial, third generation Osimertinib demonstrated improved median PFS and OS.

Methods: From electronic medical records, a database of patients with NSCLC with EGFR mutations. Inclusion criteria were EGFR Exon 19 or L858R mutations, available imaging for review and metastatic/recurrent disease. We excluded patients who discontinued osimertinib due to side effects or did not tolerate full dose of 80mg. Tumor burden at diagnosis was determined by initial PET/CT and MRI brain. Oligometastatic disease was defined as less than 3 regions while elevated tumor burden was determined by greater than 3 regions of disease. Lymph node regions and bone metastasis were separated into discrete anatomical regions; head/neck, thorax, pelvis, abdomen, and extremities.

Results: From over 400 patients with EGFR-mutated NSCLC, 125 patients met our eligibility criteria. With median follow up of 41.9 months, median PFS was 20.2 (95% CI 17.2-24.4) and median OS was 34.4 (95% CI 28.7, 45.9). The 28 patients (22.4%) with oligometastatic disease at diagnosis had longer PFS compared to non-oligometastatic disease at 26.1 months (95% CI 22.8-57.5) versus 18.2 months (95% CI 14.9-23.2) HR 1.75 (1.07-2.86, p=.025) and OS not reached (53.2 NE) vs 28.7 (95% CI 26.6-37.9) HR 4.00 (1.89-8.47, p=<.001). 38 patients received radiation after less than 3 months on Osimertinib and had worse survival compared to patients who received radiation after 12 months, OS 32.2 (95% CI 26.9-46.1) HR 2.60 (1.24-5.44, p=0.011) vs OS 52.3 (95% CI 38.1 NE) and PFS 19.9 (95% CI 15.2-34.4), HR 1.56 (0.89-2.73, p=.122) vs PFS 29.1 (95% CI 24.5-45.1). 73 patients had both hilar and mediastinal adenopathy (by PET/CT) at diagnosis with worse PFS/OS compared to single or no nodal disease PFS 17.1 (95% CI 11.8, 25.3) HR 1.53 (1.02-2.30 p=.041) versus PFS 23.2 (95% CI 18.5-38.0) and OS 28.7 (95% CI 26.0-45.7) HR 1.89 (1.15-3.11, p=0.012) versus 42.3 (95% CI 33.9-NE). 41 patients had CNS disease at diagnosis (22 received early radiation to the brain) without significant difference in survival, PFS 20.4 (95% CI 15.7-34.4) and OS 33.9 (95% CI 26.1-46.1) HR 1.29 (0.79-2.09, p=.308), compared to no CNS disease with PFS 19.5 (95% CI 16.5-26.1) HR 1.05 (0.69-1.59, p=.817), OS 37.9 (95% CI 28.2-53.9). 22 (17.6%) patients continued osimertinib with stable disease, 77 (61.6%) patients received second line therapy; the majority (51 patients) received platinum-based chemotherapy. The most common co-mutation was TP53 (73 patients) followed by EGFR amplification (17 patients). CCNE1 was more common in patients who progressed before 18 months, while MYC was more common in patients with stable disease.

Conclusions: From this retrospective evaluation of a single institution, oligometastatic disease at diagnosis, single or no hilar/mediastinal disease, late radiation were associated with improved PFS and OS. CNS disease at diagnosis had minimal change in PFS and OS. Novel RNA sequencing on the different cohorts is ongoing and results will be presented at the meeting.

EP.12A.30 Landscape of EGFR Mutations and Real-World Experience of Therapeutic Interventions - A Community Oncology Study

K. Jobanputra[1], V. Maniar[2], U. Maheshwari[1], D. Morzaria[1], A. Joshi[1], P. Kalaskar[1], K. Joshi[1], M. Randive[3], M. Mekha[4], N. Bayas[1], P. Kendre[1], S. Dhande[5], A. Shivchhand[6], C. Pethe[5], D. Pal[1], K. Chaudhari[7], [1]MOC Cancer Care and Research Centre, Mumbai/IN,[2]MOC Cancer Care & Research Centre, Mumbai/IN,[3]MOC Cancer Care and Research Centre, Nagpur/IN,[4]MOC Cancer Care and Research Centre, Pune/IN,[5]MOC Cancer Care and Research Centre, Nashik/IN,[6]MOC Cancer Care and Research Centre, Kolhapur/IN,[7]MOC Cancer Care and Research Centre, Indore/IN

Introduction: EGFR is the most commonly targeted mutation in lung cancer however the heterogeneity in these mutations has led to expansion of treatment options in metastatic settings. Herein, we comprehensively summarize the spectrum of EGFR mutations and co-mutations, clinical characteristics, treatment patterns, and survival outcomes in a real-world community oncology practice

Methods: This retrospective study included consecutive patients from community oncology centers diagnosed with metastatic EGFR mutant Non-small cell lung carcinoma (NSCLC) between March 2018 and December 2023. Clinical characteristics including the method of EGFR testing, spectrum of EGFR mutation and co-mutations, and treatment records were retrieved from the EMR. Progression-free survival and overall survival were calculated using the Kaplan-Meier analysis

Results: Out of 1068 patients with Non-small cell lung carcinoma (NSCLC), 871 were identified as adenocarcinomas, with EGFR mutations detected in 311/871 (35.7%). The median age of the cohort was 64 years (34-89) with 11 patients presenting at less than 40 years of age and the M:F ratio being 1:1.07. The majority of these patients were Stage IV (264/311) and the prevalence of EGFR was higher in females compared to males (37.3% v/s 23.1%, p<0.05). Detailed EGFR mutational testing records were available for 200 patients out of which comprehensive Next-generation sequencing (NGS) was done in 97/200 patients wherein 79.3% were tissue-based NGS, and 20.6% were liquid biopsy-based NGS while 103/200 patients were tested by Polymerase chain reaction (PCR). The Spectrum of EGFR mutations and frequency of co-mutations with EGFR are shown in Table 1. The majority of patients received tyrosine kinase inhibitors (TKIs) in the first-line (200/264, 75.7%) of which Gefitinib, Erlotinib, Afatinib, and Osimertinib were used in 55%, 7%, 22.5%, and 20.5% respectively. TKI in combination with Chemotherapy as first-line therapy was used in 64/200 patients. Median survival for the cohort was 35 months (95% CI 29.8-40.2) with a median follow-up time being 31 months (95% CI 26-36)

Conclusions: This study highlights the prevalence and spectrum of EGFR mutation and the use of NGS testing in identifying driver mutations along with co-mutations which can impact disease behavior, therapeutic interventions, and treatment outcomes. These real-world outcomes from community practice are consistent with the current literature

EP.12A.31 Clinical Characteristics and Outcomes of EGFR-Positive Non-Small Cell Lung Cancer with Acquired RET Fusions

T. Kobayashi, Y. Shinno, Y. Yamaguchi, Y. Matsumoto, Y. Okuma, T. Yoshida, Y. Goto, H. Horinouchi, N. Yamamoto, Y. Ohe, National Cancer Center Hospital, Tokyo/JP

Introduction: Osimertinib has emerged as the standard of care for treatment-naïve patients with EGFR-mutant and EGFR T790M mutation-positive NSCLC. However, the development of resistance to osimertinib is nearly inevitable in most NSCLC patients over time. Acquired RET fusions represent one of the mechanisms of resistance to osimertinib. Selpercatinib, a highly selective RET inhibitor, has demonstrated significant and durable efficacy in NSCLC patients with RET fusion-positive tumors. However, there is limited information available regarding the clinical characteristics of patients who develop RET fusions after osimertinib failure, as well as the safety and efficacy of the combination therapy comprising osimertinib and selpercatinib.

Methods: Osimertinib has emerged as the standard of care for treatment-naïve patients with EGFR-mutant and EGFR T790M mutation-positive NSCLC. However, the development of resistance to osimertinib is nearly inevitable in most NSCLC patients over time. Acquired RET fusions represent one of the mechanisms of resistance to osimertinib. Selpercatinib, a highly selective RET inhibitor, has demonstrated significant and durable efficacy in NSCLC patients with RET fusion-positive tumors. However, there is limited information available regarding the clinical characteristics of patients who develop RET fusions after osimertinib failure, as well as the safety and efficacy of the combination therapy comprising osimertinib and selpercatinib.

Results: During the study period, 523 patients with EGFR mutations received osimertinib, and 45 patients underwent NGS testing after osimertinib treatment. Among these patients, 3 (7%) were found to have acquired RET fusions. All three patients were female and presented with clinical stage IVB adenocarcinoma. Two patients had EGFR exon 19 deletion, and one had the L858R mutation. All patients initially received osimertinib as first-line treatment. NGS testing after osimertinib failure were underwent with biopsy from liver metastasis and revealed non-KIF5B fusions (ANKRD26-RET, CCDC6-RET, CGNL1-RET) in all three cases. Two patients received selpercatinib 80 mg twice daily in combination with osimertinib 80 mg daily, while the remaining patient received selpercatinib 160 mg twice daily. The median duration of treatment was 3.7 months (range; 1.1-4.5), and one patient is still undergoing treatment. Initial treatment response was stable disease in two patients who underwent at least one CT scan. Notably, although lesions with detected RET fusions responded, other lesions progressed by the 4-month follow-up evaluation. The combination therapy of osimertinib and selpercatinib was generally well tolerated, with adverse events consistent with the known profiles of each drug alone. None of the three patients experienced grade 3 or higher adverse events during treatment.

Conclusions: The combination therapy of osimertinib and selpercatinib demonstrated feasibility and showed effectiveness to a certain extent. However, selpercatinib following osimertinib resistance resulted in a mixed response, suggesting heterogeneous resistance mechanisms that warrant further investigation.

EP.12A.32 Discontinuation of EGFR-TKI in NSCLC During COVID-19 Infection: Assessing Unvaccination, Low BMI, and Comorbidities

P. Huang[1,2], L-M. Liao[1], J-L. Zhao[1,2], C. Luo[1,2], Y-L. Yi[1,2], Y. Chen[1,2], L. Huang[1,2], [1]The Second Affiliated Hospital, Jiangxi Medical College, Nanchang University, Nanchang/CN,[2]JiangXi Key Laboratory of Clinical and Translational Cancer Research, Nanchang/CN

Introduction: Although the COVID-19 emergency prevention and control phase has been over since May 2023, there is still a positive rate of 1% to 42.5% of monthly influenza-like illness in China. Whether targeted therapy with epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) affects the severity of illness from COVID-19 in patients with non-small cell lung cancer (NSCLC) is unknown. Hence, we conducted a retrospective study to determine the rate of COVID-19 infection and the factors influencing the hospitalization and prognosis of patients receiving EGFR TKI-targeted therapy at our hospital within one month after the onset of the COVID-19 pandemic.

Methods: Patients with a diagnosis of NSCLC who were receiving treatment with third-generation EGFR TKIs were included in the study. We collected and analyzed data on patients' demographic and clinical characteristics and the varieties of EGFR TKIs they received. Factors influencing the hospitalization of COVID-19-infected patients were also determined.

Results: Overall, 267 patients with NSCLC who were treated with third-generation EGFR TKI-targeted therapy were included in the analysis. Their mean age was 62.6 years, and 64.8% of them were females. Among them, 37.5% (100/267) received targeted therapy with osimertinib, 36.3% (97/267) with furmonertinib and 26.2% (70/267) with almonertinib. After a mean follow-up of 30 days, 80.5% (215/267) of the patients were infected with COVID-19, 12.6% (27/215) were hospitalized for COVID-19 treatment and 1.4% (3/215) died of COVID-19 infection. No effect of age, gender, education, smoking status, alcohol intake, gene mutation, type of targeted therapy, variety of EGFR TKI or duration of medication was found. Compared to patients who were vaccinated, had a BMI ≥ 22.3 kg/m2 and no comorbidities, those with no COVID-19 vaccination (hazard ratio [HR] = 2.072, 95% confidence interval [CI]: 0.914 to 4.696, p = 0.059), a BMI < 22.3 kg/m2 (HR = 2.287, 95%CI: 1.054 to 4.963, p = 0.036) and comorbidities (HR = 3.439, 95%CI: 1.463 to 8.083, p = 0.004) had higher rates of infection and hospitalizations. However, targeted therapy during hospitalization was not significantly correlated with the infection rate of COVID-19 among patients with a different vaccination status, BMIs and comorbidities.

Conclusions: NSCLC patients with unmet COVID-19 vaccination, low BMI, or comorbidities may need to suspend EGFR-TKI therapy after COVID-19 infection.

EP.12A.33 A Comparative Analysis of Outcomes in Patients with Single EGFR Muations for Concurrent Gene Alterations

L.T. Le[1], T.T. Nguyen[2], N.V. Nguyen[3], L.V. Dinh[1], Q.V. Le[4], [1]National Lung Hospital, Ha Noi/VN,[2]Hanoi Medical University, Ha Noi/VN,[3]University of Medicine and Pharmacy, Ha Noi/VN,[4]National Cancer Hospital, Ha Noi/VN

Introduction: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) administered as initial therapy enhance the quality of life for individuals diagnosed with EGFR mutation-sensitive non-small cell lung cancer (NSCLC). Our investigation focused on evaluating treatment outcomes among patients with EGFR-mutant NSCLC who exhibit concurrent gene alterations, aiming to ascertain their predictive significance regarding response to EGFR-TKIs treatment.

Methods: A retrospective cohort study was conducted the next gene sequencing (NGS) data from January 2019 to Jun 2023. All patients were categorized into two groups: one comprising individuals with a single EGFR mutation (group 1), and the other consisting of patients with concurrent EGFR mutations (group 2). A total of 109 patients with sequencing data prior to first-generation/second-generation EGFR TKI therapy were enrolled in the study. Progression-free survival (PFS) and overall survival (OS) of EGFR-TKIs therapy were assessed using Kaplan-Meier methods and compared between different patients using the log-rank tests.

Results: Among 109 patients with EGFR mutation showed 72 patients had partial responses (66.1%), one had complete response (0.9%) and 17 patients had stable disease (15.6%); 19 patients had progressive disease (17.4%). The ORR was 67% and DCR was 82.6%. The PFS in the group with single EGFR mutation and concurrent gene alterations group were 15.03 months (CI 95%: 13,17-16,89) and 11.00 months (CI 95%: 9,95-12,05) (P= 0.001). Among the 43 patients with concomitant mutations, patients with ALK mutation had the longest PFS (13.43 months), followed by other PIK3CA (11.00 months) and the lowest PFS was MET application (4.77 months).

Conclusions: This study has demonstrated the concurrent gene alterations in some patients with EGFR mutations, which leads to reduced outcome of EGFR-TKIs. NGS should be performed regularly in patients to determine genetic mutation status before targeting treatment.

EP.12A.34 Chemotherapy and/or Immunotherapy after Progression on Tyrosine Kinase Inhibitors in EGFR Mutant Non-Small Cell Lung Cancer Patients.

M. Okunrobo[1], D. Walker[2], K. Dumais[2], H. Powery[2], P. Izquierdo[1], L.E. Raez[2], [1]Memorial Cancer Institute, Pembroke Pines/FL/USA,[2]Memorial Cancer Institute/Florida Atlantic University (FAU), Pembroke Pines/FL/USA

Introduction: Tyrosine kinase inhibitors (TKIs) have shown promising efficacy in the treatment of metastatic non-small cell lung cancer (mNSCLC) in patients with actionable genetic aberrations (AGA). However, most patients experience progression, because previous trials have shown efficacy with the use of chemotherapy (CHM) plus immunotherapy (IMN) in treating patients without AGA, many of these patients with resistance to TKI therapy have been treated with CHM alone, chemoimmunotherapy (CHM+IMN) or IMH alone with most of the doctors favoring the first two modalities. This retrospective review evaluates the use of CHM and/or IMH as subsequent therapy for patients who progressed on targeted therapy.

Methods: This study was a retrospective review of patients with advanced NSCLC who progressed on a TKI and received either CHM or IMH alone, or a combination of both at a community cancer center between Jan 1, 2015, to October 12, 2023. Data was collected and reviewed from electronic health records of 229 patients until data cutoff on January 19, 2024. All time-to-event data were estimated using the Kaplan-Meier method and compared using Cox proportional hazard models with alpha level set to 0.05. Progression free survival (PFS) and overall survival (OS) were reported in months and compared across patients who received CHM, IMH, or CHM+IMN. Measurement data was expressed in medians and standard deviations. All statistical analyses were performed with SPSS. The primary endpoint was PFS defined as the time from therapy initiation after TKI failure to disease progression as defined by the RECIST criteria. The secondary endpoint was OS defined as time from therapy initiation to death from any cause. Other secondary endpoints include PFS of patients with non-EGFR mutated NSCLC. This will include patients with ROS, ALK, and other AGA.

Results: A total of 37 patients met criteria for inclusion of which 26 patients received both CHM+IMN (mainly IMPOWER 150 regimen), 9 patients received CHM alone and only 2 patients received IMH alone. Within 29 patients who expressed EGFR mutations, exon 19 deletions and L858R mutations accounted for nearly half of the group. All patients had progressed beyond an EGFR TKI before starting study therapy with 35% of patients failing at least two EGFR TKIs prior to data collection. The overall median PFS was 5.6 months. The median PFS for the CHM+IMN cohort was 6.3 months compared to 3.4 months and 0.4 months for the CHM and IMH cohorts respectively. The median OS was 12.8 months for patients who received CMH+IMN versus 3.4 months and 0.6 months for the CHM and IMN cohorts respectively. Survival analysis in the non-EGFR mutation populations showed no statistically significant differences between treatments.

Conclusions: Addition of immunotherapy to chemotherapy in patients with EGFR mutated mNSCLC prolonged PFS and OS in comparison to patients who received chemotherapy or immunotherapy alone. This was consistent with the results reported by the IMpower150 study group. The survival analysis result, however, was not statistically significant. due to probably the sample size. More information is needed in this field in view of other trials with challenging results.

EP.12A.35 A Phase I Open-label Study Ofnimotuzumab with Nivolumab in Advanced Non-Small Cell Lung Cancer or Head and Neck Squamous Cell Cancer

A.H. Syed[1], M. Reid[1], R. Frascati[1], A. Groman[1], A. Macias[2], P.L. Luaces[2], O. Santos-Morales[2], K. Leon[2], T. Crombet[2], G.K. Dy[1], [1]Roswell Park Comprehensive Cancer Center, Buffalo/NY/USA,[2]Centro de Immunologia Molecular, Havana/CU

Introduction: Nimotuzumab (Nimo) is a monoclonal antibody (mAb), which targets the epidermal growth factor receptor (EGFR) and is used in Asia for the treatment of head and neck squamous cell cancer (HNSCC). Nivolumab (Nivo) is an anti-programmed death 1 (PD-1) mAb, which overcomes immune checkpoint inhibition and is approved for advanced non-small cell lung cancer (NSCLC) and HNSCC. Due to preclinical studies linking EGF to PD-L1 signaling, this trial aimed to evaluate the recommended phase II dose (RP2D) as well as the safety, tolerability and efficacy of combination treatment.

Methods: This was a single-center, single-arm, non-randomized study utilizing a 3+3 dose-escalation design. Nimo was planned to be given intravenously (IV) at escalating doses of 200mg, 300mg, and 400mg after Nivo infusion at 240mg IV every two weeks in a 28-day cycle. RP2D and dose-limiting toxicities (DLT) were determined. Treatment was continued until disease progression, unacceptable toxicity or withdrawal from the trial. Serial EKG and troponin checks were performed.

Results: Seven patients were enrolled across the 200mg and 300mg Nimo dose levels. The median age was 64.1 years. Four patients (57.1%) were males. Five (71.4%) had NSCLC and the predominant histology was pure adenocarcinoma (n=4, 57.1%). Four patients (57.1%) had KRAS mutation. All patients had disease progression after platinum-based and anti-PD1 therapy prior to enrollment except two NSCLC who were enrolled to receive this treatment after initial platinum-based chemotherapy only. Four patients (two from each dose level) had troponin elevation (median 0.1 ng/ml, range 0.07 to 0.3 ng/ml) lasting at least 24 hours which normalized next week without any associated chest pain except for one patient (HNSCC) with potential treatment-related DLT. Disease control rate was 42.9% (stable disease as best response, n=3).

Conclusions: Asymptomatic troponin elevation was seen with this combination treatment. While there were no clinically significant adverse cardiac outcomes, further development was terminated due to competitive landscape.

Introduction: Clinical guidelines advise Osimertinib (Osi) as the preferred 1st-line treatment for advanced EGFR-mutated non-small cell lung cancer (NSCLC) with exon 19 deletions (del19) or L858R mutation. Recently, results from the FLAURA2 trial demonstrated better progression-free survival (PFS) at 24 months in the Osi/chemotherapy (CT) group compared with the Osi-only group (57%vs. 41%, respectively). It also found a favorable trend toward overall survival (OS) improvement at 2-years of follow-up in post-progression outcomes. However, the incidence of adverse events (AEs) >G3 from any cause was higher with the combination than with Osi alone (the percentage of AEs with an outcome of death was 6.5% and 2.9%, respectively). This study aims to collect and analyze the early outcomes of a cohort of Hispanic patients with EGFR-mutated NSCLC treated with the FLAURA2 study regimen in Latin America.

Methods: A retrospective analysis was conducted on 38 patients from five countries in Latin America who had EGFR-mutated NSCLC and were treated in 1st-line with the FLAURA2 study regimen. Patient demographics, tumor characteristics, and early treatment outcomes were analyzed. Survival analyses assessed progression-free survival (PFS) and overall survival (OS), considering the limited follow-up. Clinicobiological features, reasons for choosing the combination with Osi/CT, and perspectives on tolerance and quality of life were also evaluated.

Results: The mean age of the included patients was 62 years (+/- 7), 73% were men, 89% were never smokers, 71% had baseline cerebral involvement, and 8% had meningeal involvement. The mutational profile showed that 52.6% and 47.4% had del19 or the L858R mutation, respectively. The main reasons for choosing the FLAURA2 regimen (by treating physicians) were central nervous system (CNS) involvement (19/50%), disease burden and symptoms (11/29%), and the L858R mutation in the presence or absence of commutations (7/18.4%). The overall response rate (ORR) was 84.3%, and 5 patients (13.2%) achieved an early complete response (CR). After a median follow-up of 9.8 months, PFS (early data analysis) was 7.9 months (95%CI 7.0-8.7), and OS (immature) was 11.3 months (95%CI 10.4-14.1). At this moment, 84.2% of patients maintain the response with a >G3 toxicity of 52.6%. One patient (2.6%) died from complicated febrile neutropenia. Overall, the perspective of the treatment was that tolerance appeared to be adequate in 63.2% of cases, toxicity was more significant than expected in 18.4%, and toxicity negatively affected the quality of life vs. monotherapy in 18.4%.

Conclusions: EGFR-mutated NSCLC is more significant in Latin America; hence, the estimated impact derived from the regular use of Osi alone or in combination with CT. The findings from this multinational cohort of patients are early but demonstrate an ORR comparable to the phase III clinical trial. The reasons for choosing the FLAURA2 regimen are associated with poor prognostic factors, including CNS disease, a higher tumor burden, and the presence of the L858R mutation (especially if there are TP53 commutations). Given the increase in toxicity, a longer follow-up time and number of patients are required to estimate the real impact of using the FLAURA2 regimen.

EP.12A.37 Erlotinib: A Beacon of Hope in EGFR TKI-Progressed Lung Cancer, A Real-World Experience from a Tertiary Care Cancer Centre in South India

P. Thamarai Selvan, A. Krishnamurthy, A. John, S.S. Singh, V. Ramshankar, V. Radhakrishnan, Cancer Institute (WIA), Chennai/IN

Introduction: There are studies on the use of Osimertinib post progression on first line epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) in patients with non-small cell lung cancer (NSCLC). However, Osimertinib is expensive and beyond the reach of most patients in low-and-middle-income countries (LMICs). Currently, there is no established standard of care for patients who experience progression on Osimertinib. Here, we present our experience with Erlotinib in patients with EGFR-mutated NSCLC who have progressed on previous EGFR TKI.

Methods: We conducted a retrospective analysis of all patients with metastatic NSCLC who presented to our center between 2011 and 2024 and had experienced progression on Gefitinib and/or Osimertinib, and subsequently received Erlotinib upon progression. Patients who tested negative for EGFR receptor mutation and those who had taken Erlotinib for less than a week were excluded from the analysis. Data were extracted from the medical records. The disease control rate (DCR) was calculated as the sum of complete response (CR), partial response (PR), and stable disease (SD). Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method.

Results: The study included 32 patients, with a median age of 52 years, among whom 53% (n=17) were male. Most patients were non-smokers (n = 28, 87.5%), had adenocarcinoma (n=30, 94%), and exhibited a performance status (PS) of less than 3 (n=29, 90%). The most common mutation observed was EGFR exon-19 deletion (n=17, 53%), followed by Exon-21 L858R mutation (n=8, 25%), both exon 19 and 21 mutations in 3% (n=1), and others (n=6). Prior therapy included Gefitinib (n=31, 97%), Pemetrexed/Platinum-based chemotherapy (n=23, 72%), Docetaxel (n=8, 25%), and Osimertinib (n=12, 37.5%). Erlotinib was initiated as second-line treatment in 9 (28%) patients, third-line in 11 (34.5%), fourth-line in 10 (31.5%), and fifth-line in 2 (6.3%) patients. Liquid biopsy for T790M mutation testing was conducted after progression on Gefitinib in 11 (34%) patients, among whom it tested positive in 3 patients, all of whom received Osimertinib. Response assessment was performed on twenty-six patients, revealing 6 with PR (23%), 9 with SD (34.6%), and 11 (42.4%) with progressive disease. The DCR was 57.6%. The median duration of response was 8.2 months. The median PFS was 73 days (95% CI 27-118 days), while the median OS was 247 days (95% CI 107-387 days). Patients with exon 19 deletion exhibited a median PFS of 173 days compared to 53 days in patients with exon-21 L858R mutation (P=0.008). The median PFS in patients who received Erlotinib post-progression on Osimertinib was 63 days. Grade-2 or higher skin rash and diarrhea were observed in 28% (n=9) and 3% (n=1) of patients respectively.

Conclusions: This is the first study to report on rechallenge with Erlotinib in patients who have received prior EGFR TKI. Erlotinib shows activity in EGFR-mutated NSCLC patients who progress on EGFR TKIs (especially those with an exon-19 deletion) and can be considered as a treatment option when no other standard treatment is available, especially in LMICs where access to Osimertinib is limited.

EP.12A.38 Durable Response to Savolitinib in Advanced EGFR-WT NSCLC with MET Amplification: Case Series

J. Liu, J. Yang, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou/CN

Introduction: MET amplification plays a vital role in NSCLC development, either de novo or resistance to TKI. It's an emerging biomarker in NSCLC. MET TKI is widely used in MET-aberrant NSCLC. However, the efficacy of savolitinib monotherapy in primary MET amplification as 1st line therapy or as salvage therapy in MET-amplified patients without EGFR mutation is still unknown.

Methods: Medical records from January 2023 to November 2023 were searched to collect consecutive cases diagnosed with advanced MET amplified NSCLC without EGFR/ALK/ROS1 mutation, who received savolitinib and had subsequent disease assessment. Clinicopathological characteristics, treatment response, duration, and safety were analyzed, with a data cutoff on February 29, 2024.

Results: Four patients with stage IVb EGFR-wt NSCLC and MET amplification (detected by NGS) were treated. Two patients started with savolitinib as first-line therapy, while one received it after entrectinib failure. All patients achieved a partial response (PR) within one month and maintained it until data cutoff. Patient 1, a 52-year-old male smoker, with MET amplification (CN: 14), achieved PR after 1 month of savolitinib. Patient 2, a 75-year-old male smoker with MET amplification (CN: 17.1), also achieved PR within 1 month and maintained it for 11 months. Patient 3, a 67-year-old female non-smoker with brain metastases, received entrectinib monotherapy for CHSY1-NTRK fusion and MET amplification. Disease progressed after 1 month with a pulmonary embolism, requiring ICU care. A re-biopsy showed a MET CN of 4.1. Subsequently, she received a second-line therapy of savolitinib, which rapidly improved her PS scores and achieved PR in 1 month. Then, tumor response was observed both in the brain and lung after 3 cycles. Five months later, anlotinib was added, resulting in a PFS of 7 months with consistent safety profile. Patient 4, a 67-year-old male smoker with MET amplification, received initial combination therapy followed by second-line savolitinib with PR after 5 months. However, he developed interstitial pneumonia, so savoratinib was discontinued and steroid treatment was given. One month later, a reexamination showed improvement compared to before. (Detailed information in Table)

Conclusions: Savolitinib demonstrated a quick and durable response in EGFR-wt NSCLC patients with MET amplification regardless of lines and concomitant mutations in this case series. Meanwhile, the safety profile was tolerable. Further data from larger cohorts and longer follow-up are needed to confirm these findings.

EP.12A.39 MET Point Mutations as the Mechanism of Resistance to EGFR-TKI Therapy: A Case Report of MET H1094Y-Mediated Resistance to Osimertinib Overcome by Capmatinib and a Systematic Review.

V. Aggarwal, C. Kim, Medstar Georgetown University Hospital, Washington/DC/USA

Introduction: The EGFR tyrosine kinase inhibitors (TKIs) are the frontline standard in the treatment of metastatic EGFR-mutant NSCLC. Although response rates are impressive, most patients develop resistance through secondary EGFR mutations, upregulation of alternate signaling pathways, and histological transformation. Activation of the MET signaling pathway by means of amplification is a common resistance mechanism to EGFR-TKIs, but activation caused by point mutations in MET has only been rarely described. Here we describe MET H1094Y as the mechanism of resistance to EGFR-TKI therapy that was overcome by combination therapy with osimertinib and capmatinib.

Methods:

Results: Our patient is a 69-year-old male who has metastatic EGFR-mutant exon 19 deletion lung adenocarcinoma. Molecular profiling done on the tissue showed EGFR exon 19 deletion with EGFR amplification, and alterations in MDM2, AXIN1, and PRKDC. He received osimertinib monotherapy and achieved a partial response. Seven months later, he came off osimertinib due to progressive disease in the thorax. Blood-based next-generation sequencing (NGS; Guardant) showed no detectable genomic alterations including the EGFR mutation. As second-line treatment, he received combination immune checkpoint inhibitor therapy for seven months. Blood-based NGS (Guardant) done around the time of progressive disease showed a significant increase in the allele frequency (AF) of the EGFR mutation (nondetectable to 12.6%) along with EGFR amplification. He started third-line treatment with a novel EGFR-TKI in a clinical trial in May 2023. Due to progressive disease manifesting as rapidly accumulating pleural effusion, he was taken off the trial in October 2023 and required supplemental oxygen usage and indwelling pleural fluid catheter placement. Repeat blood-based NGS (Guardant) showed that the EGFR mutant variant AF decreased from 12% to 2%, but there was a new MET mutation (MET H1094Y). He started osimertinib with capmatinib on 10/28/23. He had rapid and dramatic reduction in his pleural effusions, with symptomatic improvement in cough and dyspnea. The indwelling pleural fluid catheter stopped draining in December 2023 and he no longer requires supplemental oxygen. He is tolerating the combination well except for grade 2 creatinine elevation from a baseline of 1.3 to 1.7 which is attributed to capmatinib and grade 2 lower extremity edema requiring dose reduction of capmatinib. Repeat blood-based NGS was done on 12/18/23 and 2/29/24 and there was disappearance of both the EGFR exon 19 deletion and MET H109Y mutation. The literature review revealed singular reported cases of MET H1094Y (treated with gefitinib and crizotinib), L1195F, D1228N/H, P97Q, I865F, Y1003N, along with a case of simultaneous D1228N/H, Y1230H and D1231Y mutations after EGFR-TKI therapy. The details of these cases will be presented.

Conclusions: Our patient's case is the first reported usage of osimertinib and capmatinib for MET H1094Y after EGFR-TKI. This case demonstrates several clinical pearls. At disease progression, molecular profiling plays a critical role in identifying resistance mechanisms. Our patient's clinical improvement suggests that the MET H1094Y point mutation can mediate resistance to EGFR-TKI therapy, which can be overcome by simultaneously targeting both EGFR and MET. Further research is needed to comprehensively catalogue actionable MET alterations beyond MET amplification.

EP.12A.40 Savolitinib Plus Osimertinib for Previously Untreated NSCLC Patients with EGFR Mutations and Met-Amplification: A Case Series

K. Xiao[1,2,3,4], T. Chu[5], Y. Zhu[1,2,3,4], S. Yang[1,2,3,4], Y. Xiao[1,2,3,4], [1]Department of Pulmonary and Critical Care Medicine, the Second Xiangya Hospital-Central South University, Changsha Hunan/CN,[2]Research Unit of Respiratory Disease, Central South University, Changsha Hunan/CN,[3]Clinical Medical Research Center for Pulmonary and Critical Care Medicine in Hunan Province, Changsha Hunan/CN,[4]Diagnosis and Treatment Center of Respiratory Disease, Central South University, Changsha Hunan/CN,[5]Department of Respiratory Medicine, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/CN

Introduction: Rarely (2-4%) observed in untreated advanced NSCLC patients, primary MET amplification (METamp) may be slightly common in NSCLC patients with EGFR mutations (m), which may induce primary resistance to EGFR tyrosine kinase inhibitors (TKIs) used as primary therapy. Preclinical data have suggested that EGFR TKIs plus MET TKIs are a possible subsequent therapy for EGFRm NSCLC patients who developed acquired resistance to EGFR TKIs. Here, we present a case series highlighting the clinical activity of savolitinib plus osimertinib as first-line therapy in previously untreated NSCLC patients with both EGFRm and METamp.

Methods: Previously untreated advanced NSCLC patients with EGFRm and METamp detected by next-generation sequencing (NGS) received concomitant oral savolitinib 400 mg QD and oral osimertinib 80 mg QD. Investigators assessed the objective response based on RECIST v1.1, and progression-free survival (PFS) was analyzed.

Results: Three patients were retrospectively reviewed: 1) A 55-year-old female patient was diagnosed with stage IVA poorly-differentiated lung adenocarcinoma. NGS revealed an EGFR L858R mutation and METamp. The patient was administered concomitant savolitinib plus osimertinib orally. After 24 days of treatment, the CT scan showed that the volume of the primary lesion was significantly reduced, and the clinical evaluation was partial response (PR). By the time of manuscript submission, the patient was still in response with a PFS of more than 22 months. The safety profile was good. 2) A 67-year-old male patient was diagnosed with stage IIIB poorly-differentiated lung adenocarcinoma. NGS identified 18 gene variations, including three driver alterations of EGFR p.L861Q, PIK3CA p.R88Q, and METamp. The patient received savolitinib plus osimertinib treatment. The CT scan after 45 days of treatment showed obvious tumor shrinkage, and the clinical evaluation was PR. As of the last follow-up visit, the patient was still in response with a PFS of over 13 months. There were no other drug-related side effects except Grade 1 nausea. 3) A 60-year-old female patient was diagnosed with stage IVA lung adenocarcinoma. NGS revealed EGFR 19del and EGFR20 p.T790M mutations, and this patient also harbored MET amplification (copy number: 4.4). The patient received a combination therapy of savolitinib and osimertinib. CT images on Day 19 of the treatment showed significant shrinkage of the primary tumor, and the clinical evaluation was PR. Up to now, the patient was still receiving treatment with no sign of progression, and the PFS is 34 months. No intolerable adverse event was observed.

Conclusions: Savolitinib plus osimertinib first-line treatment showed rapid and durable antitumor activity in previously untreated advanced NSCLC patients with EGFRm and METamp, and the safety profile was acceptable. However, the clinical activity of this combination therapy in first-line settings still requires further investigation and validation in larger cohorts.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12A.41 First-Line Treatment of EGFR-Mutant NSCLC: TKI Alone or Combinations - What I Use Today and Why in the Latin America vs the World

G.V. Bon[1], E.A. de Laia[1], C.M. Peixoto[1], G.B. Trotte[1], C.V.Y. de Oliveira[1], G.P. Silvestre[1], P.H.A. da Costa[1], R.T. Dias[1], L.F.d.L. Martins[1], C.D.C.e. Silva[1], V.M.L. dos Santos[2], [1]UFF - Universidade Federal Fluminense - Fluminense Federal University, Niterói/BR,[2]Instituto Oncomed, Niterói/BR

Introduction: Lung cancer has the highest lethality among all cancers in Latin America (LATAM), settling a huge health issue as the Continent faces a limited access to diagnosis and treatment. Non-small cell lung cancer (NSCLC) accounts for about 80% of all lung cancers. Concerning this histological type, mutations of the epidermal growth factor receptor (EGFR) are the most frequent ones, determining tumor growth and progression. Tyrosine kinase inhibitors (TKIs) represent today the first-line treatment for advanced NSCLC containing activating EGFR mutations. Despite that, it is related to acquired resistance, which suggests that maybe combinations with a different agent may improve clinical outcomes. Although, due to impaired accessibility for other agents in LATAM, TKI alone still remains the primary treatment for this disease. Therefore, there is a crescent need for more knowledge around the outcome of TKI alone or in combination in the treatment of NSCLC in LATAM and how it compares to the rest of the World.

Methods: This consists on a review study of articles available in databases PubMed and Lilacs about the treatment with EGFR-TKI for NSCLC in Latin America. Using the keywords “EGFR”, “TKI” and “NSCLC” with the Boolean operator “AND” and filtering between years 2018 - 2022, there were found 1.680 articles; by adding the marker “Latin America”, the number rechead was only 3. Then, thirty articles were selected to guide this study. Then all data was noted in a document and analyzed.

Results: Based on the findings of the articles, there is a paucity of data evaluating the scenario around EGFR-Mutant NSCLC treatment in Latin America. Although, over the world, combined therapy appears to be favored over monotherapy with EGFR - TKIs for the treatment of this kind of tumor. Studies highlighted that combining platinum-based chemotherapy with TK-inhibitors evidenced conflicting overall survival (OS) compared to monotherapy, besides greater results of progression free survival (PFS) and overall response rates (ORR). One of those shared resembling OS, but significant PFS and ORR for pacients receiving combination therapy compared to the group that got monotherapy (PFS: 5.6 vs 2.8 months, ORR: 32.1% vs 13.2%, respectively). Other studies, on the other hand, showed a significant difference of OS between the use of TKI combined or alone (OS= 25,8 months [CI,16.27-35.33] vs 19,8 months [CI, 18.60-21.00]), as well as greater PFS (PFS = 7.9 months vs 5.9 months [p = 0.015], respectively). Still, combined therapy may be related to increased toxicity and a second or third-generation EGFR-TKI may be a preferable treatment for patients with advanced disease. In LATAM, the first-line treatment is yet based on isolated TKI without emphasys on the combination regimens, mainly due to limited resources of the countries’ health systems.

Conclusions: Although some data suggesting that combination therapy may offer significant advantages over TKI monotherapy in EGFR-mutant NSCLC, poor accessibility to diagnosis and treatment in Latin America represents a barrier to overcome lung cancer within the continent.

EP.12A.42 Savolitinib Plus Osimertinib in EGFR-Mutant NSCLC with MET Overexpression and Acquired Resistance to Previous EGFR Inhibitor

Y. Mao, Z. Huang, D. Cai, R. Lou, C. Shen, X. Wang, Y. Liu, X. Qi, Affiliated Hospital of Jiangnan University, Wuxi/CN

Introduction: Aberration of MET (overexpression or amplification) is one of the primary mechanisms of acquired resistance to EGFR-TKIs. Preliminary data from TATTON and SAVANNAH trials indicated encouraging activity of savolitinib, an oral, potent, and highly selective MET-TKI, in combination with osimertinib in patients with MET-amplified/overexpressed, EGFRm advanced NSCLC with disease progression on a prior EGFR-TKI. Here, we present 6 patients with EGFR-mutant MET-overexpressed NSCLC receiving savolitinib plus osimertinib outside of clinical trials.

Methods: The medical record was accessed and reviewed retrospectively. Patients with EGFR-mutant advanced NSCLC, who experienced disease progression after prior EGFR-TKI therapy, with tissue re-biopsy indicating acquired MET overexpression (MET IHC; 3+ in ≥50% of tumor cells, MET IHC 3+) and subsequently received savolitinib plus osimertinib regimen, were included. Clinicopathological characteristics, treatment response and duration and adverse events (AEs) were analyzed. The data cut-off date was March 5, 2024.

Results: Six patients diagnosed with EGFR-mutant MET-overexpressed NSCLC, following disease progression on EGFR-TKI, were treated with savolitinib 400mg daily and osimertinib 80 mg once daily, as detailed in the table. Patients were aged 51-74 years, four were male, three had smoking history, all were adenocarcinoma and two had brain metastases at diagnosis (patient 2 and 5). Five patients were harboring EGFR L858R mutation (patient 1 had EGFR 19 exon deletion). Among all patients, three of them also observed acquired MET amplification (in re-biopsy tissue, 2 by NGS, 1 by FISH testing), with MET gene copy number ranged from 4.8 to 8.3. Five patients previously treated with third-generation EGFR-TKI and three had prior chemotherapy. The median prior lines of therapy were 2 (range, 1-5). All patients achieved a partial response as per physician assessment. Till data cutoff date, treatment was ongoing for three patients, while the remaining three discontinued due to disease progression. Median follow-up duration was 20.5 months (range, 19.3-24.9) and median progression-free survival of 13.7 months (range, 8.8-23.2), two patients are currently alive while patient 1 died on February 11, 2024. Median treatment duration was 13.3 months (range, 8.8- 23.3). The most common AEs are edema (6/6, 100%), nausea (3/6, 50%) and fatigue (3/6, 50%), mostly grade 1 or 2.

Conclusions: In this case series, savolitinib and osimertinib showed promising clinical benefit in patients with MET-overexpressed, EGFR mutation-positive, advanced NSCLC, who had disease progression on previous EGFR-TKI. Safety profile was acceptable . Meanwhile, the tissue re-biopsy could help identify resistance mechanism to guide subsequent therapy.

EP.12A.43 Savolitinib and Third-Generation EGFR-TKI Therapy in EGFRm, MET-Altered NSCLC Patients: A Case Series

X. Lai, M. Su, H. Xu, J. Ye, D. Zhang, Y. Li, The First Affiliated Hospital of Wenzhou Medical University, Wenzhou/CN

Introduction: The efficacy of EGFR-TKIs plus MET-TKIs in EGFRm lung cancers with primary/acquired MET alterations is still controversial. We aimed to assess the response of savolitinib plus third-generation EGFR-TKI in advanced or metastatic NSCLC patients with EGFRm and MET alterations in real-world setting.

Methods: Medical records were reviewed for three NSCLC patients with MET alterations and EGFRm who received savolitinib plus EGFR-TKI from July 2022 to February 2024. A retrospective analysis was conducted on the patient's symptoms, diagnosis, and the efficacy and safety of combination therapy. Progression-free survival (PFS) was calculated from the start of combination therapy.

Results: Patient 1 is a 70-year-old male smoker who has been diagnosed with advanced lung sarcomatoid cancer (cT4N2M1c, Stage IVB). EGFR L858R and MET 14 exon skipping mutations were detected by DNA-based NGS in tumor tissue. The patient was subsequently treated with savolitinib and osimertinib, and achieved PFS of 16 months, and was still in remission. The patient had only mild adverse reactions (increased aminotransferase, grade 2; edema, grade 2), which were resolved after symptomatic treatment. Patient 2 was a 50 years old non-smoking woman with lung adenocarcinoma (pT3N3M0, Stage IIIC) with EGFR L858R mutation. Brain metastases developed without symptoms during adjuvant platinum-containing chemotherapy. After 20 months of gefitinib treatment, the patient developed a central nervous system progression. EGFR T790M mutation was detected by NGS in blood and the patient was subsequently treated with osimertinib, but the effect was poor. After consultation of the Lung Cancer MDT Team, we considered that the patient had progressive aggravation of intracranial cerebral edema, obvious midline displacement, and a high risk of cerebral hernia. Brain surgery was recommended. The patient subsequently underwent two surgeries with brain metastases. Postoperative pathology suggested metastatic lung adenocarcinoma, and EGFR L858R and MET overexpression were detected by DNA-based NGS and IHC (SP44, ++-+++) respectively in tumor tissue. Then the patient received savolitinib and third-generation EGFR-TKI, improving left lower limb muscle strength. However, self-with drawing savolitinib for 1 month led to a decrease in muscle strength. Fortunately, recovery of combination therapy restored muscle strength. The patient achieved PFS of 19 months and was still in remission. No adverse events were observed in relation to the treatment. Patient 3, a 35-year-old male smoker with advanced lung adenocarcinoma (cT1N2M1c, Stage IVB) with EGFR 19Del mutation, responded initially to osimertinib, but after 13 months, the disease progressed. DNA-based NGS testing revealed EGFR 19Del and MET amplification. Chemotherapy and anti-angiogenic therapy were given for 5 months, but disease progressed. Fourth-line therapy with savolitinib and osimertinib resulted in partial response (PR) with 7-month PFS. When progressed, the patient was diagnosed as small cell neuroendocrine carcinoma with biopsy of lower abdominal. Currently, the patient was receiving albumin-paclitaxel monotherapy (7th line).

Conclusions: Combination therapy of savolitinib and third-generation EGFR-TKI shows potential in treating advanced or metastatic NSCLC patients with EGFRm and MET alterations. A comprehensive test of MET should be conducted by various ways. Dual-targeted therapy may be effective in EGFRm and MET-altered patients.

EP.12A.44 Short-course Immunotherapy Prior to Targeted Therapy in EGFR-Mutated Metastatic Non-Small Cell Lung Cancer: A Retrospective Study

P. Chen, J. Li, Y. Feng, W. Liang, J. He, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN

Introduction: Despite epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) being the standard treatment for patients with EGFR-mutated (EGFRm) metastatic non-small cell lung cancer (mNSCLC), the extended duration required for genetic mutation testing and the urgency to treat patients with rapidly progressing disease often lead to the initiation of immunotherapy (IO) before obtaining mutation testing results in clinical practice. This study evaluates the efficacy and safety of a sequential treatment regimen, transitioning from a short course of IO to targeted therapy upon confirmation of EGFR mutations (including exon 19 deletions or L858R mutations) in NSCLC patients.

Methods: We conducted a retrospective analysis of EGFRm mNSCLC patients who received first-line (1L) IO±chemotherapy (CT) (1-4 cycles) ± anti-angiogenesis therapy (AAT) followed by EGFR TKI (first, second, or third generation)±CT±AAT at our center from June 17, 2019, to June 17, 2023. Follow-up continued until March 28, 2024. The primary endpoints were objective response rate (ORR), disease control rate (DCR), and safety, with progression-free survival (PFS) evaluated through Kaplan-Meier analysis.

Results: The study included 22 patients, with an average age of 59.27±9.57 years, of whom 86.36% were diagnosed with adenocarcinoma, and 36.36% were female. Thirteen patients were carriers of EGFR exon 19 deletions, and nine had the L858R mutation. Prescriptions for IO were all issued before the results of EGFR mutation testing were available. The sequential strategy yielded an ORR of 77.27%, with an ORR of 44.44% (4/9) and a DCR of 100% assessed after the short-course IO. Adverse events of grade ≥3 were documented in 2 patients (9.09%), including hepatic dysfunction and myelosuppression, both of which were manageable. Sixteen patients were included in the survival analysis, with a median PFS estimated at 879.125 days (95% CI: 638.139-1120.111).

Conclusions: This study reveals that the compelling sequential treatment strategy initiated by clinical necessity, with short-course IO followed by targeted therapy, demonstrated manageable safety without significant adverse reactions. However, the impact of short-course IO on subsequent targeted therapy, whether positive or negative, requires further clarification. Based on an in-depth analysis of existing clinical data, our findings allow us to explore strategies for the effective combination of IO with targeted therapy to address complex clinical challenges within the framework of personalized treatment, especially over larger patient cohorts and longer follow-up periods.

EP.12A.45 Study of the Mutational Profile of EGFR-Mutated Lung Cancer in the Russian Population on the Example of the City of Moscow

I. Kanner[1], A. Danilova[2], D. Stroyakovsky[2], N. Savelov[2], I. Demidova[2], Y. Akhmadiyarova[2], D. Sekhniaidze[2], M. Agasiev[2], N. Lapkin[2], D. Kanner[2], [1]Lomonosov Moscow State University, Moscow/RU,[2]Moscow City Oncological Hospita No.62, Moscow/RU

Introduction: EGFR-mutations are the most common driver mutations in patients with non-small cell lung cancer. This paper investigates the mutational profile and survival of patients with EGFR-positive lung cancer in the Russian population using the example of Moscow city.

Methods: We analyzed databases of the State budgetary health care institution “Moscow City Oncology Hospital No. 62”. We analyzed 1113 cases of non-small cell lung cancer with EGFR mutation in the period from 2013 to 2021. Statistical analysis of the results was performed using GraphPad Prism 9.5.1 (GraphPad Software, San Diego CA, USA). Quantitative and qualitative features were evaluated, and the nonparametric log-rank test was used to compare survival curves. Differences were considered statistically significant at $p<0.05$.

Results: The majority of the sample patients (74%) were female. The age range was from 29 to 94 years, with a median age of 66 years. Most frequently the mutation was found in exons 19 and 21 (55.6% and 37.4%, respectively), less frequently in exons 18 and 20 (4.6% and 1.9%, respectively). The T790M mutation was detected in 89 patients (8.0%), more commonly in patients with a mutation in exon 19 (55.6%). The median progression-free survival of patients with locally advanced or metastatic lung cancer was 13.3 months, and overall survival was 28.8 months. No correlation between the localization of mutation in the EGFR gene and patient survival was found.

Conclusions: The data on the sex and age structure of the sample, the distribution of occurrence of various EGFR mutations in patients with EGFR-positive lung cancer are consistent with the data of the world literature. The results of survival analysis of patients with EGFR-positive locally advanced or metastatic lung cancer are comparable to the results of the randomized phase III clinical trial FLAURA.

EP.12A.46 Age, Health Utility Scores (HUS), and Survival Outcomes in EGFR-Mutated Lung Cancer Patients Receiving 1L TKI Treatment

E. Faour[1], L. Everest[2], L. van Esveld[3], L. Zhan[2], M.C. Brown[2], K. Balaratnam[2], K. Khan[2], A. Ashkary[2], J. Reibel[2], E. Tsang[2], S. Barghout[2], F. Al-Agha[2], R. Raptis[2], K. Kuang[4], L. Eng[2], A. Sacher[2], P. Bradbury[2], N.B. Leighl[2], M. Tsao[2], F.A. Shepherd[2], W. Xu[2], S.M. Alibhai[2], G. Liu[2], [1]Dr. H. Bliss Murphy Cancer Centre, St. John's/NL/CA,[2]Princess Margaret Cancer Centre, Toronto/ON/CA,[3]Utrecht University, Utrecht/NL,[4]St. Michael's Hospital, Toronto/ON/CA

Introduction: EGFR-mutated cancers span a broad age-range. We evaluated whether there were differences in HUS, treatment course and survival while on first-line (1L) tyrosine kinase inhibitor (TKI) therapy, by age.

Methods: Patients with EGFR-mutated lung cancers were recruited prospectively (2015-2023; CARMA-BROS-real-world-observational study; NCT:04151342). Clinico-demographic, treatment, outcome data, and patient-reported EQ-5D-5L questionnaires were collected. Health Utility Scores (HUS) were derived from Canadian population norms. Older group was defined as age 70+ years. Younger group was defined as <70 years at time of diagnosis of advanced/metastatic EGFR-mutated lung-cancer.

Results: Among 233 older (median age 77 [IQR:73-82] years) and 396 younger patients (median 59 [IQR:52-64] years), major demographics were similar (64% female, among known-ethnicity, 62%/Asian, 25%/White; 70%/never-smoker) except for performance-status (ECOG-PS), where older patients had worse ECOG-PS (p<0.001). Among all EGFR-mutations, 87% were common; 9% were exon-20-insertions (p>0.05 between younger/older). Among common mutations, older patients were more likely to have L858R mutation (56% older vs 39% younger) than exon 19-deletion (p<0.001), and had greater number of comorbidities by modified-Charlson-comorbidity-index (mCCI) scores (11% mCCI=3+ and 34% mCCI=0 in older versus 8% mCCI=3+/ 54% mCCI=0 in younger; p<0.001). The table shows mean-HUS at initiation of, on, and progression on 1L-TKI by age-group; the main difference between older versus younger groups was the larger drop in HUS at progression on 1L-TKI in older adults. Median PFS on 1L-gefitinib/1L-osimertinib in older versus younger patients are presented in the Figure; PFS appears similar between age-groups, with caveat of short median-follow-up for Osimertinib patients.

Conclusions: Older patients with EGFR-mutated advanced/metastatic lung cancers derive similar benefit (in efficacy and quality-of-life) while on monotherapy TKIs, despite older patients having more comorbidities, worse ECOG-PS, and more EGFR-L858R-mutations at baseline. However, at progression on 1L-TKI, older patients suffer greater decreases in quality-of-life, signifying an unmet need to improve 1L PFS in such patients.

EP.12B.01 Weight Gain and Metabolic Changes Associated with Alectinib Use in ALK-Positive Lung Cancer

J. Maturi[1], M. Guo[1], P. Ghanem[2], J. Murray[3], S. Scott[3], S. Houseknecht[3], J. Feliciano[3], C. Hann[3], D. Ettinger[3], P. Forde[3], J. Brahmer[3], B. Levy[3], K. Marrone[3], V. Lam[3], [1]Johns Hopkins School of Medicine, Baltimore/MD/USA,[2]Johns Hopkins University School of Medicine, Baltimore/MD/USA,[3]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore/MD/USA

Introduction: Alectinib is a widely used ALK tyrosine kinase inhibitor (TKI) and thought to be generally well tolerated. However, weight gain and other adverse metabolic effects associated with alectinib may be under-reported and the real-world prevalence of these metabolic changes with potential impact on cardiovascular health and long-term quality of life is unknown.

Methods: In this single-institution retrospective analysis, we analyzed clinical data for 72 patients with advanced ALK-positive NSCLC treated with first-line alectinib. Additionally, 59 patients with advanced EGFR-mut NSCLC treated with first-line osimertinib were also analyzed as a comparator cohort with similar demographics and performance status as ALK-positive patients and with usage of a comparably well tolerated and highly effective TKI. Clinical data analyzed included patient demographics, cardiovascular and endocrine comorbidities, duration of TKI therapy, and changes in weight during therapy. Chi-square analyses and t-tests assessed differences in metabolic changes between ALK-positive and EGFR-mut groups during TKI therapy. Univariate and multivariate logistic regression assessed metabolic and genomic factors associated with weight gain.

Results: Median follow-up time for the alectinib and osimertinib group was 27.7 months and 19.4 months, respectively, with no significant difference in baseline performance status (p=0.33). Treatment-emergent weight gain was observed at 23.2% Grade 1, 29.0% Grade 2, 5.8% Grade ≥ 3 for alectinib and 23.6% Grade 1, 9.0% Grade 2, 1.8% Grade ≥ 3 for osimertinib. Relative weight gain (%) in patients treated with alectinib was significantly greater than those treated with osimertinib at 6, 12, and 18 months (all timepoints $p < 0.001$), with increasing magnitude of difference at each time point. After 12 months on TKI, patients treated with alectinib had a mean weight gain of 7.3% and 1.61-fold increase in BMI compared to a 0.8% weight decrease and 0.12-fold BMI decrease in patients treated with osimertinib ($p < 0.001$). After controlling for comorbidities including diabetes, hypertension, pre-treatment dyslipidemia, and smoking status, patients on alectinib were significantly more likely to have a grade 2 or higher (≥ 10% increase) weight gain relative to patients on osimertinib (OR 7.07, 95% CI 2.12-29.09). Among patients with baseline and on-treatment LDL results (alectinib n=20, osimertinib n=7) and Hemoglobin A1c results (HbA1c; alectinib n=11, osimertinib n=4), there was no significant treatment-related changes in LDL (mean LDL change +10.9 points for alectinib, +15.1 points for osimertinib, p=0.87) or HbA1c (mean HbA1c change -0.1 points for alectinib, -0.4 points for osimertinib, p=0.23).

Conclusions: First-line alectinib in a real-world cohort is associated with >30% incidence of G1-G2 weight gain, more than 3-fold higher than previously reported in Phase 3 clinical trial results and significantly increased relative to a similar EGFR-mut cohort treated with a comparably well tolerated and highly effective TKI. Prospective evaluation of weight and potential long-term metabolic complications related to alectinib and other ALK TKIs is warranted.

EP.12B METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - FUSIONS: ALK / ROS1 / RET / NTRK
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12B.02 Real-World Treatment Patterns and Effectiveness in Patients with ALK+ Advanced NSCLC Treated with 1L ALK TKIs

Y. Chen[1], H.M. Lin[2], Y. Wan[2], Y. Yin[2], Y. Wu[2], L. Hernandez[3], C. Danes[3], E.N. Churchill[3], A. Dimou[4], [1]The Cancer and Hematology Centers, Grand Rapids/MI/USA,[2]Takeda Development Center Americas, Inc., Lexington/MA/USA,[3]Takeda Pharmaceuticals U.S.A. Inc., Lexington/MA/USA,[4]Mayo Clinic College of Medicine, Rochester/MN/USA

Introduction: This retrospective cohort study described real-world treatment patterns and effectiveness in patients with anaplastic lymphoma kinase positive (ALK+) advanced non-small cell lung cancer (NSCLC) treated with first-line (1L) ALK tyrosine kinase inhibitors (TKIs).

Methods: Data for adults with ALK+ advanced NSCLC initiating 1L alectinib, brigatinib, lorlatinib, or crizotinib monotherapy (index date: initiation of 1L ALK TKI) were extracted from the US Flatiron EMR-derived database (Jan 2011-Sept 2023). First subsequent treatment (2L) after 1L ALK TKI, real-world time to treatment discontinuation (rwTTD) and time to next treatment (rwTTNT) of 1L ALK TKI were evaluated. A multivariate Cox proportional hazard model to compare rwTTD and rwTTNT for 1L brigatinib or 1L alectinib vs. crizotinib, adjusting for relevant covariates (age, sex, race, ECOG-PS, smoking, baseline brain metastasis, time from advanced diagnosis to index) was performed. To further compare the real-world effectiveness of 1L brigatinib vs. 1L alectinib or 1L crizotinib, propensity score matching using an inverse probability of treatment weighting (IPTW) method was applied.

Results: The study included 832 patients: 1L alectinib, 643; 1L brigatinib, 28; 1L lorlatinib, 17; 1L crizotinib, 144; mean age: 62, 61, 61, 70 years; % male: 44%, 57%, 35%, 45%; ECOG-PS 0-1 at index: 69%, 50%, 65%, 60%. In the 1L alectinib cohort, 2L lorlatinib was the most common ALK TKI (17%) followed by 2L brigatinib (6%). In the 1L brigatinib cohort, 2L lorlatinib was the most common ALK TKI (18%). 1L alectinib and 1L brigatinib were associated with improved rwTTD or rwTTNT vs. 1L crizotinib (Table). IPTW analysis showed similar effectiveness for 1L alectinib and 1L brigatinib and improved effectiveness for 1L brigatinib vs. 1L crizotinib (Table).

Conclusions: In patients with ALK+ advanced NSCLC, 1L alectinib and 1L brigatinib had similar rwTTD and rwTTNT. These real-world findings mirror and support the Phase 3 ALTA-1L trial data demonstrating the efficacy of 1L brigatinib vs. crizotinib in patients with ALK+ advanced NSCLC.

EP.12B.03 Cognitive Impact of Lorlatinib Administration in Advanced Non Small Cell Lung Cancer with ALK and ROS1 Fusions

A. Tanzilli, L. Tosetto, L. Landi, V. Villani, V. Di Noia, F. Fusco, A. Pace, V. Stati, F. Cappuzzo, F. Cecere, IRCCS Regina Elena National cancer Institute Rome Italy, Rome/IT

Introduction: Lorlatinib is a third-generation ALK and ROS1 tyrosine kinase inhibitor (TKI) recently been approved in Italy for the treatment of ALK and ROS1 rearranged Non-Small-Cell Lung Cancer. Compared with first and second-generation ALK and ROS1 TKI, lorlatinib has a specific Adverse Events (AEs) profile including neuropsychological effects. Lorlatinib neurotoxicity has been partly attributed to pharmacokinetics, specifically its ability to penetrate the blood-brain barrier and accumulate in the central nervous system (CNS) and partial inhibition of trkB. Since many patients do not experience cognitive AEs during treatment, it is possible that different and non-characterized factors beyond drug concentration in the CNS, could influence susceptibility to neuropsychological AEs of lorlatinib. Moreover, the exact prevalence of cognitive sequelae in "real-life" setting is unclear. The aim of our preliminary experience, based on patients' initial report of subjective cognitive deficits, was to evaluate the neuropsychological impact of lorlatinib treatment.

Methods: A battery of neuropsychological tests, tapping: learning (L); short and long-term memory (STM; LTM); executive functions (EF); reasoning (R); attention (ATT) and visuo-constructional abilities (CA) was administered to each patient. We furtherly collected demographic and clinical data: sex, age at diagnosis, education, Performance status, histology, smoking history, dose reduction, presence of brain metastases and previous local treatment (surgery or RT).

Results: We included 15 never or ex light smoker lung adenocarcinoma patients (12 males) with median age at diagnosis of 64 years (range 25-84), 14 harboring alk fusion and 1 ros 1 positive. At therapy initiation, 10/15 (66%) were PS:0, 4/15 (26%) and 1 (6%) PS:2. 9/15 (60%) had BM at baseline, 1/15 (6%) had previous WBRT and 2/15 (13%) SBRT. Among the 9 patients with BM, 2 had brain complete response, 3 stable disease, 3 partial response, 1 was not evaluable. Interestingly, all the 3 patients who achieved brain PR were pretreated with RT while complete response was observed in no RT patients. 3 patients with brain metastases (20%) presented with at least one cognitive deficit (range 0-2), while 12 (80%) showed no impairment. Deficits affected EF (n=3), LTM (n=1), STM (n= 1), L (n=1) and CA (n=1). A subgroup of 9 patients underwent a follow-up test session at a median time of 12 months (range: 6-15). Adverse events of grade ^{3}2 leading to dose reduction were experienced in 4 patients (26%), 1 for dizziness, 1 for psychotic reaction, 1 for severe peripheral edema, 1 for hypercholesterolemia and hypertriglyceridemia. 3 patients showed a stable and impaired cognitive status, with deficits affecting EF (n=2), LTM (N=2), L (n=1) and CA (n=1). Neuropsychological functions in the remaining 6 patients was preserved and, in 2 of them, tests scores (memory and attention) slightly improved.

Conclusions: Our preliminary data seem to indicate that cognitive functions in these patients are influenced by a set of factors rather than by administration of lorlatinib alone. Despite the small sample size, this is one of the first studies performing an in-depth neuropsychological assessment on a long time-span.

The study is currently ongoing to prospectively follow treatment naïve patients in first line.

EP.12B.04 BMF Deficiency Leads to an Increase of Drug Tolerant Persister Cells in ALK-Positive Lung Cancer

T. Utsumi[1,2], K. Uchibori[3], M. Nishio[3], I. Okamoto[1], R. Katayama[2], [1]Graduate School of Medical Sciences, Kyushu University, Fukuoka/JP,[2]The Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo/JP,[3]The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo/JP

Introduction: ALK-rearranged non-small cell lung cancer (NSCLC) often shows remarkable tumor shrinkage by the treatment with ALK inhibitors (ALKi) with long-lasting efficacy. However, acquired resistance inevitably leads to tumor relapse, and a small fraction of patients experience relapse within a short period. Pre-existing drug-resistant cells harboring genetic alterations in ALK or other oncogenes, and drug tolerant persister (DTP) cells have been implicated as the cause of the development of resistant tumors. However, the mechanism by which these tumor cells survive exposure to ALKi has not been fully elucidated. To identify this mechanism, we performed a genome-wide CRISPR/Cas9 knockout screening using ALK-positive patient-derived cell lines (PDCs) that are sensitive to ALK-TKIs. Recently, we found and reported that loss of ERRFI1 (MIG6) causes ALKi resistance induced by low-dose EGF ligand-mediated EGFR activation (JCI Insight 2023). In addition, we have identified several factors that can induce DTP phenotypes in the ALK-TKI naïve cells. In the current study, we identified that loss of Bcl-2 modifying factor (BMF), a pro-apoptotic protein, increased DTP cells, and analyzed the detailed mechanisms how BMF loss induces the DTP cells and how to overcome these DTP phenotypes.

Methods: A genome-wide sgRNA library was introduced Cas9 overexpressed ALK-TKI sensitive ALK-positive NSCLC cells, and cultured in alectinib or lorlatinib containing medium for 9 days. Genomic DNA from the remaining DTP cells was purified for sgRNA sequences analysis by NGS. Identified candidate sgRNA target genes were knocked out by creating additional sgRNA in ALK-TKI sensitive cells, and DTP phenotypes were confirmed by various assays. Regarding the BMF, the mechanisms of gene expression regulation and the effect of mitochondria-mediated apoptosis were investigated by quantitative PCR, and immunoblot of related proteins. To overcome the DTP phenotypes by BMF loss, knockdown of pro- and anti-apoptotic proteins or inhibitor treatments were performed.

Results: BMF loss was identified as one of the top hits in the CRISPR/Cas9 screening. Since BMF is known to induce mitochondria-mediated apoptosis by inhibiting anti-apoptotic proteins, deletion of BMF in ALK-positive NSCLC cell lines resulted in a decrease in apoptosis induction and an increase in the number of DTP cells under ALKi treatment. BMF protein levels significantly increased within 24 hours of ALK-TKI treatment, and the increase was also observed upon co-inhibition of both ERK and PI3K. In BMF knockout cells treated with ALKi, apoptosis was effectively induced by knocking down or inhibiting MCL-1. Concurrent knockdown of MCL-1 and BCL-XL further enhanced the induction of apoptosis by ALKi.

Conclusions: BMF deficiency increases DTP cells by attenuating apoptosis induction during ALKi therapy, which reduces the therapeutic effect. Combination therapy with MCL-1 inhibitors may overcome this attenuation. BMF loss has been observed in approximately 1% of NSCLC cases in the cBioportal database, but further evaluation of clinical significance is needed using pre- and post-TKI treated samples. Additionally, preclinical in vivo studies are needed to assess the efficacy and toxicity of the potential combination therapy for depleting DTP cells after ALK-TKI treatment.

EP.12B.05 Drivers of Treatment Choice in ALK-Positive Metastatic Non-Small Cell Lung Cancer from Patients' and Caregivers' Perspectives

C. Danes[1], W. Wan[1], J. Seo[2], M. Trapali[3], H. Clarke[2], J.A. Whitty[3], K.W. Culver[4], [1]Takeda, Cambridge/MA/USA,[2]Evidera, Bethesda/MD/USA,[3]Evidera, London/GB,[4]ALK Positive, Atlanta/GA/USA

Introduction: With the emergence of NSCLC treatments tailored to ALK rearrangement (ALK+), patients and caregivers face a choice between multiple targeted therapies, requiring them to weigh benefits and risks. We aimed to identify drivers of treatment choice from patients' and caregivers' perspectives.

Methods: Ten adults with ALK+ Stage IV NSCLC and ten informal caregivers in the US participated in semi-structured qualitative interviews. Participants 1) ranked four benefit measures by meaningfulness to evaluate efficacy, 2) rated adverse events (AEs), and 3) selected two most important AEs to avoid. Interview data were analyzed using descriptive and content analysis.

Results: Patients were 35 years old on average (range 23-56), mostly female (n=7) and White (n=6) and diagnosed with NSCLC on average 2 years (range: 1-5) ago, with 4 patients also reporting brain metastasis. The study included 8 patient-caregiver dyads and 2 non-dyads. Patients and caregivers surveyed stated that progression free survival (n=16) was more meaningful than overall survival (n=11) as a measure of benefit. They valued quality of life with less or no symptoms, but many ultimately hoped to buy time until a new treatment becomes available. Patients and caregivers ranked prevention of brain metastasis 3rd (n=9) and symptom relief 4th (n=11) as they translated metastasis-free and symptom-free to progression-free. Among the prespecified treatment-associated AEs, lung complications (n=17), abnormal lab results (n=9) and cognitive/mood effects (n=6) were most frequently selected as the most important AEs to avoid. The top 4 AEs that were rated high by degree of concern by patients were lung complications, cognitive/mood effects, myalgia and weight gain, while caregivers cited lung complications, hypertension, abnormal lab results and cognitive/mood effects as the most concerning AEs (Table). Lung complications were frightening due to the lack of management options and their potential impact on future clinical trial eligibility and on the existing lung cancer. Abnormal lab results were alarming as they may imply treatment discontinuation and dose reduction. Patients and caregivers were concerned about the impact of cognitive/mood effects on their relationship.

Conclusions: Patients and caregivers generally consider PFS as the most meaningful benefit measure and lung complications, abnormal lab results, cognitive/mood effects, myalgia and weight gain as concerning AEs. A subsequent study is planned to quantify the extent to which these attributes drive treatment choice.

Mean Rates of AE by Degree of Concern on a Scale of 0 (Not Concerning) to 10 (Extremely Concerning)

Keywords: NSCLC, ALK inhibitors, Patient and caregiver perspectives

	Patient (n=10)	Caregiver (n=10)
Lung complications	8.3	8.3
Cognitive/mood effects	6.8	6.5
Myalgia	6.3	5.6
Weight gain	6.1	4.5
Nausea	6.0	6.1
Fatigue	5.8	5.5
Abnormal lab results	5.6	6.7
Diarrhea	5.3	5.8
Hypertension	4.9	6.9

EP.12B.06 Efficacy of Lorlatinib in Advanced ALK-Positive Non-Small Cell Lung Cancer Patients in Thailand: A Multicenter Study

K. Maneenil[1,2], T. Baisamut (Reungwetwattana)[3], P. Sitthideatphaiboon[4], S. Payapwattanawong[1], K. Korphaisarn[5], T. Suksomboon charoen[6], C. Vinayanuwattikun[4], [1]Rajavithi Hospital, Bangkok/TH,[2]College of Medicine, Rangsit University, Bangkok/TH,[3]Ramathibodi Hospital, Mahidol University, Bangkok/TH,[4]Chulalongkorn University and the King Chulalongkorn Memorial Hospital, Bangkok/TH,[5]Siriraj Hospital, Mahidol University, Bangkok/TH,[6]Chiang Mai University, Bangkok/TH

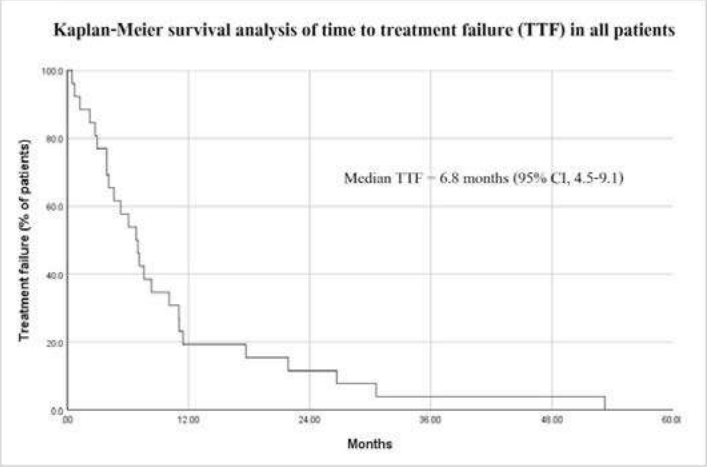
Introduction: Anaplastic lymphoma kinase (ALK) translocation is an uncommon driver alteration in non-small lung cancer (NSCLC). This study aimed to evaluate the efficacy of lorlatinib as a subsequence treatment in ALK-positive NSCLC in a real-world, multi-center observational study.

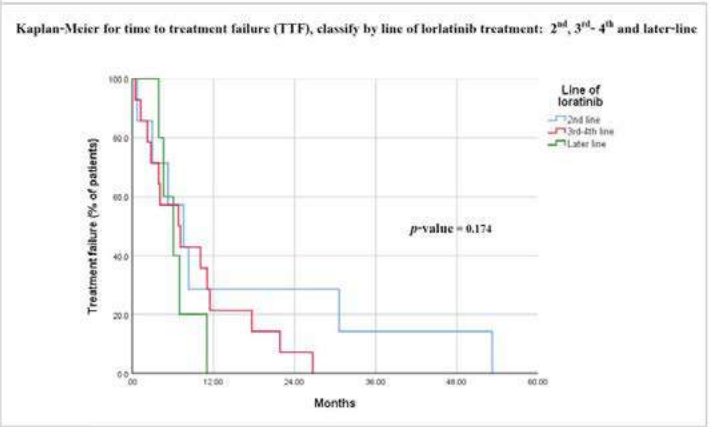
Methods: Retrospective cohort of 26 ALK-positive advanced NSCLC patients in 5 centers of Thailand who received lorlatinib under Named Patient Use program between April 2019 and February 2021 was conducted by Thai Lung Cancer Group (TLCG) under Thai Society of Clinical Oncology. Demographic characteristics, treatment response, and toxicity were collected. The primary endpoint was time to treatment failure (TTF). The secondary endpoints were overall survival (OS), and toxicity profile.

Results: The median follow-up was 51.2 months (range, 11.8-122). The median age was 61 years. Majority of the patients were female (69.2%), never smoker (76.9%), and ECOG PS 0-1 (84.6%). Initial and subsequent brain metastasis were reported in 23.1 and 65.4% of patients, respectively. Median OS was 90.6 months (95% CI, 51.7 - 90.6) and 5-year OS was 70.3%. Lorlatinib was used in 26.9%, 26.9%, and 46.2% as second-, third- and later-line treatment, respectively. The median TTF of lorlatinib in overall cohort was 6.8 months (95% CI, 4.5-9.1). In detail, median TTF of lorlatinib in second-line, third-line, and later-line were 7.6 months (95% CI, 1.7-13.5), 6.8 months (95% CI, 1.3-12.4), and 6.1 months (95% CI, 3.0-9.2), respectively which was not affect TTF by regression analysis. Fifteen patients (57.7%) experienced all grade treatment-related toxicities. The most common grade 3/4 toxicities were dyslipidemia (30.7%), weight gain (3.8%), and mood-cognitive effect (3.8%). Dose interruption and/or dose reduction was observed in 30.7%.

Conclusions: Lorlatinib demonstrated clinical benefits in ALK-positive NSCLC with good tolerability. The efficacy was consistent with the reported clinical trials.

Keywords: ALK, lorlatinib, advanced NSCLC





EP.12B METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - FUSIONS: ALK / ROS1 / RET / NTRK

EP.12B.07 Identification of Candidate Therapeutic Targets Using Single Cell RNA Sequencing in ALK-Positive Lung Cancers

M.A. Muskavitch[1], R.B. Hall[2], J. Lowy[3], E. Gefroh[4], E.S. Venanzi[5], J. Noonan[3], K. Li[6], [1]ALK Positive Inc, Millis/MA/USA,[2]ALK Positive Inc, Annville/PA/USA,[3]Regeneron, Tarrytown/NY/USA,[4]Just-Evotec Biologics, Seattle/WA/USA,[5]ALK Positive Inc, West Newton/MA/USA,[6]EirClin Co, Lexington/MA/USA

Introduction: Oncogenic ALK fusion proteins in lung cancer (LC) cells are not expressed on cell surfaces, except as HLA-bound peptides following ALK intracellular domain proteolysis. Consequently, development of surface-targeting therapeutics for treatment of ALK+ LC cells, such as antibody-drug conjugates (ADCs), bi- and tri-specific antibodies, CAR-T cells, and vaccines, has been limited. To identify potential cell surface targets in ALK+ LC cells, we developed a computational pipeline to analyze publicly available single cell RNA sequence (scRNAseq) data from LC tumor samples.

Methods: Analysis of scRNAseq data from 11 ALK+ LC patients (Maynard et al 2020, Bischoff et al 2021, Wu et al 2021) versus 107 normal lung samples (Sikkema et al 2023) identified candidates for such therapies. The CellXGene VIP visualization interface we employed enables assessment of gene expression in a cell cluster format, in relation to over 18,000 genes expressed among the 61 cell types enumerated in the Human Lung Cell Atlas (Sikkema et al 2023), as well as on a cell-by-cell basis.

Results: We compared computationally identified genes transcribed in ALK+ AT2 cells (Figure 1) that encode FDA-registered/IND-approved drug targets, regardless of their disease area of approval. First, we identified expressed candidate targets from FDA-registered/IND-approved lists of antibody-drug conjugates (16), bi- and tri-specific antibodies (11), CAR-T cell therapies (10) and cancer vaccines (11). Second, we found support for clinical trials of solid tumor vaccines like BNT116 for ALK+ and EGFR+ LC patients because 70% of ALK+ patients and 59% of EGFR+ patients sampled express one or more among the six proteins in this mRNA vaccine. Third, our analysis of gene ensembles relevant to ALK-driven carcinogenesis identified genes within ALK signaling and ALK TKI bypass resistance pathways (24) and the epithelial-mesenchymal transition pathway (52) and among immune checkpoints (18). We are currently analyzing additional tumor RNA datasets for additional drivers from publicly available sources for comparison.

Conclusions: Taken together, we believe these types of data offer opportunities to expedite therapeutic development of improved treatments for ALK+ and other oncogene-driven LC patients. We will extend this work to include validation of transcriptome-nominated targets in tumor cells using immunohistochemistry, mass spectrometry and other protein expression assays, and in vitro and in vivo models.

Keywords: ALK, Single cell RNA sequencing, Drug targets

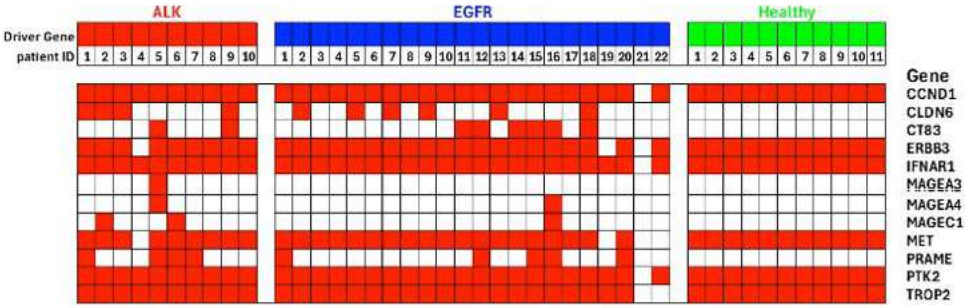

Figure 1. Binary heatmap displays the presence of gene expression for 12 target genes across 43 individuals, categorized into ALK+ (N=10), EGFR+ (N=22), and Healthy (N=11) groups. Columns represent individual patients; rows correspond to the genes. Red squares indicate detectable expression of a gene in at least one cell within a patient sample, based on single cell transcriptomics data. The distribution of red across the heatmap provides insight into the gene expression landscape, highlighting differences and similarities in the expression profiles of patients with different driver genes and healthy individuals.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12B.08 Characterizing the Severity and Timing of Real-World ALK-Inhibitor Associated Weight Gain in Non-Small Cell Lung Cancer

A.S. Watson, J.M. Taormina, B. Yoder, S.J. Iwamoto, T. Patil, E.L. Schenk, D.R. Camidge, University of Colorado, Aurora/CO/USA

Introduction: As second and third generation Anaplastic Lymphoma Kinase (ALK) tyrosine kinase inhibitors (TKIs) extend progression-free survival beyond 3 years in ALK-fusion positive NSCLC, long-term toxicities are increasingly recognized. ALK-Inhibitor associated Weight Gain (AIWG) is a described toxicity in first-line registrational trials; in the CROWN trial of lorlatinib, rates of grade 2 (10 to <20%) and grade 3 (>=20%) weight gain were 17% and 20% respectively. Improved understanding of real-world severity, timing and risk factors for AIWG is important for clinician-patient decision making.

Methods: We performed a retrospective review of ALK-fusion positive metastatic NSCLC patients receiving FDA-approved ALK TKIs at our institution from 1/1/2020-12/31/2023. Demographics and treatment history were gathered. Clinic-measured weight (kg) was noted at 12-24 week intervals (as available) from baseline until progression on each TKI. Descriptive statistics were summarized with mean (range) or frequency. TKI-specific weight gain (mean % change from baseline [95% CI], or grade per CTCAE v5.0) was compared via ANOVA (p<0.05).

Results: Our cohort included 89 patients receiving 158 total treatment lines of TKI; 23 patients received crizotinib (100% first line [1L]), 2 received ceritinib (100% 2L - excluded from analyses for small N), 25 received brigatinib (20% 1L, 60% 2L, 20% 3/4L), 68 received alectinib (80.9% 1L, 13.2% 2L, 5.9% 3/4L), and 40 received lorlatinib (17.5% 1L, 47.5% 2L, 22.5% 3L, 12.5% 4/5L). Mean age at first TKI was 55yrs (range 25-88), 74% were female, 76% were never-smokers. At first TKI, mean weight was 73.7kg (42.2-127), 32% of patients were overweight (BMI 25 to <30 kg/m2), 13% were obese (BMI >=30 kg/m2). Shown in Table 1, mean maximum weight gain was highest for patients on lorlatinib versus other TKI (+13.3% from baseline, p<0.001), as was mean weight gain by 6 months (+5.8% from baseline, p=0.02). Lorlatinib weight gain did not significantly vary by line of therapy (p=0.19). 11 patients received a weight loss-associated medication; excluding these patients did not alter findings (not shown). 29% of lorlatinib weight gain was grade 3 (p<0.001 versus other TKIs). Time to maximum gain was similar between TKIs (p=0.24), ranging from 16-24.6 months on treatment. Further analysis to follow.

Conclusions: These data help characterize real-world AIWG, demonstrating >10% weight gain (grade 2-3) for a significant portion of patients. Real-world weight gain was most common with lorlatinib and more severe than in its registrational trial. Future investigation of optimal prevention and management of weight gain is encouraged.

Keywords: NSCLC, ALK Tyrosine Kinase Inhibitors, Weight Gain

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12B.09 Real-World Efficacy and Toxicity Comparison Between the RET Inhibitors (RETi) Pralsetinib and Selpercatinib in Patients with Stage IV NSCLC

G. Sacchi de Camargo Correia[1], S. Li[1], Y. Loy[1], Y. Zhao[1], V. Ernani[2], K. Parikh[3], A. Dimou[3], R. Manochakian[1], [1]Mayo Clinic, Jacksonville/FL/USA,[2]Mayo Clinic, Phoenix/AZ/USA,[3]Mayo Clinic, Rochester/MN/USA

Introduction: RET fusions occur in 1-2% of patients with NSCLC, with 2 US-FDA approved RETi for patients with stage IV NSCLC harboring it. Due to recent approvals, there is limited data of their real-world outcomes and adverse events (AEs). We aimed to compare the utilization of pralsetinib and selpercatinib in this population.

Methods: We performed a retrospective chart review of the electronic medical records of all patients with stage IV NSCLC treated with RETi between the date of FDA-accelerated approval of these drugs, 09/04/2020 for pralsetinib and 05/08/2020 for selpercatinib, and 02/15/2024. All patients were treated at the Mayo Clinic Health System. We collected data about baseline characteristics, diagnosis, AE, and outcomes. Chi-squared test was used to compare AEs frequency, while Kaplan-Meier method was used to calculate median progression free survival (mPFS), and Cox proportional hazards regression for hazard ratio (HR).

Results: Thirty-four patients were treated with RETi. Pralsetinib was used in 23 patients, selpercatinib in 17, while 2 received pralsetinib after selpercatinib, and 4 received selpercatinib after pralsetinib. In the pralsetinib group, median age of diagnosis was 63 years, 43.48% were male, and median number of previous lines of therapy (mPLT) was 1. In the selpercatinib group, median age of diagnosis was 62 years, 52.94% were male, and mPLT was 1. For both groups, median ECOG at time of diagnosis was 0. KIF5B-RET fusion was present in 78.26% of those treated with pralsetinib and 70.59% with selpercatinib. The mPFS was not reached in neither group. 2-year PFS was 73.6 % (95% CI 56.1-96.6) for pralsetinib, and 53.3% (95% CI 29.8-95.4). HR was 1.12 (95% CI 0.27-2.91). Most common AEs are reported in table 1. Pralsetinib was discontinued in 30.43% of patients, and selpercatinib in 5.88%. Temporary drug hold occurred in 21.74% and 41.18% of cases with pralsetinib and selpercatinib, respectively, while dose reduction happened in 43.48% of cases with pralsetinib, and 41.18% with selpercatinib.

Conclusions: We observed similar efficacy with both RETi, but relevant AEs differences. These may guide treatment in patients with underlying comorbidities. Selpercatinib may be favored in patients with underlying respiratory comorbidities, due to significantly lower incidence of pneumonitis. Despite no statistical difference, pralsetinib may be preferred in those with renal diseases, and selpercatinib in cases with hepatic dysfunction. Nonetheless, over 40% of cases required dose reductions, stressing the need for close treatment monitoring. Prospective multi-centric studies would provide further information regarding differences between these drugs.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12B.10 Patterns and Clinical Impact of Alectinib Dose Reduction in Patients with ALK-Positive Non- Small Cell Lung Cancer (NSCLC)

B. To, S. Farid, S. Zhao, M. Li, N. Amirmokhtari, L. Wei, R. Memmott,, A. Alahmadi, K. He, J. Kaufman, L. Roof, P. Shields, D. Carbone, G. Otterson, C. Presley, D. Owen, The Ohio State University Medical Center, Columbus/OH/USA

Introduction: The second generation ALK inhibitor alectinib is a standard treatment for patients with advanced ALK positive NSCLC, and has substantial CNS efficacy. In the landmark phase 3 ALEX clinical trial, adverse events led to dose reductions in 16% of patients. However, the frequency of dose reduction and impact on outcomes including CNS disease and overall progression has not been well characterized outside of clinical trials.

Methods: We conducted a single-institution retrospective study of non-small lung cancer patients who were treated at The Ohio State University Comprehensive Cancer Center (OSUCCC) between 2005-2022. Data was extracted from patient's electronic medical records (EMR) and collected in REDCap. Patients with ALK positive NSCLC who received alectinib were included in this study. Fischer's exact test was used to compare incidence of general progression or CNS progression between reduced and non-reduced groups. Kaplan-Meier survival analysis was used to evaluate survival outcomes. Statistical analysis was done in SAS 9.4.

Results: We identified 73 patients whose tumors harbored an ALK rearrangement; 57 of these patients received alectinib either as their first (59.7%), second (31.6%) or third (8.8%) line targeted therapy. The median age at diagnosis was 55 years (IQR 48-64); 55.4% were female. The predominant ethnic group among patients was Caucasian (78.6%), followed by African American (16%), with the remainder categorized as " Asian and Other" (5.4%). 37% of patients had CNS disease prior to initiation of alectinib. 22.8% of patients underwent dose reduction during their treatment with the majority of those patients decreasing from 600 mg alectinib BID to 450 mg BID. The median time to dose reduction was 3 months (IQR 0.9-15.4). The most common reasons for dose reduction include fatigue (25%), elevated creatine kinase (15%), myalgia (15) and liver toxicity (15%). Other less common causes include muscle weakness, lower extremity edema, bradycardia, rash and vision changes. The median time on treatment with alectinib was 13.3 months (IQR 10.8-15.4) in patients who underwent dose reduction compared to 5.7 months (IQR 1.7-20.1) in patients without dose reduction. New or progressive CNS disease was observed in 30% of patients who underwent dose reduction compared to 13.6% in those who did not undergo dose reduction (p-value=0.94). There were no significant differences in progression-free survival or overall survival between patients with and without dose reduction (log-rank p-values of 0.5724 and 0.7854, respectively).

Conclusions: In this single institution retrospective study, there was no significant difference in the rate of new or progressive CNS disease in patients with or without drug reduction. There was also no significant difference in overall survival in both groups. Overall, findings from this study suggest that when dose reduction is needed, it does not appear to negatively impact patient outcomes including CNS disease control, however further studies are needed to confirm findings and to determine whether the same holds true for other ALK inhibitors.

Keywords: alectinib, dose reduction, CNS disease

EP.12B.11 Clinical Treatment Selected by Patient-Derived Organoid in a Patient with Stage IV Lung Adenocarcinoma with Unique ALK Alternation

H. Li[1], W. Wang[1], L. Ye[1], X. Xu[2], [1]Wenzhou Medical University, Wenzhou/CN,[2]Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Anaplastic lymphoma kinase (ALK) fusion is prevalent in 3-5% of non-small cell lung cancers (NSCLC) and represents a crucial molecular target in this disease. Apart from the common EML4-ALK fusions, novel fusion variants are continuously being identified, but their response to ALK tyrosine kinase inhibitors (ALK-TKIs) remains uncertain. The use of patient-derived organoids (PDOs) for drug screening to offer personalized treatment options for cancer patients is gaining attention.

Methods: We report a case of stage IV lung adenocarcinoma harboring a unique combination of non-reciprocal/reciprocal ALK translocation (EML4-ALK and NBAS-ALK), ALK 1171N and ALK 1171S mutations, and establish a corresponding PDOs model. PDO-based drug sensitivity testing was compared to clinical efficacy to evaluate their potential in clinical practice.

Results: The treatment process is detailed in Figure 1. H&E staining and IHC (Figure 2)indicated that PDOs maintained the histopathologic characteristics of the original tumor tissue, while gene detection results showed consistent expression of EML4-ALK and NBAS-ALK with the primary tumor. The drug sensitivity tests accurately predicted the patient's clinical response to treatment.

Conclusions: This study validates the use of organoids as predictive preclinical models for lung cancer treatment development especially for the rare and uncommon mutations.

Keywords: patient-derived organoids, lung adenocarcinoma, ALK alternation

EP.12B.12 Intrinsic ALK-TKI Resistance Due to Met-Coamplification in ALK+ NSCLC, Effectively Treated by Alectinib-crizotinib Combination

E.M. Urbanska[1], L.C. Melchior[1], J.B. Sørensen[1,2], E. Santoni-Rugiu[1,2], [1]Copenhagen University Hospital, Rigshospitalet, Copenhagen/DK,[2]Department of Clinical Medicine, University of Copenhagen, Copenhagen/DK

Introduction: The vast majority of advanced ALK-rearranged (ALK+) NSCLC patients experience prolonged response to second generation (2G) ALK-TKIs. Yet, to our knowledge, we present herein the first case of ALK+ NSCLC rapidly progressing on 1st line Brigatinib treatment due to de novo MET-amplification. This represents an underrecognized mechanism of intrinsic resistance to ALK-TKIs.

Methods: A 46-year-old female, never-smoker, without comorbidities, in performance status 2, was diagnosed with T4N3M1c pulmonary adenocarcinoma. NGS analysis of DNA (Oncomine Comprehensive Assay v.3; ThermoFisher Scientific) and RNA (Archer FusionPlex® Lung panel v1.0; ArcherDX, Inc.) extracted from the diagnostic biopsy detected EML4-ALK fusion variant 1 (EML4-ALK v.1) and a TP53 co-mutation (p.G245S). The patient was treated with 1st line Brigatinib.

Results: Unexpectedly, we observed modest mixed response after three months and highly symptomatic progression after six months of treatment with this 2G ALK-TKI. A rebiopsy from new hepatic metastasis showed maintained adenocarcinoma histology without phenotypic transformation to SCLC, squamous carcinoma or sarcomatoid carcinoma (EMT). DNA- and RNA-NGS analysis of the rebiopsy displayed persistence of the original EML4-ALK v.1 fusion and TP53 mutation, without any additional variants or copy number variations. Supplementary IHC for MET receptor (CONFIRM anti-MET, clone ID, SP44 rabbit mAb; Ventana Medical Systems, Inc.) and FISH analysis for MET gene (dual-color Zyto-Light SPEC MET/CEN7 probe; Zytovision GmbH) revealed MET receptor overexpression (3+ in 80% of tumor cells) and heterogeneously increased MET gene copy number (CN) in tumor cells, including 20% with MET clusters (≥15 gene copies, thus uncountable) and the other 80% with median MET CN of 8.3, indicating high-level MET amplification. To investigate whether MET amplification was intrinsic or acquired, we retrospectively performed MET-IHC and -FISH on the diagnostic biopsy from the primary lung tumor. Thereby, we revealed increased MET receptor expression (2+ in 100%) and MET amplification (median MET CN 6.1), which otherwise had not been detected by NGS. Thus, given the well-documented efficacy of Alectinib towards EML4-ALK v.1, combined 2nd line treatment with Alectinib and the MET-TKI, Crizotinib, was implemented. This resulted in a very pronounced objective response (RECIST v.1.1.) without adverse events and with significantly improved quality of life so far (5 months).

Conclusions: Intrinsic ALK-TKI resistance is rare in patients with ALK+ NSCLC. Yet, our case advocates for more awareness of de novo co-alterations which may cause primary treatment failure on ALK-TKIs. MET-amplification is a frequent form of acquired resistance to 2G ALK-TKIs, whereas to our knowledge, this is the first reported case of intrinsic resistance to a 2G ALK-TKI due to de novo MET-amplification. Our case also demonstrates that the combination of Alectinib and Crizotinib is a feasible and effective treatment for ALK+ NSCLC with de novo MET amplification. The recognition of this mechanism of ALK-TKI resistance by FISH, especially in NGS-negative cases, should be considered before initiating 1st line treatment. This is of clinical importance, as effective combined therapy with ALK-TKI and MET-inhibitor is feasible.

Keywords: de novo MET-amplification, intrinsic ALK-TKI resistance, TKIs combination

EP.12B METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - FUSIONS: ALK / ROS1 / RET / NTRK
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12B.14 Platinum-Pemetrexed Chemotherapy and Lorlatinib Combination in Advanced ALK Positive NSCLC Progressing to Lorlatinib: A Case Series

E. Bertoli, E. De Carlo, M. Montico, A. Del Conte, B. Stanzione, A. Bearz, CRO IRCCS, Aviano/IT

Introduction: Advanced, anaplastic lymphoma kinase ALK positive (ALK+) non-small cell lung cancer (NSCLC) is currently treated with a 2nd generation ALK tyrosine kinase inhibitor (TKI) followed by the potent, brain-penetrant, third-generation TKI lorlatinib, with broad coverage of ALK mutations, or upfront lorlatinib. Currently, subsequent treatment to overcome lorlatinib resistance remains an unmet clinical need. After failure of targeted therapies, platinum and pemetrexed-based chemotherapy (PT/pem-based-CT) might still be a valid option, albeit with modest effectiveness (Lin JJ et al. J Thorac Oncol. 2020;15(2):258-265.) and frequent brain metastasis (BM) progression.

Methods: This retrospective analysis investigated the clinical effectiveness and safety of the PT/pem-based-CT and lorlatinib combination after lorlatinib failure in second- or later-line setting in six advanced consecutive ALK+ NSCLC patients (pts). Clinical-pathological data collected at our institutional database between June 2020 and November 2023 were used. Kaplan Meier's survival curves for progression-free survival (PFS) (defined as the time from starting combination therapy to progression or death) and intracranial-PFS (defined as the time from starting combination therapy to brain progression or death) were performed.

Results: 4/6pts had BM at disease onset. The average of treatment lines prior to lorlatinib was of two 1st/2nd generation ALK-TKI. Progression site on lorlatinib were: lymph nodes (2/6), lung (2/6), liver (2/6), brain (2/6). Regarding BM, one patient received SBRT immediately before starting induction phase, the other was clinically asimptomatic. Available tissue biopsy after lorlatinib progression, did not demonstrated ALK resistance mechanisms/ histology transformation. Treatment monitoring with liquid biopsy was negative for both on-target and off-target resistance mutations in all six patients. Following multifocal progression, therapy with lorlatinib was continued and all pts were added a PT/pem-based-CT with the association of pembrolizumab in half of the cases. In 3/6pts four induction cycles were administered, one patient stopped treatment after only two cycles and 2/6pts received six total platinum cycles. Subsequently a maintenance with pemetrexed +/- pembrolizumab was carried out. In half of the cases, a reduction in chemotherapy dose was necessary, in two cases for hypercreatininemia grade 2 and in one for transaminase increase grade 2. All dose reductions occurred during maintenance and the drug concerned was pemetrexed. No lorlatinib dosage reduction occurred. PT/pem-based-CT and lorlatinib combination was found to be active in 5/6pts, bringing the best response to partial response (PR) in 2pts and stability (SD) in 3/6pts. Analyzing pts with CT dose reduction, 2 PR and 1 SD were recorded. Only one patient, who had not even completed induction phase, recorded systemic disease progression as best response and was a solely clinical progression. In only one case BM progression occurred. Median PFS was 5.5 months (interquartile range 3.5 - 9.0) and intracranial median PFS 7.7 months (interquartile range 5.5 - not reach).

Conclusions: This is the first proof of efficacy and safety of PT/PEM-based-CT and lorlatinib combination after lorlatinib failure in advanced in ALK+ NSCLC. To confirm this evidence, we developed a prospective, multicenter, phase II trial combining PT/PEM-based-CT and lorlatinib for the treatment of ALK+ NSCLC pts extracranially progressed on lorlatinib

Keywords: ALK+ NSCLC, lorlatinib, chemotherapy and lorlatinib combination

EP.12B.15 ALK-Fusion Positive NSCLCs: Diversity in Mutations and Co-Mutations with Therapeutic Perspective and Clinical Outcomes

A. Joshi[1], K. Joshi[2], U. Maheshwari[1], K. Jobanputra[1], D. Morzaria[1], V. Maniar[1], P. Kalaskar[1], R. Wategaonkar[3], R. Dave[3], S. Jagiasi[1], S. Sheth[1], T. Sethjiwala[4], C. Bose[1], P. Devde[5], P. Khandare[1], [1]MOC Cancer Care and Research Centre, Mumbai/IN,[2]MOC Cancer Care & Research Centre, Mumbai/IN,[3]MOC Cancer Care and Research Centre, Pune/IN,[4]MOC Cancer Care and Research Centre, Indore/IN,[5]MOC Cancer Care and Research Centre, Aurangabad/IN

Introduction: ALK-positive lung cancers are known to have aggressive biology, and advanced disease at presentation which further gets complicated by concurrent co-mutations and makes therapeutic interventions challenging. This study describes ALK mutations and co-mutations, clinical presentations, treatment, and survival outcomes from a community oncology practice in India

Methods: A retrospective analysis was conducted for ALK-fusion-positive NSCLCs treated between March 2018 and December 2023 from a community oncology setup. Clinical and molecular data was extracted from electronic medical records, highlighting ALK mutation types, treatment modalities, and clinical outcomes

Results: A total of 1068 patients of Non-small cell lung carcinoma (NSCLC) were assessed and ALK mutations were found in 50 of these patients (4.7%). The median age was 56.5 years (30-82) with 2 patients presenting at less than 40 years of age and the M:F ratio being 1:1.08. The majority of these patients were Stage IV (46/50) and adenocarcinomas (48/50) with a baseline brain metastasis seen in 15/50 patients. ALK mutations were tested by NGS in 17/50 patients, IHC in 9/50, and FISH in 1/50 patients. NGS test further elucidated EML-ALK fusions in 10 patients, point mutation in 2 patients, and G1202R in 2 patients. Co-mutations were seen in 14/50 (28%) patients where EGFR was co-mutated in 9/14, followed by TP53 in 4/14 and ROS, PIK3CA, and BRAF in 1 patient each. The treatment landscape constituted of 1st line Tyrosine kinase inhibitors (TKIs) used in 37/50 (74%) patients where 1st, 2nd, and 3rd generation TKI was used in 34%, 38%, and 2% respectively. Chemotherapy as 1st line therapy was used in 8/50 patients while chemotherapy + TKI was used in 1/50 patients. 3rd Generation TKI was used in 7/50 patients wherein more than 70% of cases it was used in 3rd line and beyond. Median survival for the cohort was 35 months (with 95% CI 13.5-56.5) with a median follow-up time being 36 months (with 95% CI 18.7-53.5)

Conclusions: ALK-directed therapies have changed the treatment paradigms in NSCLCs. Easy availability of testing, cost-effectiveness of 1st generation TKIs, and encouraging patient assistance programs have led to the increased usage of these drugs in first-line settings leading to better outcomes. ALK co-mutations especially with EGFR are common and may affect the treatment decisions and survival

EP.12B.16 Effectiveness of Alectinib in ALK Rearrangement NSCLC: Real World Data of Peru

K. Roque[1,2], M. Galvez-Nino[1], R. Ruiz[1], M. Heredia[1], M. Castro-Mollo[1], O. Coanqui[1], N. Valdiviezo[1], M. Olivera[1], R. Andrade de Mello[2], L. Mas[1],
[1]Instituto Nacional de Enfermedades Neoplasicas, Lima/PE,[2]Nine of July University (UNINOVE), Sao Paulo/BR

Introduction: Non-small cell lung cancer (NSCLC) with ALK rearrangement represents approximately 5% of cases. Tyrosine kinase inhibitor therapy has improved the survival of this group of patients. We describe the clinical features and survival outcomes in a developing country.

Methods: Retrospective study based on case review of patients with metastatic NSCL with ALK rearrangement who received alectinib at Instituto Nacional de Enfermedades Neoplasicas (INEN), Lima- Peru. Descriptive analysis was conducted for clinical and epidemiological characteristics. PFS was calculated from the date of started treatment until the first documented progression and OS was calculated with Kaplan Meier curve.

Results: 23 patients were included for this analysis. Median age at diagnosis was 51 yo (range 31-68), 47.8% (n=11) of patients were female, 25% (n=6) were smokers and 16.6% (n=4) were exposed to wood smoke. The most common histology subtype was adenocarcinoma (87%), and 13% was NOS carcinoma. 21.7% (n=5) of patients had only intrathoracic disease, 34.7% (n=8) had systemic metastasis without brain metastasis and 47.8% (n=11) brain metastasis. 17.4% (n=4) started alectinib as second line of therapy, 78% (n=18) presented with ECOG 1-PS and 22% (n=5) presented with ECOG 2-PS at the beginning of treatment. ORR were reached in 74% (RC=4 + RP=13), 13 % had EE (n=3), 8.7% had PD (n=2) and 4.3% (n=1) was not evaluated yet. Regarding CNS response, 18.2% (n=2) achieved CR, 27.3% (n=3) PR, 45% (n=5) SD and 9% (n=1) was not evaluated yet. Median PFS and median OS was not reached. PFS rate at 4 year was 66.7% and OS rate at 4 year was 64.1%. Finally, 13% (n=3) presented grade 2-3 hyperbilirubinemia.

Conclusions: Tyrosine kinase inhibitor therapy, such as alectinib, has shown significant improvement in the survival outcomes of patients with ALK rearrangement NSCLC. Alectinib demonstrated high ORR, even favorable responses in patients with CNS metastasis, which is often a challenging site of management. Median PFS and median OS were not reached, suggesting a potentially durable benefit from alectinib therapy in this patient population.

EP.12C.01 Sotorasib vs Adagrasib: Matching-adjusted Indirect Comparison in Prior Treated KRAS G12C Advanced Non-Small Cell Lung Cancer

D. Chopra[1], D.M. Waterhouse[2], B. Sylvester[1], A. Jamotte[3], B. Stollenwerk[3], [1]Amgen, Thousand Oaks/CA/USA,[2]OHC (Oncology Hematology Care), Cincinnati/OH/USA,[3]Amgen, Rotkreuz/CH

Introduction: Sotorasib and adagrasib are two approved KRASG12C inhibitors with demonstrated efficacy in previously treated patients with KRAS G12C advanced non-small cell lung cancer (NSCLC). However, comparative efficacy data is unavailable. A matching-adjusted indirect comparison (MAIC) was hence performed to assess their relative efficacy using patient-level data for sotorasib and aggregate data for adagrasib.

Methods: Systematic literature reviews identified CodeBreaK 100, CodeBreaK 200 trials for sotorasib and KRYSTAL-1 for adagrasib. CodeBreak 100 and KRYSTAL-1 phase 2 trials were determined as the most comparable trials for this analysis due to similarities in trial design, inclusion criteria and distribution of key baseline patient characteristics. A set of five covariates identified as prognostic for NSCLC outcomes were used for adjustment in the base-case model based on clinical expert guidance: gender, race, Eastern Cooperative Oncology Group performance score, metastatic disease and brain metastases. An additional 4 covariates were included in the sensitivity model (bone metastases, liver metastases, smoking status, prior treatment with anti-programmed cell death (ligand)-1 (anti-PD-[L]1) and platinum-based chemotherapy). Further scenario analyses limiting patients from CodeBreaK 100 to North America ensuring comparability with the US population of KRYSTAL-1 was conducted. Hazard ratios (HRs) were used for overall survival (OS) and progression-free survival (PFS). Odds ratios (ORs) were estimated for objective response rates (ORRs).

Results: CodeBreaK 100 included 126 patients receiving sotorasib, with 62.7% from North America whereas all 116 patients enrolled in KRYSTAL-1 were from the US. After matching on key covariates in the base-case model, an effective sample size of 80.6 from CodeBreaK 100 was obtained. The adjusted results suggested that in the overall population subjects receiving sotorasib had an 8% lower risk of death during the study period compared with patients receiving adagrasib (Hazard Ratio [HR] 0.92; 95% Confidence Interval [CI] 0.61-1.38; p=0.69); however, the results were not statistically significant. Restricting the CodeBreaK 100 population to patients enrolled in North America, produced similar results suggesting a 13% non-significantly lower risk of death with sotorasib compared to adagrasib (HR 0.87 [95% CI 0.55-1.36]; p=0.54). The risk of progression was not significantly different for subjects receiving sotorasib compared to adagrasib in either the overall (HR 1.20 [95% CI 0.86-1.68]; p=0.28) or North American subgroup (HR 1.13 [95% CI 0.78-1.63]; p=0.52). The likelihood of achieving an ORR was similar between the two treatment groups in the overall population (OR 0.99 [95% CI 0.59-1.66]; p=0.97) and was 18% higher for sotorasib in the North American subgroup (OR 1.18 [95% CI 0.66-2.11]; p=0.58); the results did not achieve statistical significance. Robustness of findings was confirmed in sensitivity analyses (crude analysis, alternative model with additional covariates and exclusion of outliers).

Conclusions: Using an MAIC approach, comparable efficacy was estimated between sotorasib and adagrasib in treating patients with KRAS G12C advanced NSCLC. The results are specifically relevant for informing clinical practice and payer decisions in the 2L+ treatment setting.

EP.12C.02 5-Azacytidine DegradedKRAS By Recruiting E3 Ubiquitin Ligase UBE3C

H. Liu, Shanghai General Hospital, Shanghai/CN

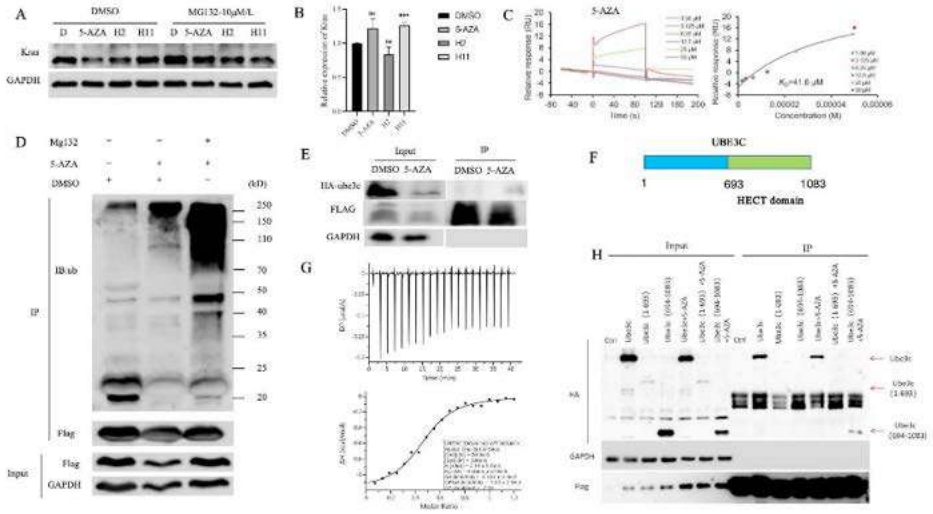
Introduction: KRAS mutations promote tumorigenesis, invasion, drug resistance and poor prognosis in lung cancer. Development of degradation agents targeting KRAS may help target tumors and alleviate chemotherapy resistance.

Methods: A compound screening system for the lentivirus infected RFP-KRAS-EGFP-FLAG monoclonal cell line was constructed, and identified candidate compound 5-Azacytidine through compound library screening. Clarify the molecular mechanism of compound degradation of KRAS. Various techniques and methods such as computational simulation and molecular biochemical experiments to further optimize and modify 5-Azacytidine, and conduct in vivo and in vitro pharmacological activity and safety evaluations.

Results: Study showed that compound 5-Azacytidine can degrade both wild-type and mutant KRAS proteins, and its degradation could be inhibited by MG132. Immunoprecipitation results showed that compound 5-Azacytidine promoted the ubiquitination of KRAS, and MG132 can protect KRAS from degredating. Compound 5-Azacytidine exhibited time- and concentration-dependent degradation of KRAS protein. We performed protein profiling of compound 5-Azacytidine-treated KRAS protein and found that the E3 ligase UBE3C could bind to KRAS.

Conclusions: Compound 5-Azacytidine can act as a molecular glue between KRAS and UBE3C protein and induce KRAS degradation via ubiquitin-proteasome system.

Keywords: Lung cancer, 5-Azacytidine, Degradation



(A) Compound 5-Azacytidine can reduce the level of KRAS protein, and the level of KRAS protein increases after treatment with MG132. (B) qPCR detection was used to verify the expression changes of KRAS mRNA after treatment with compound 5-Azacytidine. (C) SPR experiment verifies the affinity of compound 5-Azacytidine with KRAS mutant protein. (D) Compound 5-Azacytidine promotes ubiquitination of KRAS. (E) By constructing HA labeled ube3c plasmid, exogenous IP showed that after 5-AZA treatment, KRAS can bind to ube3c. (F) The protein structure of UBE3C, 693-1083aa, contains the HECT domain region. (G) The ITC results showed that 300 umol UBE3C was dropped into 300 umol KRAS+20umol 5-AZA, and the results showed binding between 5-AZA, UBE3C, and KRAS. (H) Western blot experiments showed that grouping ctrl, ube3c, ube3c (1-693), ube3c (694-1083), ube3c+5-AZA, ube3c (1-693)+5-AZA, ube3c (694-1083)+5-AZA was performed, and the above plasmids were transferred into stable flag kras PC-9 cell lines and IP was performed using flag beads. The results showed that ube3c (694-1083) is a functional segment that binds to kras, and 5-AZA promotes the binding of ube3c (694-1083) to kras.

EP.12C METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - KRAS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12C.03 Toxicities Associated with Immune Checkpoint Inhibitors Followed by KRAS G12C Inhibitors in Patients with Metastatic NSCLC

S. Kagalwalla, M. Patel, N. Fujioka, B. Manning, R. Kratzke, A.A. Kulkarni, University of Minnesota, Minneapolis/MN/USA

Introduction: KRAS G12C inhibitors are approved for KRAS G12C mutated non-small cell lung cancer (NSCLC) following progression on first line systemic treatment, which typically includes an immune checkpoint inhibitor (ICI). KRAS G12C inhibitors are associated with an increased risk of hepatotoxicity and pneumonitis. Sequential treatment with ICI followed by KRAS G12C inhibitors has previously been associated with an increased risk of hepatotoxicity. In this study, we evaluated whether ICI exposure prior to KRAS G12C targeted therapy was associated with an increased risk of hepatotoxicity and pneumonitis.

Methods: This is a single center, retrospective review of the electronic medical records of patients with KRAS G12C mutated metastatic NSCLC who received a KRAS G12C inhibitor in the second or later line between June 2021 and November 2023. Patients were stratified based on timing of exposure to ICI prior to KRAS G12C initiation (< 3 months, ≥ 3 months, or no exposure to ICI). We collected data on the development of treatment-related hepatotoxicity and pneumonitis. Adverse events were graded based on the National Cancer Institute Common Terminology Criteria for Adverse Events, Version 5.

Results: Twenty-eight patients were included in the analysis. Of the twenty-three patients with prior ICI exposure, 16 (70%) received ICI <3 months before receiving a KRAS G12C inhibitor. All patients received sotorasib. Of these, 8 (50%) experienced any grade hepatotoxicity i.e. transaminitis. Four patients (25%) experienced ≥ Grade 3 transaminitis and 4 patients (25%) experienced Grade 1-2 transaminitis. Two patients discontinued treatment and two patients required dose reduction due to hepatotoxicity. Only one (14%) patient who had exposure to ICI ≥ 3 months prior and one patient (20%) without any prior exposure to ICI experienced Grade 1-2 transaminitis. No grade ≥ 3 hepatotoxicity was noted. Across all patients, only one patient (4%) experienced pneumonitis (Grade 3) after starting a KRAS G12C inhibitor. This patient had ICI exposure ≥3 months prior. The pneumonitis occurred shortly after the KRAS G12C inhibitor was discontinued due to disease progression. The patient had received radiation to the mediastinum and right lung three years before developing pneumonitis.

Conclusions: Sequential treatment with ICI and KRAS G12C inhibitors is associated with an increased risk of hepatotoxicity. The risk appears highest if patients received a KRAS G12C inhibitor within 3 months of ICI. The risk for pneumonitis was much lower. More studies are needed to elucidate the mechanism and optimal timing of KRAS G12C inhibitors following exposure to ICI.

Keywords: KRAS G12C Inhibitors, Pneumonitis, Hepatotoxicity

Patient Cohort	Patients (n)	Age in years (Mean)	Sex (Male %)	Patients with two/ ≥ two lines of prior treatment (%)	Grade transaminitis n (%)	Grade 3-4 transaminitis n (%)	Any grade pneumonitis n (%)

Immunotherapy <3 months before KRAS G12C	16	68.7	31.3%	75/25	8 (50%)	4 (25%)	0
Immunotherapy ≥ 3 months before KRAS G12C	7	70.3	0%	57/43	1 (17%)	0	1 (17%)

EP.12C METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - KRAS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12C.04 Location of Metastases and Prognosis of Patients with Metastatic KRAS-Mutant Non-Small Cell Lung Cancer

L. Gutiérrez Sainz[1], I. Ozáez[1], O. Higuera Gómez[1], J. Villamayor[1], I. Esteban Rodríguez[1], R.M. Regojo Zapata[1], A. Peláez García[1], V. Heredia Soto[1], M. Mendiola[1], R. Rosas Alonso[1], C. Rodríguez Antolín[1], I. Ibáñez de Cáceres[1], J. de Castro Carpeño[1], [1]La Paz University Hospital, Madrid/ES

Introduction: KRAS is the most frequently mutated oncogene in Non-Small Cell Lung Cancer (NSCLC), occurring mostly at codon 12. KRASG12C is present in 10 to 13% of patients with NSCLC and KRASG12V in 5% of patients. KRAS status as a prognostic factor or predictor of response to immunotherapy in NSCLC remains a topic of debate.

Methods: In this study, we carried out a retrospective analysis including all patients with metastatic KRAS-mutant NSCLC diagnosed at La Paz University Hospital from May 2022 to September 2023. KRAS status was determined by the Oncomine precision assay and/or the Oncomine comprehensive assay V3, using the Genexus Integrated Sequencing System (Thermo fisher scientific). PD-L1 expression was analyzed by immunohistochemistry (22C3).

Results: : A total of 49 patients with metastatic KRAS-mutant NSCLC were identified throughout this period. The majority (n=27, 55.1%) were males with a median age of 66 years old. 47 patients (95.9%) had smoking history. Most patients had adenocarcinoma (n=44, 89.8%). Regarding KRAS mutations, around one third of the patients (32.7%) had G12C, 24.5% G12V, 10.2% G12D, 8.2% Q61L and 24.4% had other less frequent mutations. The most frequent co-mutations found were TP53 (14.3%) and CDKN2A (10.2%). The most frequent locations of metastases were the bone (38.8%), the brain (36.7%), the lungs (36.7%), the liver (20.4%) the pleura (26.5%) and the adrenal glands (26.5%). The presence of bone metastases was significantly less frequent in patients with KRASG12V mutation (8.3% vs 48.6%, p:0.01). The median progression-free survival (PFS) after first-line (1L) and overall survival (OS) were 9.02 (95%CI:2.69-15.34) and 14 months (95%CI:0.00-37.00), respectively. KRASG12C and KRASG12V-mutant patients had non-significantly longer PFS after 1L with chemoimmunotherapy and OS than other patients with other less frequent KRAS mutations. On the other hand, KRASG12D-mutant patients had non-significantly shorter PFS after 1L.

Conclusions: In our cohort, KRAS-mutant patients appear to have a different metastatic pattern depending on their KRAS mutation subtype. In addition, KRASG12C and KRASG12V-mutant patients seem to have better prognosis and response to chemoimmunotherapy than KRASG12D-mutant patients.

EP.12C.05 KRASG12c-Mutant NSCLC Under Targeted Therapy in China: Lessons from Eight Cases

Y. Li[1], M. Dai[2], R. Zhang[2], X. Nie[2], [1]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology,, Wuhan [430022], Hube,/CN,[2]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan [430022], Hubei/CN

Introduction: KRAS mutations are one of the commonest oncogenic driver mutations of non-small cell lung cancer (NSCLC), while KRASG12C mutation is the most prevalent subtype in Chinese population. Only until recently, two selective KRASG12C inhibitors (KRASG12Ci), called sotorasib and adagrasib, have been approved under fast-track by the U. S. Food and Drug Administration (FDA) for patients with NSCLC harboring KRASG12C mutation. However, there are limited data regarding the efficacy of selective therapy for KRASG12C-mutant NSCLC in real world. To our knowledge, this is the first study to characterize the clinicopathological features, genomic characteristics, and clinical outcomes of patients with KRASG12C-mutatant NSCLC under KRASG12Ci treatment in Chinese patients.

Methods: Patients with KRASG12C-mutatant NSCLC under KRASG12Ci treatment, identified by next-generation sequencing from January 2019 to March 2023 were enrolled. Time to KRASG12C inhibitor discontinuation, progression-free survival, overall survival, clinicopathological features and genomic alterations were evaluated.

Results: All the 8 KRASG12C patients were male (100%) and 7 of them were smokers (87.5%), with the median age 64.5 years (range 52 to 70 years). Current cohort enrolled 2 patients with stage IIIB (25%) and 6 patients with stage IV (75%) at initial diagnosis. One patient in stage IIIB developed stage IV disease (brain metastasis) at 5 months after surgery. 3 cases (37.5%) presented with ECOG score 0-1, and 5 cases (62.5%) with ECOG score 5. The most common metastatic sites were bone (6/8, 75%), contralateral lobe (3/8, 37.5%), brain (2/8, 25%), pleura (2/8, 25%), adrenal gland (2/8, 25%). The histologic types of these patients were all lung adenocarcinomas (8/8, 100%). The prevalence of concurrent type I mutation in these patients was MET (1/8, 12.5%). For concurrent type II mutations, there were TP53 (5/8, 62.5%), MYC (1/8, 12.5%), EGFR (1/8, 12.5%), STK11(1/8, 12.5%). The median overall survival (OS) was 19.0 months (95% confidence interval [CI] 2.77-35.23) and median progression-free survival (PFS) was 8.0 months (95%CI 2.22-13.78). Only 1 patient (12.5%) received G12Ci as first-line therapy. This patient was initially diagnosed with clinical stage IV lung adenocarcinoma at 64 years old, the OS was 3 months and PFS was 1 months. While the median OS was 19.0 months (95%CI 3.32-34.68) and median PFS was 8.0 months (95%CI 4.29-11.71) for patients who had received KRASG12Ci as second/later-line therapy.

Conclusions: Our survival data reinforce the view that the efficacy of KRASG12Ci is inferior to what has been reported for targeted therapy in other oncogene-addicted subsets of NSCLC (e.g. EGFR mutations, reported median OS was 40.5 months (95%CI 27.1-54.0) and median PFS was 19.4 months (95%CI 14.3-24.4) for advanced EGFR-mutated patients who had first-line EGFR targeted therapy). Clinical outcomes with KRASG12Ci vary widely among patients. Additionally, patients with KRASG12C have a predilection to bone metastasis, which is consistent with the current literature. Larger prospective study on efficacy of KRASG12Ci will be needed to validate our findings and clarify the markers for further patient classification and stratification.

EP.12D.01 Clinical Outcomes of Patients with HER2-Mutant NSCLC in Real-World Settings: A Systematic Literature Review

X. Le[1], Q. Said[2], J. Zong[2], K-J. Lou[3], S. Ng[4], D. Nellesen[3], A. Majdi[5], F. Lopez-Rios[6], [1]MD Anderson Cancer Center, Houston/TX/USA,[2]Bayer HealthCare Pharmaceuticals Inc, Whippany/NJ/USA,[3]Analysis Group, Menlo Park/CA/USA,[4]Analysis Group, Los Angeles/CA/USA,[5]Bayer HealthCare SAS, La Garenne-Colombes/FR,[6]Hospital Universitario [12] de Octubre, Madrid/ES

Introduction: The identification of oncogenic drivers led to several approved therapies for NSCLC, and a new wave of investigational agents. HER2 mutations account for 2% to 4% of NSCLC and were first described 20 years ago. Developing effective therapies for this molecularly-defined patient population presents specific challenges. To gain further insight into the unmet medical need for patients with HER2-mutant NSCLC, we conducted a global systematic literature review (SLR) to identify and analyze real-world studies published in the last 5 years describing clinical outcomes among patients with advanced NSCLC harboring such mutations.

Methods: The SLR covered English language articles published between January 2019 and November 2023 and followed PICOS (Population, Patient, or Problem; Intervention; Comparison; Outcome; Study) design elements recommended by the Centre for Reviews and Dissemination (CRD) guidance for conducting reviews in healthcare. The review window aimed to capture outcomes of interest from studies that reflect modern molecular testing practices and standard of care in NSCLC.

Results: The SLR identified 66 studies, including studies describing the frequency of HER2 alterations, activating mutations, and/or ex20ins (n=38), PFS outcomes (n=32), tumor response outcomes (n=30), and OS outcomes (n=27). The reported frequency of HER2 activating mutations and ex20ins in patients with NSCLC ranged from 0.8-5.4% and 0.8-5.77%, respectively. HER2 mutation frequencies trended numerically higher among East Asian populations, including China. Median PFS reported across included studies ranged from 1.7-15.67 months, but were typically in the 2-6-month range. ORRs reported across included studies were typically in the 10-35% range. Median PFS and ORR outcomes were primarily from studies evaluating HER2/EGFR targeted therapies, followed by those evaluating single-agent immunotherapy or immunotherapy plus chemotherapy, or chemotherapy alone. Reported median OS among patients with advanced NSCLC ranged from 5.9-23 months in those harboring HER2 activating mutations, and from 1.3-35 months in those harboring ex20ins.

Conclusions: Excluding amplifications, HER2 ex20ins mutations are the most common HER2 genomic alteration in advanced NSCLC. Patients with NSCLC harboring HER2 ex20ins mutations tended to have poorer treatment outcomes compared to those with non-ex20ins mutations. Notable evidence gaps include lack of studies reporting prognostic impact of HER2 activating mutations in comparison to the general advanced NSCLC population, treatment duration outcomes, and HER2 mutational frequencies from large epidemiologic studies, especially in European countries. Future studies to validate reported associations as well as the lack of observed associations in larger patient cohorts and in more general settings are needed.

EP.12D.02 Treatment Strategies and Survival Outcomes of Advanced NSCLC with HER2 Mutation and BM: A Multicenter Retrospective Study

Y. Fan, Q. Zhang, Y. Yu, Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: Human epidermal growth factor receptor 2 (HER2) mutation occur in 1-4% of non-small-cell lung cancer (NSCLC). Approximately 10-47% of HER2-mutant NSCLC will develop brain metastasis (BM) which is a poor prognostic factor, while chemotherapy alone yielded limited benefits for patients with BM. Fortunately, novel HER2-TKIs and antibody drug conjugates (ADCs) have shown certain efficacy; in particular, HER2-ADCs represented by T-DXd demonstrated promising intracranial efficacy. However, no available real-world data on such patients have been reported. We thus conducted this retrospective study to investigate the treatment regimens and clinical outcomes of advanced HER2-mutant NSCLC with BM.

Methods: From July 2018 and June 2023, this multicenter retrospective study included 178 patients with advanced HER2-mutant NSCLC who had received at least two cycles systemic antitumor therapy. The primary endpoint was overall survival (OS), measured from the diagnosis of BM until death or the last follow-up. Secondary endpoints included objective response rate (ORR), intracranial objective response rate (iORR), progression-free survival (PFS), and intracranial progression-free survival (iPFS).

Results: The study included 85 patients with HER2-mutant NSCLC with BM; 54.1% was female, median age was 60 years (range 31-88), 68.2% was nonsmokers, and 80.0% had a ECOG PS 0-1. The median OS after BM diagnosis was 15.7 months (95% CI: 13.5-17.9). In the first line (1L) treatment setting, patients were stratified into four groups based on the treatment regimens: chemotherapy (N=23), chemotherapy combined with immune checkpoint inhibitors (ICIs) (N=27), chemotherapy combined with anti-angiogenesis agents (N=28), and HER2-TKIs (N=7). The ORR for the above groups was 21.7/29.6/35.7/28.6%; the iORR was 18.2/25.9/26.9/28.6%, respectively. Patients who received chemotherapy plus antiangiogenic agents had a longer median PFS than those who received chemotherapy alone or combined with ICIs (6.8 months vs. 5.9 months vs. 4.9 months, P=0.032); while no significant differences were found in either median iPFS (4.3 vs. 5.2 vs. 5.8 months, p=0.088) or OS (14.4 vs. 17.4 vs. 16.0 months, p=0.880). In the second-line or later line (≥2L) setting, 25 patients who received next-generation HER2-ADCs treatment had the ORR and iORR of 52.0% and 27.3% respectively; the median PFS and iPFS were 7.2 months (95% CI: 4.7-9.7) and 6.7 months (95% CI: 5.2-8.2), respectively. Further analysis of patients who received with ADCs showed a longer median OS than those without ADCs (18.7 vs. 12.0 months, p=0.028). Besides, cranial radiotherapy significantly prolonged OS in patients with BM (17.9 vs. 9.0 months, p=0.0014). Inferior ECOG PS (HR=4.27, 95% CI: 2.02-9.05, P<0.001), undergoing intracranial radiotherapy (HR=0.49, 95% CI: 0.26-0.92, P=0.027), and receiving ADC treatment (HR=0.47, 95% CI: 0.24-0.93, P=0.030) were independent predictors for OS.

Conclusions: For HER2-mutated NSCLC and BM, 1L chemotherapy combined with anti-angiogenesis therapies brings greater survival benefits than chemotherapy alone; besides, next-generation HER2-ADCs and cranial radiotherapy could improve OS.

EP.12D.03 Characterization of HER2Alterations in 23,321 NSCLC Cases and Real-World Therapeutic Pattern in Chinese HER2-Mutant NSCLC the CHAPTER Study

B. Jia[1], J. Zhao[1], Z. Wang[1], T. An[1], Y. Wang[1], M. Zhuo[1], J. Li[1], X. Yang[1], H. Chen[1], Y. Chi[1], J. Wang[1], X. Zhai[1], R. Nuersulitan[1], X. Wang[1], Y. Tai[1], Y. Liu[1], G. Guan[1], Z. Dai[2], J. Song[2], [1]Key laboratory of Carcinogenesis and Translational Research (Ministry of Education/ Beijing), Department of Thoracic Medical Oncology, Peking University Cancer Hospital & Institute, Beijing/CN,[2]Department of Thoracic Oncology, The second affiliated hospital of dalian medical university, Dalian/CN

Introduction: The FDA has granted approval for fam-trastuzumab deruxtecan-nxki (Enhertu) in the treatment of non-small cell lung cancer (NSCLC) harboring ERBB2 activating mutations, although it is yet to receive approval in China. The studies on treatment pattern and the clinical efficacy of different regimens among Chinese population in the real-world setting are scare.

Methods: We analyzed the comprehensive genomic profiling results of tissue samples from 23321 NSCLC patients through Lung Cancer Big Data Precise Treatment Collaboration Group (LANDSCAPE) project (Cohort I). Samples of ERBB2 alterations (alt) and sequencing data covered the following genes, including EGFR, MET, KRAS, BRAF, ALK, RET, ROS1, ERBB3, PIK3CA, PTEN, CCNE1, IGF1R, were used for ERBB2 co-occurrent analysis. We also retrospectively collected clinical and survival data of 236 NSCLC patients who had ERBB2 alt from Peking University Cancer Hospital and Institute between December 2015 and March 2024 (Cohort II).

Results: Pathogenic/likely pathogenic alterations in ERBB2 were identified in 5.0% (n = 1174) of NSCLC tissue samples. Among these, ERBB2 mutations (mut) accounted for 3.8% (snv, indel) and amplification for 1.5%. ERBB2 alt were significantly more prevalent in patients under 45 years old compared to those ERBB2 wild type (WT) (12.8% vs. 4.4%, p<0.001), and also exhibited significant more female patients (55.5% vs. 44.5%, p<0.001). ERBB2 alt were more common in lung adenocarcinoma (89.1% vs 82.5%, p<0.01). ERBB2 mutations occur mainly in the kinase domain (KD, 85%, 91% of which were exon20ins), followed by the extracellular domain (ECD, 11%) and transmembrane domain (TMD,3%). ERBB2 mutations (n=519) were relatively mutually exclusive with other known oncogenic drivers (EGFR, KRAS, BRAF, MET, ALK, ROS1, RET; each p<0.01). Notably, as many as 83% of ERBB2 pathogenic/likely pathogeinc mutations in our data were observed in the DESTINY-Lung01 trial. Meanwhile, in Cohort II, of 236 NSCLC patients who had ERBB2 alt, 44.1% (104/236) were ERBB2 exon20ins. For unresectable locally advanced or metastatic patients received first-line treatment (N=195), the median progression-free survival (PFS) of chemotherapy/bevacizumab/immunotherapy (N=7), chemotherapy/immunotherapy (N=63), chemotherapy/bevacizumab (N=32), chemotherapy (N=32), EGFR-TKIs (N=52), and anti-ERBB2 inhibitors (N=9, mostly pyrotinib) was 13.0 months (95%CI: 6.5-19.5), 8.5 months (95%CI: 6.5-10.5), 6.0 months (95%CI: 4.7-7.3), 6.5 months (95%CI: 5.4-7.6), 10.0 months (95%CI: 7.0-13.0), and 6.0 months (95%CI: 3.4-8.6), respectively (P=0.42). For patients received subsequent-line Enhertu (mostly third-line or fourth-line), the objective response rate (ORR) was 54.5%, which is higher than other anti-HER2 inhibitors (pyrotinib, ORR=9.1%; afatinib/dacomitinib, ORR=27.8%; trastuzumab, ORR=0%; others, ORR=22.2%, P=0.077). A numerically longer mPFS was also observed with Enhertu (N=14, mPFS 7 months, 95%CI: 3.3-10.7) versus pyrotinib (N=33, mPFS 4.0 months, 95%CI: 2.6-5.4), afatinib/dacomitinib (N=19, mPFS 3.3 months, 95%CI: 1.7-4.9), trastuzumab (N=7, mPFS 3.0 months, 95%CI: 2.1-3.9), and other therapy regimens (N=11, mPFS 2.6 months, 95%CI: 1.2-4.0) (P=0.34)

Conclusions: A comprehensive analysis of the molecular characteristics and real-world treatment patterns in patients with ERBB2-mutated NSCLC can aid in optimizing the treatment of these patients, ultimately enhancing their prognosis. The more favorable efficacy benefit demonstrated by Enhertu compared with all other anti-HER2 regimens indicates the optimal treatment choice for Chinese NSCLC patients with ERBB2 alterations.

EP.12D.04 Treatment Pattern and Clinical Outcome in Chinese NSCLC Patients with MET Alterationwho Had Disease Progressionon EGFR-TKIs

X. Wang, Z. Huang, R. Lou, Y. Liu, Y. Qin, X. Qi, Y. Mao, Affiliated Hospital of Jiangnan University, WuXi/CN

Introduction: Dysregulation of the MET signaling pathway, including MET amplification/over-expression (amp/OE), is one of the most common acquired resistance mechanism to EGFR-TKIs in patients (pts) with advanced EGFRm NSCLC. Previous studies indicated the combination of MET-TKIs and EGFR-TKIs had shown encouraging clinical efficacy and a tolerable safety profile in these pts with MET amp/OE. However, the data of treatment pattern and clinical outcome for these patients in real-world setting is still limited.

Methods: We performed a retrospective, real-world study to analyze treatment pattern and clinical outcome in advanced or metastatic EGFRm NSCLC pts with MET amp/OE who progressed on EGFR-TKIs between Feb. 2022 and Oct. 2023 in China. MET amp was detected by fluorescence in situ hybridization (FISH; MET copy number ≥5 and/or MET:CEP7 signal ratio ≥2), and MET OE by immunohistochemistry (MET IHC; 3+ in ≥50% of tumor cells). Data of patient characteristics, treatment pattern, clinical outcome and safety were collected and analyzed. The objective response rate (ORR), time to treatment failure (TTF) were evaluated.

Results: 32 advanced EGFRm NSCLC pts with MET amp/OE who progressed on EGFR-TKIs were included this study. 93.5% pts had adenocarcinoma histology, 56.3% pts were ECOG 0~1, and 40.6% pts had brain metastases. Overall, 31.3% pts received the combination therapy of MET-TKI and EGFR-TKI, 46.9% pts received chemotherapy(chemo)-based regimen and 21.8% pts received other regimens as subsequence therapies. The ORR of pts who received MET-TKI plus EGFR-TKI was 61.5%. The median TTF (mTTF) of these pts was 9.5 months(m). Of these pts, the ORR of the pts who received savolitinib plus osimertinib was 77.8%, the mTTF was 10.2m. However, the mTTF of the pts who received chemo-based therapies was only 4.4m. The ORR of the pts who received MET-TKI plus EGFR-TKI as second-line(2L) was 75% and the mTTF was 12.8m. The ORR of the pts who received chemo-based regimen as 2L was only 33.3%, the mTTF only was 5.5m. The safety profile of the combination therapy of MET-TKIs plus EGFR-TKI and chemo-based therapy were similar to previously reported data.

Conclusions: Chemo-based therapy remained most common treatment regimen for these advanced NSCLC pts with MET amp/OE who have progressed on EGFR-TKIs in the real-world setting. The combination of MET-TKI and EGFR-TKI showed encouraging clinical benefit in these pts with acceptable safety. Future prospective studies are warranted to confirm the benefit of MET-TKIs plus EGFR-TKIs in these pts.

EP.12D.05 MAIC of OS and TRAE Comparing Capmatinib with Other MET Inhibitors for Treatment of Ansclc with MET Exon 14 Skipping Mutations

Y-I. Wu[1], S. Yong[2], Y. Yao[3], Z. Cheng-Zhi[4], L. Wu[5], J. Zhao[6], J. Hu[7], Y. Yin[8], Y. Lei[8], X. Gao[8], M. Tang[8], R. Gupta[9], C. Biswas[9], P. Orfanos[10], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN,[2]Department of Respiratory Medicine, Jinling Hospital, Nanjing University School of Medicine, Nanjing/CN,[3]Department of Oncology, The First Affiliated Hospital of XI'AN Jiaotong University, Shaanxi/CN,[4]Department of Pulmonary and Critical Care Medicine, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN,[5]Department of Thoracic Medical Oncology, Hunan Cancer Hospital and the Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha/CN,[6]Department of Thoracic Oncology, Peking University Cancer Hospital, Beijing/CN,[7]Department of Pulmonary and Critical Care Medicine, Zhongshan Hospital, Fudan University, Shanghai/CN,[8]Novartis Healthcare Private Limited, Beijing/CN,[9]Novartis Healthcare Private Limited, Hyderabad/IN,[10]Novartis Healthcare Private Limited, Basel/CH

Introduction: Highly selective mesenchymal-epithelial transition (MET) inhibitors are preferred treatments for advanced non-small cell lung cancer (aNSCLC) with MET exon 14 skipping mutations1. At the time of this analysis (Aug 2023), 4 MET inhibitors (Capmatinib (CAP), savolitinib (SAV), glumetinib (GLU), and tepotinib (TEP)) had clinical data published based on respective single arm trials. In the absence of head-to-head studies, unanchored matching-adjusted indirect comparison (MAIC) of overall survival (OS) in first-line (1L) setting and treatment related adverse events (TRAE) in overall population was performed to adjust differences in clinical trial settings and estimate relative efficacy and safety of CAP vs other MET inhibitors.

Methods: The baseline characteristics of CAP treatment patients from the GEOMETRY mono-1 study were weighted to match aggregate data from published comparator trials (NCT02897479 for SAV, NCT04270591 for GLU, NCT02864992 for TEP). Cox proportional hazard regression analysis was used to identify the matching variables that had a significant association with OS. Post-MAIC, the CAP weighted Kaplan Meier OS curves was compared against comparator's curves to estimate hazard ratio (HR) in treatment naive patients. For TRAEs, baseline characteristics of both the overall population and the Asian population were adjusted and then recalculated.

Results: In the 1L setting, CAP was found to have numerically better OS than SAV (HR 0.532, 95%CI 0.265-1.068), TEP (HR 0.870, 95%CI 0.579-1.307), and the comparison with GLU was not able to be performed due to OS immaturity of GLU. The rate of any grade TRAEs for CAP were significantly lower than SAV and GLU in the overall population (Risk difference CAP vs SAV: -9.3%, GLU: -7.1%), and numerically lower than TEP (Risk difference CAP vs TEP: -1.1%). In the Asian population, CAP showed the lowest rate of any grade TRAEs against all comparators (Risk difference CAP vs SAV: -11.4%, GLU: -12.6%, TEP: -11.1%).

Conclusions: Considering all comparators, CAP showed numerical OS advantage trend in the first line setting and a lower incidence of TRAEs in both the overall population and the Asian population.

EP.12D.06 Real-World Cases on Efficacy and Safety of Savolitinib for Elderly Patients with NSCLC Harbouring METex14 Skipping Mutations

L. Li, Z. Zhang, Y. Xu, K. Xu, H. Wang, J. Li, T. Tian, H. Zhou, L. Xu, C. He, H. Tang, S. Wei, The First Affiliated Hospital of USTC, Hefei/CN

Introduction: Savolitinib is an oral targeted agent that selectively inhibits MET tyrosine kinase. Limited real-world data have been reported on the long-term survival of elderly (≥75 years) NSCLC patients with METex14 skipping. We reported three elderly NSCLC patients with METex14 skipping who were treated with savolitinib to explore the efficacy and safety of savolitinib.

Methods: Three patients with advanced METex14 skipping NSCLC between 2022 and 2024 were retrospectively reviewed (the database cut-off date was March 20, 2024). All the patients received savolitinib in the first-line therapy. The data analyzed by investigators included objective response (RECIST1.1), progression-free survival (PFS), and safety.

Results: The median age of the three patients was 81.6 (76-86) years. Case 1) An 83-year-old man complained of cough was diagnosed of lung adenocarcinoma with the stage of T3N0M0. Computed tomography (CT) scan showed a mass in the posterior upper lobe of the right lung, with right visceral pleural invasion. Lung tissue biopsy confirmed lung adenocarcinoma, and METex14 skipping was confirmed by NGS. The patient received savolitinib at a standard dose of 600 mg once daily (Qd). The patient achieved partial response (PR) after three months and subsequently achieved stable disease (SD), who continued to receive savolitinib until now. The PFS was 15 months. He experienced Grade 1 fatigue and pruritus sequentially. Case 2) An 86-year-old woman presented with chest distress was diagnosed with stage IVa NSCLC with cervical lymph node metastases. CT showed left upper lobe mass and lymph node metastases in the left hilar region, mediastinum, left supraclavicular region, left side of the neck, and left axillary region. NSCLC was confirmed by cervical lymph node biopsy (Not Otherwise Specific), and METex14 skipping was confirmed by NGS. She started savolitinib 400 mg Qd based on the weight of 45kg. After two months of treatment, the dosage was reduced to 300mg because of Grade 3 hepatic dysfunction, then further reduced to 200 mg Qd because of Grade 2 hepatic dysfunction after 2 days. The patient developed grade 2 hypoproteinemia after 6 months of savolitinib. Hypoproteinemia improved after diet adjustment. The PFS was 22 months. Case 3) A 76-year-old man presented with cough was diagnosed of adenocarcinoma with stage IV NSCLC (T3N1M1)from a thoracoscopic biopsy. He started savolitinib 600 mg Qd for a month and reduced to 300 mg because of grade 4 hepatic dysfunction, then further reduced to 200mg because of grade 2 hepatic dysfunction after 3 days. After 17 months of treatment with savolitinib, he was added radiotherapy (PTV 60Gy/30f) on the residual lesions in the left hilar region. The PFS exceeded 25 months. He also experienced Grade 2 limb edema and rash.

Conclusions: From the case series, savolitinib showed a favorable clinical benefit and safety profile, which may make it one of the best treatment options for elderly NSCLC patients with METex14 skipping. It provides long-term survival and is tolerable.

EP.12D.07 Efficacy and Safety of Savolitinib for MET-Altered Non-Small Cell Lung Cancer (NSCLC) In First-Line Setting: A Case Series

Y. Hua[1], W. Xu[1], H. Shi[1], X. Zheng[1], X. Li[1], [1]Beijing Tiantan Hospital, Capital Medical University, Beijing/CN

Introduction: Recognition and detection of MET alterations, including MET exon14 skipping mutation (METex14), MET amplification (METamp), and overexpression, have fueled the clinical development of MET tyrosine kinase inhibitors (TKIs). In METex14 NSCLCs, MET TKIs have become a standard therapy, but the clinical data is limited for METamp EGFR wild-type (EGFRw) patients. Here, we present a case series of MET-altered EGFRw NSCLCs receiving savoltininb in the first-line setting.

Methods: Four patients with stage IV NSCLCs were retrospectively reviewed, including three with primary METamp (cases 1-3) and one with METex14 (case 4). Cases 2-4 had brain metastasis. All patients received savolitinib 600mg once daily in a first-line setting. Objective response by investigators and progression-free survival (PFS) were analyzed based on RECIST v1.1; the safety profile was evaluated according to CTCAE v5.0.

Results: The MET gene copy numbers of case1-3 were 2.46, 8, and 5, respectively, and all of these patients also harbored PD-L1 high expression (60%-80%). For cases 1, 2, and 4, the overall tumor response was PR after approximately one month of therapy. At the time of cut-off, they were receiving continuous treatment, and the primary lesions were still in response with a PFS of 17 months, 26 months, and 19 months, respectively. In the brain metastasis subgroup, case 2 and case 4 received stereotactic radiotherapy (SRT) and achieved a PR in brain lesions; the intracranial PFS was 26 months and 19 months. In case 3, a male patient also accompanied by 34 other gene mutations, the primary lesion achieved PR after therapy, but brain metastatic lesions showed a disease progression despite multiple therapies (including surgery, radiotherapy, and laser interstitial thermal treatment), with overall survival (OS) of only nine months. Three patients experienced peripheral edema (grade 2 for cases 1 and case 2, grade 1 for case 4), leading to savolitinib dose reduction to 400mg once daily. Still, the edema was manageable after dose reduction and diuretic therapy. No other serious adverse events were observed.

Conclusions: MET-altered EGFRw NSCLCs treated with savolitinib in the first-line setting showed promising primary tumor shrinkage and a durable response, regardless of brain metastatic status. For the brain lesions, savolitinib plus local radiotherapy could cause a prominent intracranial PFS. The safety profile was manageable. The mechanism of MET TKI resistance needs further study, especially in brain metastatic lesions. This study was supported by the grants from Beijing Natural Science Foundation (NO. 7242007)

EP.12E METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - MULTIPLE TARGETS

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12E.01 OBX02-011, a Novel Oral ALK and EGFR Dual-target Tyrosine Kinase Inhibitor for the Treatment of Advanced NSCLC Patients, S. Heo[1], S. Lee[2], T. Ha[2], M. Baek[2], M. Kim[2], K. Jung[2], S-E. Kim[2], [1]ONCOBIX CO., LTD., Gyeonggi-Do,/KR,[2]ONCOBIX CO., LTD., Gyeonggi-Do/KR

Introduction: Multiple ALK and EGFR TKIs have been developed for patients with ALK-positive and EGFR-positive non-small-cell lung cancer. Despite the outstanding efficacy of inhibitors in the current market, resistance is inevitable. Both on-target and off-target mechanisms of resistance have been identified in patients who have progressed disease after prior treatment with ALK or EGFR TKIs. To address the limitations of existing targeted therapies, Oncobix is developing OBX02-011, a novel, synthetic, orally administered TKI.

Methods: OBX02-011 was evaluated for selectivity by testing its in vitro activity against more than 450 human kinases and disease relevant mutant variants using a binding assay. Kinase assays were also performed to investigate kinase selectivity. To confirm selectivity from the kinase assays, OBX02-011's potency in cell-based assays was compared to other ALK and EGFR TKIs. OBX02-011 was evaluated for in vivo anti-tumor activity in mice implanted with tumor cell lines expressing fusions with EML4-ALK_G1202R, EGFR sensitizing mutations, and EGFR acquired mutations. In addition, OBX02-011 was also evaluated for in vivo anti-tumor activity in the intracranial NCI-H2228-luc brain metastasis model.

Results: OBX02-011 showed high potency against ALK and EGFR, as well as a panel of acquired ALK and EGFR mutations that developed resistance to the marketed ALK or EGFR inhibitors. In the kinase assays, OBX02-011 inhibited ALK wild type and a panel of crizotinib, alectinib, and brigatinib resistant ALK mutations, including G1202R and L1196M. OBX02-011 inhibited EGFR as well as sensitizing mutations (exon 19 deletion and L858R) and acquired resistance (exon 19 deletion/C797S, L858R/C797S, exon 19 deletion/T790M/C797S, and L858R/T790M/C797S). In cell-based assays, OBX02-011 showed similar inhibition to lorlatinib in the ALK wild-type. In addition, OBX02-011 demonstrated superior inhibition compared to lorlatinib in ALK_C1156Y, G1202R, and L1196M mutations associated with clinical resistance to the first generation ALK inhibitor crizotinib and/or the second generation ALK inhibitors alectinib, brigatinib, and ceritinib. In the in vivo studies, OBX02-011 demonstrated tumor regression in EML4-ALK_G1202R, EGFR_exon 19 deletion, EGFR_L858R, EGFR_exon 19 deletion/C797S models, EGFR_L858R/C797S models. OBX02-011 also demonstrated tumor regression in the osimertinib-resistant lung cancer patient-derived xenograft model with EGFR_exon 19 deletion/T790M/C797S. OBX02-011 also demonstrated potency in the ALK wild-type brain metastasis model.

Conclusions: Non-clinical studies have shown that OBX02-011 is a potent inhibit of ALK and EGFR, including the respective ALK G1202R mutation and EGFR sensitizing and acquired mutations. In vitro cell-based assay results showed that OBX02-011 does not inhibit NTRK2 (TRKB), which causes neurological toxicity, and there were also no significant findings for OBX02-011 in the CNS safety pharmacology study. Based on these studies, a first-in-human study will be conducted in 2024 to address the current resistance mechanisms in ALK-positive or EGFR-positive NSCLC patients and prolong progression free survival.

Keywords: ALK, EGFR, TKI

EP.12E METASTATIC NON-SMALL CELL LUNG CANCER - TARGETED THERAPY - MULTIPLE TARGETS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12E.02 Landscape, Management & Outcome of Real-World Fusion-positive Non-Small Cell Lung Cancer (NSCLC)

A.J. Gibson[1], M. Dean[1], A. Box[2], E. Nohr[2], D. Twa[3], V. Navani[4], [1]University of Calgary - Cumming School of Medicine, Calgary/AB/CA,[2]Alberta Precision Laboratories, Calgary/AB/CA,[3]University of Calgary, Calgary/AB/CA,[4]University of Calgary; Alberta Health Services, Calgary/AB/CA

Introduction: The discovery of oncogenic driver genes in NSCLC and subsequent development of targeted therapies has dramatically changed the management and prognosis of these malignancies. For patients with NSCLC driven by kinase fusions or oncogenic isoforms, barriers persist with regards to diagnostic confirmatory testing, histology-restricted genomic sequencing algorithms, and reimbursement restrictions of molecularly targeted therapies. We aim address a current knowledge gap in the understanding of the characteristics, real world treatment, and outcomes of fusion- or isogenic isoform-positive NSCLC.

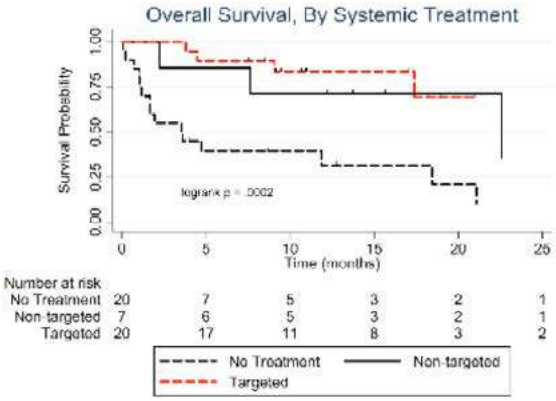
Methods: Alberta patients with advanced/metastatic (M1) NSCLC, meeting the criteria for funded provincial genomic sequencing between April 2022 and May 2023, received reflexive (SNV-hotspot driver negative) RNA next-generation sequencing (NGS) by Alberta Precision Laboratories. Testing was performed by Archer FusionPlex (IDT) with sequencing on Genexus (ThermoFisher). Demographic, clinical, treatment, and outcome details were extracted from a province-wide, real-world outcomes registry of patients treated in routine practice.

Results: Forty-seven individuals with an oncogenic fusion or isoform were identified. Median age at diagnosis was 70 years, 62% female, 51% never-smokers, 57% ECOG ≤ 1; 87% adenocarcinoma histological subtype. Alterations identified in this cohort were: MET exon 14 skipping (38%), BRAF oncogenic isoform (2%), and fusions: ALK (34%), RET (11%), ROS1 (9%), and FGFR2/3 (6%). Alterations were identified/reported a median 1.1 months following histological diagnosis of M1 lung cancer. Twenty-seven individuals (57%), predominantly with ECOG ≤1 (81%), received some form of systemic therapy, comprised of n=7 (26%) receiving a non-targeted systemic therapy (chemotherapy and/or immune checkpoint inhibitors), and n=20 (74%) receiving a targeted therapy. Median time-to-progression was 8.4 and 15.8 months, respectively. Targeted therapy availability, use, and survival outcomes (data cut-off: March 15, 2024) are described in Figure 1.

Conclusions: The advent of precision medicine relies on identification of both an effective therapy and amenable target. This analysis provides evidence of the number and variety of oncogenic fusions and isoforms in NSCLC identified in the era of NGS-testing, and encountered in routine clinical practice. These findings also reveal the low uptake of approved targeted therapies when self-funding is required for access. Inclusion of NGS-based genomic profiling and targeted therapies as part of standard of care within the public healthcare system supports appropriate clinical management to optimize patient outcome among those with actionable oncogenic fusions.

Keywords: genomic testing & targeted therapies, fusion-positive NSCLC, real-world management and outcomes

Figure 1: Systemic Treatment and Survival Outcome



Alteration	Systemic Therapy Received	Targeted Therapy Approved & Funded*	Targeted Therapy Received	Survival Analysis Post- Metastatic Disease◊

EP.12E.04 Understanding the Dynamics of TKI Induced Changes in the Tumor Immune Microenvironment for Improved Therapeutic Effect

C. Lu, Z. Gao, D. Wu, J. Zheng, C. Lin, R. Han, Y. He, Daping Hospital, Army Medical University, Chongqing/CN

Introduction: Understanding the functional dynamics and resistance mechanisms of tyrosine kinase inhibitors (TKIs) is pivotal for advancing non-small cell lung cancer (NSCLC) therapeutics

Methods: Multiplex Immunofuorescence and Immunohistochemistry (IHC) staining to explore the features of immune cell composition in the TME. Cell viability assay, Western blot analysis, Enzyme-Linked Immunosorbent Assay and T cell-mediated cancer cell killing assay to assessed the impact of TKI treatment on T-cell function. Animal experiments used to assessed aspirin potential role in overcoming TKI resistance by modulating the TME.

Results: In this study, we examined the influence of TKI interventions on the tumor immune microenvironment (TME) in NSCLC. Short-term TKI application enhanced T cell-mediated tumor clearance, reduced immunosuppressive M2 macrophage infiltration, and downregulated laminin subunit γ-2 (LAMC2), a key protein involved in tumor immune evasion. In contrast, long-term TKI treatment led to an immunosuppressive TME, fostering drug resistance and signifying a shift toward immune escape over time. Additionally, we observed differential TME responses to epidermal growth factor receptor (EGFR) and anaplastic lymphoma kinase (ALK) mutations, with ALK-targeted therapies eliciting stronger anti-tumor immunity. Notably, aspirin emerged as a promising adjunct in combating TKI resistance, modulating the TME and enhancing T cell-mediated tumor clearance.

Conclusions: These findings provide new insights into the dynamics of TKI-induced changes in the TME, improving the understanding of NSCLC-related challenges and opening up new avenues for strategies to overcome TKI resistance.

EP.12E.05 Exploring Clinical Characteristics and Treatment Outcomes of Squamous Cell Lung Cancers Harboring EGFR and ALK Mutations: A Case Series

P. Chattopadhyay[1], K. Sureshkumar[2], S. Kareff[3], E. Rodriguez[3], [1]University of Miami/Jackson Memorial Hospital, Miami/FL/USA,[2]University of Miami, Miami/FL/USA,[3]University of Miami's Sylvester Comprehensive Cancer Center and Jackson Memorial Hospital, Miami/FL/USA

Introduction: Squamous cell carcinoma (SCC) of the lung accounts for approximately 30% of non-small cell lung cancer (NSCLC) cases and is the second most common histological type of lung cancer. The Cancer Genome Atlas project and similar studies have detected a significant number of somatic gene mutations/amplifications in lung SCC (5-20%), mostly in TP53, CDKN2A, KMT2D, PIK3CA, and NFE2L2. In comparison with lung adenocarcinoma, EGFR/ALK mutations in SCC are relatively rare, with a reported prevalence of 3% to 18% and thus testing for these mutations is not commonly performed.1 Prior case reports have described ALK/EGFR mutations in SCC lung cancer patients with limited smoking history and worse prognosis despite treatment with targeted therapies.2,3 This case series presents three patients diagnosed with Stage III/IV squamous cell lung cancer and rare EGFR/ALK mutations, examining their demographics, smoking status, mutational profiles, and treatment outcomes.

Methods: This case series retrospectively analyzed three patients diagnosed with locally advanced/metastatic SCC and EGFR/ALK alterations at Sylvester Comprehensive Cancer Center between 2019 and 2024. Data on patient demographics, including ethnicity, smoking status, mutational profiles, treatment regimens, progression-free survival (PFS), and overall survival (OS), were collected from electronic medical records.

Results: All the patients in this series were women, never-smokers, ages 64-71 at diagnosis. Two patients had mixed adenocarcinoma-squamous histology (one ALK/one EGFR), while another patient had squamous histology only. One patient was diagnosed with Stage IIIB disease and treated with induction chemotherapy and surgery followed by adjuvant osimertinib with a PFS of 23 months. One of three patients progressed in the brain after initial treatment with targeted therapy. Pathology from the brain specimen revealed squamous histology with the same EGFR mutation at the site of metastases. Tolerance to treatment was similar to patients with adenocarcinoma with commonly reported adverse events related to skin and GI toxicity to osimertinib. Responses to platinum-based chemotherapy were varied. No common pattern of resistance mutations were identified.

Conclusions: In conclusion, advanced/metastatic squamous cell lung cancer with EGFR/ALK mutations are rare but can respond to treatment. In our case series, we found increased response to treatments that target the driver EGFR/ALK mutations, in patients with no smoking history with both mixed histology adenosquamous cell carcinoma or SCC. Despite the heterogeneity observed, osimertinib remains a promising treatment modality. Further research is warranted to elucidate specific patterns of resistance to EGFR-ALK targeted therapies in lung SCC.

Keywords: Squamous cell cancer of lung, EGFR, ALK

EP.12F.01 Genome-wide CRISPR-Cas9 Screening Identifies ITGA8 Responsible for Abivertinib Sensitivity in Lung Adenocarcinoma

X. Li, H. Huang, H. Liu, J. Chen, Tianjin Medical University General Hospital, Tianjin/CN

Introduction: The recent emergence of epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) has improved the prognosis of lung cancer patients with EGFR-driven gene mutations; however, the subsequent acquired resistance to EGFR-TKIs presents a major challenge to treatment. Studies on acquired resistance to EGFR-TKIs have primarily focused on developing next-generation targeted drugs based on the molecular mechanisms of resistance or inhibiting the activation of bypass pathways to suppress or reverse drug resistance. This study used a novel approach by applying CRISPR-Cas9 whole-genome library screening to identify genes that enhance sensitivity to EGFR-TKIs in lung adenocarcinoma.

Methods: Using the CRISPR-Cas9 whole-genome screening library, genes that increased the sensitivity of lung adenocarcinoma to abivertinib were identified. Bioinformatics, RT-qPCR, western blot analysis, and immunohistochemical staining were employed to validate gene expression differences between adjacent normal tissues and lung adenocarcinoma tissues. CCK8, clonogenic, EDU cell proliferation, and Transwell assays were done to assess the sensitivity of lung adenocarcinoma to abivertinib and the impact of ITGA8 on the proliferative, migration and invasion capacities of lung adenocarcinoma. Western blot analysis was used to detect changes in downstream signaling pathways at various ITGA8 expression levels. Rescue experiments were done to validate the interaction between ITGA8 and downstream FAK. In vivo experiments in nude mice were conducted to validate the effect of various ITGA8 expression levels on tumor proliferation and abivertinib sensitivity.

Results: Through CRISPR-Cas9 whole-genome library screening, ITGA8 was identified as a key gene that enhances the sensitivity of lung adenocarcinoma to abivertinib. In lung adenocarcinoma tissues, the expression of ITGA8 was markedly lower compared with that in adjacent normal tissues. ITGA8 was positively correlated with the sensitivity of lung adenocarcinoma to abivertinib and negatively correlated with the proliferation, migration, and invasion of lung adenocarcinoma. It sensitizes lung adenocarcinoma cells to EGFR-TKIs by attenuating the downstream FAK/SRC/AKT/MAPK signaling pathway.

Conclusions: ITGA8 reduces the proliferation, invasion, and migration capabilities of tumor cells, enhances the sensitivity of lung adenocarcinoma to EGFR-TKIs, improves treatment efficacy, and prolongs the duration of acquired resistance. ITGA8 is a potential therapeutic target that may address acquired resistance to EGFR-TKIs from a novel perspective.

EP.12F.02 Brigatinib, a Newly Discovered AXL Inhibitor, and Suppresses AXL Mediated Acquired Resistance to Osimertinib in NSCLC

C. Lu[1], R. Han[1], C. Hu[1], D. Wu[1], Y. He[1], [1]Daping Hospital, Army Medical University, Chongqing/CN

Introduction: In addition to the classical resistance mechanism, receptor tyrosine-protein kinase AXL is a main mechanism of resistance to third-generation epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) osimertinib in EGFR-mutated non-small cell lung cancer (NSCLC). Therefore, developing an effective AXL inhibitor is particularly important to sensitize osimertinib in clinical application. Here, the present study aimed to investigate a small molecule inhibitor, currently available in clinical settings, for its potential to enhance the sensitivity of EGFR-TKI in osimertinib resistance cells.

Methods: Small molecule screening and human phospho-RTK array to discover potent inhibitory activity toward AXL. Molecular modeling studies and thermal shift assay used to determine brigatinib bind with AXL kinase. Cell viability, colonial survival and cell-derived xenograft (CDX) models were used to determine antitumor activities.

Results: We established an AXL-overexpression NSCLC cell line and conducted high-throughput screening of a small molecule chemical library containing 510 anti-tumor drugs. We found that brigatinib potently inhibited AXL expression. We demonstrated that brigatinib had a potential ability to bind AXL kinase protein and further inhibit its downstream pathways in NSCLC cell lines. and that brigatinib (0.5 μM) significantly enhanced the anti-tumor efficacy osimertinib (1 μM) in AXL-mediated osimertinib-resistant NSCLC cell lines in vitro. In AXL-high expression osimertinib-resistant PC-9OR and HCC827OR cell derived xenograft mouse models, administration of osimertinib (10 mg·kg-1·d-1) alone for 3 weeks had no effect, and administration of brigatinib (25 mg·kg-1·d-1) alone caused a minor inhibition on the tumor growth; whereas combination of osimertinib and brigatinib caused marked tumor shrinkages.

Conclusions: In conclusion, our study indicated that brigatinib may be a promising clinical strategy for enhancing osimertinib efficacy in AXL-mediated osimertinib-resistant NSCLC patients.

EP.12F.03 Trametinib in the Treatment of Patients with Metastatic Lung Adenocarcinoma Harboring NF1 Mutation

F. Kim[1], M. Borgeaud[1], C. De Vito[1], P. Tsantoulis[1], A. Addeo[1], [1]University Hospital Geneva, Geneva/CH

Introduction: The neurofibromin 1 (NF1) protein regulates the downstream RAS/RAF/MEK/ERK pathway and functions as a tumor suppressor. Germline mutations in NF1 are linked to Neurofibromatosis type 1. Somatic pathogenic mutations in NF1 are found in various tumor types, including Non-Small-Cell Lung Cancer (NSCLC). Trametinib, a MEK inhibitor, has demonstrated activity in tumors with NF1 alteration in preclinical models, and clinical activity in low-grade glioma and plexiform neurofibromas in Neurofibromatosis type 1. However, trametinib had limited clinical efficacy in other tumor types with NF1 mutations in the NCI-Match trial. However, only one NSCLC patient included in the former trial was evaluable for response, with a good partial response. Thus, data for MEK inhibitors in NF1 mutant NSCLC remains limited and more data is needed.

Methods: We report here 4 cases of NSCLC patients with NF1 pathogenic mutations treated with trametinib. All patients underwent extensive molecular analysis through Next Generation Sequencing (400 genes panel), copy number variations analysis (Oncoscan Assay), and were deemed to have potential NF1-loss driven tumors after case discussion in multidisciplinary molecular tumorboard. All patients were treated with oral trametinib 2mg once daily, after failure of standard therapies.

Results: Patients characteristics are shown in Figure-1. Patients were between 62 and 80 years old, had relatively altered performance status (ECOG 1-2), and were all current or former smokers. Genomic alterations are shown in Figure-2. No patients exhibited co-mutations on the MAP-kinase pathways. Trametinib was administered for a maximum duration of nine weeks. The best response observed was a stable disease in one patient. All patients died within three months of treatment initiation. No side effects warranted treatment cessation.

Conclusions: In this small case series, NSCLC patients with NF1 alterations did not benefit from trametinib. These data do not support the use of trametinib for NF1 mutated NSCLC.

Keywords: Trametinib, NF1 mutation, Non-small-cell lung cancer

EP.12G.01 PFS as a Surrogate Endpoint for OS in Real-World Patients with ROS1+ advNSCLC in the United States

X. Ma[1], Y. Lu[1], A. Lee[2], C. Cho-Phan[1], I-H. Su[3], Y. Zhang[4], R. Camidge[5], J.R. Penrod[4], Y. Yuan[4], [1]Flatiron Health, New York/NY/USA,[2]Bristol-Myers Squibb, Uxbridge/GB,[3]University of North Carolina, Chapel Hill/NC/USA,[4]Bristol-Myers Squibb, Princeton/NJ/USA,[5]University of Colorado Cancer Center, Aurora/CO/USA

Introduction: Emerging targeted therapies have broadened treatment options for patients with advanced non-small cell lung cancer (advNSCLC), including those with rearrangements of ROS1 (ROS1+). Overall survival (OS) is a gold standard in efficacy studies but requires an extended follow-up period and may be immature when progression-free survival (PFS) or objective response rate (ORR) data are available. Thus, intermediate endpoints can be attractive surrogates for OS and provide direct evidence of drug activity. This study aims to estimate the relationship between real-world PFS (rwPFS) and rwOS in patients with ROS1+ advNSCLC in a real-world setting.

Methods: The primary analyses included patients with ROS1+ advNSCLC (stage IIIB-IVB at initial diagnosis or early stage with subsequent recurrence or progression) who received at least 1 line of therapy for advNSCLC from the nationwide Flatiron Health electronic health record-derived deidentified database with a data cutoff of June 30, 2023. Kaplan-Meier (KM) estimators were used to characterize rwPFS and rwOS from first-line (1L) treatment start. Relationships between rwPFS and rwOS were evaluated using Spearman's rank correlation coefficient (ρ). In addition, Copula models were employed to estimate Kendall's tau as a supportive measure. Cox proportional hazard models were used in landmark analyses to evaluate rwOS between patients with or without progression at 12 months, adjusting for prognostic factors. Alternative landmark time points of 6 and 18 months were considered. Sensitivity analyses were performed in a similar population using Flatiron Health-Foundation Medicine NSCLC clinicogenomic database (CGDB), including patients who underwent comprehensive genomic profiling with detailed data on biomarker testing and treatment response.

Results: There were 383 patients with ROS1+ advNSCLC eligible for the primary analyses. From 2011 to 2023, 52% of the cohort received ROS1 tyrosine-kinase inhibitors (TKIs), while 14% received immunotherapy (monotherapy or in combination with chemotherapy) and 12% received chemotherapy as 1L. Median rwOS for the overall cohort was 30.6 months (95% CI: 24.0, 36.6). Median rwPFS was 7.5 months (95% CI: 6.5, 8.8). For patients receiving TKI, which is the current standard of care, median rwOS and rwPFS were 29.1 months (95% CI: 19.9, 44.5) and 8.6 months (95% CI: 6.7, 11.2), respectively. The Spearman rank correlation coefficient for the overall cohort was 0.68 (0.59, 0.76), and supplementary Kendall's tau was 0.56 (95% CI: 0.49, 0.63). In landmark analyses, disease progression at 12 months was significantly associated with higher risk of death (HR=2.1 [1.4, 3.2]); similar association was observed at 6 and 18 months. Results in the sensitivity analyses using CGDB were largely consistent with the primary results.

Conclusions: The median rwOS of the overall cohort and TKI subgroup falls within the mid-range of previous studies of similar populations, while the median rwPFS is on the lower end. Both landmark analyses and Spearman's correlation coefficient suggest that rwPFS can potentially be a good candidate surrogate endpoint for rwOS in a ROS1+ advNSCLC population, although future research is warranted to confirm the correlation on a trial/cohort level.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.12G.02 Real-World Biomarker Testing and Treatment Patterns for Locally Advanced and Metastatic Non-Small Cell Lung Cancer in Canada

C. Laforty[1], M. Tong[1], A. Sharma[2], Y. Kim[3], N. Devost[3], R. Qadeer[3], V. Navani[4], [1]IQVIA, Toronto/ON/CA,[2]IQVIA, Ottawa/ON/CA,[3]AstraZeneca Canada, Mississauga/ON/CA,[4]Tom Baker Cancer Centre, University of Calgary, Calgary/AB/CA

Introduction: There is limited evidence outlining somatic genomic profiling uptake and treatment patterns for patients with locally advanced/metastatic non-small cell lung cancer (NSCLC) in routine clinical care. This study assessed real-world biomarker testing and treatment patterns for locally advanced/metastatic NSCLC in Canada.

Methods: This observational retrospective cohort review leveraged IQVIA's Oncology Patient Outcomes platform to obtain data regarding patients diagnosed with de novo locally advanced/metastatic NSCLC between Jan 2018 - Apr 2023. Eligible patients were not amenable to curative intent therapy and had exposure to at least 2 lines of therapy (2LOT). Patient demographics/characteristics, biomarker testing patterns, and treatment patterns were analysed descriptively.

Results: 205 patients with locally advanced (23%) or metastatic (77%) NSCLC were included. 51% were ≥65 years, 55% were male, 72% had active/prior tobacco exposure, 87% had ECOG of 0/1 at first line (1L) therapy, and 81% had adenocarcinoma. 31% (63/205) of all patients were tested for all known actionable genomic alterations (AGAs: EGFR, ALK, KRAS, BRAF, HER2, ROS-1, MET, RET, or NTRK), including 40% (53/134) and 14% (10/71) in academic vs. community settings, respectively. Among all patients tested, 57% (98/171) had an AGA present. 50% (49/98) of patients with AGAs received a targeted therapy in 1L; cumulatively, 69% (68/98) received a targeted therapy by 2LOT. 59% (63/107) of patients without AGAs received either pembrolizumab/atezolizumab monotherapy (35%, 37/107) or immune checkpoint inhibitor (ICI) + chemotherapy (24%, 26/107) in 1L. Additional treatment patterns are shown in Table 1.

Conclusions: In Canada, most patients do not receive complete testing for AGAs, highlighting the need for improved access to biomarker testing. Only 69% of patients with an AGA received a targeted therapy by their 2LOT and 59% of patients without AGAs received ICI +/- chemotherapy in 1L, indicating an unmet need for increased use of guideline recommended systemic therapies.

Keywords: Locally Advanced and Metastatic NSCLC, Biomarker, Treatment Patterns

Table 1. Treatments received in 1L and 2L by AGA status

	1L AGA (n=98)	1L No AGA (n=107)	2L AGA (n=98)*	2L No AGA (n=107)*
ICI	19% (n=19)	35% (n=37)	8% (n=8)	27% (n=29)
ICI + chemotherapy	17% (n=17)	24% (n=26)	5% (n=5)	13% (n=14)
Targeted therapy	50% (n=49)	0% (n=0)	45% (n=44)**	0% (n=0)
Chemotherapy only	13% (n=13)	41% (n=44)	40% (n=39)	56% (n=60)

Notes:
*In 2L, 2 patients with AGA and 4 patients without AGA received "Other"
**Includes 25 patients who received targeted therapy in 1L and 2 patients who received chemotherapy in addition to targeted therapy
*** Platinum doublets were the most common chemotherapy in 1L AGA/No AGA and 2L AGA, while docetaxel was the most common for 2L No AGA

Introduction: The epidermal growth factor receptor (EGFR) is one of the most commonly mutated oncogenes in non-small cell lung cancer (NSCLC). In addition to the classical EGFR mutations Ex19del and L858R, there are over 100 non-classical oncogenic EGFR driver mutations which comprise 20-30% of all EGFR mutated NSCLC. Current generation EGFR small molecule inhibitors including osimertinib are poorly active against this broad spectrum of mutations and are limited by the emergence of on-target EGFR resistance mutations including C797S and low brain penetration. There is a major unmet medical need for a well-tolerated next generation EGFR inhibitor to address the full spectrum of classical and non-classical EGFR oncogenic driver mutations. BDTX-1535 is a fourth-generation oral, brain-penetrant small molecule inhibitor of oncogenic EGFR classical driver mutations, non-classical driver mutations, and the acquired resistance C797S mutation. BDTX-1535 has a MasterKey profile to target the full spectrum of mutations, and in preclinical studies potently inhibits more than 50 oncogenic EGFR mutations. The Phase 1 portion of the BDTX-1535-101 study established 100 mg QD and 200 mg QD doses as preliminary recommended Phase 2 doses based on a favorable safety and tolerability profile and EGFR target PK coverage. Durable radiographic responses by RECIST were demonstrated across all groups of mutations accompanied by mutant EGFR variant allele frequency and plasma ctDNA clearance. These results led to the expansion into the ongoing Phase 2 portion of the study.

Methods: The objective of the Phase 2 portion of the BDTX-1535-101 (NCT05256290) open-label, multicenter, multicohort study is to assess antitumor activity, safety, tolerability, PK, and optimal dose of BDTX-1535 in locally advanced or metastatic NSCLC with or without CNS disease. Patients with NSCLC are being enrolled into one of 3 cohorts based on next generation sequencing confirmed EGFR alterations at the time of enrollment; Cohort 1: patients with a non-classical driver EGFR mutation following up to 2 lines of therapy with only one prior EGFR TKI; Cohort 2: patients with the acquired resistance C797S mutation following up to 2 lines of therapy, including only one third-generation EGFR TKI; and Cohort 3: treatment-naïve (first-line) patients with a non-classical driver EGFR mutation. NSCLC patients may enroll with or without CNS metastases and must not be known to express excluded resistance mutations such as EGFR T790M or MET alterations. Cohorts 1 and 2 were initiated in September 2023, and Cohort 3 was initiated in March 2024; enrollment is ongoing. For additional information, please contact blackdiamondtx@careboxhealth.com.

EP.12H.02 Amivantamab, An EGFR-MET Bispecific Antibody, with Cetrelimab, An Anti-PD-1 Antibody, In Advanced NSCLC: Phase 1/2 Polydamas

P.J. Voon[1], J-L. Tan[2], A.I. Spira[3], B. Keam[4], S-H. Lee[5], B. Xia[6], E. Artis[7], J. Dobbs[8], C. Baudelet[9], M. Baig[7], J.M. Bauml[10], M.A. Sendur[11], B.C. Cho[12], [1]Department of Radiotherapy and Oncology, Sarawak General Hospital, Kuching, Sarawak/MY,[2]Department of Medicine, University of Malaya, Kuala Lumpur/MY,[3]Virginia Cancer Specialists, Fairfax/VA/USA,[4]Department of Internal Medicine, Seoul National University Hospital, Seoul/KR,[5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/KR,[6]Janssen Research & Development, San Diego/CA/USA,[7]Janssen Research & Development, Raritan/NJ/USA,[8]Janssen Research & Development, Bridgewater/NJ/USA,[9]Janssen Research & Development, Beerse/BE,[10]Janssen Research & Development, Spring House/PA/USA,[11]Department of Medical Oncology, Ankara Yildirim Beyazit University, Ankara City Hospital, Ankara/TR,[12]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul/KR

Introduction: Amivantamab, an EGFR-MET bispecific antibody with immune cell-directing activity, is effective against EGFR-mutated advanced non-small cell lung cancer (NSCLC) as monotherapy or in a combination. Cetrelimab is an anti-PD-1 monoclonal antibody with clinical activity in previously treated NSCLC (Felip et al. Cancer Chemother Pharmacol 2022;89(4):499-514). Simultaneous targeting of the innate and adaptive immune systems with amivantamab and cetrelimab may improve antitumor activity versus either agent alone. The PolyDamas study (NCT05908734) aims to identify the recommended phase 2 combination dose (RP2CD) and evaluate the antitumor effect of amivantamab-cetrelimab in patients with advanced NSCLC.

Methods: This open-label, multicenter, interventional study will have a combination dose selection phase, followed by an expansion phase. The primary endpoints include safety (phase 1 dose selection) and objective response rate by investigator using RECIST 1.1 criteria (phase 2 dose expansion). For dose selection, 20 patients with advanced NSCLC, with or without known driver mutations, who have progressed on or after standard of care anti-cancer therapy, will be enrolled. Dosing will be in 28-day cycles, starting with a reduced amivantamab dose (700 mg IV; 1050 mg if ≥80 kg) given once weekly (the initial dose is given as a split infusion over the first 2 days) for the first 4 weeks (Cycle 1), then every 2 weeks (Q2W) thereafter (Cycle 2 onwards). Cetrelimab will be dosed intravenously at 240 mg Q2W, with the first dose given on Day 2 of Cycle 1. Dose escalation/de-escalation will be based on the observation of dose-limiting toxicities. The RP2CD will be selected through a Bayesian optimal interval design with a 3+3 design run in.

The phase 2 expansion cohorts will enroll 30 patients each after identification of the RP2CD. Cohort A will enroll patients with advanced NSCLC harboring an EGFR exon 19 deletion or L858R mutation, who have progressed on a 3rd-generation tyrosine kinase inhibitor and platinum-based chemotherapy. Cohort B will enroll patients with treatment-naïve, wild-type advanced NSCLC (no known driver mutations) and a PD-L1 tumor proportion score ≥50%. The phase 2 secondary endpoints include duration of response, disease control rate, progression-free survival, and overall survival.

This study is exploratory in nature and hypothesis-generating; no formal statistical hypotheses exist for either phase. In both phases, patients will continue study treatment until disease progression, unacceptable toxicity, or until another criterion for treatment discontinuation is met. This study is currently enrolling, with an enrollment goal of 80 patients total.

EP.12H.03 Study Protocol of the Korean EGFR Registry: A Multicenter Prospective and Retrospective Cohort Study in NSCLC Patients with EGFR Mutation

C.D. Yeo[1], D.W. Park[2], S.H. Jang[3], S.J. Kim[4], [1]Eunypyeong St. Mary's Hospital, Seoul/KR,[2]Hanyang Medical Center, Seoul/KR,[3]Hallym University Sacred Heart Hospital, Anyang/KR,[4]Seoul St. Mary's Hospital, Seoul/KR

Introduction: The provision of treatment for epidermal growth factor receptor (EGFR)-mutated non-small cell lung cancer (NSCLC) patients has increased in Korea. However, multicenter studies on the clinicopathologic dataset and treatment outcomes, using large-scaled dataset, have not been conducted. The current study is a prospective and retrospective multicenter observational cohort study that registers all stages of EGFR-mutated NSCLC patients.

Methods: The Korean EGFR Registry, a prospective multicenter observational cohort study, was designed to enroll 2,000 patients with all stages of EGFR-mutated NSCLC from forty university hospitals across Korea. This study, encompassing both retrospective and prospective cohorts, aims to analyze clinical characteristics, treatment modalities, and outcomes in these patients. Data collection includes patient demographics, smoking history, quality of life assessments, pathologic data, and treatment outcomes, with follow-up until December 2026. The primary endpoint is disease-free-survival in patients who have undergone definitive therapy or progression-free-survival patients who have undergone palliative therapy according to stages of EGFR-mutated NSCLC. The study will explore the diagnostic methods for EGFR mutations, clinical outcomes based on treatment modalities, and metastatic patterns in NSCLC patients with EGFR mutations. Moreover, it will investigate various aspects, including the safety and efficacy of a new third-generation EGFR tyrosine kinase inhibitors (TKI), lazertinib, approved for both first- and second-line treatments.

EP.12H.04 Phase II Study of Brigatinib for ALK-Positive Advanced Non-Small Cell Lung Cancer with Brain Metastases: BRAVES Trial (LOGIK2201)

Y. Nakahara[1], Y. Shiraishi[2], H. Sakamoto[3], H. Tanaka[3], Y. Watanabe[4], H. Watanabe[5], I. Okamoto[2], K. Naoki[1], [1]Kitasato University School of Medicine, Sagamihara/JP,[2]Graduate School of Medical Sciences, Kyushu University, Fukuoka/JP,[3]Hirosaki University Graduate School of Medicine, Hirosaki/JP,[4]Saitama Cancer Center, Kitaadachi-gun/JP,[5]Kyushu University Hospital, Fukuoka/JP

Introduction: Patients with advanced ALK positive non-small cell lung cancer (NSCLC) are highly responsive to ALK-tyrosine kinase inhibitors. However, it has been reported that approximately 30-35% of ALK positive NSCLC patients have brain metastases at diagnosis, which are associated with a poor prognosis. The efficacy of brigatinib for CNS metastases has been reported in a subgroup analysis of a phase III trial (ALTA-1L), but sample size was small and the patients with symptomatic metastases were excluded. Thus, we planned this phase II trial to analyze the genuine efficacy of brigatinib for CNS metastases of ALK positive NSCLC.

Methods: This is a multicenter single-arm phase II trial. Eligible patients have ALK-positive NSCLC with at least one brain metastasis ≥5 mm in size that has not been previously treated. Symptomatic brain metastases are also eligible, however brain metastases that require urgent radiation or emergency surgery are excluded. Patients receive brigatinib (180 mg once daily with a 7-day lead-in period at 90 mg). The primary endpoint is intracranial response rate as determined by modified Response Evaluation Criteria in Solid Tumors (RECIST) for brain metastases of ≥5 mm as target lesions. Secondary endpoints are intracranial progression free survival, extracranial response rate, extracranial progression free survival, systemic response rate, systemic progression free survival, overall survival, and safety. The expected intracranial response rate was assumed to be 70%, and we set a threshold value for the intracranial response rate of 45%. Given this assumption, the study was designed to have a power of 80% with 2-year accrual and 1-year follow-up periods, resulting in a requirement for 19 patients. Allowing for ineligibility of patients for analysis, we planed on enrolling 22 patients. Study enrollment began in June 2023 and will continue for two years among 25 sites in Japan. Four patients were enrolled at the time of submission. Clinical trial information: jRCTs071230025

Keywords: ALK, Brigatinib, brain metastases

EP.12H.05 Phase II Study on Platinum-Pemetrexed and Lorlatinib Combination in ALK-Positive NSCLC Extracranially Progressing on Lorlatinib

E. Bertoli[1], E. Da Carlo[1], A. Del Conte[1], B. Stanzione[1], M. Montico[1], F. Mazzoni[2], A. Camerini[3], D. Cortinovis[4], A. Delmonte[5], G. Metro[6], G. Pasello[7], G. Pelizzari[8], M. Tiseo[9], T. Battistuzzi[1], A. Bearz[1], [1]CRO IRCCS, Aviano/IT,[2]Azienda Ospedaliera Universitaria Carreggi, Firenze/IT,[3]Ospedale della Versilia, Viareggio/IT,[4]IRCCS-Sangerardo, Monza/IT,[5]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Meldola/IT,[6]Azienda Ospedaliera di Perugia, Perugia/IT,[7]IOV-IRCCS, Padova/IT,[8]Azienda sanitaria universitaria Friuli Centrale, Udine/IT,[9]University of Parma and Medical Oncology Unit, University Hospital of Parma, Parma/IT

Introduction: Lorlatinib, a potent, brain-penetrant third-generation Anaplastic Lymphoma Kinase (ALK) inhibitor may be used as first or further--line treatment in advanced ALK-positive Non Small Cell Lung Cancer (NSCLC) patients. Currently, subsequent treatment to overcome lorlatinib resistance remains an unmet clinical need. Platinum/pemetrexed-combined chemotherapy (PT/pem-based-CT) is still a valid option, although with modest efficacy and poor activity in the brain, with a median Progression Free Survival (PFS) of 3.2 months reported in the literature (Lin JJ, et al.. J Thorac Oncol. 2020;15(2):258-265). Association between chemotherapy and ALK inhibitors is feasible and with interesting activity, as reported from others' and from our experience on 6 patients, in progression extra-cranially on lorlatinib and treated off-label with lorlatinib and PT/pem-based-CT (Lin JJ, et al.. J Thorac Oncol. 2020;15(2):258-265, De Carlo E et al. J Thorac Oncol., 2021 May;16(5): e31-e32).

Methods: : We conceived a multicenter, Italian, single-arm, no profit, phase II interventional study to evaluate the activity and safety of PT/pem-based-CT plus Lorlatinib in ALK-positive NSCLC with exclusively extra-cranial disease progression on Lorlatinib. Approximately 45 patients will be enrolled. Patients must be exclusively extracranially in progression on Lorlatinib; Lorlatinib may be in first- or further-line, without limitations regarding previously received therapies. Brain metastases are allowed, but they have to be stable or in response on Lorlatinib.PT/pem-based-CT plus Lorlatinib will be administered for an induction phase of four cycles. Subsequently, patients with response or stability of disease at radiological assessment will start the maintenance phase with pemetrexed-Lorlatinib in 21-day cycles until progression, unacceptable toxicity, death, or withdrawal of consent. Tumor imaging with computed tomography (chest, abdomen, and pelvis) (CT) and brain magnetic resonance (MR) will be performed at baseline, after the induction phase and then every 9 weeks (+/- 1 week) for the first 12 months and then every 12 weeks (+/- 1 week) thereafter during the maintenance phase. A liquid biopsy for DNA isolation will be performed at baseline, at disease progression, and during the treatment at every radiologic assessment. Adverse events monitoring, according to the guidelines outlined in the NCI CTCAE, version 5.0, will be recorded throughout the study. Patients reported outcomes (PROs) measures, including global quality of life (QoL), functioning domains and symptoms, will be assessed by the EORTC Quality of Life Questionnaire Core 30 (QLQ-C30) and the 13-item Lung Cancer (QLQ-LC13) module. Primary endpoint is PFS. Secondary endpoints are: intracranial PFS, Overall Survival (OS), safety, PROs and QoL. Exploratory endpoint is to explore genetic alterations of resistance detected in circulating tumor DNA at baseline, during treatment and at disease progression.

Results: The protocol has been approved through the Clinical Trials Information System/EMA platform (CTIS) - CTIS ID: 9647 - by Italian Agency AIFA and Ethical Commettee on 23 February 2024 and has started enrollment in March 2024. EUDRACT 2023-506714-43-00.

Conclusions: Updates of the trial will be provided at the Congress.

EP.12H.06 A Patient-Centric, Phase II Trial of First-Line Lorlatinib&alk TKIs in China Advanced ALK+ Non-Small Cell Lung Cancer

J. Lin, Guangdong Provincial People's Hospital, Guangzhou/CN

Introduction: Lorlatinib is a potent third-generation ALK tyrosine kinase inhibitor (TKI). CROWN study demonstrated remarkable efficacy data and manageable AEs of first-line lorlatinib treatment for advanced NSCLC with ALK fusion. However, only 10 ALK+ NSCLC patients were randomized to the lorlatinib group in China mainland. There is a vast vacancy of efficacy and safety regarding first-line lorlatinib treatment in China advanced ALK+ NSCLC. Additionally, understanding of the benefit-risk profile of lorlatinib in a broader population and real-world data of diversity of ALK-TKIs are limited. Here, we adopted a patient-centric trial (PCT) design to generate more generalizable data to better inform clinical decision-making. We investigate the efficacy, safety profile of first-line lorlatinib in Chinese patients with restrictive eligibility criteria and broadening eligibility criteria. And we concomitantly set up a prospective real-world observing (RO) cohort to observe the clinical outcomes of these patients treated with different ALK-TKI who received physician's therapy of choice.

Methods: This is a three cohorts, open-label, multi-center, phase II study in China, designed to prospectively enroll 189 advanced ALK+ NSCLC patients, which was divided into treatment intervention cohorts and RO cohort. The treatment intervention cohorts include 84 subjects fulfilled CROWN criteria as "CROWN criteria (CC) cohort", another 42 subjects ineligible for CROWN criteria as "Expand Eligibility Criteria (EC) cohort". The CC cohort and the EC Subjects will receive continuous daily PO dosing of lorlatinib 100mg QD, from the date of first dosing until disease progression, unacceptable toxicity, or withdrawal for any reason, or death, whichever occurs first. The primary endpoints are progression-free survival (PFS) of CC cohort per investigator, and resistance mechanism of first-line lorlatinib. Secondary endpoints are 1/2/3-year PFS, cumulative rate of central nervous system (CNS) progression, intracranial-time to progression (IC-TTP), objective response rate (ORR) and intracranial ORR (IC-ORR), overall survival (OS), safety and PRO. Exploratory endpoints include evaluation of candidate biomarkers of sensitivity or resistance to lorlatinib, dynamic ctDNA change during treatment, and effective treatment after lorlatinib resistance. The RO cohort is designed to serve as comparison cohort, which will enroll 63 treatment-naive subjects who may receive crizotinib, ceritinib, alectinib, brigatinib, ensartinib, lorlatinib, etc. Real-world efficacy and safety data of ALK TKIs were collected in the same cross-section. The primary endpoint is real-world progression-free survival (rwPFS) of ALK TKIs in the first-line treatment of advanced NSCLC patients with ALK fusion.

EP.12H.07 A Phase I Clinical Trial of Carfilzomib in Combination with Sotorasib in Patients with KRASG12C Mutated NSCLC

J. Malhotra, X. Li, J. Palmer, T.W. Synold, A. Mohanty, S. Singhal, P. Kulkarni, R. Salgia, City of Hope National Medical Center, Duarte/CA/USA

Introduction: The clinical development of covalent inhibitors of KRASG12C such as sotorasib and adagrasib is an important milestone for the treatment of advanced or metastatic non-small cell lung cancer (NSCLC). While these agents have promising clinical activity, many patients experience disease progression by the 1-year mark. It is therefore imperative to identify and overcome mechanisms of resistance to these agents. Integrin Subunit Beta 4 (ITGB4) and paxillin (PXN) in the focal adhesion complex are highly expressed in KRAS-mutated lung adenocarcinoma and their interaction plays an important role in mediating therapeutic resistance (Mohanty, iScience, 2020). By virtually screening a library of FDA-approved compounds that bind to the N-terminal region of paxillin, carfilzomib was identified to be the most effective (IC50 = 193.4 nM) (Nam, Cancer Res, 2020). We hypothesize that resistance KRAS G12C inhibitors can be through a non-genetic mechanism via ITGB4/PXN pathway that can be targeted by disrupting this pathway using carfilzomib. In preclinical experiments using mouse models, carfilzomib and sotorasib exert synergistic activity through down-regulating ITGB4 (Mohanty, Sci Adv, 2023), supporting further the development of this combination in KRASG12C mutated NSCLC. We have initiated a Phase I trial in which the combination of sotorasib and carfilzomib will be investigated for the treatment of KRASG12C inhibitor-resistant NSCLC.

Methods: This is a Phase I dose-finding study with a traditional 3+3 dose escalation. Patients with KRAS G12C mutated NSCLC who have progression on a prior KRAS inhibitor will be treated with the combination of sotorasib and carfilzomib to determine whether the combination is safe and tolerable. Participants will receive protocol therapy until disease progression or intolerable toxicity. Dose-limiting toxicities (DLT) and treatment-related toxicities will be defined by the NCI Common Terminology Criteria for Adverse Events (NCI CTCAE) v5. The primary endpoint is to determine the maximum tolerated dose (MTD) and the recommended Phase II dose (RP2D) of the combination and up to 18 patients are estimated to be enrolled. The secondary objective is to measure efficacy endpoints such as objective response rate (ORR) and progression-free survival (PFS) using RECIST1.1. The dose of sotorasib will be fixed at 240 mg oral daily at all dose levels. Carfilzomib will be administered intravenously on two consecutive days, each week for three weeks (Days 1, 2, 8, 9, 15, and 16), followed by a 12-day rest period (Days 17 to 28). Carfilzomib dose will be determined as per the dose escalation schema, with each dose level specifying a separate loading dose (Cycle 1, Days 1-2) and a dose for subsequent infusions (different than the loading dose). Each 28 days is considered one treatment cycle. Correlative studies include carfilzomib and sotorasib pharmacokinetics, along with serial tumor biopsies, serum proteomic analyses, and circulating tumor DNA (ctDNA) assessments to explore biomarkers of response and resistance. Clinical trial information: NCT06249282.

EP.12H.08 SOHO-02: Phase III Trial of BAY 2927088 In Patients with Locally Advanced or Metastatic NSCLC with HER2-Activating Mutations

K. Goto[1], J.C. Brase[2], J. Xu[3], S-F. Pu[3], M. Montague-Dale[4], L. Mongay Soler[3], A. Passaro[5], [1]National Cancer Center Hospital East, Kashiwa/JP,[2]Bayer Consumer Care AG, Basel/CH,[3]Bayer HealthCare Pharmaceuticals, Inc., Whippany/NJ/USA,[4]Bayer plc, Reading/GB,[5]European Institute of Oncology IRCCS, Milan/IT

Introduction: Activating human epidermal growth factor receptor 2 (HER2) mutations account for approximately 2-4% of non-small cell lung cancer (NSCLC) but represent a major area of unmet medical need as no first-line HER2-targeted therapies are currently approved for patients with locally advanced or metastatic NSCLC harboring HER2-activating mutations. BAY 2927088 is an oral, reversible tyrosine kinase inhibitor that targets HER2 and mutant epidermal growth factor receptor and has demonstrated anti-tumor activity and a manageable safety profile in previously treated patients with NSCLC and HER2-activating mutations in the Phase I/II SOHO-01 trial (LBA8598 accepted at 2024 ASCO Annual Meeting). Here we introduce the SOHO-02 trial evaluating the efficacy and safety of BAY 2927088 as first-line therapy in patients with locally advanced or metastatic NSCLC with HER2-activating mutations.

Methods: SOHO-2 is an ongoing Phase III, open-label, randomized multicenter trial of BAY 2927088 in patients with locally advanced or metastatic NSCLC with HER2-activating mutations (Figure). Eligibility criteria include patients aged ≥18 years with documented histologically or cytologically confirmed locally advanced or metastatic non-squamous NSCLC; documented activating mutation in the tyrosine kinase domain of HER2 in tumor tissue; measurable disease per RECIST v1.1; ECOG PS of 0 or 1; and adequate bone marrow, kidney, liver, coagulation, and cardiac function. Overall, 278 eligible patients will be randomized to oral BAY 2927088 (20 mg twice daily) or standard of care (SoC; pembrolizumab in combination with platinum-based chemotherapy [cisplatin or carboplatin] and pemetrexed) administered in 21-day cycles. The primary objective is to evaluate the effect of BAY 2927088 vs. SoC on progression-free survival per RECIST v1.1 by blinded independent central review (BICR). Key secondary objectives are to evaluate the efficacy of BAY 2927088 vs. SoC on overall survival, overall response rate, and duration of response per RECIST v1.1 by BICR and to assess the safety and tolerability of BAY 2927088 compared with SoC. Patients' health-related quality of life and symptomatic side effects will be measured using the EORTC QLQ-C30, NSCLC-SAQ, and EQ-5D-5L, including VAS. Enrollment is ongoing.

Keywords: NSCLC, Phase III, HER2

Introduction: Immune checkpoint inhibitors (ICI) have improved outcomes in non-small cell lung cancer (NSCLC), but primary or acquired resistance limits treatment options for patients with disease progression on anti-PD-(L)1 and platinum-based therapies. Growing evidence indicates that ataxia telangiectasia and Rad3-related protein kinase inhibition (ATRi) modulates antitumor immunity, and the ATRi + ICI combination is active in patients with ICI-resistant tumours. ATRi + ICI may have the potential to overcome ICI resistance and induce antitumor immune responses in patients with advanced NSCLC, particularly in tumours harbouring ATRi-sensitizing mutations.

This abstract was previously presented at the European Lung Cancer Congress (ELCC) 2024 held in Prague, Czech Republic (20-23 March 2024)

Methods: This open-label, multicentre, Phase 1b/2a study (NCT05882734) evaluates the efficacy, safety, tolerability, and pharmacokinetics of tuvusertib + cemiplimab. Eligible patients have non-squamous NSCLC that has progressed on prior anti-PD-(L)1 and platinum-based therapies, with a response of stable disease or better to prior anti PD-(L)1-therapy. Patients with tumours harbouring actionable EGFR or ALK genomic alterations are excluded. In the randomised Phase 1b, two dosing regimens, tuvusertib 100 mg once-daily (QD) + cemiplimab 350 mg every three weeks (Q3W) (n=30) or tuvusertib 180 mg QD 2 weeks on/1 week off + cemiplimab 350 mg Q3W (n=30), are being evaluated. Based on a totality of evidence approach, the most favourable regimen will be selected for investigation in Phase 2a, in which patients will be treated in 3 separate strata based on genetic alterations detected in circulating tumor DNA: stratum A (n=40), STK11 or KEAP1; stratum B (n=40), ATM or ARID1A or SMARCA4 or PBRM1; stratum C (n=40), any other/no alterations. Tumour genetic characteristics will be assessed by a central liquid biopsy assay. Primary endpoints are investigator-assessed objective response (OR; RECIST v1.1), occurrence of adverse events (AE), and treatment-related AEs in Phase 1b, and OR in Phase 2a. Secondary endpoints in both phases include duration of response, progression-free survival, and overall survival. The study is open for enrollment in centres across the USA, Belgium, Italy, Spain, France, Japan and Korea.

EP.13A.01 Preliminary Efficacy and Safety of Adebrelimab Plus Famitinib as Later-line Treatment for Extensive-Stage Small Cell Lung Cancer: A Phase 2 Trial

T. Chen[1], M. Wang[1], Y. Chen[1], Y. Cao[1], X. Hu[1], L. Tian[2], C. Zhao[2], Y. Liu[1], [1]Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/CN, [2]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai/CN

Introduction: The advent of immune checkpoint inhibitors (ICIs) has completely changed the treatment landscape of extensive-stage small cell lung cancer (ES-SCLC). However, the majority of patients (pts) eventually progress during immunotherapy. It has been reported that the addition of antiangiogenic agents potentially enhanced the antitumor activity of ICIs and expanded the spectrum of pts who responded to them. Famitinib is a novel and promising multitarget receptor tyrosine kinase inhibitor (TKI) against stem-cell factor receptor, vascular endothelial growth factor (VEGF) receptor 2/3 and platelet-derived growth factor receptor β (PDGFR β). This phase II trial aimed to evaluate the efficacy and safety of adebrelimab (anti-PD-L1 antibody) plus famitinib for pretreated ES-SCLC.

Methods: Eligibility criteria included aged 18-80 years, histologically or cytologically confirmed ES-SCLC, ECOG performance status 0-1, failed or intolerant to second-line systemic chemotherapy. Pts received adebrelimab (20 mg/kg, administered intravenously every 3 weeks) and famitinib (20 mg, administered orally once daily) until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR). Key secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR), duration of response (DoR) and safety. A Simon two-stage design was applied. If there were more than 1 patient achieved response within the first 13 pts, the cohort would expand to 34 pts.

Results: As of December 2023, a total of 13 pts were enrolled and received at least one dose of adebrelimab and famitinib. Of these pts, the median age was 64 (range 48-70), 84.6% were male and 84.6% were current or former smokers. The number of prior lines of cancer therapy ranged from 1 to 2 (median 1). 3 pts achieved confirmed partial response (PR), 6 pts achieved stable disease (SD) and 4 pts had progressive disease (PD) as best response. The ORR was 23.1% (3/13) and DCR was 69.2% (9/13). The median PFS was 4.0 months (95% CI, 2.0 to 6.0). Treatment-related adverse events (TRAEs) occurred in 11 (84.6%) pts. The most common TRAEs were white blood cell count decreased and neutrophil count decreased.

Conclusions: Adebrelimab plus famitinib demonstrated promising antitumor activity and acceptable toxicity in relapsed ES-SCLC. The results warranted further validation.

EP.13A.02 Adebrelimab Combined with Famitinib and Chemotherapy as First-Line Therapy for ES-SCLC: A Phase II, Single-Arm Exploratory Research

Y. Zhao[1], Y. Yu[1], M. Zhang[1], M. Liu[2], S. Wang[3], L. Zhang[4], [1]Harbin Medical University Cancer Hospital, Harbin/CN, [2]Beidahuang Group General Hospital, Harbin/CN, [3]Mudanjiang Cancer Hospital, Mudanjiang/CN, [4]Daqing Oilfield General Hospital, Daqing/CN

Introduction: Small cell lung cancer is known as a type of highly aggressive neuroendocrine malignancy, in consequence the majority of small cell lung cancer patients are diagnosed in extensive-stage accordingly due to high growth fraction and early metastasis. It can be concluded in recent research that the adebrelimab plus carboplatin and etoposide have demonstrated promising anti-tumour activity in first-line treatment for extensive-stage small-cell lung cancer (ES-SCLC) in CAPSTONE-1 trial, while famitinib is a selective multiple-target tyrosine kinase inhibitor that exhibits both anti-angiogenesis and anti-proliferative effects by targeting VEGFR-2, PDGFR, c-kit, FGFR where the anti-angiogenic agents have been reported to facilitate immune infiltration. Whereupon, this study aims to explore the efficacy and safety of adebrelimab combined with famitinib and chemotherapy as the first-line treatment of ES-SCLC.

Methods: In this multicenter, open-label, phase II trial, 40 patients with ES-SCLC diagnosed pathologically or cytologically according to the Veterans Administration Lung Study Group pathology and without receiving prior systemetic therapy are anticipated to be enrolled. Patients must be 18-80 years old, have an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, an expected life expectancy of at least 3 months, and adequate organ function. Patients will be excluded if they have risk of bleeding, uncontrolled hypertension, active serious infections, or uncontrolled symptomatic brain metastases. Due to a lack of data concerning the combination of famitinib, a safety run-in phase with 6 patients is performed before the phase II. If ⩽1 of the first 6 patients experience dose-limiting toxicity, the phase II trial will be performed. Patients will be dosed adebrelimab (1200 mg, iv, q3w) in combination with etoposide/platinum drugs (cisplatin 75 mg/m2 or carboplatin AUC 5, iv, q3w, 4 cycles). The primary endpoint is 6-month progress-free survival (6-month PFS) rate, and the secondary endpoints are objective response rate, disease control rate, 12-month PFS, PFS, overall survival, safety and quality of life. The study is actively recruiting.

EP.13A.03 A Phase II Study of Vobramitamab Duocarmazine in Patients with Relapsed or Refractory Extensive-Stage Small Cell Lung Cancer

B. Gupta[1], J.P. Zaemes[1], V. Yeung[2], J. Reuss[1], V. Aggarwal[1], J. Thompson[1], N. Swanson[1], D. de Miguel Perez[3], J. Ahn[1], K. Chen[4], I. Veytsman[5], M. Gutierrez[6], C.D. Rolfo[3], S.V. Liu[1], C. Kim[1], [1]Lombardi Comprehensive Cancer Center, Georgetown University, Washington/DC/USA, [2]Rutgers Cancer Institute of New Jersey, Newark/NJ/USA, [3]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York/NY/USA, [4]Medstar Franklin Square Medical Center, Baltimore/MD/USA, [5]MedStar Washington Hospital Center, Washington/DC/USA, [6]John Theurer Cancer Center at Hackensack University, Hackensack/NJ/USA

Introduction: Extensive-stage small cell lung cancer (ES-SCLC) is a highly aggressive form of lung cancer, known for its frequent recurrence, even after initial response to therapy. In patients (pts) with relapsed or refractory (R/R) ES-SCLC, outcomes are poor with limited treatment options. There remains a significant need for novel therapeutic approaches for ES-SCLC. B7-H3, an immune checkpoint molecule, plays an important role in the immune evasion of cancer cells, as well as in tumor growth and metastasis. It is overexpressed in a wide range of cancer types, including SCLC, where its overexpression correlates with a poor prognosis. Its expression is limited in normal tissues, making it an ideal target for novel antibody-drug conjugates (ADCs). Vobramitamab duocarmazine (vobra duo) is an ADC comprised of an antibody targeting B7-H3 linked to duocarmazine, a duocarmycin-based payload which causes DNA alkylation. This phase II trial seeks to evaluate the efficacy of vobra duo in pts with R/R ES-SCLC.

Methods: This is an open-label, phase II, multi-center, single-arm study evaluating the efficacy and safety of vobra duo in pts with R/R ES-SCLC. Pts with ES-SCLC will be considered eligible who have experienced progression during or following treatment with platinum-based chemotherapy. Other eligibility criteria include an ECOG performance status of 0-2, measurable disease, and adequate hematologic and end-organ function. Pts with EGFR-mutant NSCLC that has transformed to SCLC will be eligible. Pts will receive vobra duo 2.7 mg/kg every 28 days continuously until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) according to RECIST v1.1, with secondary endpoints including safety (adverse events per CTCAE v5.0), duration of response (DOR), progression-free survival (PFS), and overall survival (OS). A total of 17 pts will be enrolled. The null hypothesis that the true response rate is 5% will be tested against a one-sided alternative. A Simon's optimal two-stage design will be used such that 9 pts will be enrolled initially, and if at least one response is identified, the trial will proceed to the second stage with enrollment of an additional 8 pts. This design yields a type I error rate of 4.7% and power of 81.2%, when the true response rate is 25%. Exploratory analyses will be conducted to investigate the correlation between B7-H3 expression in blood (specifically within extracellular vesicles) and tumor tissue and their impact on treatment outcomes. Clinical trial information: NCT06227546.

EP.13A.04 A Study of Surufatinib Combined with Low Dose Topotecan in Second or Third-Line Multiple Distant Organ Metastatic ES-SCLC

H.s. Qian[1], L. Zhang[1], S. Wang[1], J. Wang[1], W. Liang[1], Y. Zhang[2], Y. Du[2], [1]Fuyang Cancer Hospital, Fuyang/CN, [2]The First Affiliated Hospital of Anhui Medical University, Hefei/CN

Introduction: The addition of immune checkpoint inhibitors has expanded the therapeutic options for the first-line treatment of extensive-stage small cell lung cancer (ES-SCLC). However, there remains a significant lack of effective second- or third-line treatment options following disease progression. Surufatinib, a potent small-molecule tyrosine kinase inhibitor (TKI) with selective targeting of VEGF receptors (VEGFR)1,2, and 3, FGFR 1, and CSF-1R, has shown promise in addressing this unmet need. Additionally, topotecan hydrochloride capsules are approved for use in the second-line treatment of SCLC. This study aims to evaluate the efficacy and safety of surufatinib combined with topotecan capsules in the second- or third-line treatment of ES-SCLC.

Methods: This study is a single-arm, prospective, exploratory trial (ChiCTR2200061709) in which patients with ES-SCLC who had previously failed one or two lines of treatment were enrolled following screening and meeting the inclusion and exclusion criteria. Patients were treated with surufatinib (250mg, orally, once daily, every 3 weeks) combined with topotecan (1.4mg/m2, orally, on days1-5, every 3 weeks) until disease progression, unacceptable toxicity, or death. The primary endpoint was progression-free survival (PFS), while secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS), and safety.

Results: From May 2022 to March 2024, a total of 23 subjects were enrolled, with 21 patients being evaluable. All of them had extensive-stage small-cell lung cancer. There were 20 males and 14 patients with a history of smoking. The mean age was 65 years. ECOG scores were as follows: 22 (95.7%) patients had an ECOG score of 1 and 1(4.3%) patient had an ECOG score of 0. In terms of previous first-line regimens,15(65.2%) patients received EP/EC and 8(34.8%) received PD-1/L1 + EP/EC,9(39.1%) of the patients had received radiotherapy.21(91.3%) patients were treated as second-line treatment and 2(8.7%) as third-line treatment. All patients had distant metastasis at the time of enrollment, indicating a poor prognosis among these individuals. Among them, 12 cases (56.5%) had 3 or more distant organs metastasis;brain metastases were present in 5(21.7%) patients while liver metastases were observed in 11(47.8%) patients. As of March 25, 2024, the median follow-up was 10.6 months. Among patients with at least one post-baseline tumor assessment (evaluable pts, n=21), the median PFS was 4.2 months (95%CI 2.7-5.7). The ORR was 14.2%, and the DCR was 76.2%, including 3 cases of PR and 13 cases of SD. The median OS was 7.4 months (95%CI 5.2, 9.6). The overall safety of the study was manageable, with no unexpected adverse events reported. Most adverse events were grade 1-2, and there were 4 cases (18.1%) that were grade ≥3, including neutropenia, leukopenia,hrombocytopenia and hypertension; none of these treatment-related adverse events led to death.

Conclusions: Conclusions: The combination of surufatinib and low dose topotecan capsules has demonstrated significant clinical efficacy and a manageable safety profile when used as a second- or third-line treatment for patients with multiple distant organ metastases ES-SCLC.

Introduction: Small cell lung cancer (SCLC) is characterized by rapid progression and recurrence. Prognostic assessment is challenging due to the lack of standardized prognostic markers beyond disease stage. IMfirst (EudraCT: 2019-002784-10) is a phase IIIb study evaluating the safety of 1L atezolizumab + carboplatin or cisplatin + etoposide in patients with extensive-stage SCLC (ES-SCLC) in Spain. Previous analysis from IMfirst showed an association between low baseline neutrophil, leukocyte and neutrophil-to-lymphocyte ratio (NLR) values and long-term benefit (LTB). In this exploratory analysis from IMfirst, we aimed to further examine the potential association of laboratory parameters with prognosis in patients with ES-SCLC treated with chemoimmunotherapy.

Methods: Laboratory parameters were categorized as below or equal to (≤) or above (>) their median baseline values. To assess their potential association with overall survival (OS) and progression-free survival (PFS), univariate Cox regression analyses, as well as multivariate Cox proportional hazard models adjusted for confounding variables with p-value <0.05 were performed. LTB patients were defined as those who lived ≥24 months, while No-LTB pts were defined as those who died within 24 months post-randomization. Parametric (Student's t) or non-parametric (Wilcoxon Mann Whitney) tests were used to evaluate differences in baseline laboratory parameters between LTB and No-LTB patients. A p-value <0.05 was considered statistically significant for all analyses.

Results: In total, 155 patients were included. Median follow-up was 28.4 months (data cut off: 14 December 2022). Table 1 shows univariate analysis of selected baseline laboratory variables for OS and PFS. Variables that showed association with OS included: leukocyte and neutrophil counts, NLR, platelet-albumin-bilirubin (PALBI) score, alanine aminotransferase (ALT), alkaline phosphatase (ALP), aspartate aminotransferase (AST), phosphate, calcium, potassium, chloride, bilirubin, glucose and lactate dehydrogenase (LDH). Parameters with a significant association with PFS included: leukocyte and neutrophil counts, NLR, PALBI score, ALT, ALP, calcium, phosphate and chloride. Of all evaluated parameters, ALP, phosphate and bilirubin showed association with OS in the multivariate analysis and only phosphate showed association with PFS in the multivariate analysis. Baseline laboratory parameters that showed significant differences between LTB and No-LTB patients included leukocyte and neutrophil counts, NLR, PALBI score, ALP, AST, calcium, chloride and LDH.

Conclusions: This exploratory analysis from IMfirst, although limited due to the single-arm nature of the study, suggests biochemical and haematological parameters of potential prognostic value in ES-SCLC patients treated with atezolizumab + chemotherapy. Further validation in prospective studies is required.

EP.13B SMALL CELL LUNG CANCER AND NEUROENDOCRINE TUMORS - IMMUNOTHERAPY/SYSTEMIC THERAPY
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.13B.01 Selection of Optimal Therapy for Extensive-Stage Small Cell Lung Cancer: A Systematic Review and Network Meta-Analysis

W. Zhang, W. Zhao, Z. Guo, L. Ye, Z. Chen, H. Wang, L. Zhao, K. Xu, X. Liu, Y. Liu, Y. He, Shanghai Pulmonary Hospital, Shanghai/CN

Introduction: Multiple immunotherapy-based combination regimens have been widely explored in the first-line treatment of extensive-stage small cell lung cancer (ES-SCLC). Recently reported results from the ETER701 study showed that a novel immunotherapy-based regimen, anlotinib (multi-target angiogenesis inhibitor)+benmelstobart (programmed cell death ligand 1 inhibitor)+chemotherapy (Anl/Ben/CT), provided a median overall survival (OS) of 19.3 months in ES-SCLC, which is the longest OS obtained to date. However, there is no evidence-based medicine available proving that Anl/Ben/CT is the optimal regimen due to the lack of direct or indirect comparisons among varying immunotherapy-based regimens.

Methods: The eligible randomized controlled trials (RCTs) were identified by searching PubMed, Embase, Cochrane Library databases and major international conferences. Then, the network meta-analysis (NMA) was analyzed to compare the efficacy and safety among 15 first-line regimens in ES-SCLC.

Results: A total of 12 immunotherapy-related RCTs reporting 6178 ES-SCLC individuals were enrolled. The results indicated that most of immunotherapy-based regimens could significantly prolong progression-free survival (PFS) compared with chemotherapy alone, especially Anl/Ben/CT (HR 0.32, 95% CI 0.25-0.40) (Figure A). Among immunotherapy-based regimens, significant prolongation of PFS was observed for ES-SCLC with Anl/Ben/CT compared to the others (all HR < 1 and 95% CIs did not cross 1) (Figure A). Similar results were observed in terms of OS, that is, most immunotherapy-related regimens dramatically reduced the risk of death in ES-SCLC, with Anl/Ben/CT being the most prominent (HR 0.61, 95% CI 0.47-0.80) (Figure A). The results of Bayesian ranking probabilities showed Anl/Ben/CT ranked first in both PFS, OS and objective response rate among 15 regimens (Figure B). There are almost identical results from the sensitivity analysis to the originals, demonstrating the reliability and robustness of he NMA (Figure B).

Conclusions: To the best of our knowledge, this NMA demonstrated for the first time that adding anlotinib and benmelstobart to chemotherapy significantly improved PFS and OS compared with chemotherapy alone or chemotherapy plus immunotherapy, with an acceptable safety profile in patients with ES-SCLC. In conclusion, Anl/Ben/CT could be a new and clinically preferable first-line treatment option for this population.

EP.13B.02 Real-World Insights: Treatment Patterns and Overall Survival in Patients with Small-Cell Lung Cancer in South Korea a Single Center Experience

S. Park[1], D. Kang[1,2], H. Lee[3], H. Lim[3], J. Cho[1,2], M-J. Ahn[1], J. Kim[1], [1]Samsung Medical Center, Seoul/KR, [2]SungkyunKwan University, Seoul/KR, [3]Amgen Korea, Seoul/KR

Introduction: Small Cell Lung Cancer (SCLC) represents a highly aggressive subtype of lung cancer, accounting for about 15% of all lung cancer cases worldwide. Despite relatively high initial response rates to current treatment, the prognosis for SCLC patients is dismal due to its rapid progression and development of resistance to treatment. In the current therapeutic landscape, the effectiveness of different lines of therapy, including the emerging role of immunotherapy, has not been fully elucidated, particularly outside of clinical trials. We conducted a real-world data analysis to explore the clinical characteristics, treatment patterns, and overall survival of SCLC patients in Korea.

Methods: This study is a retrospective cohort study of patients with SCLC who were diagnosed and treated at Samsung Medical Center (SMC) from 1 January 2018 to 31 December 2021, with follow-up available through 13 March 2023. The data was obtained from the Clinical Data Warehouse of SMC. The first systemic therapy regimen following initial SCLC diagnosis was classified as first-line of therapy. Subsequent lines of therapy were determined based on new regimens administered after disease progression. Overall survival (OS) from the initiation of new lines of therapy was assessed using Kaplan-Meier estimates. Death information was linked with National Administrative Data of Ministry of Interior and Safety. Patients who received a clinical study drug in any line of therapy were excluded.

Results: Out of 515 patients identified, 343 patients had extensive stage (ES) and 172 had limited stage (LS) disease at diagnosis. Both ES and LS patients were predominantly male, 92.1% and 90.1%, respectively, with a median age of 70 years for ES and 67 years for LS. A high prevalence of smoking history was observed in both groups (79.3% ES, 89.0% LS). Most patients had an ECOG performance score of 0 or 1 at diagnosis (89.2% ES, 93.0% LS). The majority of ES patients received etoposide/platinum (209/343, 60.9%) or atezolizumab plus etoposide/platinum (130/343, 37.9%) as first-line therapy; while nearly all of LS patients (164/172, 95.3%) received concurrent chemoradiotherapy (CCRT) with etoposide/platinum as their initial therapy. Irinotecan/platinum was the most common second-line therapy for ES (124/202, 61.4%) and as initial therapy for LS patients who showed disease relapse after CCRT (29/72, 40.3%). As a subsequent therapy, paclitaxel was the most common for ES (64/97, 66.0%) and LS (12/32, 37.5%) patients. In ES patients, the median OS from the initiation of first-line therapy was 11.3 months (95% confidence interval (CI), 9.7-12.2). From the initiation of second and third-line therapies, the median OS was 6.9 months (95% CI, 6.3-7.9) and 5.1 months (95% CI, 3.9-5.8), respectively. In LS patients, the median OS from the initiation of CCRT was 33.4 months (95% CI, 26.0-46.9), from the initiation of first-line systemic therapy was 11.9 months (95% CI, 7.9-16.8), and from the initiation of second-line systemic therapy was 8.3 months (95% CI, 5.1-10.8).

Conclusions: Our findings confirm once again the poor survival outcomes in SCLC. Results highlight the limitations of current treatment and underscore the urgent need for effective therapeutic strategies to improve this challenge.

EP.13B.03 Real-World Outcomes of Platinum-immunotherapy as First-Line (1L) Treatment of Extensive-Stage Small Cell Lung Cancer (ES-SCLC)

A.K. Ganti[1], T. Prince[2], S. Back[2], A. Chansakul[2], A. Boccuti[3], B. Rengarajan[4], D. Chakrabarti[3], W. Li[3], L. Fan[3], Y. Cao[3], R. D'Agostino Jr[5], X. Fan[3], [1]VA Nebraska Western Iowa Healthcare System and University of Nebraska Medical Center, OMAHA/NE/USA, [2]Aetion Inc., New York/NY/USA, [3]Jazz Pharmaceuticals, Philadelphia/PA/USA, [4]Jazz Pharmaceuticals, Palo Alto/CA/USA, [5]Wake Forest University School of Medicine, Winston-Salem/NC/USA

Introduction: Atezolizumab and durvalumab were approved alongside platinum-based chemotherapy as 1L treatment for ES-SCLC, based on data from two phase 3 trials, IMpower133 and CASPIAN. This retrospective, descriptive study assessed clinical characteristics and outcomes in patients with ES-SCLC receiving 1L platinum-immunotherapy in the real-world setting.

Methods: Data from the US-nationwide Flatiron Health electronic health record-derived deidentified database were collected in ES-SCLC patients aged ≥18 years receiving 1L carboplatin/cisplatin plus atezolizumab/durvalumab, with/without etoposide, between 9/25/2018 and 4/4/2021 (overall group), including patients receiving ≥1 cycle of immunotherapy as maintenance treatment (maintenance subgroup). Baseline characteristics (assessed between initial diagnosis and start of 1L treatment), treatment patterns, real-world effectiveness, and laboratory-derived adverse events of special interests (AESIs), including grade ≥3 hematological events, for each group were reported descriptively.

Results: This analysis included 1144 patients with ES-SCLC who received 1L platinum-immunotherapy. Of these, 764 patients received maintenance immunotherapy. The table presents baseline demographics/characteristics and treatment patterns. All patients received 1L platinum-etoposide plus immunotherapy, and most patients in the overall group (90.6%) and maintenance subgroup (91.2%) received atezolizumab as immunotherapy. Overall, the median (interquartile range [IQR]) duration of immunotherapy, including maintenance treatment, was 4.9 (2.8-7.1) months, and the median (IQR) duration of maintenance immunotherapy was 2.8 (1.4-4.9) months. The median (95% confidence interval) real-world overall survival (OS), progression-free survival, and time to next treatment from the start of 1L platinum-immunotherapy were 10.4 (9.8, 11.1), 5.4 (5.3, 5.6), and 6.7 (6.5, 6.9) months, respectively, in the overall group, and 13.1 (12.2, 14.1), 5.8 (5.6, 6.0), and 7.2 (7.0, 7.6) months in the maintenance subgroup. Among patients continuing immunotherapy for maintenance treatment, values were 9.7 (8.6, 10.6), 3.0 (2.7, 3.1), and 4.0 (3.9, 4.3) months from start of maintenance immunotherapy. The most common AESIs were grade ≥3 neutropenia (31.8%), anemia (24.8%), and thrombocytopenia (17.9%). Frequency of AESIs during maintenance immunotherapy was ≤2.5%. Unfavorable changes in lactate dehydrogenase levels and neutrophil-to-lymphocyte ratios were less frequent in the maintenance subgroup than in the overall group.

Conclusions: To date, this is the largest real-world study of platinum-immunotherapy in 1L ES-SCLC. Although this study population had poorer prognostic factors than those from pivotal trials (e.g., ECOG performance status ≥2 vs <2, respectively), survival outcomes were similar. Consistent with previous findings, less frequent AESIs and better prognostic factors were observed in the maintenance subgroup. The modest OS in this study underscores the unmet need for effective 1L treatment to improve survival for ES-SCLC.

EP.13B.04 The Value of Radiotherapy Based on the Failure of Extensive-Stage Small Cell Lung Cancerin the Era of Immunotherapy

Q. Zhang, Shanghai Chest Hospital, Shanghai Jiao Tong University, school of Medicine, Shanghai/CN

Introduction: Immune checkpoint inhibitors (ICIs) have significantly prolonged overall survival (OS) in patients with extensive-stage small cell lung cancer (ES-SCLC). The role of radiotherapy (RT) in the era of immunotherapy is unclear. We assessed the value of RT based on the first failure pattern of ES-SCLC.

Methods: We conducted a retrospective analysis of patients with ES-SCLC receiving first-line chemotherapy and immunotherapy at Shanghai Chest Hospital. Our study recorded the first failure pattern in ES-SCLC, analyzed the main sites of disease progression, explored factors that may affect prognosis, estimated the value of RT, and showed the potential for patient survival extension in the immunotherapy era.

Results: Disease progression occurred in 86 patients (68%). For dismissing the impact of RT on first failure pattern, 72 patients were divided into the non-pre-progression RT group and 14 patients were divided into the pre-progression RT group. Concerning the first failure pattern in non-pre-progression RT group: 25 patients with local failure, 28 patients with distant failure, and 19 patients failed both. As for the first failure pattern in pre-progression RT group: 5 patients with local failure, 8 patients with distant failure, and only one patient failed both.The mOS of the RT group was 21.4 months (95% CI:17.0-25.8 months), while that of the non-RT group was 11.9 months (95% CI:7.5-16.3 months). he results showed that the mPFS was 8.6 months (95% CI: 7.1-10.1 months) for the pre-progression radiotherapy group and 6.7 months (95% CI: 5.7-7.7 months) for the post-progression radiotherapy group. Pre-progression RT significantly improved PFS (hazard ratio for death, 0.513; 95% CI: 0.298-0.883; P = 0.013).

Conclusions: Distant failure is still the main failure pattern for ES-SCLC patients received first-line chemotherapy and ICIs. RT improved OS in these patients, and pre-progression RT improved PFS further. Therefore, it is likely that the appropriate timing for RT is before the tumor progression, and we plan to conduct further clinical trials to verify it.

EP.13B.05 Comparison of the Effectiveness of Cisplatin and Carboplatin with Etoposide in Treatment of Small Cell Lung Cancer: Single-center Experience

E. Hasdemir, A. Farzaliyeva, M.N. Ramazanoglu, S. Rahatli, A. Oguz, Z. Akcali, O. Altundag, Baskent University, Ankara/TR

Introduction: Small cell lung cancer (SCLC) is an aggressive type of lung cancer with poor survival. SCLC responds well to chemo(radio) therapy. Etoposide and cisplatin is most common first line treatment option, but carboplatin can be used instead of cisplatin in these group of patients. The aim of our study is to compare the effectiveness of cisplatin and carboplatin with etoposide as first-line treatment option in SCLC and demonstrate if present carboplatin is not non-inferiorty over to cisplatin.

Methods: In this single-center, retrospective study 135 patients diagnosed with SCLC were evaluated and compared according to progression-free survival (PFS) and overall survival (OS) Patients analysed according to receiving cisplatin plus etoposide (EP) and those receiving carboplatin plus etoposide(EC) in the first line restropectively. Both limited and extensive stage patients included this analysis.

Results: 53(%39,2) patients received EP, 82(%60,7) patients received EC. The median age was 60 years in the EP arm and 67.5 years in the EC arm. There was no significant difference between PFS values in limited stage patients and those receiving cisplatin and carboplatin (16 vs 10 mos p = 0,133). However, a significant OS difference in favor of cisplatin was detected in this patient group (31,2 vs 20,2 mos p = 0,021). In extensive stage patients, carboplatin was statistically more advantageous than cisplatin regarding PFS (8 vs 7 mos p = 0,025). However, no significant difference was detected in OS in the EP and EC groups (10,8 vs 11,30 mos p = 0,545). Objective response rates (ORR) were 72% in the EP arm and 83% in the EC arm in limited stage patients. In extended stage patients, the ORR were 96.4% in the EP arm and 96.2% in the EC arm.

Conclusions: Cisplatin and carboplatin with etoposide is cornerstone of SCLC treatment. While cisplatin treatment appears to be more effective in limited stage patients, its effect profile is similar to carboplatin in extensive stage patients. In our retrospecitve study no significant OS difference was shown with cisplatin vs carboplatin based combination. Due to its tolerable toxicity, carboplatin treatment may be preferred in the extensive stage patients.

Keywords: Small cell lung cancer, cisplatin, carboplatin

EP.13B.06 Efficacy and Safety Analysis of Atezolizumab Continuation Beyond Progression in Extensive Small Cell Lung Cancer(ES-SCLC)

Y. Peng, W. Shi, X. Bao, J. Xiong, Z. Yang, The Second Affiliated Hospital of Chongqing Medical University, Chongqing/CN

Introduction: Immunotherapy has opened up a new chapter for tumor treatment and significantly improved the survival of patients with extensive-stage small cell lung cancer (ES-SCLC), with anti-programmed death-ligand 1 (PD-L1) antibody represented by atezolizumab attaining overall survival (OS) beyond one year in the IMpower133 trial. However, a considerable number of patients acquired immunotherapy resistance or recurrence. Despite immune checkpoint inhibitors (ICIs) have brought significant benefits to patients, there has been little research on the efficacy analysis of immunotherapy continuation beyond progression, as well as the possible population of benefit. The aim of our study was to evaluate the efficacy and safety of immunotherapy continuation therapy to further optimize the immunotherapy rechallenge strategies.

Methods: We conducted a retrospective analysis of the demographic and treatment data of patients with ES-SCLC from multiple centers between January 2020 and April 2024. All enrolled patients progressed after receiving first-line (1L) atezolizumab combination therapy upon initial diagnosis of ES-SCLC and continued to receive immunotherapy combination therapy as second-line (2L) treatment. We aimed to evaluate the efficacy of immunotherapy rechallenge, measured by median OS (mOS) and median progression free survival (mPFS). The incidence of adverse events (AEs) was used to evaluate safety.

Results: Twenty-eight patients were eligible for this study, and the whole cohort received continuing atezolizumab combination therapy. After a median follow-up time of 15.7 months, 2L-mPFS was 4.07 months [95% CI: 1.15 to 6.98], the mOS was 18.87 months [95% CI: 15.28 to 22.45]. Further subgroup analysis demonstrated that the response to the 1L therapy was proposed as prognostic factor for OS. Responder group (1L-PFS ≥ 6 months) achieved longer mOS: 19.98 [95 %CI: 14.91-25.05] compared with resistant group (1L-PFS < 6 months) (p=0.021). Besides, receiving radiotherapy in 2L treatment after progression of atezolizumab was favorable prognostic factors accounting for PFS. Surprisingly, patients were with primary brain metastasis experienced more benefit in PFS and OS than those were not. In safety analysis, there were no treatment-related deaths. The most common AEs included dyspnea (53.5%), cough (39.2%) and nausea (28.5%), 1 patient developed grade 3 dyspnea.

Conclusions: The continuing immunotherapy combination therapy demonstrated favorable response in patients who experienced progression following 1L immunotherapy, especially for those who achieved PFS more than six months in 1L treatment. Additionally, combined radiotherapy during the immunotherapy continuation treatment can bring PFS benefit.

EP.13B.07 Evaluation of Trilaciclib Use and Chemotherapy Induced Myelosuppression in Extensive-Stage Small Cell Lung Cancer

F.A. Dela Cruz[1], N. Seetharamu[2], S. Kim[2], W.Y. Aung[2], C-S. Lee[2], [1]St. John's University, Queens/NY/USA, [2]Northwell Health Cancer Institute, Lake Success/NY/USA

Introduction: The 5-year survival rate for extensive-stage small cell lung cancer (ES-SCLC) patients is about 3% from the time of diagnosis. Chemotherapy-induced myelosuppression (CIM) is a common dose-limiting and potentially fatal toxicity of chemotherapy. This substantial burden leads to suboptimal health outcomes and increased healthcare utilization. A previous real-world study has shown that up to 98% of ES-SCLC patients had at least 1 myelosuppressive episode during follow-up and across all-chemotherapy lines of therapies. Trilaciclib is a transient cyclin-dependent kinase 4/6 inhibitor and is the first and only myeloprotection therapy approved to decrease CIM among adults with ES-SCLC when administered prior to a platinum/etoposide-containing regimen or topotecan-containing regimen. Studies elucidating the real-world outcomes of trilaciclib have been limited since its approval in 2021. The objective of this study is to evaluate CIM outcomes of patients with ES-SCLC who received platinum/etoposide-containing or topotecan-containing chemotherapy with or without trilaciclib.

Methods: This was a single-center retrospective study of patients with ES-SCLC who received chemotherapy with or without trilaciclib from January 3, 2018 to October 31, 2023, at Zuckerberg Cancer Center. The inclusion criteria for analysis included: adults 18 years and older, histologically confirmed ES-SCLC, and administration of platinum/etoposide-containing or topotecan-containing chemotherapy with or without trilaciclib. Outcomes included myelosuppression events and grade (anemia, neutropenia, thrombocytopenia) and supportive care utilization (granulocyte-colony stimulating factor (G-CSF) and RBC and/or platelet transfusion). Information on progression of disease and death was also collected. Data was analyzed using the T test and Chi-square test. For all analyses, a p-value < 0.05 was considered statistically significant.

Results: Patients in the trilaciclib cohort (N=36) and control cohort (N=58) were administered, on average, 4 cycles of chemotherapy, with the majority receiving carboplatin, etoposide, and atezolizumab. Fewer patients in the trilaciclib group experienced anemia (61.1% vs 77.6%, p = 0.207) and thrombocytopenia, (61.1% vs 19.4%, p=0.557) compared to those in control group across all grades. However, a higher percentage of patients in the trilaciclib group experienced neutropenia (25% vs 10.3%, p = 0.062). 86.2% of patients in the control group received G-CSF compared to 25% in the trilaciclib group (p <0.001).

Conclusions: Early real-world outcomes following treatment with trilaciclib suggest a potential reduction in myelosuppressive HAE among patients with ES-SCLC who receive platinum/etoposide-containing regimen or topotecan-containing regimen. However, limitations to this study include its retrospective study design, small sample size, and that analysis for the two cohorts involved two different time frames.

EP.13B.08 Enhanced Efficacy of Anlotinib in Small Cell Lung Cancer after Immune Checkpoint Inhibitor Exposure

J. Shan, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou/CN

Introduction: Small cell lung cancer (SCLC) is a malignancy associated with poor prognosis. Anlotinib, an anti-angiogenesis medication, has been approved in China as a third-line treatment option for SCLC. Nowadays, the current standard first-line treatment for SCLC includes PD-L1/PD-1 immune checkpoint inhibitors (ICI) in combination with chemotherapy. Several recent retrospective studies have suggested that patients with non-small cell lung cancer (NSCLC) and gastric cancer previously treated with ICI may have increased progression-free survival (PFS) with subsequent anti-angiogenic therapy compared with patients not treated with ICI.

Methods: We conducted a retrospective analysis of the data of patients with extensive-stage SCLC who received anlotinib as third-line therapy at our hospital between January 2021 and April 2023. The primary endpoints were PFS and overall survival (OS).

Results: Twenty patients who had not received prior ICI therapy (control group) and 39 patients who had received ICI therapy (treatment group) received anlotinib as third-line therapy. the treatment group significantly prolonged PFS compared with the control group (median, 11 months vs. 4 months; HR=0.34, 95%CI, 0.12-0.92, log-rank P=0.0345). Median OS was 21 months vs. 10 months (HR=0.48, 95%CI, 0.23-1.00, log-rank P=0.0228). The incidence of grade ≥ 3 adverse events (AEs) was similar between groups, 35.9% in the treatment arm and 30% in the control arm, with proteinuria being the most common AE.

Conclusions: Anlotinib shows improved efficacy in patients with SCLC who have been previously exposed to immune checkpoint inhibitors. Further prospective studies are warranted to validate these findings and elucidate the underlying mechanisms of this synergism.

EP.13B.09 Outcomes of Inpatient Chemotherapy for Patients with Newly Diagnosed Extensive Stage Small Cell Lung Cancer

S. Gauthier[1], P. Wheatley-Price[2,3], D. Stewart[2,3], S. Brule[2,3], M. Ney[2,3], G. Nicholas[2,3], S. Moore[2,3], [1]University of Ottawa, Ottawa/ON/CA, [2]The Ottawa Hospital, Ottawa/ON/CA, [3]Ottawa Hospital Research Institute, Ottawa/ON/CA

Introduction: Small-cell lung cancer (SCLC) accounts for 15% of all lung cancers, of which 70% are diagnosed at extensive-stage (ES). SCLC has high sensitivity to chemotherapy due to its rapid proliferation, and treatment is considered even in patients who are very unwell. Despite this, little is known about outcomes of patients with ES-SCLC treated in the inpatient setting.

Methods: With ethics approval, we conducted a retrospective review of all patients with a de novo diagnosis of ES-SCLC at The Ottawa Hospital between January 2013 and December 2021 who had an inpatient medical oncology consultation. The primary endpoint was overall survival (OS) among patients who received systemic therapy versus those who did not. Secondary endpoints included hospital length of stay (LOS) and incidence of tumour lysis syndrome (TLS).

Results: Of the 127 patients identified, 92 (72%) received systemic therapy. Baseline characteristics at initial diagnosis: median age 68 years (range 50-87); 74 (58%) female; 121 (99%) with former or current smoking history; 27 (22%) brain metastases; 80 (64%) liver metastases. Patients in the non-treatment cohort had significantly poorer Eastern Cooperative Oncology Group performance status (ECOG-PS) versus the treatment cohort (p<0.001), with 88% and 53% patients with an ECOG-PS of 3-4, respectively. Of the 92 patients who received systemic therapy, 87 (95%) received platinum-etoposide as first-line treatment, most receiving either 1 (85%) or 2 (12%) cycles in the inpatient setting. Median OS from initial diagnosis was 4.0 months (m) (95% CI, 2.5-5.5m). The systemic therapy cohort had a median OS of 5.9m (95% CI, 4.5-7.3m), 30-day survival of 80%, 6 m survival of 50%, and median LOS of 14 days. The no treatment cohort had an abysmal median OS of 0.5 m (95% CI, 0.2-0.7 m), 30-day survival of 30%, 54% death rate in-hospital, and median LOS of 11 days. Of the 76 patients with blood work evaluable for TLS, 6 (8%) developed TLS, all of whom died within 7 days of chemotherapy. All patients with TLS had liver metastases, ECOG-PS of 2-3 and lactate dehydrogenase (LDH) >1500 (unknown for 1).

Conclusions: Despite admission to hospital, 72% of patients received systemic therapy for treatment of ES-SCLC. Patients receiving systemic therapy lived longer than those who did not. The risk of developing TLS was associated with liver metastases, poor ECOG-PS, and LDH>1500. Aggressive TLS prophylaxis should be considered among patients with these factors.

EP.13B.10 Impact of Pneumonitis from Radiotherapy Combined with Immune Checkpoint Inhibitor Therapy on Tumor Progression and Survival in Patients with Small Cell Lung Cancer

Z. Wang[1,2], W. Jiang[1], J. Lu[1], D. Chen[1], J. Liang[1], L. Wang[1,3], [1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Shenzhen/CN, [2]Graduate School of Bengbu Medical University, Anhui/CN, [3]Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Beijing/CN

Introduction: Chemoradiotherapy is the main treatment for small cell lung cancer (SCLC). With the development of immunotherapy, chemotherapy combined with immune checkpoint inhibitors (ICI) has become the first-line standard care for extensive-stage (ES) SCLC and its application in patients with limited-stage (LS) SCLC is under investigation. How the promotion of pneumonitis produced by the synergy of immunotherapy and radiotherapy affects the prognosis of SCLC is an unanswered question.

Methods: Clinical and prognostic data were retrospectively collected from ES-SCLC patients who received consolidation thoracic radiotherapy and LS-SCLC patients who received concurrent or sequential thoracic radiotherapy after ICI from January 2019 to August 2023 at our center. Treatment-related pneumonitis occurring within 6 months of completion of radiotherapy was assessed and graded by two radiation oncologists using the Common Terminology Criteria for Adverse Events version (CTCAE 5.0). The Kaplan-Meier method and log-rank test were used to evaluate the correlation of pneumonitis with progression-free survival (PFS) and overall survival (OS).

Results: A total of 35 patients treated with radiotherapy combined with ICI were included. There were 22 (62.9%) ES-SCLC and 13 (37.1%) LS-SCLC patients. The median radiotherapy dose was 45 Gy, and 17 patients (48.6%) received concurrent radiotherapy and immunotherapy. The median PFS and OS were 9(95% CI,0.4-46) months and 22(95% CI,8-46) months, respectively. ES-SCLC patients underwent consolidation radiotherapy after chemoimmunotherapy achieved a similar PFS (vs. p=0.83) and OS (vs. p=0.50) to LS-SCLC counterparts. However, PFS of LS-SCLC here was shorter than the historical data limited to the small sample size. Twenty-one patients (60%) developed treatment-related pneumonitis, of which six patients (27.3%) were grade 2 and two patients (9.1%) were grade 3, with no grade 4 or 5 pneumonitis. Of these, seven patients (31.8%) experienced radiation pneumonitis, one patient (4.5%) experienced checkpoint inhibitor pneumonitis, and five patients (22.9%) experienced mixed pneumonitis. Patients who developed grade 2 and above pneumonia had worse PFS [7(95% CI-22) months vs. 12(95% CI-46) months, log-rank, p = 0.155] but no significant difference in OS compared to those who developed grade 1 or no pneumonitis. Mixed pneumonitis appeared to contribute the most, but there was no statistical difference in the impact of the three types of pneumonitis on PFS and OS. The prognostic impact of pneumonitis was similar in the two subgroups of LS-SCLC and ES-SCLC.

Conclusions: In this study, ≥grade 2 treatment-associated pneumonitis induced byradiotherapy combined with immunotherapy shortened the PFS but not OS of SCLC patients. Mixed pneumonitis appeared to have more adverse effects, but more sample sizes are needed to confirm. Based on this, the risk of pneumonitis should be assessed more carefully when administering combination therapy with immunoradiotherapy for SCLC. Moreover, the suboptimal outcomes of LS-SCLC patients suggests that the role of immunotherapy combined with chemoradiotherapy warrants further investigation.

EP.13B.11 Clinical Outcomes of Continuous Immunotherapy Beyond Progression in Patients with Extensive-Stage Small Cell Lung Cancer

C. Wang[1], T. Xuan[2], Y. Wang[3], C. Yang[4], R. Zhang[4], W. Zhao[1], C. Li[3], L. Cong[5], X. Meng[3], J. Li[1], [1]Department of Medical Oncology, Qilu Hospital, Cheeloo College of Medicine, Shandong University, jinan/CN, [2]Department of Medical Oncology, Qilu Hospital (Qingdao), Cheeloo College of Medicine, Shandong University, qingdao/CN, [3]Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, jinan/CN, [4]Qilu Hospital, Cheeloo College of Medicine, Shandong University, jinan/CN, [5]Department of Oncology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan/CN

Introduction: Immunochemotherapy has been approved as first-line treatment for extensive-stage small-cell lung cancer (ES-SCLC) with a 2-4 months OS benefits compared with chemotherapy only. However, the efficacy of continuous immune-checkpoint inhibitors (ICIs) beyond immunochemotherapy progression is still unknown. This multi-center retrospective study aimed to investigate the efficacy of regimens containing continuous immunotherapy as second-line treatment for ES-SCLC after first-line immunochemotherapy.

Methods: We retrospectively reviewed the medical records of ES-SCLC patients treated with first-line immunochemotherapy at Qilu hospital of Shangdong University and Shandong Cancer Hospital. All the patients enrolled achieved disease control during first-line immunochemotherapy and then suffered disease progression. Patients with primary resistance to immunochemotherapy with a progression-free survival (PFS)<3 months was excluded.

Results: From January 2020 to September 2023, a total of 97 ES-SCLC patients treated with first- line immunochemotherapy were enrolled, with a median age of 62 (range, 39-79) and ECOG score of 0-1. There were 77 males and 55 with a history of smoking, 24 with brain metastases, 28 with liver metastases, and 34 with bone metastases. Seventy-eight patients received PD-L1 antibody including atezolizumab, durvalumab, adebrelimab and envafolimab, while 19 patients received PD-1 antibody including pembrolizumab, serplulimab and tislelizumab. Overall response rate of first-line immunochemotherapy was 54.6% (95% confidence interval [CI]:44.6%-64.7%), including 51 cases of PR and 2 cases of CR. The median PFS was 6.8 (95%CI: 6.2-7.4) months. Median cycle of immunotherapy was 7.0 (range, 4-14). As for second-line therapy, 68 (70.1%) patients received continuous immunotherapy beyond progression, including 39 with immunochemotherapy±local radiotherapy, 15 with immunotherapy±local radiotherapy and other 14 patients with anti-angiogenic therapy plus immunotherapy or immunochemotherapy. A total of 29 (29.9%) patients received chemotherapy±local radiotherapy without immunotherapy as second-line therapy, and 9 of above patients received anti-angiogenic agents at the same time. The continuous immunotherapy group showed longer second-line PFS (mPFS of second-line therapy) of 4.2 months (95%CI: 3.4-5.0) compared with 3.2 months (95%CI: 2.2-4.1, p=0.126) for chemotherapy group, excluding patients treated with anti-angiogenic agents. The second-line PFS of 23 patients receiving anti-angiogenic therapy such as anlotinib and sorafenib (14 in combination with immunotherapy or immunochemotherapy and 9 in combination with chemotherapy) was 5.3 months (95%CI: 3.5-7.1), indicating combined anti-angiogenic therapy may yield better survival benefit for ES-SCLC patients treated with first-line immunochemotherapy. Overall survival data is currently immature.

Conclusions: Continuous ICIs beyond progression in ES-SCLC provide a favorable prognosis tendency. Anti-angiogenic agent containing strategy may further improved survival after first-line immunochemotherapy. The long-term efficacy is still under follow-up.

EP.13B.12 Chemotherapy Sensitivity for Recurrent Small-Cell Lung Cancer Based on Chemotherapy-Free Interval and Treatment Regimens

Y. Akazawa[1], A. Kubota[2], Y. Mihashi[1], Y. Yano[1], M. Mori[1], J. Uchida[1], [1]NHO Osaka Toneyama Medical Center, Toyonaka/JP, [2]Kyoto University Graduate School of Medicine, Kyoto/JP

Introduction: Small-cell lung cancer (SCLC) is an aggressive subtype of lung cancer. Most cases are diagnosed at advanced stages. Despite the high response rate to initial treatment, most cases experience disease recurrence. In cases whose disease recurs at least 3 or 6 months after the last initiation of cytotoxic chemotherapy, re-challenge of the first-line regimen is considered the standard of care due to the lack of effective treatment options for recurrent SCLC. The definition of sensitive relapse differs between treatment guidelines. ESMO and Japan's Lung Cancer Association guidelines define sensitive relapse as cases that experienced chemotherapy-free interval (CTFI) of 90 days after the initial response, whereas the threshold of CTFI of sensitive relapse for NCCN guidelines is 180 days. The concept of sensitive relapse was established before the advent of amrubicin (available in Japan) and lurbinectedin (recommended in ESMO and NCCN guidelines), which are effective for recurrent SCLC.

Methods: We retrospectively analyzed sequential 206 cases with SCLC who started first-line treatment from January 2014 to December 2023 at Osaka Toneyama Medical Center. Twenty-nine patients received ICI+platinum doublet, and 36 were treated with chemoradiotherapy. We analyzed the treatment sequence and response for SCLC.

Results: At the time of the abstract submission, 183 cases experienced disease recurrence (CTFI<90 109 cases, 90<CTFI<180 41 cases, CTFI>180 33 cases). Among 74 sensitive relapse cases, 63 received second-line chemotherapy. Some reasons for not receiving second-line therapy in 11 patients included rapid deterioration of the patient's condition due to disease progression, development of other malignancies, and patients' refusal of treatment. Thirty-four were treated by platinum-doublet re-challenge, and 29 received monotherapy of amrubicin, topotecan, or irinotecan. One patient received an ICI combination regimen for second-line therapy. In 90<CTFI<180 group, response rates to platinum-doublet rechallenge and monotherapy were 19% and 35%, respectively. In CTFI>180 groups, response rates to re-challenge and monotherapy were 56% and 33%, respectively. Phase 3 trials, CASPIAN and Impower133, proved that the addition of ICI to platinum+VP-16 helped improve overall survival and duration of response in patients with advanced SCLC, even with a similar response rate to conventional platinum-doublet chemotherapy. However, more than half of patients experience progression of disease within 90 days from the last dose of first-line cytotoxic chemotherapy. Treatment choice for chemotherapy resistance is crucial, but treatment options are limited.No major amendment to the definition of refractory/sensitive relapse has not been performed for about 20 years. In our limited analysis, response rates by monotherapy for recurrent SCLC were consistent regardless of CTFI. In contrast, platinum doublet rechallenges presented promising responses only in patients with CTFI>180. However, there is not enough data on the safety and efficacy of second-line chemotherapy following ICI combination regimens for SCLC.

Conclusions: PSF in first-line chemotherapy has been proven to be a surrogate marker of survival for SCLC. Treatment option with high response is warranted to improve the outcome of SCLC. It is still unclear whether the response of second-line chemotherapy following ICI is elevated compared to conventional chemotherapy. Further investigation is needed.

EP.13B.13 Radioactive Seed Implantation Combined with PD-L1 Antibody and Chemotherapy Gt in the First-Line Treatment of ES-SCLC: A Retrospective Study.

X. Li, W. Zhang, Nankai University Affiliated First Central Hospital, Tianjin/CN

Introduction: Radioactive seed implantation (RSI) combined with immune checkpoint inhibitor PD-L1 antibody and chemotherapy can not only reduce the occurrence of radiation damage, but also potentially induce more abscopal effects and improve the efficacy of anti-tumor treatment. Small cell lung cancer (SCLC) is one of the deadliest cancers in humans, with a 5-year survival rate of less than 7%. This study analyzes the clinical efficacy of patients receiving RSI combined with PD-L1 antibody and chemotherapy, aiming to explore the first-line combined treatment model for ES-SCLC.

Methods: Retrospective collection of 21 ES-SCLC patients who received PD-L1 antibody and chemotherapy combined with RSI treatment from July 2020 to March 2024. Received PD-L1 antibody, etoposide, Cisplatin or carboplatin treatment every 3 weeks for a total of 4 cycles; Percutaneous RSI is performed 3-10 days before the first cycle. The treatment plan is developed based on the patient's CT image. The prescribed should be 110~160 Gy. Until the disease progresses significantly, intolerable toxicity or death.

Results: This study included a total of 21 samples, 15 males and 7 females, with a median age of 64 years, 62% of patients were smokers, 7 patients had mediastinal metastasis, 4 patients had bone metastasis. The Median PFS was 10.0 month; Median OS was 14.0 month, 3 patients experienced Grade 3/4 drug-related adverse reactions, and 1 patient discontinued medication. Because the number of patients is less, the OS data is not mature.

Conclusions: RSI combined with PD-L1 antibody and chemotherapy is safe and feasible in the first-line treatment ES-SCLC, and could effectively control the recurrence and metastasis of the disease.

EP.13B.14 Extensive Small Cell Lung Cancer (SCLC): Maintenance Oral Etoposide Daily for 6 Days Every 3-4 Weeks Until Tumor Progression

D.J. STEWART, University of Ottawa, Ottawa/ON/CA

Introduction: For extensive SCLC, progression-free survival (PFS) curve log-linear plots are moderately or highly convex due to rapid tumor regrowth following induction chemotherapy[1]. Three cycles of maintenance oral etoposide (50 mg/m2/day x 21 days q28 days) improved PFS[2].

Methods: From early 2020, patients who were progression-free 3 weeks following 4-6 cycles of induction carboplatin plus etoposide were considered for maintenance oral etoposide using a convenient schedule (100 mg/m2/day for 6 days). Treatment was continued until progression. Cycles were repeated every 3 weeks. From mid 2022, durvalumab 1500 mg q28days was publicly funded in Canada and was given with oral etoposide. With durvalumab, etoposide schedule was adjusted to 100 mg/m2/day x 6 days q28days. Patients from 2018 onwards who received no maintenance therapy but were progression-free 3 weeks post induction chemotherapy served as a comparison group.

Results: Fifteen patients received no maintenance, 14 received etoposide alone and 19 received etoposide plus durvalumab. From 3 weeks post day 1 of last cycle of induction treatment, median PFS was 51 days for no treatment, 176 days for etoposide alone, 166 days for etoposide + durvalumab, and 166 days for the 33 patients with any etoposide (alone or with durvalumab) (p=0.02 across the 3 groups, p=0.006 and hazard ratio 0.43 for any etoposide vs none, p=0.98 and hazard ratio 1.01 for etoposide +durvalumab vs etoposide alone). Median post induction overall survival (OS) was 207 days with no maintenance, 293 days with etoposide alone, 313 days with etoposide +durvalumab and 315 days for etoposide +/- durvalumab (p=0.04 across all groups, p=0.03 and hazard ratio 0.49 for any etoposide vs none and p=0.68, hazard ratio 0.84 for durvalumab +etoposide vs etoposide alone). From initiation of induction chemotherapy, PFS was 188 days with no maintenance, 330 days with etoposide alone, 265 days with etoposide +durvalumab and 284 days for etoposide +/- durvalumab (p=0.24 across all groups, p=0.04 and hazard ratio 0.52 for any etoposide vs none and p=0.34, hazard ratio 1.41 for durvalumab +etoposide vs etoposide alone). From initiation of therapy, OS was 338 days with no maintenance, 429 days with etoposide alone, 456 days with etoposide +durvalumab, and 456 days for etoposide +/- durvalumab (p=0.14 across all groups, p=0.047 and hazard ratio 0.52 for any etoposide vs none and p=0.99, hazard ratio 1.001 for durvalumab +etoposide vs etoposide alone). Maintenance oral etoposide was well tolerated and demonstrated no cumulative toxicity.

Conclusions: This preliminary assessment suggests maintenance oral etoposide until progression prolongs PFS and OS. Since patient numbers are small and treatment assignment was by selection, results require confirmation. The apparent lack of added benefit from durvalumab could be due to small patient numbers. Alternatively, it might have arisen from change of etoposide to a potentially less effective 4-week schedule from a 3-week schedule when durvalumab is used. We have initiated assessment of maintenance oral etoposide with atezolizumab (3-week schedule), which has comparable efficacy to durvalumab. References: 1. Stewart DJ et al. EP.13B.15 Radiotherapy Combined with Immunotherapy in the Treatment of Brain Metastases from Small Cell Lung Cancer

W. Feng[1], S. Que[1], H. Wang[1], E. Dai[1], S. Zhai[1], Q. Mo[1], Y. Li[1], J. Wang[1], X. Liang[1], [1]The Cancer Hospital of Zhejiang Province, Hang Zhou/CN

Introduction: To explore the efficacy and safety of the combination of brain radiationtherapy (BRT), chemotherapy and immune checkpoint inhibitors (ICI) in the treatment of brain metastases in patients with Extensive stage small cell lung cancer(ES-SCLC).

Methods: A retrospective analysis of 187 patients with ES-SCLC brain metastases treated from January 2017 to October 2023 in Zhejiang Cancer Hospital was performed. They were divided into BRT group, ICI group and brain radiotherapy-immunotherapy combination treatment (ICI+BRT) group based on the different first-line treatment regimens.The first-line treatment regimens of the three groups of patients included chemotherapy. The differences in age, number of brain metastases, symptoms of brain metastases, underlying diseases, KPS score, smoking history, GPA score and survival time among the three groups were evaluated separately. Cox's proportional risk regression model was used to conduct univariate and multivariate analyses of prognostic factors. Finally, the differences in efficacy were assessed between the synchronized group (ICI and BRT interval ≤4w) and the asynchronized group (ICI and BRT interval >4W).

Results: The median overall survival (OS) was 11.6 months, 11.6 months and 20.9 months in the BRT, ICI and ICI+BRT groups respectively ($p < 0.001$). Median progression-free survival (PFS) was 6.2 months, 4.8 months and 12.6 months ($p < 0.001$) respectively. The median intracranial progression-free survival (iPFS) was 7.2 months, 5.3 months and 14.9 months respectively ($p < 0.001$). Systemic and intracranial ORR and DCR were also significantly superior in the ICI+BRT group. No statistically significant difference was seen between the BRT group and ICI+BRT group at Classification criteria for acute radiation injury (Central nervous system) ($p = 0.314$). Multivariate Cox regression showed that the first-line regimen, chemotherapy cycles ≥4, bone metastases, number of brain metastases ≥3, ICI cycles ≥6, second to multiple lines antiangiogenesis targeted therapy and first-line extracranial radiotherapy had an impact on patients' OS. Immunotherapy regimen (atezolizumab, serplulimab) and radiotherapy regimen (WBRT, WBRT+boost) had a certain degree of efficacy for patients. In the synchronized group compared with the asynchronized group, PFS (P=0.013) and iPFS (P=0.029) had a significant advantage.The rest of the main therapeutic indexes and the incidence rate of adverse reactions did not show any statistically significant differences.

Conclusions: Under the premise of universal use of chemotherapy, ICI+BRT as the first-line therapy for patients with baseline ES-SCLC brain metastases has better efficacy than ICI or BRT alone.There is a trend that ICI asynchronous BRT therapy is superior to ICI synchronous BRT therapy.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.13C.01 Prognosis of Surgically Resected Pure and Combined Small Cell Lung Cancer Undergoing Adjuvant Chemotherapy

N. Tsurumaki[1,2], Y. Goto[1], Y. Shinno[1], Y. Okuma[1], T. Yoshida[1], H. Horinouchi[1], N. Yamamoto[1], Y. Matsumoto[1], S. Watanabe[1], Y. Yatabe[1], Y. Ohe[1], [1]National Cancer Center Hospital, Tokyo/JP, [2]National Center for Global Health and Medicine, Tokyo/JP

Introduction: Small cell lung cancer (SCLC) accounts for approximately 10-15% of all lung cancers. It is characterized by rapid proliferation and high malignancy, often resulting in early lymph nodes and distant metastases. Adjuvant chemotherapy following surgical resection is recommended for cases of SCLC to improve outcomes. Within the spectrum of SCLC, approximately 5-28% of cases exhibit components of non-small cell lung cancer (NSCLC) histological subtypes, termed combined SCLC. However, there is limited research comparing the prognosis of patients undergoing adjuvant therapy after surgical resection for histopathologically diagnosed pure SCLC versus combined SCLC.

Methods: We retrospectively reviewed the medical record system, and conducted analysis on 65 patients diagnosed with limited disease SCLC (LD-SCLC) who underwent surgical resection and adjuvant chemotherapy between January 1, 2008, and August 14, 2023 in National Cancer Center Hospital, Japan. Patients were categorized into two groups based on histopathological diagnosis; pure SCLC (43 patients) and combined SCLC (22 patients). Disease free survival (DFS) and overall survival (OS) curves were analyzed for both groups using EZR software.

Results: Among the 65 participants, the median follow-up period was 2.7 years. The median age at surgical resection was 71 y (range 47-84 y), with 52 patients (80%) aged 65 years or older. There were 54 male (83%) patients. The adjuvant chemotherapy regimens administered were as follows: carboplatin+etoposide (ETP) was given to 17 patients in the pure SCLC group and 8 in the combined SCLC group, cisplatine (CDDP)+ETP to 8 patients in the pure SCLC group and 9 in the combined SCLC group, and CDDP+irinotecan (IRI) to 8 patients in the pure SCLC group and 3 in the combined SCLC group.The median DFS for pure SCLC was 115.4 months (95% CI 54.2-NA), which was longer than that of combined SCLC (24.2 months (95% CI 17.5-NA)). Similarly, the median OS for pure SCLC was 115.4 months (95% CI 90.4-NA), while the arm of combined SCLC has not reached. While there was no statistically significant difference in DFS and OS between the two groups, a trend towards poorer prognosis in the combined SCLC group was observed.

Conclusions: No statistical significance was observed in DFS and OS between pure and combined SCLC groups, however the divergence in the survival curves suggests a potential poorer prognosis in combined SCLC. Further investigation should include histopathological patterns of relapse on account of the heterogeneity of combined SCLC.

EP.13C.02 High-Dose Radiation Therapy for Limited-Stage Small-Cell Lung Cancer: Real-World Experience from Two Tertiary Centers

O. Icht[1], B. Krayim[2], M. Moskovitz[1], D. Reinhorn[1], O. Rotem[1], I. Averbuch[1], N. Peled[2], A. Allen[2], [1]Davidoff Cancer Center, Rabin Medical Center, Petach-Tikva/IL, [2]Helmsley Cancer Center, Shaare Zedek Medical Center, Jerusalem/IL

Introduction: A recent phase 2 clinical trial by Gronberg et al. have demonstrated improved survival outcomes with high-dose, twice-daily radiation therapy (RT) for limited-stage small-cell lung cancer (LS-SCLC). However, this regimen has not been widely adopted in routine practice. This study evaluates the real-world experience of dose-escalated RT in LS-SCLC patients treated at two tertiary centers.

Methods: We retrospectively reviewed consecutive LS-SCLC patients treated with concurrent chemoradiation using a high-dose, twice-daily RT regimen (60 Gy in 40 fractions over 4 weeks) between 2020-2023. Baseline characteristics, oncologic outcomes (progression-free survival [PFS], overall survival [OS], patterns of failure, response rates), and RT-related toxicity were evaluated. Dosimetric parameters, including gross tumor volume (GTV) and lung dose, were collected.

Results: Thirteen patients were included, with a median age of 59 years and 61.5% female. The median follow-up time was 27 months. The majority (92.3%) completed the planned RT course. The median OS was 30.9 months (95% CI:14.3-NR), and the median PFS was 9.1 months (95% CI: 6.1-NR). Best response rates were: complete response (CR) 46.2%, partial response (PR) 15.3%, progressive disease (PD) 23.1%, and non-evaluable 15.4%. Among patients with progression, only 1 (7.7%) had local failure, while the rest experienced distant metastases. Common adverse events included esophagitis (69.2%; Grade 1-2: 61.5%, Grade 3: 7.6%), neutropenia (61.5%; Grade 1-2: 23%, Grade 3-4: 38.4%), and pneumonitis (38.4%, all Grade 1). No Grade 5 events occurred. The median GTV was 156 cc (range: 36-444), and the mean lung dose was 15.03 Gy (range: 7.9-24).

Conclusions: In this real-world experience, high-dose RT (60 Gy in 40 fractions over 4 weeks given twice daily), for LS-SCLC resulted in promising response rates, excellent local control, and favorable early survival outcomes. These findings, consistent with the previous phase 2 trial, support the broader implementation of this intensive regimen in clinical practice.

EP.13C.03 Investigating Surgery's Role in Stage IIB-IIIB Small Cell Lung Cancer Following Chemo-immunotherapy

Z. Chen[1,2,3], c. huang[1], Y. Pan[1], j. chen[4], z. chen[1], r. fu[1], j. kang[1], y. wu[1], w. zhong[1,2,5], [1]Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/CN, [2]Guangdong Lung Cancer Institute, Guangzhou/CN, [3]School of Medicine, South China University of Technology, Guangzhou/CN, [4]Guangzhou Twelfth People's Hospital, Guangzhou/CN, [5]Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangzhou/CN

Introduction: The role of surgery in treating advanced stages of small cell lung cancer (SCLC), specifically stages IIB-IIIB is contentious, despite its acceptance for early-stage disease.This study assesses the efficacy of surgical intervention following chemotherapy and immunotherapy in these patients.

Methods: We retrospectively analyzed data from 11 patients with SCLC at stages IIB-IIIB treated at Guangdong Provincial People's Hospital between 2021 and 2024. All patients underwent four cycles of etoposide and platinum-based chemotherapy combined with immunotherapy, preceding surgical resection. The primary endpoint was pathological complete response (pCR), while progression-free survival (PFS) and safety were considered secondary endpoints.

Results: The study included 3 patients with stage IIB, 5 with stage IIIA, and 3 with stage IIIB. pCR was achieved in 7 (63.6%) patients, and major pathological response in 8 (72.7%). The median follow-up was 12 months (95% CI, 6.8-17.2 months), with median progression-free survival (PFS) not reached. One patient experienced disease progression characterized as distant metastasis, which occurred 9 months post-surgery. The 12-month and 18-month PFS rates were 100.0% and 75.0%, respectively, according to Kaplan-Meier estimates. During neoadjuvant therapy, 6 (54.5%) patients experienced grade 3 or higher adverse events (AEs), and 4 (36.3%) had grades 1-2 immune-related adverse events.

Conclusions: Surgery after neoadjuvant chemo-immunotherapy improves pCR and PFS in stage IIb-IIIb SCLC, with manageable AEs, supporting its consideration as a treatment strategy.

EP.13C.04 Is Neoadjuvant Chemoimmunotherapy Better Than Chemotherapy in Patients with Limited-Stage Small Cell Lung Cancer

T. Wang[1,2], K-L. Huang#[2,3], D. Pu[2,3], T. Mei[2,3], M-Y. Fan[2,3], L. Tian[2,3], L. Li[2,3], Q-H. Zhou*[2,3], [11] Department of Thoracic Surgery, West China Hospital, Sichuan University, Chengdu/CN, [22] Lung Cancer Center, West China Hospital, Sichuan University, Cheng du/CN, [31] Department of Thoracic Surgery, West China Hospital, Sichuan University, Cheng du/CN*

Introduction: The addition of immune checkpoint inhibitors to chemotherapy significantly improves survival in extensive-stage small cell lung cancer (ES-SCLC). However, up to now, no study has been conducted in order to compare the effect of chemoimmunotherapy with chemotherapy in the neoadjuvant for LS-SCLC. Hereby, we conduct a retrospective study in this setting.

Methods: Patients with LS-SCLC who received neoadjuvant PD-L1/PD-1 inhibitor plus platinum-based chemotherapy or platinum-based chemotherapy alone followed by surgery between Jan 2018 and Oct 2023 in our institute were included. The primary endpoints were pathologic complete response rate and major pathologic response. The second endpoints were R0 resection rate, downstaging rate and disease-free survival.

Results: Of the 51 eligible patients, 26 received neoadjuvant chemoimmunotherapy and 25 received neoadjuvant chemotherapy (Table 1). There were 39 males and 12 females across both groups combined. Mean (range) age at diagnosis was 61.6 years (43.1-74.5) for the chemoimmunotherapy group and 59.5 years (45.8-73.2) for chemotherapy group. Pathologic complete response rate was 38.5% (10/26) in chemoimmunotherapy group versus 4.0%, (1/25) in chemotherapy group (OR 7.2, 95% CI 1.4-37.3) (Table 2). Major pathologic response rate was 53.8% (10/26) in chemoimmunotherapy group versus 12.0% (3/25) in chemotherapy group (OR 8.6, 95% CI 2.0-35.8). R0 resection rate was 92.3 (24/26) in chemoimmunotherapy group versus 80.0% (20/25) in chemotherapy group (OR 3.0, 95% CI 0.5-17.2). Pathologic downstaging rate (88.5% vs 36.0) and N2 downstaging rate (68.2 vs 24.0) were higher in chemoimmunotherapy group. After a median follow up of 17.2 months, median DFS was not reached in chemoimmunotherapy group versus 11.3 (95% CI, 6.1-16.5) months in chemotherapy group.

Table 1 Main results of study

Conclusions: Neoadjuvant chemoimmunotherapy demonstrated promising efficacy and feasibility, and are a potential strategy for the management of LS-SCLC. Further prospective randomized controlled trials need to explore.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.13C.05 Factors Affecting Outcomes of Limited Stage (IIB-IIIC) Small Cell Lung Cancer: An Analysis of the National Cancer Database.

H.M. Abdullah, A.C. Das, O.K. Abughanimeh, K-L. Muir, B.B. Sharma, A.S. Marr, L.M. Smith, A.K. Ganti, University of Nebraska Medical Center, Omaha/NE/USA

Introduction: Limited stage small cell lung cancer stage IIB-IIIC (T3-T4, any N, M0) is typically treated with chemoradiation. A retrospective analysis of the National Cancer Database (NCDB) was conducted to identify factors associated with worse outcomes.

Methods: Patients with limited-stage small cell lung cancer (T3-4, N any, M0) diagnosed between 2010 and 2020, were identified from the NCDB. The following information was abstracted: age, sex, race, type of insurance, facility type, and treatment. Treatments received included: no treatment, surgery only, and chemotherapy + radiation (concurrent or sequential). Factors associated with survival were assessed using the Cox proportional hazards model.

Results: This cohort included 2534 patients <65 years of age, 2915 between 65-75 years, and 1668 >75 years of age. The median overall survival (OS) for this group was 11.3 months (14.0, 12.65, and 6.01 months for the three age groups respectively). Factors associated with worse overall survival were: age > 75 (HR= 1.26 P <0.001), Age 65-75 (HR= 1.10 P=0.005), Male sex (HR= 1.15 P <0.001), year of diagnosis 2010-2015 (HR= 1.20 p= <0.001). Better OS was noted in Other races (races other than Caucasian, African American, and Native American) (HR= 0.55 p= 0.008). Better OS was also noted in patients who had private insurance (as compared to Medicare or uninsured patients) (HR= 0.91 p=0.01).

Patients who received chemoradiation were divided into two groups: concurrent and sequential chemoradiation. Patients who underwent sequential chemotherapy and radiation had a median overall survival of 23.3 months (95% CI 21.6-27.2) compared to concurrent chemoradiation who had a median overall survival of 17.4 months (95% CI 16.6-18.4) (p< 0.001) (Figure 1).

Conclusions: For patients with (T3-4, N any, M0) small cell lung cancer, overall survival was lower in patients who were >75 years of age as compared to those who were <65 years of age. Other factors associated with worse outcomes include male sex and diagnosis between 2010-2015. Better outcomes were noted in patients who had private insurance. Patients who underwent sequential chemotherapy and radiation had significantly improved overall survival as compared to patients who underwent concurrent chemotherapy and radiation, contrary to previous findings.

Figure;1- Overall survival in patients who underwent concurrent chemotherapy and radiation (yellow) vs sequential chemotherapy and radiation (blue).

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.13C.06 Feasibility of Hippocampal Sparing Radiotherapy in Lung Cancer Patients Requiring Cranial Irradiation (HSWBRT-LC)

D. Khosla, T. Dey, R. Kapoor, N. Singh, G. Trivedi, V. Kataria, A.K. Singla, R. Madan, S. Goyal, A.S. Oinam, A. Sharma, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh/IN

Introduction: Hippocampal Sparing Whole Brain Radiotherapy (HSWBRT) mitigates cognitive decline, thereby enhancing the quality of life for patients. This study assesses the feasibility of HSWBRT in lung cancer patients receiving cranial irradiation for prophylactic or therapeutic purposes and aimed to determine its impact on neurocognitive function and quality of life (QoL).

Methods: In this prospective study (2021-23), histopathologically proven 15 lung cancer patients requiring prophylactic cranial RT or WBRT due to brain metastasis (>5mm from hippocampus) were treated with HSWBRT. All patients underwent neurocognitive testing with Montreal Cognitive Assessment (MOCA) test, Trail A and B, Controlled Oral Word Association Test (COWAT), and QoL assessment with EORTC QLQ BN20 and C30 at baseline and then at 2, 4, 6, 9 and 12 months. The primary objective was to assess the neurocognitive function and QOL. Secondary objectives included determining intracranial relapse rates in those undergoing PCI, and overall survival (OS). These scores were compared with retrospectively collected QoL and neurocognitive scores of 15 lung cancer patients who underwent whole-brain radiotherapy without hippocampal avoidance (prophylactic or therapeutic). Differences between the baseline scores between the two groups were compared using the Chi-square test and the impact of HSWBRT was assessed using repeated measures ANOVA. Kaplan Meier curves were used for survival analysis and comparison between the two groups was done using log-rank test. All statistical analysis was done using SPSS version 23 and p-value<0.05 was considered as statistically significant. The trial has been approved by the Institute Ethics Committee (IEC/2021/SP6-865).

Results: There was no significant difference in the baseline characteristics of patients in HSWBRT and WBRT group. The median follow-up was 19 months (HSWBRT 14 vs WBRT 22, p=0.045) months. There was no significant difference in the intracranial relapse rates or overall survival between the two arms. There was no significant difference in the baseline cognitive function scores between the two arms but the risk of self-reported cognitive failure (as per QLQ C30) was lower in HSWBRT arm compared to WBRT at 12 months (scores at baseline 100 in both arms, 6 months 83.33 in both arms, 12 months: 83.33 in HSWBRT vs 66.67 in WBRT, p=0.072). Similar results were also observed in QoL analysis where the scores remained stable both at baseline and 6 months in HSWBRT arm but showed a steady decline in the WBRT arm (baseline 83.33 in both arms, 83.33 in HSWBRT vs 66.67 in WBRT, p=0.069). In the HSWBRT arm, the MOCA scores remained stable throughout even at 12 months post-treatment completion. Time required to complete Trails A and B test improved at 2 months post treatment completion in HWBRT arm (p=0.056 for Trail A and 0.06 for Trail B), then showed a slight non-significant rising trend at 4-6 months after which the scores were stable at 9 and 12 months and remained below the baseline value.

Conclusions: The utilization of HSWBRT in this study demonstrates promising outcomes in safeguarding neurocognitive function and enhancing quality of life without increase in intracranial relapse rates.

EP.13C.07 Long-Term Oncological Outcomes of Resected Bronchopulmonary Neuroendocrine Tumors

M.E. Cano, A.M. García Cardoso, J.J. Camargo, S.M. Camargo, J.C. Felicetti, A.C. Gonçalves Castelo, V.A. Livramento Jr, F.A. Perin, S.A. Soder, Hospital Santa Casa de Misericordia de Porto Alegre, Porto Alegre/BR

Introduction: Bronchopulmonary neuroendocrine tumors (bpNET) are well-differentiated malignancies with an overall favorable prognosis. Primary surgical resection is considered the gold standard treatment for this disease. The present study analyzes the results of lung resections for bpNET, both typical carcinoid (TC) and atypical carcinoid (AC), in a tertiary Thoracic Oncology Center.

Methods: A retrospective review of a single institution prospectively collected database was performed. Between January 2013 and December 2023, all consecutive patients (>18 years-old) who underwent curative-intent surgical resection for histopathological confirmed bronchopulmonary neuroendocrine tumors were included. Demographics, clinical, surgical and pathological data were evaluated. Patients were divided in two groups according to the histologic subtype. The primary outcome was long-term overall survival.

Results: A total of 142 patients were included, 124 with TC and 18 with AC. Baseline characteristics and comparisons for the two subgroups are described in Table 1. The median follow-up for all patients was 29 months (IQR 10-60). The median in-hospital length of stay was 4 days. Seventy-eight (54.9%) patients were approached using a video-assisted thoracic surgery (VATS) approach, requiring 10 conversions. Of the 142 patients analyzed, 4 bilobectomies, 68 lobectomies, 20 segmentectomies, 46 wedge resections, and 4 bronchial sleeve resections without lung resection were performed.Only 1 patient died because of bpNET. The 10-years overall survival was 71.6%. The mean survival time for the TC group was 116 months and for the AC group it was 89.6 months, (p=.209). Kaplan-Meier curves are shown in the

Conclusions: In this retrospective cohort study, we observed an overall favorable long-term prognosis for patients undergoing surgical resection for bpNET. There was a trend for longer median overall survival in the TC group comparative to the AC group, not achieving a statistically significant difference, possibly related to the study sample size.

EP.13C.08 Leukoencephalopathy and Brain Metastasis in LS-SCLC Patients with and without PCI after Curative Thoracic RT

A.I. Saito, Juntendo University Shool of Medicine, Tokyo/JP

Introduction: Our aim was to compare the risk of leukoencephalopathy and brain metastasis in patients with and without prophylactic cranial irradiation (PCI) of limited stage small cell lung cancer (LS).

Methods: Retrospective review of the chart from 2012 to 2022 was done for all LS patients who received curative thoracic radiotherapy (TRT) in our institution. Out of them patients who had undergone screening brain magnetic resonance imaging (MRI) before and after TRT was chosen. Overall survival (OS), progression free survival (PFS), brain metastasis free survival (BFS), and leukoencephalopathy worsening free survival was calculated and compared between the two groups. Pre-therapeutic and sequential MRIs after TRT were analyzed for leukoencephalopathy based on the modified Fazekas (MF) score by two neuroradiologists blinded to patients PCI use. MF score of one or more was regarded as worsening. Kaplan-Meier method and log rank test were used for the univariate and Cox regression analysis was used for the multivariate analysis.

Results: There were 15 female and 39 male. The median age was 67.5 (range: 50-78) years. Out of them two were patients of local recurrence after TRT. PCI was performed in 15 patients (PY) and omitted in 39 patients (PN). Median follow up was 61.5 (range: 53-293) months. MF before TRT was 1 in 45 patients, 2 in 5 patients and 3 in 4 patients. MF was worsened in 13 patients (PY 6, PN 7). OS showed a trend (5year, PY 93%, PN 66%, p=0.07) and, PFS (5year, PY 58%, PN 31%, p<0.01) and BMS (5year, PY 91%, PN 43%, p<0.01) showed statistically significant difference. These has not changed if, age, stage, recurrence/du novo were added as confounding variables in the multivariate analysis. MF scored worsening did not showed any significant difference (5year, PY 18%, PN 62%, p=0.21). This did not changed if age was added as a confounding variable in the multivariate analysis.

Conclusions: In this study the use of PCI for LS patients significantly reduced the PFS and BFS but even statistically not significant 40% of the patients in the PY showed worsening of the MF.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.13D.01 Prognostic Factors and Outcomes of Large Cell Neuroendocrine Carcinoma of Lung: A Single Center Retrospective Cohort Study

L.L.H. Sutanto, J.C.H. Chow, K.M. Cheung, H.Y.H. Yiu, Queen Elizabeth Hospital, Hong Kong/HK

Introduction: Pulmonary large cell neuroendocrine carcinoma (LCNEC) is a rare entity that is historically associated with poor outcomes and underrepresented in clinical trials. The molecular landscape and optimal treatment options and sequence are not well defined. Herein, we set out to review the prognostic factors and outcomes of patients with pulmonary LCNEC.

Methods: All consecutive patients with pulmonary LCNEC in 2000 - 2022 treated in single tertiary institution were reviewed. Clinical characteristics, molecular profile, treatment modalities and outcomes were recorded. Survival time was estimated with Kaplan-Meier analyses.

Results: Forty-one patients (35 male, 6 female) were included in this study. The median age at diagnosis was 66.4 years (43.3 - 85.7). A strong association with active smoking status was identified (32 patients, 78.0%, p = 0.002), in particularly for male patients (88.6% of male vs. 16.7% of female, p = 0.002). At diagnosis, twenty-eight patients (68.3%) were diagnosed with node positive disease, of which twenty-five (61%) were with N2 or above nodal status. Twelve patients (29.3%) had distant metastases at presentation. Twenty-five patients received definitive treatment, of which nineteen received surgery and eight patients received chemoirradiation (2 overlap between two groups). Eight patients (32.0%) received adjuvant chemotherapy after surgery, with the most common regime being Etoposide-platinum based. For those ineligibles for definitive treatment, twelve patients (80%) received palliative systemic therapy, with the majority exposing to etoposide-based chemo (66.7%) with a median response of 3 months. At a median follow-up of 8.4 years, twenty-one (85.2%) patients who underwent primary treatment developed disease recurrence. The median time to recurrence was 9.2 months (range, 3.2 - 30.1 months), and the 5-year recurrence free survival at 9.3%. The median overall survival of those who received surgery and chemoirradiation was 23.9 months and 14.8 months, respectively. The median overall survival of those who were ineligible for definitive treatment was 6.9 months (3.1 - 74.4 months). Male sex is suggested to be correlated with shorter survival (HR 8.5, p = 0.096), but smoking status (HR1.18, p = 0.882) and presence of mutation status (HR 1.37, p = 0.723) were not. Twenty patients had molecular diagnostic studies performed on their pathology specimens, and 6 patients (30.0%) were identified with druggable targets, namely EGFR mutation (3 patients), ALK overexpression (2 patients) and RET translocation (1 patient). Presence of druggable targets was found to be associated with female sex (female 75.0% vs. male 18.8%, p = 0.061) and in non-smokers (non-smoker 83.3% vs. smoker 7.1%, p = 0.02). All six patients eventually received corresponding palliative treatments with tyrosine kinase inhibitors, with five patients (83.3%) achieving at least partial response. The duration of response was variable, ranging from 2 months to 65 months.

Conclusions: Our series echoed the prior literature suggestions that LCNEC remain an aggressive subtype of non-small cell lung cancer with high recurrence rate post definitive treatment. Molecular diagnostic studies were able to identify druggable mutations in a sizable portion of patients that is higher than has been traditionally reported, highlighting a potential role of personalized treatment.

EP.13D.02 Low to Intermediate Grade Lung Neuroendocrine Tumours. A Single Centre Real World Experience

J. Martin[1], M. Alrehaili[2,3,4], H. Marginean[1], R. Goodwin[1,2,3], P. Wheatley-Price[1,2,3], [1]The Ottawa Hospital Research Institute, Ottawa/ON/CA, [2]University of Ottawa Division of Medical Oncology, Ottawa/ON/CA, [3]The Ottawa Hospital Cancer Centre, Ottawa/ON/CA, [4]Department of Medical Oncology, King Abdullah Medical City, Makkah/SA

Introduction: Lung neuroendocrine tumours (LNETs) are a rare heterogenous group of tumours with varying clinical behaviours, whose incidence has been increasing. We aimed to investigate the diagnosis, treatment, and survival patterns of patients with low to intermediate grade LNETs.

Methods: With ethics board approval, a retrospective chart review of patients with confirmed low to intermediate grade LNETs, treated at a Canadian tertiary level cancer centre from June 2010 to June 2021 was performed. Demographic, staging, treatment, and survival data were collected and analyzed.

Results: We identified 60 patients: median age 65.5; 68.3% female; average Charlson Comorbidity Index 3.5. Pathological grade was only available for 24/60 patients and differentiation available for 31/60 patients. Where reported, most were G1 (n=8) or G2 (n=10) and well (n=22) or moderately differentiated (n=8). Mitotic rate was frequently documented (n=45) and 51.7% had mitotic rates less than 2. Ki67 proliferative index was also commonly reported (n=53) with an index of less than 20% in 48/60 patients. Radiologic staging with octreotide scintigraphy was performed in 19 patients and Ga68 in only 5 patients. Forty-eight patients presented with local or locally advanced disease, of which 27 (56.2%) received curative intent surgery, with the rest receiving either radiation or palliative systemic treatment including chemotherapy or octreotide. The 5-year overall survival (OS) for those treated surgically was 84% compared to 44% in the non-surgical group. Metastatic disease was seen in 24/60 (40%) patients, with a 5-year OS in patients with stage 4 disease of 39%. Of those with advanced or unresectable disease (n=33), 26 received palliative systemic treatment with up to 3 lines of therapy. First-line treatment was most commonly chemotherapy with platinum and etoposide combination or somatostatin analogue therapy. Second-line treatment involved targeted everolimus in 5 patients and chemotherapy in 4. PRRT was also used once as a first-line and once as second-line therapy. Third-line included lanreotide or chemotherapy with capecitabine and temozolomide combination.

Conclusions: Overall, patients with surgically resectable disease had a good 5-year OS. However, inoperable or more advanced disease was associated with a poorer OS and despite a variety of different treatment options, the sequence of treatments is not well established. A number of patients received 1L chemotherapy despite low Ki67 %. This highlights the need for further research or treatment guidelines for LNET patients.

Sequence of palliative treatment options in patients with advanced or unresectable disease.

EP.13D.03 Prognostic Factors of First-Line Immune Checkpoint Inhibitors in Combination with Chemotherapy in Extensive-Stage Small Cell Lung Cancer

Y-T. Liao[1,2], R-L. Sun[1,2], H-C.H. Huang[1,2], C-I. Shen[1,2], Y-H. Tseng[1,2], Y-H. Luo[1,2], Y-M. Chen[1,2], C-L. Chiang[1,2], [1]Taipei Veterans General Hospital, Taipei/TW, [2]National Yang Ming Chiao Tung University, Taipei/TW

Introduction: Immune checkpoint inhibitors (ICIs) have demonstrated survival benefits when combined with platinum and etoposide (EP) in first-line (1L) treatment for extensive-stage small cell lung cancer (ES-SCLC). We investigated the real-world outcomes, adverse events (AEs), and prognostic factors of Taiwanese patients with ES-SCLC receiving 1L ICI + EP.

Methods: We analyzed the clinical characteristics, objective response rates, disease control rates (DCR), progression-free survival (PFS), overall survival (OS), and treatment-related AEs of patients with ES-SCLC who received ICI + EP or EP alone as 1L treatment.

Results: A total of 33 patients received ICI + EP, and 199 received EP alone. The 1L ICI + EP group had longer OS than did the 1L EP group (median: 13.93 months vs. 8.5 months, p = 0.003). Baseline liver metastasis was associated with shorter 1L PFS, whereas undergoing consolidative thoracic radiotherapy (cTRT) was associated with longer 1L PFS. Baseline liver metastasis, severe hematological AEs (grade equal or more than 3), and a neutrophil-to-lymphocyte ratio (NLR) of equal or more than 4 were associated with shorter OS.

Conclusions: Adding ICIs to 1L chemotherapy provides survival benefits in ES-SCLC, although patients receiving such therapy require close monitoring for AEs. Liver metastasis is associated with shorter PFS and OS, and cTRT may improve tumor control. Severe hematological AEs and an elevated NLR predict poor OS in patients with ES-SCLC.

EP.13D.04 The Conflicting Impacts of G-CSF on the Therapeutic Efficacy of Chemoimmunotherapy for Extensive Stage Small Cell Lung Cancer

Y. Tsukazaki[1], H. Ogino[1], Y. Okano[2], S. Kakiuchi[3], S. Harada[4], Y. Toyoda[5], Y. Matsumura[2], S. Ichihara[2], T. Imakura[3], R. Matsumoto[1], R. Ozaki[1], E. Ogawa[1], Y. Morita[1], A. Mitsuhashi[1], Y. Yabuki[1], H. Yoneda[1], M. Hanibuchi[1], K. Hase[4], E. Takeuchi[2], T. Haku[3], Y. Nishioka[1], [1]Graduate School of Biomedical Sciences, Tokushima University, [3-18-15], Kuramoto-cho, Tokushima [770-8503]/JP, [2]National Hospital Organization Kochi Hospital, [1-2-25] Asakuranishimachi, Kochi [780-8507]/JP, [3]Tokushima Prefectural Central Hospital, [1-10-3], Kuramoto-cho, Tokushima [770-8539]/JP, [4]Tokushima Municipal Hospital, [2-34] Kitajosanjima-cho, Tokushima [770-0812]/JP, [5]Japanese Red Cross Kochi Hospital, [1-4-63-11], Hadaminamimachi, Kochi [780-8562]/JP

Introduction: Granulocyte colony-stimulating factor (G-CSF) has been reported to attenuate the immune responses of T-cells by increasing immune suppressive neutrophils and myeloid-derived suppressor cells in preclinical models. However, the clinical impacts of G-CSF on the anti-tumor immune responses induced by immune checkpoint inhibitor (ICI) are still unknown. In this multi-center retrospective analysis, we investigated the impacts of G-CSF on the therapeutic efficacy of chemo-immunotherapy for extensive-stage small cell lung cancer (ES-SCLC).

Methods: We selected 65 patients with ES-SCLC who completed four cycles of induction chemo-immunotherapy (atezolizumab or durvalumab combined with carboplatin plus etoposide) in Tokushima University Hospital and four affiliated hospitals between January 2019 and July 2022. For reference, we also analyzed 67 patients with ES-SCLC who received more than four cycles of carboplatin plus etoposide (without ICI) in Tokushima University Hospital between 2010 and 2023. We evaluated the impacts of G-CSF on progression-free survival (PFS), overall survival (OS) and durable response to ICI which was defined as PFS ≥ 12 months. G-CSF administration was defined as the following classifications in this study; Classification A: use of any G-CSF (at least one dose of either filgrastim or pegfilgrastim), Classification B: use of at least one dose of pegfilgrastim, and Classification C: use of either more than five doses of filgrastim or at least one dose of pegfilgrastim.

Results: Among 65 patients who were treated with chemo-immunotherapy, 15 patients did not receive any G-CSF. Fifty, 26, or 38 patients were defined as G-CSF users in Classification A, B, or C, respectively. No significant differences in patient characteristics at baseline were found between the groups with or without G-CSF. The patients who received at least one dose of any G-CSF (Classification A) showed significantly poorer PFS than the patients who did not receive any G-CSF (median PFS 9.5 vs. 5.3 months, p=0.005). This result was consistent in other classifications (Classification B; median PFS 6.5 vs. 5.3 months, p=0.004, Classification C; median PFS 7.9 vs. 5.3 months, p=0.02). On the other hand, the administration of G-CSF did not influence on PFS of the patients who were treated with only chemotherapy (without ICIs). The patients who received any G-CSF tended to show poorer OS, however, no statistically significant difference was observed between two groups (median OS 26.4 vs. 17.8 months, p=0.139). In the multivariate analysis, the administration of G-CSF was associated with poorer PFS (hazard ratio [HR] 3.529, 95% CI 1.600-7.782, p=0.002), regardless the other variables such as dose intensity of chemotherapy. Furthermore, in the binomial logistic regression analysis, the administration of G-CSF was identified as a determinant factor for durable response (HR 0.161, 95% CI 0.037-0.714, p=0.016). Similar results were observed in the other classifications.

Conclusions: Our study suggests that the indication of G-CSF administration during chemo-immunotherapy should be carefully considered to avoid attenuating the therapeutic efficacy of chemo-immunotherapy in the patients with ES-SCLC.

EP.13D.05 Predictive Impact of Peripheral Blood Lymphocyte Subsets and Serum Markers in First-Line Immunotherapy for ES-SCLC——A Real-World Study

N. Wang[1], M. Tian[1], X. Song[2], [1]Shanxi Medical University, Taiyuan/CN, [2]Shanxi Provincial Cancer Hospital;Cancer Hospital of Chinese Academy of Medical Sciences Shanxi Hospital;Affiliated Cancer Hospital of Shanxi Medical University, Taiyuan/CN

Introduction: In recent years, the emergence of immune checkpoint inhibitors become the first-line treatment for extensive small cell lung cancer, which have brought new hope to patients with extensive small cell lung cancer.However, real-world data are still lacking, and the search for potential biomarkers is essential. Our research aimed to evaluate the effectiveness of first-line immune checkpoint inhibitors (ICIs) and explore the potential predictive markers including lymphocyte subsets and serum markers in peripheral blood.

Methods: In the "CAPTRA-LUNG" database(NCT03334864),a total of 278 ES-SCLC patients including the first-line ICIs plus platinum-containing chemotherapy patients (n=152) as the study group and the first-line simple chemotherapy patients (n=126) as the control group in the Shanxi Cancer Hospital from January 2020 to January 2023. Patients who applied first-line immunotherapy were collected clinical parameters, including tumor markers(NSE,CYFRA-211,PROGRP), inflammatory markers(NLR,PLR,LMR,SII,SIRI,ALI,LDH,ALB,A/G), lymphocyte subsets(CD3+CD45+T cells,CD3+CD4+T cells, CD3+CD8+ T cells, CD4+/CD8+, CD45+CD19+B cells, NK cells and Tregs cells). The follow-up deadline was January 20, 2024.

Results: There were significant differences in OS (mOS: 16.93m vs 14.0m,P<0.05) and PFS (mPFS: 9.17m vs 5.93m,P<0.05) among subgroups.The ORR of the study group and the control group were 79.5%and 64.3%, and the DCR was 91.7% and 85.7%, respectively.In the study group, there was significant difference in OS between the two groups (mOS:17.07m vs16.93m,P=0.0007)but no significant difference in PFS (mPFS:7.43mvs.10.20m,P=0.624).Multivariate analysis showed that NLR,ALI and A/G are risk factors for PFS. 91 of total ES-SCLC patients were evaluated peripheral blood lymphocyte subsets by flow cytometry before treatment with immune checkpoint inhibitors (ICIs),we didn't find any meaningful indicator related to PFS and OS unfortunately.

Conclusions: Our real-world data suggests that immune checkpoint inhibitors combined with platinum-containing chemotherapy as first-line treatment could be beneficial to the ORR, DCR, PFS, and OS of ES-SCLC patients with comparable safety.Baseline NLR,ALI and A/G have the potential to serve as biomarkers for immunotherapy in SCLC.

EP.13D.06 Factors Affecting Outcomes of Limited-Stage I, IIA (T1-T2, N0, M0) Small Cell Lung Cancer: An Analysis of the National Cancer Database.

H.M. Abdullah, A.C. Das, O.K. Abughanimeh, K-L. Muir, B.B. Sharma, A.S. Marr, L.M. Smith, A.K. Ganti, University of Nebraska Medical Center, Omaha/NE/USA

Introduction: Surgery is recommended for patients with early-stage small cell lung cancer (SCLC)(T1-T2, N0, M0). A retrospective analysis of the National Cancer Database (NCDB) was conducted to see factors associated with receipt of treatment and outcomes.

Methods: Patients with T1-2, N0, M0 (SCLC) diagnosed between 2010 and 2020, were identified from the NCDB. Data abstracted included: age, sex, race, type of insurance, facility type, and treatment. Factors associated with survival were assessed using the Cox proportional hazards model.

Results: For early stage I-IIA (T1-2, N0, M0) we identified 2602 patients <65 years of age, 8081 aged 65-75, and 1756 patients >75 years of age. The median overall survival (OS) for this group was 12.2 months (15.2, 13.4, and 6.6 months for the individual age groups respectively). Factors associated with a higher risk of death included age > 75 (HR= 1.28 P <0.001), age 65-75 (HR= 1.11 P = 0.001), male sex (HR= 1.17 P <0.001), year of diagnosis 2010-2015 (HR= 1.35 p < 0.001). When compared with Caucasians, Native Americans have worse OS (HR= 1.48 p=0.03) while Other races (which include Non-Caucasian, African American, or Native American races) have better OS (HR= 0.76 p=0.007). Patients who were recommended surgery but did not receive it (HR= 2.15 p- <0.001) and those who were not recommended surgery at all (HR= 2.18 p- <0.001) had worse outcomes compared to those who received surgery. A greater proportion of patients >75 were not recommended surgery compared to 65-75 and <65 years (57.92%, 45.76%, vs 47.27% respectively). A greater proportion of patients >75 years were not recommended radiation compared to those 65-75 and <65 years (16.57; 10.16; 7.38). A larger proportion of younger patients were treated in Academic/Research centers (30.33% vs 26.03% vs 23.12%). Analysis for patients who underwent surgery showed that OS was worse in patients who were > 75 years of age (HR= 1.37; P <0.001), 65-75 years (HR= 1.12; P <0.001) compared to younger patients. OS was also worse for uninsured patients (HR= 1.20; P = 0.02). On the other hand, Female patients (HR= 0.83; P < 0.001), Other races (HR= 0.49; P = 0.001), African American race (HR= 0.62 P = 0.02), treatment at Academic/Research Program (HR= 0.90 P = 0.04) and year of diagnosis 2016-2020 (HR= 0.72 P-value < 0.001) has better OS

Conclusions: For patients with T1-T2, N0, M0 small cell lung cancer, OS was lower for patients who were >75 years of age, male patients, and patients diagnosed between 2010-2015. Patients who received surgery had the best OS. Patients who were > 75 were less likely to be offered surgery or radiation. For patients who underwent surgery, OS was worse for older and uninsured patients. Female gender, age <65, diagnosis between 2016-2020, and treatment at an Academic/Research facility was associated with better OS.

EP.13D.07 Impact of Antiemetic Steroid Use on Survival in Small Cell Lung Cancer Patients with Immune Checkpoint Inhibitors and Chemotherapy Combination

S.M. Park[1,2], J. Jeong[2], Y.J. Kim[3], J-Y. Lee[2], [1]Seoul National University Bundang Hospital, Seongnam-si/KR, [2]Seoul National University, Seoul/KR, [3]Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam-si/KR

Introduction: First-line treatment for extensive stage small cell lung cancer (SCLC) often involves combination therapy with immune checkpoint inhibitors (ICIs) and conventional chemotherapy. The chemotherapy regimens combined with ICIs are mainly platinum-based compounds. These agents, being highly emetogenic, necessitate the use of prophylactic anti-emetic medications. However, antiemetic regimens often include steroids, known for their immunosuppressive properties, which can adversely affect the efficacy of ICIs. While the impact of steroids on ICI monotherapy has been extensively studied, there is a lack of information regarding their effects in combination therapy with ICIs. Therefore, this study aims to investigate the effects of prophylactic steroid use for anti-emetic purposes on the survival and treatment efficacy in patients with SCLC undergoing combination therapy.

Methods: This retrospective cohort study utilized data from the National Health Insurance Service, focusing on patients diagnosed with lung cancer between August 2020 and June 2022 who received treatment with atezolizumab, etoposide, and carboplatin. The study estimated the use of antiemetic steroids, specifically dexamethasone, within a 4-day window following chemotherapy administration. Patients were categorized into three groups based on the steroid dosage: low (0-12mg of dexamethasone), moderate (13-24mg), and high (25-36mg). We conducted a 3:1:1 propensity score matching across these groups to assess the impact of anti-emetic steroid dosage on overall survival (OS) and time to next treatment (TTNT).

Results: A total of 3,186 patients were initially identified for the study. After a 3:1:1 propensity score matching, the analysis included 1,425 patients in the low dose group, 475 in the moderate dose group, and 475 in the high dose group. Median OS and TTNT were 8.7 months (interquartile range [IQR], 5.0-13.9) and 6.5 months (IQR, 4.0-11.4) in the low group, 8.2 months (IQR, 5.0-13.2) and 6.6 months (IQR, 4.1-10.3) in the moderate group, and 8.2 months (IQR, 4.3-12.9) and 6.8 months (IQR, 3.7-11.2) in the high group, respectively, with no statistically significant differences between the groups. The 1-year overall survival rate was 31.7% in the low group and 27.8% in the high group. When the analysis was expanded to include total steroid dose for other purposes, patients receiving doses of 36 mg or greater had significantly increased hazard ratios for OS (1.27 [95% CI, 1.13-1.44]) and TTNT (1.25 [95% CI, 1.12-1.39]).

Conclusions: The dosage of antiemetic steroids used in combination therapy with ICIs and chemotherapy does not appear to have a significant impact on survival and treatment response in SCLC. However, the total administration of larger dosages of steroids, including for purposes other than antiemetics can significantly affect outcomes. Further investigation is warranted to explore the nuances of steroid use in cancer therapy.

EP.13D.08 Impact of Thoracic Radiotherapy on First-Line Treatment Outcomes in ES-SCLC Patients

M. Xiaoli[1], L. Yan[2], [1]West China Hospital, Sichuan University, Chengdu/CN, [2]Lung cancer center, Chengdu/CN

Introduction: The therapeutic advantage of thoracic radiotherapy (tRT) as an adjunct to first-line immunotherapy and chemotherapy in patients with extensive-stage small cell lung cancer (ES-SCLC) remains unclear. We sought to elucidate this in a retrospective cohort study comparing the effectiveness and safety of tRT in combination with first-line immunotherapy and chemotherapy.

Methods: Our retrospective study included patients with ES-SCLC, treated at the West China Hospital between January 2019 and December 2022. They received first-line immunotherapy and chemotherapy and were categorized into two cohorts based on the administration of tRT. The primary outcomes were overall survival (OS) and progression-free survival (PFS). Cox regression analysis was utilized to identify potential independent predictors of prognosis and to compare the treatment outcomes across various patient subgroups. Treatment-related toxicities across both cohorts were compared using the Chi-square test.

Results: Out of 99 patients eligible for the study, 55 received tRT. The median duration of follow-up was 23 months. Remarkably, patients who received tRT demonstrated superior OS and PFS in comparison to those who did not (P<0.001). Subgroup analysis confirmed these findings. Multivariate analysis identified staging and treatment group as independent prognostic factors (P<0.05). The incidence of grade 3-4 adverse events showed no statistically significant difference between the two cohorts.

Conclusions: Thus we confirm that the addition of tRT to the conventional regimen of first-line chemotherapy and immunotherapy yields better survival outcomes without a significant increase in toxicity.

Provencio[2], [1]University of Santiago de Compostela, Santiago de Compostela/ES, [2]Hospital Universitario Puerta de Hierro, Madrid/ES, [3]Regional and Virgen de la Victoria University Hospitals, Málaga/ES, [4]Hospital Universitario Insular de Gran Canaria, Las Palmas de Gran Canaria/ES, [5]Institut Català D'Oncologia Badalona- Hospital Germans Trias i Pujol, Badalona/ES, [6]Hospital Clínico Universitario de Valladolid, Valladolid/ES, [7]Complejo Hospitalario Universitario A Coruña, A Coruña/ES, [8]Hospital Universitario Virgen del Rocio, Sevilla/ES, [9]Catalan Institute of Oncology, Hospital Universitari Dr. Josep Trueta and Precision Oncology Group (OncoGIR-Pro), Institut d'Investigacions Biomèdiques de Girona (IDIBGI), Girona/ES, [10]Hospital General Universitario Dr. Balmis de Alicante, Alicante/ES, [11]Hospital Universitario Fundación Jiménez Díaz. IIS, Madrid/ES, [12]Hospital General Universitario de Valencia, Valencia/ES, [13]Hospital Universitario de Jaén, Jaén/ES

Introduction: Small cell lung cancer (SCLC) is the most aggressive histological type of lung cancer, with a one-year survival rate of 35.6% and a five-year survival rate of 7.9%. SCLC is strongly associated with tobacco use and there is limited scientific evidence available on this type of lung cancer in never smokers. Thus, the objective of this study was to characterize subjects diagnosed with SCLC who have never smoked and to analyze their survival.

Methods: The main data source was the Thoracic Tumor Registry of the Spanish Lung Cancer Group, which is representative of lung cancer cases diagnosed in Spain by age and sex. Patients have been recruited since 2016 by oncologists in more than 80 participating hospitals. SCLC cases in never smokers were included in this analysis. Descriptive analysis was performed on their characteristics, as well as their symptoms at diagnosis, globally and according to the stage of the disease (extended or limited). To analyse survival, we performed a time-dependent analysis using the Kaplan-Meier survival analysis.

Results:

A total of 86 never-smoking SCLC cases were included, comprising 2.7% of all lung cancer cases registered among never smokers. Median age at diagnosis was 71.0 years (interquartilic range 59.0-78.0 years) and 69.8% were women. Of the 86 cases included, 61 (70.9%) had extended SCLC and 59 (68.6%) had at least one comorbidity at diagnosis. Fourteen (16.3%) cases were exposed to environmental tobacco smoke at home in the past 20 years and 3.5% indicated that their longest occupation was in agriculture/farming or professional cleaning. Cough was the most common symptom at diagnosis (34.1%). There were no significant differences between the frequency of any symptom at diagnosis according to disease stage. Overall, one-year survival rate was 47.1% (95% Confidence Interval (95%CI) 35-59%), 66.0% (CI95% 41.3-82.2%) and 37.9% (CI95% 24.1-51.6%) for limited and extended SCLC, respectively ($p<0.05$) (Figure 1).

Conclusions: SCLC in never smokers is more frequent in women compared to men and almost two out of three of these patients present extended disease at diagnosis. One-year survival rate is lower in extended compared to limited SCLC.

EP.13D.10 Breast Metastases from Small Cell Lung Carcinoma

J.I. Mikov[1,2], G. Stojanović[1], N. Lalić[1,2], A. Tepavac[1], M. Bugarčić[1,2], I. Čanak[1,2], D. Sazdanić Velikić[1,2], [1]Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica/RS, [2]Faculty of Medicine, University of Novi Sad, Novi Sad/RS

Introduction: Metastases are the leading cause of morbidity and mortality in cancer patients. Small cell lung carcinoma (SCLC) accounts for approximately 15% of all lung tumors and is considered a systemic disease, often presenting with distant metastases at the time of diagnosis.

Methods: Case report of metastasis of small cell lung carcinoma.

Results: A 73-year-old female patient was hospitalized in July 2021 for diagnostic evaluation of radiologically detected changes in the right lung lobe. A chest CT scan revealed a soft tissue mass in the right lung lobe in segment 2 measuring 47x37 mm, with enlarged lymph nodes at positions 10R and 4R with diameters up to 21 mm. Bronchoscopy was performed, revealing a tumor (possibly compressive) in the depth of the right segment 2. Histopathological examination of bronchial biopsy from the tumor and transbronchial puncture through the tumor and lymph nodes at positions 10R and 4R confirmed a diagnosis of small cell lung carcinoma, clinical stage T3N2M0. Upon decision of the Oncology Council, she received chemotherapy according to the PE protocol, four cycles, on November 5, 2021, followed by radiotherapy with a dose of 52Gy/26 fractions on April 8, 2022. A CT scan of the head was performed on November 21, 2022, for planning prophylactic cranial radiotherapy, revealing a 3cm diameter frontal right lesion with perifocal edema, most likely representing a secondary deposit. In January 2023, palliative radiotherapy to the cranium was administered. Upon admission, a change involving the entire left breast and another round lesion in the left anterior axillary line were observed. Both lesions were subjected to puncture, and cytological analysis confirmed metastases of small cell lung carcinoma.

Conclusions: Breast metastases are rare, and it is important to differentiate between primary and metastatic breast malignancy, which influences further therapeutic planning.

EP.13D.11 Proportion and Characterization of Pulmonary Neuroendocrine Carcinoma via Synaptopysin IHC

A.C. Putra, G. Setiawan, S.L. Andarini, R. Beginta, Faculty of Medicine, Universitas Indonesia-National Respiratory Center Persahabatan Hospital, Jakarta/ID

Introduction: Pulmonary neuroendocrine carcinoma represents a significant entity within the spectrum of lung cancers, characterized by diverse biological behaviors and prognosis. The diagnosis and subclassification of neuroendocrine tumors rely heavily on immunohistochemical markers, among which Synaptopysin stands out for its specificity. This study aims to determine the proportion of pulmonary neuroendocrine carcinoma and its subtypes through Synaptopysin immunohistochemistry at Persahabatan Hospital National Respiratory Center, thereby contributing to refined diagnostic accuracy and therapeutic strategies.

Methods: This cross-sectional descriptive study retrospectively analyzed the medical records of patients diagnosed with pulmonary neuroendocrine neoplasms through histopathological examination at the oncology clinic of Persahabatan Hospital National Respiratory Center from January 2019 to May 2023. Immunohistochemistry using Synaptopysin was conducted to confirm the diagnosis. Data on patient demographics, smoking history, and clinical outcomes were also collected to ascertain the characteristics of the neuroendocrine carcinoma population within the study setting.

Results: Out of 50 samples analyzed, a significant proportion demonstrated positive Synaptopysin expression, indicative of neuroendocrine differentiation. The study found that the majority of patients with neuroendocrine carcinoma were male, aged ≥60 years, with a heavy smoking history, emphasizing the potential etiological role of tobacco in neuroendocrine tumor development. The histopathological analysis revealed a diverse distribution of neuroendocrine tumor subtypes, with small cell lung carcinoma and large cell neuroendocrine carcinoma representing the high-grade variants in the cohort. The application of Synaptopysin IHC not only confirmed the neuroendocrine nature of the tumors but also facilitated the accurate subclassification essential for guiding therapeutic decisions.

Conclusions: The significant proportion of Synaptopysin-positive pulmonary neuroendocrine carcinomas at Persahabatan Hospital National Respiratory Center underscores the prevalence and diagnostic challenge of these tumors. Immunohistochemistry with Synaptopysin proves to be a crucial tool in the confirmation and subclassification of pulmonary neuroendocrine neoplasms, aiding in the development of targeted treatment approaches. This study highlights the importance of comprehensive diagnostic protocols that include Synaptopysin IHC in the effective management of neuroendocrine carcinoma patients, contributing to the body of knowledge on the epidemiology and pathology of these tumors within the Indonesian context.

Introduction: The landscape of extensive disease small cell lung cancer (ED-SCLC) management has changed over the last several years with the addition of immunotherapy to platinum-doublet chemotherapy following results from the pivotal trials (CASPIAN and IMpower133). Translating these trials into clinical practice requires an understanding of how similar outcomes of the control arms of these trials are to the real-world setting. Contextualizing the potential benefit of these new immunotherapies for funders also requires an understanding of the potential prognostic factors in ED-SCLC.

Methods: There were 1,964 patients analyzed, from 19 sites across Europe, North America, and Asia in the harmonized international lung cancer consortium (ILCCO) dataset, who were diagnosed with ED-SCLC between 1990 and 2020 and have available stage and clinicodemographic data. Cox regression models were generated to evaluate potential prognostic factors for overall survival (OS). Median follow-up time was measured in years using the reverse Kaplan-Meier method.

Results: Data was acquired from 12 North American, 6 European and 1 Asian studies. Median age was 65 years (interquartile-range: 58-72) and 90% were White, 47% had a cardiometabolic comorbidity, of which 13% had diabetes and 40% had a respiratory comorbidity, including 25% with COPD. With a mature median follow-up of 8.6 years, median OS was 10.3 months (95% CI: 10.0, 10.9). The Kaplan Meier survival curve for all patients with ED-SCLC, and survival probabilities for different ED-SCLC time cohorts defined by year of diagnosis are presented in the figure. In univariate analyses, being male, a former smoker (vs current), and being 70+ years were each associated with having poorer OS (at p<0.05). In multivariate analysis, poorer OS was associated with male sex, HR=1.39 (95% CI: 1.22, 1.57; p<0.001) and older age, HR (per 10 year increase) = 1.22 (1.14, 1.30; p<0.001). OS did not vary across the year of diagnosis or cohort time.

Conclusions: Disappointingly, overall survival in ED-SCLC has not changed in the 30 years prior to the introduction of immunotherapy. When comparing aggregate OS in our international cohort of patients from across the world to the standard of care arms in the CASPIAN and IMPOWER133 studies, we observed identical median OS of 10.3 months. Further, our demographics were similar to these trials: predominantly male, white, in their 60s and ever-smokers. Our international, multi-site real-world data supports the global generalizability of the CASPIAN and IMpower133 trial results.

EP.13D.13 Exploring COVID-19's Impact on Treatment and Survival in Small Cell Lung Cancer

L. Hou[1], A. Sood[1], W.Y. Aung[1], S.H. Peketi[2], J. Elengickal[3], M. Locke[1], X. Zou[1], A. Sangari[4], N. Seetharamu[5], [1]North Shore University Hospital at Northwell Health, Manhasset/NY/USA, [2]Nassau University Medical Center, East Meadow/NY/USA, [3]Prisma Health-Midlands, Columbia/SC/USA, [4]Stony Brook University, Stony Brook/NY/USA, [5]Northwell Health Cancer Institute, New Hyde Park/NY/USA

Introduction: Emerging data has indicated that the COVID-19 pandemic severely impacted patients with cancer. Descriptive analyses have found the 30-day mortality rate in patients with newly diagnosed small cell lung cancer (SCLC) significantly increased with the pandemic. However, little research has explored the effect of COVID-19 infection on mortality or adverse outcomes associated with chemoimmunotherapy treatment. This analysis aims to fill this gap.

Methods: We conducted a propensity score-matched, retrospective study focusing on patients diagnosed with small cell lung cancer (SCLC) undergoing chemotherapy or immunotherapy after January 1, 2019. We utilized datasets from the TriNetX database and the US Collaborative Network, which includes 60 healthcare organizations. We performed propensity score matching accounting for variables including age, race, gender, and existing comorbidities. The primary objective was to assess risk of mortality at 1 and 3 years, with secondary aim focusing on the incidence of adverse events related to their cancer treatments.

Results: The initial study population consisted of 98 patients with a diagnosis of SCLC and a concurrent COVID-19 positive status, and 649 SCLC patients who were COVID-19 negative. After propensity score matching, the analytic cohort consisted of 86 matched patients. For the outcome of overall mortality at the 1-year interval, the COVID-19 positive group demonstrated a significant decrease in the relative risk (RR) of mortality at 0.73 (95% CI: [0.54, 0.98], $p<0.03$). However, at the 3-year mark, the reduction in mortality risk was not statistically significant, with an RR of 0.87 (95% CI: [0.70, 1.08], $p<0.20$). For the outcome of adverse effects of chemoimmunotherapy, there was no significant difference between the COVID-19 positive and negative groups at 1-year (RR 1.3, 95% CI:[0.87, 1.85], $p<0.22$) or 3-year mark (RR 1.3, 95% CI: [0.90, 1.83], $p<0.17$).

Conclusions: This retrospective analysis showed no significance of COVID infection on mortality at three years and adverse effects of chemoimmunotherapy over both 1 and 3-year periods. The significant decrease in mortality at 1-year with COVID-19 was unexpected, but potentially suggestive of an overlapping benefit from the supportive therapies traditionally employed in the management of SCLC and COVID-19. This convergence in treatment modalities may have inadvertently contributed to improved survival rates, underscoring the importance of a multidisciplinary approach in patient care and the potential for cross-application of therapeutic strategies. This study's limitations include inherent constraints of retrospective reviews such as the limited ability to establish causality, biases from variations in staging data availability, and diverse coding practices among healthcare providers. Future studies can include analyses of COVID-19 vaccination status to better understand its role in survival and treatment outcomes.

EP.13E.01 Genetic Landscape and Prognostic Markers of Small Cell Lung Cancer: A Comprehensive Study

W. Guan[1,2,3], G. Qiu[1,2,3], W. Zhou[1,2,3], M. Liu[1,2,3], C. Zhou[1,2,3], [1]the First Affiliated Hospital of Guangzhou Medical University, Guangzhou/CN, [2]Guangzhou Institute of Respiratory Health, Guangzhou/CN, [3]National Center for Respiratory Medicine, Guangzhou/CN

Introduction: Preliminary analysis at the genetic and molecular levels has provided us with in-depth insights into small cell lung cancer. However, the correlation between genomic profiles and clinical characteristics, differences in genetic profiles between Eastern and Western populations, and genomic alterations before and after frontline treatment remain unclear.

Methods: A retrospective analysis was conducted on 88 patients with pathologically confirmed SCLC, who underwent various chemotherapy or immunotherapy treatments at different clinical stages. Genomic profiling of these patients was carried out utilizing a next-generation sequencing-based gene panel. Additionally, a cohort of Western population samples from a public database was randomly enrolled to explore genetic differences between Eastern and Western populations.

Results: In the study cohort, there were 15 female and 73 male participants, with a median age of 64.5 years (range: 58-70). Among them, 56 were current or former smokers, with a median smoke index of 800 (range: 300-1400).In the cohort receiving chemotherapy combined with PD1 or PD-L1 inhibitors, patients with PD-L1 TPS ≥1% exhibited improved progression-free survival (PFS) compared to those with TPS <1%, a trend not observed in the chemotherapy-alone group. Across all treatment modalities, patients harboring mutations in the MAPK pathway demonstrated improved overall survival (OS) (Multivariate Cox analysis: HR: 0.0905, 95% CI: 0.0125-0.656, P=0.0175), while those with mTOR/Ras pathway mutations within the chemotherapy group experienced compromised PFS. Moreover, patients with baseline mutations in the PI3K-Akt pathway in the chemotherapy arm displayed improved PFS. However, no significant disparities in PFS and OS were discerned based on tumor mutational burden (TMB) levels. Analysis of specific gene variants unveiled associations between certain mutations (KDR/KIT, CSF3R, RICTOR, MNT2D) and adverse prognostic outcomes. Patients with concurrent TP53/RB1 mutations manifested a higher incidence of LRP1B mutations compared to those with sole TP53 mutations, although the latter exhibited higher PD-L1 expression level than the former. Chromosomal instability and whole-genome duplication were correlated with advancing age. Additionally, smokers displayed a heightened prevalence of SMAD4 mutations, whereas females exhibited a greater frequency of EGFR mutations. A subset of 43 Chinese and 49 Western individuals was randomly recruited. Both Chinese and Western SCLC populations were predominately male smokers around 65 years old, with TMBs averaging 8.5 mutations/Mb. In the Western cohort, mutation frequencies in CSMD3, NAV3, CSMD1, EP300, and PCDH11X were significantly elevated compared to those in the Chinese cohort; however, KMT2D, KMT2C, and PRKDC mutations were more prevalent in the Chinese group. Notably, the NHEJ pathway exhibited markedly higher mutation rates in the Western population. Comparative analysis of genomic alterations pre- and post-first-line treatment was performed in three advance-stage SCLC patients. Patient 1, treated with etoposide and carboplatin, exhibited AKT1 CN_amp upon recurrence. Patient 2, subjected to EC with atezolizumab, displayed TMPRSS2_p.R289H post-treatment, along with deletions at the INSF_p.M531I, FGFR1_p.S109T, and JAK1_p.H421Y loci. Patient 3 demonstrated MYC amp loss following etoposide and afatinib therapy.

Conclusions: This study provides insights into the gene profile and prognosis of SCLC in Chinese patients, emphasizing the importance of understanding ethnic variations and individualizing treatment strategies.

Introduction: Although chemoimmunotherapy (Chemo-IO) is the standard of care in patients with extended-disease small cell lung cancer (ED-SCLC), the prolongation of progression-free survival (PFS) was almost one month. To explore the potential biomarkers of efficacy, we conducted this analysis.

Methods: APOLLO-Bio (UMIN000039600) is the translational analysis of APOLLO study: a multi-centered, prospective study to explore the efficacy and safety in ED-SCLC patients with Chemo-IO in the real-world data setting (Fujimoto D, JAMA Network Open 2023). Of 207 participants, we collected 137 formalin-fixed paraffin-embedded specimen and DNA and RNA were extracted. Gene alterations and expression were analyzed using next-generation sequencing. Immunohistochemistry (IHC) was stained for ASCL1, NEUROD1, YAP1, and POU2F3. Clinical information was integrated to explored the predictive biomarker of response with Chemo-IO.

Results: Patients background was as follows: median age was 73, 83% was male, and 97% had smoking history. Overall PFS and overall survival were 5.0 months and 14.8 months, respectively. Primary lung lesion was the most common site of specimen collection (68%), followed by lymph nodes (22%) and others (10%). Of those, 94.6% had at least one gene alteration and TP53 (73%), RB1 (33%), and EPHB4 (25%) mutations were frequently observed. Median tumor mutation burden was 3 (range, 0-11). KMT2D mutation was found in 10% of patients and mostly co-occurred with TP53 mutation. Patients with TP53 and KMT2D mutation had significantly worse PFS compared with those with TP53 mutation only or TP53 wild-type (HR 2.07-2.27, $p < 0.05$). Regarding IHC, ASCL1- or NEUROD1-positive populations were dominant (48 patients, each) and others were either positive for POU2F3, or YAP1 (18 and 4 patients, respectively). Patients with ASCL1 / NEUROD1-negative by IHC tended to have shorter median PFS (3.94 months) than NEUROD1-, or ASCL1-positive groups (5.72 and 5.06 months, respectively). Through the hierarchical clustering by gene expression profile, we could categorize patients into two groups. Although their prognosis did not significantly differ, one group mainly consisted of patients with ASCL1 / NEUROD1-negative by IHC. Finally, we compared the gene expression profile between long responders (PFS ≥ 360 days) and non-responders (PFS < 60, or 90 days) and found that genes encode immunoglobulin receptor-binding, chemokines and IDO activity were significantly upregulated in long-responders. Gene set enrichment analysis demonstrated that interferon-related and JAK-STAT signaling pathway were upregulated in long-responders.

Conclusions: This multi-omics study revealed the potential of molecular subtyping in patients with ED-SCLC who receive Chemo-IO.

EP.13E.03 ASCL1 Regulated by HDAC1/RBBP7 Inactivates Gsk3ß to Reverse Drug Resistance in Small Cell Lung Cancer

l. guo, x. zhou, Zhujiang Hospital, Southern Medical University, guangzhou/CN

Introduction: Achaete-scute homolog 1 (ASCL1) is a transcription factor with a helix-loop-helix (bHLH) domain. Numerous studies have reported that ASCL1 is crucial for neuronal differentiation and the early development of neuroendocrine progenitor cells. regulatory mechanism of ASCL1 in chemosensitivity remains elusive. In this study, we aim to investigate the biological function, mechanism and clinical significance of ASCL1 in small cell lung cancer (SCLC).

Methods: Differentially expressed ASCL1 between chemoresistant and chemosensitive cell lines were identified using qRT-PCR and Western Blot. The functional roles of ASCL1 and its structural fragments were demonstrated through a series of in vitro and in vivo experiments. Co-immunoprecipitation (quantitative proteomic analyses), serial deletion analysis, and luciferase assays were employed to investigate the potential mechanisms of ASCL1.

Results: The results revealed that ASCL1 expression was significantly downregulated in chemoresistant cell lines compared to parental chemosensitive cell lines. In a cell-derived xenograft model, both ASCL1 and ASCL1 (B) enhanced the chemosensitivity of small cell lung cancer. Overexpression of Ascl1-mutant eliminated the original chemosensitivity function of ASCL1, further specifying the specific region of chemosensitivity function. In exploring the underlying interaction between HDAC1/RBBP7 and ASCL1, we identified that the bHLH domain was acetylated at lysine 156 on ASCL1 by the NuRD complex (HDAC1/RBBP7), thereby promoting Ser9 phosphorylation on GSK3β and inhibiting tumor stemness and EMT.

Conclusions: In summary, our findings demonstrate the essential role of ASCL1 regulated by HDAC1/RBBP7 in inactivating GSK3β and inhibiting tumor stemness and EMT, thereby reversing SCLC chemoresistance, and providing insights toward a better understanding of the mechanism of resistance to chemotherapy drugs of SCLC.

EP.13E.04 Racial Disparities in Genomic Subtypes of Small Cell Lung Cancer Patients

M.M. Godbole, F. Abu Rous, S. Ghosh, D. Chitale, S. Gadgeel, Henry Ford Health, Detroit/MI/USA

Introduction: Recent studies have identified 4 distinct subtypes of small cell lung cancer (SCLC) defined by the expression of several transcription factors. Immunohistochemistry (IHC) based analysis can help define these genomic subtypes. Previous analyses included very few samples from Black patients with SCLC. We present the initial results of IHC expression of relevant transcription factors in tumor samples from Black and White SCLC patients.

Methods: SCLC patients diagnosed between January 2018 and January 2023 at Henry Ford Health were included. Demographics, including self-defined race, clinical characteristics and therapeutic details were retrieved from electronic medical record. A tissue microarray (TMA) was constructed using standard published protocols (1.0 mm cores in triplicate). The constructed TMA and an additional subset of whole sections were used for IHC staining for ASCL1, NEUROD1, POU2F3 and YAP1. IHC scoring was performed using H-score (score >10 was considered positive). Chi-square statistics and independent t-test was used for statistical analysis in the SPSS 28 software.

Results: Of 258 patients with SCLC, adequate tissue for IHC scoring of all transcriptional factors was obtained for 58 patients (32 on TMA; 26 on whole sections). Of these, 28 were male and 30 female, mean age was 68 years (range: 52-86). 98% of patients were current or former smokers. Nine patients were Black and 49 were White. No statistical differences were observed for demographics, stage at diagnosis and presence of brain metastases between Black and White patients. YAP1 expression was more common in tumors of Black patients compared to tumors of White patients (33% vs 12%, p=0.136), while the expression of POU2F3 (0 vs 13%, p=0.575) and NEUROD1 (22% vs 45%, p=0.282) were more common in White patients. Positivity for more than one marker was noted in 22% of Black vs 8% of White patients (p=0.231). POU2F3 negative patients had significantly better overall survival than positive patients (p=0.034). Other markers did not show a statistically significant difference in survival. Survival analysis stratified by race was not conducted due to limited sample size.

Conclusions: The initial results of our study show that the prevalence of genomic subsets of SCLC defined by IHC expression of relevant transcription factors differs between self-defined Black and White patients. We are evaluating more samples to confirm our initial results. If these differences persist with further analysis, this data could suggest differences in SCLC biology among different racial groups and may have therapeutic implications.

Comparison between White vs Black patients

EP.13E.05 Proteomics Profiling Reveals the Metastasis Mechanism of Small Cell Lung Cancer

H. Shi, H. zhu, J. Lu, K. Zhu, X. Hu, National Clinical Research Center for Cancer Cancer Hospital, Beijing/CN

Introduction: Small cell lung cancer (SCLC) is a highly metastatic and recalcitrant malignancy with poor overall survival, while the molecular biological mechanisms underlying its aggressive characterization still remains largely unexplored.

Methods: In order to comprehensively explore molecular mechanisms of SCLC metastasis, we performed an unbiased proteomic study of 111 SCLC tumor samples, including 85 primary tumors, 15 patient-matched lymph node metastatic tumors and 11 brain metastatic tumors. All of the FFPE specimens were obtained from patients who underwent surgical resections. Liquid chromatography tandem mass spectrometry analysis was conducted based on the data-independent acquisition method. Unsupervised clustering and pathway enrichment analysis were performed to reveal the heterogeneity of protein expression profiling.

Results: 31 primary tumors, 54 primary tumors and 26 metastatic tumors were respectively assigned to non-potential metastatic (NMp) group, potential metastatic (Mp) group and metastatic (M) group, in which Mp and M group were clustered together. This was also supported by the results of the Uniform Manifold Approximation and Projection dimension reduction. Following Gene set enrichment analysis, proteomaps, protein-protein interactions network and two-dimensional annotation enrichment analysis of the significant differentially expressed proteins between different groups (NMp vs Mp, NMp vs M) revealed the strikingly biological resemblance of the protein profile between the Mp group and the M group. The NMp group was dominated by higher levels of cell adhesion, extracellular matrix, extracellular exosome, lipid metabolism and immune stimulation-related proteins, while the Mp group and the M group were enriched in pathways associated with cell cycle, cell division and chromosome.

Conclusions: There are distinct metastatic potentials between NMp and Mp groups, which could be further utilized to explore the metastasis mechanism of small cell lung cancer.

EP.14A.01 Prospective Analysis of Patterns of Care and Clinical Outcomes for People Diagnosed with Mesothelioma in Australia

S. Harden[1,2,3], D. Samankula[2], S. Tissera[2], M. Lloyd[2], V. Hamilton[4], B. Healey[4], K. Healey[4], E. MacFarlane[2], K. Walker-Bone[2], S. Muruganandan[5], B. Dunne[6], T. John[1], F. Brims[7], R. Stirling[2], J. Zalcberg[2], [1]Peter MacCallum Cancer Centre, Melbourne/AU, [2]Monash University, Melbourne/AU, [3]University of Melbourne, Melbourne/AU, [4]Asbestos Council of Victoria/GARDS, Moe/AU, [5]Northern Health, Melbourne/AU, [6]Royal Melbourne Hospital, Melbourne/AU, [7]Curtin University, Perth/AU

Introduction: The Victorian Mesothelioma Outcomes Registry (VMOR) was set up in 2022 to collect clinical information and report on standards of care for people diagnosed with mesothelioma across the state, linked to an established lung cancer registry (VLCR). Australia has a high incidence of mesothelioma and the aim of this state-based registry was to collect additional clinical information about quality of care, not routinely collected by the federal Australian Mesothelioma Registry.

Methods: Hospital Health Information Services thoracic cancer coding extracts received by the VLCR for 2022 were prospectively analysed to identify patients diagnosed with mesothelioma (ICD C45). Data was collected and entered into a secure database for the following variables: diagnosis, clinical staging, co-morbidities, performance status, treatment planning, surgery, radiatiotherapy, systemic anti-cancer therapy (SACT) including chemotherapy and immunotherapy, palliative and supportive care and overall survival. Baseline VMOR reporting included assessing the feasibility of reporting on ten key clinical quality indicators (CQIs) identified through a national modified Delphi process run through TOGA (Thoracic Oncology Group Australasia) for benchmarking care: time from referral to diagnosis, discussion at a multidisciplinary meeting (MDM), documentation of asbestos exposure, performance status and histologic sub-typing, receipt of systemic anti-cancer therapy (SACT), access to a cancer nurse specialist for support, evidence of supportive care screening and (for pleural mesothelioma only) definitive management of pleural effusion and use of pleural-phase contrast CT for diagnosis.

Results: 105 participants diagnosed with mesothelioma in 2022 from 19 health services were registered into VMOR. Median age at diagnosis was 76 years (IQR 67-82), 81% were male, 92% with pleural mesothelioma. 59% participants had referral to diagnosis in under 28 days, 67% were presented at an MDM, 94% had histologic subtype documented (60% epithelioid). 77% had a documented performance status and 65% documentation of prior asbestos exposure in medical records. Active treatment including SACT (59%), radical surgery (6%) and radiotherapy (13%) was received in combination by 69%, with 31% receiving supportive care alone. 30% had access to a cancer nurse specialist and 28% a record of supportive care screening. For pleural mesothelioma 18% had definitive effusion management. It was feasible for VMOR to collect 9/10 CQIs but not possible to ascertain use of pleural phase contrast CT based on granularity of current data collection methods. One year overall survival was 19% for the whole cohort, and significantly higher 31% (HR 4.29 p<0.001) for those receiving SACT compared to those who did not.

Conclusions: This real-world data supports clinical trials showing improved survival for people diagnosed with mesothelioma who receive SACT and offers an opportunity to understand reasons why people did not receive SACT and variation across health services. Increasing the proportion of mesothelioma cases discussed at an MDM may help increase active treatment and access to clinical trials. Our findings highlight an unmet need to increase support for people diagnosed with this high burden disease and their carers, in particular access to cancer nurse specialists. A customised patient survey has also been introduced for 2023 to explore this further.

EP.14A.02 Prognostic Factors in Malignant Pleural Mesothelioma Patients Receiving First-Line Chemotherapy: A Baseline Risk Score

A. Guijosa[1], W. Muñoz-Montaño[1], R. Trejo-Rosales[2], A.P. Gómez-García[1], L.A. Cabrera-Miranda[1], D. Flores[1], O. Arrieta[1], [1]National Cancer Institute Mexico (INCan), Mexico City/MX, [2]National Medical Center, Century XXI, IMSS, Mexico City/MX

Introduction: Malignant Pleural Mesothelioma (MPM) is a highly aggressive cancer with a dismal prognosis, often detected at advanced stages where systemic modalities are the mainstay, with chemotherapy remaining the most commonly used therapy. Prognostic assessment is crucial for balancing chemotherapy's adverse effects with its survival benefits and for guiding treatment decisions, but the interplay of multiple factors complicates it. Traditional prognostic scores like EORTC and CALGB have limitations, especially in reflecting contemporary chemotherapy regimens and demographic diversity, while newer scores often depend on novel biomarkers that are not widely accessible or validated. Our study aimed to develop a simple and effective prognostic score for patients with MPM, based on readily available clinical and laboratory data.

Methods: A retrospective study was conducted at two large Mexican cancer centers. It included patients with unresectable MPM who received first-line chemotherapy from 2010 to 2023. We evaluated baseline variables from electronic medical records and their relationship with overall survival (OS) and progression-free survival (PFS). Variables with prognostic value identified through univariate analysis and subsequently confirmed as independent factors in a Cox-proportional hazard model were used to create a weighted baseline-risk score. The score's performance in predicting 1-year OS was compared with CALGB and EORTC scores using the area under the curve (AUC) of receiver operating characteristic (ROC) curves. Its prognostic capacity in creating distinct groups was assessed through Kaplan-Meier analysis.

Results: Among 262 patients (69.1% male, 80.5% with epithelioid histology), a 0-7 point PLECH score was developed based on five variables: Platelet count (P: +2), high LDH (L: +1), ECOG ≥ 2 (E: +1), Chest pain at diagnosis (C: +2), and non-epithelioid Histology (H: +1). The score had an AUC of 0.70 for predicting 1-year OS, outperforming CALGB and EORTC scores (0.60 and 0.57, respectively), with an optimal cutoff of 2.5 (sensitivity 75%, specificity 55%). Patients with a high-score (≥3) had significantly shorter OS (12.3 vs. 20.1 months; p<0.001) and PFS (6.4 vs. 11.3 months; p<0.001) compared to those with a low score. Significance was maintained when evaluating patients from both centers independently.

Conclusions: The PLECH score, developed from a substantial cohort, offers a straightforward and accessible prognostic tool for MPM patients, surpassing traditional scores in our demographic. It identifies a "high-risk" group potentially unsuited for conventional chemotherapy, suggesting that alternative treatment strategies could enhance their survival and quality of life.

EP.14A.03 Analyzing the Impact of COVID-19 Infection on Adverse Outcomes in Mesothelioma: A Multicenter Study

A. Sood[1], L. Hou[1], W. Aung[1], J. Elengickal[2], S.H. Peketi[3], M. Locke[1], X. Zou[1], A. Sangari[4], N. Seetharamu[5], [1]Northwell Health, Manhasset/NY/USA, [2]Prisma Health, Columbia/SC/USA, [3]Nassau University Medical Center, East Meadow/NY/USA, [4]Stony Brook Medicine, Stony Brook/NY/USA, [5]Northwell Health Cancer Institute, New Hyde Park/NY/USA

Introduction: Little research has explored how COVID-19 affects the efficacy and side effects of mesothelioma treatments. This multicenter propensity matched retrospective cohort study, the largest of its kind, aims to explore the effect of COVID-19 infection on risk of mortality and adverse outcomes of chemotherapy and immunotherapy in patients being treated for mesothelioma.

Methods: Data were gathered from the TriNetX database and the US Collaborative Network, which includes 60 healthcare organizations. A propensity-matched retrospective cohort study was conducted on patients with mesothelioma undergoing treatment. Patients were divided into two cohorts based on their COVID-19 status and treatment: those treated for mesothelioma with immunochemotherapy without a positive COVID-19 test (unmatched n=819, matched= 128) and those undergoing the same treatments with a positive COVID-19 test (unmatched n=137, matched = 129). Cohorts were matched for age, race, sex, and comorbidities The study focused on post-infection outcomes at one and three years, with mortality as the primary endpoint, and adverse effects of immunotherapy/chemotherapy as the secondary endpoint.

Results: Risk of mortality did not change with COVID infection: relative risk of mortality at one year was 0.70 (95% CI: [0.46, 1.07], p<0.094), and at three years, relative risk was 1.03 (95% CI: [0.75, 1.41], p<0.86). COVID infection did not increase risk of adverse events associated with immunochemotherapy treatment: Relative risk of adverse effects of immunotherapy/chemotherapy was 0.81 at one year (95% CI: [0.48, 1.36], p<0.42) and 0.83 at three years (95% CI: [0.51, 1.34], p<0.44).

Conclusions: Mesothelioma patients experienced stable outcomes across risk for mortality and adverse events of treatment over the course of the study. The results suggest that COVID-19 infections were not substantially associated with an increased risk of mortality or adverse events associated with immunochemotherapy, contrary to early concerns regarding immunosuppression and inflammation associated with COVID-19 as potential exacerbators of cancer progression. However, this study faces limitations, including the inherent challenges of database research such as variations in ICD coding, as well as other limitations in staging data and treatment variations. Future research exploring the long-term inflammatory effects of COVID-19 and its interaction with chronic inflammation in mesothelioma is required, as well exploration into COVID-19 related complications such as hospitalization, mechanical ventilation, and venous thromboembolism.

EP.14A.04 Microbial Supernatant Library Screening Suggested that Induction of Ferroptosis is an Effective Therapeutic Strategy Against Mesothelioma

Y. Sekido, T. Sato, Aichi Cancer Center Research Institute, Nagoya/JP

Introduction: Therapeutic drugs for mesothelioma are limited, and there is a need to identify and develop novel agents. Ferroptosis is a programmed cell death caused by iron ion-dependent lipid peroxidation. Induction of ferroptosis in mesothelioma cells is considered as a novel therapeutic strategy, but the mechanism determining susceptibility to ferroptosis remains unclear.

Methods: Fifteen human mesothelioma cell lines and four immortalized mesothelial cell lines were used. The library of 1,188 soil- and marine soil-derived microbial supernatant used to search for new candidate agents was provided by Kitasato University, Japan. Mesothelioma cells were spread in 96 wells, 1/100 volume of microbial supernatant was added, and calorimetric assay was performed after 72 hrs. Substances in the supernatant that showed growth inhibitory effects were separated by HPLC and their structures were analyzed by NMR. RSL3 was used as the ferroptosis inducer. Ferroptosis induction was determined by nonapoptotic cell death, increased lipid peroxidation levels, and inhibition by a ferroptosis inhibitor, ferrostatin-1. Gene knockdown was performed by shRNA transfection using lentivirus.

Results: The microbial supernatant library screening was performed to examine induction of cell death in three mesothelioma cell lines and one immortalized mesothelial cell line, which revealed supernatants that specifically cause cell death of mesothelioma cell lines. NMR analysis of the supernatant identified Brefeldin A. Using the purified compound of Brefeldin A, we confirmed that it is a strong cell death inducer of mesothelioma cells and that the cell killing effect of Brefeldin A is not apoptosis, but rather ferroptosis. Since Brefeldin A is highly toxic and future clinical development is difficult, we proceeded with the analysis using a known ferroptosis inducer, RSL3. We detected that easy induction of ferroptosis was detected in approximately 40% of the mesothelioma cell line panel. In contrast, immortalized mesothelial cells and the other 60% of cell lines showed resistance. Comprehensive gene expression analysis of the ferroptosis-sensitive and non-sensitive cell lines identified 13 genes that were significantly up-regulated in the sensitive lines and 9 genes that were down-regulated. Knockdown of each of these genes was examined for changes in susceptibility to ferroptosis. Currently, candidate genes involved in susceptibility have been picked up and their detailed mechanisms are under investigation.

Conclusions: Microbial supernatant library screening suggested that small molecular compounds that induce ferroptosis in mesothelioma cells are important for the development of novel drugs against mesothelioma. Furthermore, our results suggest that the expression of specific genes is involved in the susceptibility of mesothelioma cells to ferroptosis.

EP.14A.05 Targeting ADAR1 for Mesothelioma Therapy

B. Jacobson, E. Stoian, R. Khadlikar, K. Lan, H. Saveraid, A. Sehgal, M. Patel, R. Kratzke, University of Minnesota, Minneapolis/MN/USA

Introduction: Adenosine deaminase for double-stranded RNA 1 (ADAR1) is proposed to be an important protein in promoting cancer development and growth. In melanoma and colon cancer models, inhibition of ADAR1 by shRNA leads to markedly improved response to immune therapy in murine models and delayed tumor growth. In addition, tumor-derived type I interferon (IFN) primes cancer cells for susceptibility to immune checkpoint therapies following ADAR1 loss. ADAR1 is highly expressed in malignant mesothelioma, and in this context is hypothesized to play a role in the development of the cancer phenotype. While the role of ADAR1 in cancer is complex, it is possible that a targeting strategy for ADAR1 in mesothelioma cells may generate a robust response and lead to impaired tumor growth.

Methods: ADAR1 gene editing was carried out by CRISPR/Cas9 in the AB12, 40L, H2373, and H2461 cell lines. Sequencing and western blot analyses were carried out to confirm loss of ADAR1. Tumor formation was assessed in syngeneic, nude, and NSG mouse models. In addition, evaluation of interferon response was carried out by western blot analyses. A to I editing was confirmed by RNA-seq analyses.

Results: ADAR1 gene editing by CRISPR/Cas9 was confirmed with sequencing and western blot in both murine (40L and AB12) and human (H2373 and H2461) mesothelioma cells. For 40L ADAR1 knockout (40LKO), there was complete abrogation of tumorigenicity in syngeneic immune competent mice as well as athymic and NSG mice, suggesting that the mechanism of ADAR1 mediated tumorigenesis is not dependent on the presence of an intact immune response. AB12KO (in BALB/c mice) tumor formation was observed, however these were markedly smaller and slower growing compared to parental AB12 tumors. H2373KO formed small tumors when compared to parent cells when xenografted into nude mice As ADAR1 is involved in regulation of interferon (IFN) response, we further examined downstream interferon response genes after interferon beta stimulation (IFNβ) for both the parent and KO cells. ADAR1 parent and KO cells express similar levels of phospho- and total STAT1 and PKR in the presence of IFNβ stimulation. In addition, elf2alpha was not activated or induced by IFNβ. H2373 and the KO cells were IFNβ treated or left untreated in triplicate and RNA-seq analysis was performed. Genes were identified that were differentially expressed and the clustering pattern determined. Also, the level of A to I editing was evaluated indicating a difference between the parent and the knockout cells. Finally, the effect of blocking the in vivo interferon response on the tumorigenic phenotype in both the parental and KO cells was assessed.

Conclusions: ADAR1 silencing is a strong signal in mesothelioma cells reversing the tumorigenic phenotype. The loss of tumorigenicity is unlikely to be dependent on T cell related responses but possibly is mediated through interferon response pathways. In light of abrogation of tumor formation being less dependent on immune factors, specific therapies targeting the adenosine deaminase activity of ADAR1 may prove attractive in mesothelioma therapy.

EP.14A.06 Outcome of Multimodality Therapy Including Radical Surgical Treatment for Malignant Pleural Mesothelioma at a Japanese Regional Institution

R. Waseda, Y. Ueda, S. Miyahara, Y. Masuda, H. Nakashima, T. Sato, Fukuoka University, Fukuoka/JP

Introduction: The role of surgical therapy for malignant pleural mesothelioma (MPM), including the results of the MARS trials, is currently controversial. On the other hand, excellent results of multimodality treatment including radical surgery have been reported mainly from leading centers in Japan. It has been suggested that the size of the facility and the caseload may play an important role in the outcome of treatment for MPM. In the present study, we report the results of multimodality treatment at our institution, which is a medium-sized regional institution in Japan.

Methods: Of the 110 patients diagnosed with MPM at our institution during the 15-year period from 2009 to 2023, 25 received multimodality treatment including radical surgical treatment with extra pleural pneumonectomy (EPP) or pleurectomy/decortication (P/D). The patients who ended up with exploratory thoracotomy were excluded. These 25 cases were retrospectively reviewed in detail based on clinicopathological parameters and the survival outcome was analyzed focusing on changes of treatment strategy and the surgical procedure. Survival duration was defined as the date of death or last confirmed date of survival from the start of treatment.

Results: The mean age of all 25 patients was 65.2 ± 8.7 (48-79) years, 24 were male and 1 female, and the pathologic types of mesothelioma were 17 epithelioid, 6 biphasic, 1 sarcomatoid, and 1 other. Regarding pathologic stage (UICC ver. 8), 21 patients had stage IB disease, 1 patient with stage IIIA, and the remaining 3 had stage IIIB.As for surgical procedure, EPP was performed in 13 patients and P/D in 12 cases. In terms of the treatment era, 10 cases were treated in the first 8 years and 15 cases in the second 7 years. Regarding surgical procedure, P/D was performed in only one case in the early era, but 11 patients underwent P/D in the second era. In the second half, all patients received any chemotherapy including immunocheckpoint inhibitor prior to surgery. No surgical mortality was observed in the cohort. Major morbidity occurred in 5 patients, 4 of them were observed in the early era.13 death were observed in the series, only one of which was due to COVID-19, but all the others were due to progression of MPM. The median survival time (MST) for all patients was 30.3 months (95% CI: 20.6-169.8), with 1-year OS 79%, 2-year 68%, 3-year 47%, and 5-year 24%. Comparing survival outcomes in the first and second treatment era, MST in the first era was 19.8M (95%CI: 2.7-43.3) and MST in the second era was significantly longer (p=0.01) with 42.3 months (95%CI: 28.7-67.9), 1-year OS 93%, 2-year 93%, 3-year 58% and 5-year 29% in the second era.

Conclusions: The outcomes of multimodality therapy for MPM including radical surgical treatment at our institution were acceptable enough compared to other reported outcomes or historical results, although the cohort may have been biased. Additionally, in the latter seven years, treatment outcomes have clearly improved. However, there are still issues regarding long-term survival.

EP.14A.07 Molecular Characterization and Validation of Live Cell Biobank for Pleural Mesothelioma

M. Meerang[1], M.B. Kirschner[1], F. Schlaepfer[1], M. Ronner[1], E. Felley-Bosco[1], I. Schmitt-Opitz[1], [1]University Hospital Zurich, Zurich/CH

Introduction: The use of tumor derived primary cell cultures for research approaches, especially for in vitro drug testing, can overcome the drawbacks of long-term cultures of cell lines. Here we aim to fully characterize 228 pleural mesothelioma (PM) low passage primary cell cultures generated over the past 16 years at our hospital. In addition to data presented at ESTS 2024, we have completed the cultivation of all available cell cultures and performed analyses in many more cultures.

Methods: For the identification of tumor cells, we performed a stepwise characterization. To exclude fibroblasts, we evaluated epithelial cell origin by immunohistochemical staining (IHC) of pan-Cytokeratin (pan-CK) in FFPE cellblocks. Pan-CK staining intensity was scored as weak (1), moderate (2) and strong (3). Finally, histo (H)-score (sum of intensity multiplied with % positive cells, range 0-300) was calculated. We performed cell growth characterization using colorimetric assay for cell metabolic activity (MTT assay).

Results: We have taken all the frozen stock cells to grow in culture using our established workflow. 132 primary cultures (57.9%) grew after thawing and we could generate more frozen aliquots. Median pan-CK H-score analyzed from 106 primary cultures was 79.6 and ranged from 0-300 (figure 1a). Among them, 34 primary cultures have an H-score over 150. The doubling time, analyzed from 121 cell cultures, ranged from 37-1136 hours (median 89.7 hours) (figure 1b).

Conclusions: We have successfully re-cultured a large number of primary cell stocks, and shown that the doubling time is within a good range for future experiments. Only pan-CK high expressing cell cultures (H-score >150) will be selected for further staining with additional PM tumor markers by IHC compared to the original tumor tissues. The cultures with concordant marker expression compared to the original will be further selected for assessment of copy number variation assay for the final validation. These primary cells represent an invaluable tool for the future use as translational research model for PM.

Keywords: Primary culture, mesothelioma

EP.14A.08 Pleural Mesothelioma: Changes the 9th TNM Staging Brought,a Critical Appraisal of the Clinical T-Stage

Y. Kahya, G. Kocaman, S. Dursun, A. Kayı Cangır, Ankara University Faculty of Medicine, Ankara/TR

Introduction: Debate regarding the diagnosis, treatment and staging of pleural mesothelioma (PM) is still ongoing. Based on the PM 9th TNM Staging Project of the International Association for the Study of Lung Cancer (IASLC), pleural thickness is the main component to determine the clinical T-stage. However, there is not enough information about the clinical T-stage of PM patients with pleural effusion alone without pleural thickening. This study investigates how survival would be affected in the absence of pleural thickening in PM patients.

Methods: This study included 34 patients between 2009 and 2021 who received multimodal treatment including Pleurectomy/Decortication (P/D). Age, gender, tumour localization, preoperative Computed Tomography findings [(Patients were divided into two groups as the ones with pleural thickening (PT) and pleural effusion (PE)], histological subtypes, pathological stage, and overall survival were evaluated. For statistical analysis, 23.0 software (IBM Corp., Armonk, NY, USA) was used. Median survival was calculated with Kaplan-Meier analysis. A confidence level %95 and a P-value of <0.05 were accepted as statistically significant.

Results: The demographical, clinical and pathological data are summarized in Table 1, and no significant statistical difference was to be found between the groups (p>0.05). The median follow-up time was 30.5 months. The 2-year overall survival was calculated as 63.3% for all patients, 66.7% and 62% for the PE and PT groups, respectively (p = 0.28).

Conclusions: The cardinal issue regarding PM staging is an incompatibility between clinical and pathological staging. The main goal of the 9th TNM staging is to redefine clinical T-stage descriptors to eliminate this inconsistency and to reveal clear survival differences between stages. Hence, T-stage groups were defined by using tumour thickness measurements at different levels of the thorax by utilizing computed tomography. This study reveals that the survival of PM patients with only pleural effusion without pleural thickening is similar to those with present pleural thickening. This group of patients may be included as a brand new T stage descriptor with future staging studies to come feasibly.

EP.14A.09 Influence of Post-Pleurectomy/Decortication Peritoneal Dissemination Recurrence of Pleural Mesothelioma on Long-Term Survival

A. Nakamura, M. Hashimoto, A. Fukuda, K. Takegahara, A. Kuroda, S. Matsumoto, N. Kondo, S. Funaki, S. Hasegawa, Hyogo Medical University, Nishinomiya/JP

Introduction: In clinical practice, peritoneal dissemination after curative-intent surgery for pleural mesothelioma occasionally recurs. We aimed to investigate the risk factors and prognosis associated with post-pleurectomy/decortication peritoneal dissemination in pleural mesothelioma, which is rarely reported.

Methods: In this retrospective review, we included 160 patients who experienced recurrence after pleurectomy/decortication for pleural mesothelioma between January 2011 and December 2021. Patients with recurrence were classified according to the initial recurrence pattern: the P group developed recurrence with peritoneal dissemination, and the non-P group developed recurrence without peritoneal dissemination. We determined the risk factors of peritoneal dissemination by multivariable analysis. Survival was analysed using the Kaplan-Meier method and log-rank test.

Results: Of the 160 patients, 20 (12.5%) exhibited peritoneal dissemination and were assigned to the P group, whereas 140 (87.5%) had recurrence without peritoneal dissemination and were assigned to the non-P group. Multivariable analysis revealed that female sex (odds ratio 3.7, 95% confidence interval 1.26-10.8, p = 0.017) and diaphragm reconstruction (odds ratio 2.8, 95% confidence interval 1.0-8.0, p = 0.048) were associated with the P group. Post-recurrence survival was worse in the P group than in the non-P group (1-year post-recurrence survival: 22.2% vs 65.3%, median: 6.7 months vs 19.4 months, p = 0.0013).

Conclusions: Peritoneal dissemination occurred in approximately one in every eight patients with recurrence after pleurectomy/decortication for pleural mesothelioma, and the incidence was significantly higher in females and patients undergoing diaphragm reconstruction. Moreover, post-operative recurrence of peritoneal dissemination was associated with poor prognosis.

EP.14A.10 The Impact of Serum-Based Inflammatory Biomarkers on Tumor Proliferation and Prognosis in Malignant Pleural Mesothelioma

R. Sumitomo[1], T. Menju[1], H. Sakai[2], H. Date[1], [1]Graduate School of Medicine, Kyoto University, Kyoto/JP, [2]Hyogo prefectural Amagasaki general medical center, Amagasaki/JP

Introduction: Malignant pleural mesothelioma (MPM) is a highly aggressive disease with a poor prognosis. However, prognostic biomarkers for MPM patients are not yet fully understood. This study aims to evaluate the impact of serum-based inflammatory biomarkers on tumor proliferation and prognosis in MPM patients.

Methods: A total of 83 MPM patients diagnosed from 1998 to 2010 were studied. Tumor proliferation was evaluated using the Ki-67 proliferation index. The cut-off values for pretreatment levels of white blood cell count, neutrophil count, lymphocyte count, platelet count, C-reactive protein, neutrophil-to-lymphocyte ratio, platelet-to-lymphocyte ratio (PLR), and systemic immune-inflammation index (SII, platelet count × neutrophil count / lymphocyte count) were determined using receiver operating characteristic curve analysis for predicting 5-year survival. Univariate and multivariate Cox regression analyses were performed to estimate the prognostic impact of parameters on 5-year overall survival (OS).

Results: There were 45 epithelioid, 22 sarcomatoid, and 16 biphasic types. Patients were distributed as follows: 10 in stage I, 14 in stage II, 26 in stage III, and 33 in stage IV. Twenty-three cases underwent surgical treatment, and all of them were treated with extrapleural pneumonectomy. The mean ± standard deviation of the Ki-67 proliferation index in MPM samples was 43.5 ± 31.5%. The median OS was 15.0 months. Platelet count was significantly associated with the Ki-67 proliferation index in MPM cells. In univariate analysis, platelet count, PLR, and SII were significant prognostic factors. Multivariate Cox regression analyses revealed platelet count and PLR as significant prognostic factors for 5-year OS, after adjusting for clinicopathological factors.

Conclusions: Among serum-based inflammatory biomarkers, platelet count may be a useful prognostic marker related to tumor proliferation in MPM patients.

EP.14A.11 Mortality Based on Treatment in Stage III Non-Epithelioid Pleural and Pericardial Mesothelioma - A Review from a National Cohort

J.W. Zweigle, R. Mohamed, S.A. Batoo, M. Qadir, Brody School of Medicine at East Carolina University, Greenville/NC/USA

Introduction: Mesothelioma is a rare condition with an extremely high mortality rate. The epithelioid pathology pattern has previously been associated with significantly better outcomes and responses to treatment when compared to the non-epithelioid patterns. Since immunotherapy was introduced as a preferred treatment option in mesothelioma, data on patients who are not eligible for treatment has been difficult to obtain. This study aimed to evaluate mortality outcomes in these patients with stage III non-epithelioid mesothelioma using the Surveillance, Epidemiology, and End Results (SEER) database.

Methods: The SEER*Stat software was utilized to extract data on patients diagnosed with pleural and pericardial non-epithelioid mesothelioma (ICD-O-3 codes 8810, 8811, 8820, 8821) between 2004 and 2017. The patients were further categorized by stage (III) and treatment received (chemotherapy alone, surgery alone, surgery with chemotherapy, or no chemotherapy or surgery). The primary outcome was overall survival (OS), analyzed using Kaplan-Meier curves and compared with hazard ratios (HR) with a 95% confidence interval (CI). These outcomes were calculated using SPSS software.

Results: Of the patients (n=872) diagnosed with stage III non-epithelioid mesothelioma with known survival, 53.9% were under the age of 75, 80.2% were male and 13.0% received some form of radiation therapy. Of those who received surgery (n=250), 62.8% were under 75, 80.0% were male and 35.6% had a total pneumonectomy. The 3-year survival for patients who did not receive chemotherapy or surgery was 9.7%. The mortality of patients who received chemotherapy and surgical treatment as well as surgery alone was significantly better than those who did not receive these treatments (Figure 1), especially in the first year. Those who received chemotherapy alone did not receive any significant benefit from treatment.

Conclusions: The benefit of surgical treatment noted in this study with and without chemotherapy has not been noted previously in patients with stage III non-epithelioid mesothelioma. The survival of the patients receiving surgery with stage III disease was like a previous study from Flores et al. in 2008 showing a median survival of 11 months for their patients overall with worse results in non-epithelioid histology. This new data may improve our understanding of surgical treatment in these patients and may provide evidence for further exploration of surgical treatment of these patients.

Keywords: Mesothelioma, Non-Epithelioid, Survival

Treatment	Patients (%)	Hazard Ratio (95% CI)	1-Year Survival (p-value)	2-Year Survival (p-value)	3-Year Survival (p-value)
No Chemotherapy or Surgery	341 (39.1)	--	32.8%	14.1%	9.7%
Chemotherapy Alone	281 (32.2)	1.06 (0.897-1.25)	26.3% (0.078)	13.9% (0.944)	7.8% (0.419)
Surgery Alone	95 (10.9)	0.857 (0.759-0.968)	44.2% (0.040)	20.0% (0.157)	12.6% (0.403)
Chemotherapy and Surgery	155 (17.8)	0.922 (0.864-0.985)	40.9% (<0.001)	16.1% (0.550)	6.5% (0.237)

EP.14A.12 Impact of a Multidisciplinary Team on Overall Survival in Patients with Pleural Mesothelioma: Experience from a Single Institution in Mexico

S. Campos-Gomez[1], J. Esquivel-Gutierrez[2], A. Mandujando[2], E. Gomez[2], E. Escobedo[2], A. Morales[2], D. Martinez[2], A.M. Mendoza[2], A. Ovando[2], M. Gonzalez[2], K.A. Campos[2], [1]Centro Oncológico Estatal ISSEMyM, Monterrey/MX, [2]Centro Oncologico Estatal ISSEMYM, Toluca/MX

Introduction: Pleural mesothelioma is a complex disease that often requires specialized treatment approaches. Multidisciplinary team (MDT) provide patients with access to a wide range of expertise and resources that may not be available in a single medical specialty or institution. The MDT for thoracic malignancies was established in 2014 in our center.

Methods: All cases diagnosed between January 2011-January 2023 were assigned to pre- and post- MDT intervention cohorts. Local databases were the source of the data extraction. Overall survival was recorded from date of first suspicious imaging to death. A 12-months follow-up was conducted on all cases. Kaplan-Meier survival analysis and the log-rank test were used to calculate OS. Univariate and multivariate analysis to identify variables associated with OS were assessed using Cox regression model. The data capture and statistical analysis will be carried out in the SPSS v.20 program (SPSS Inc,Chicago, IL, USA).

Results: We evaluated a total of 49 patients. The median age for the patients was 53.1 ± 13.4 years old. Patients comprised 83.8 % males and 16.1 % female; male/female ratio: 1/0.26). By WHO classification criteria for pleural tumor, 80.6% of the tumors were epithelioid cell type and 19.4 % nonepithelioid cell type. Among these patients, 29% were classified as stage III and 71% stage IV. According to pre and post MDT, 15 (30 %) were pre and 34 (70 %) post MDT group. Median OS of patients in the pre and post MDT were 9.9 and 22 months, respectively. The Kaplan Meier method and log-rank test indicated that MDT intervention was associated with superior OS (p=0.032).

Conclusions: The establishment of MDT is associated with improved overall mean survival. Our results may be explained by improved access to more specialized care, novel therapies, advanced surgical techniques and supportive care services, more research is needed. These findings supports a boader adoption of MDT.

Keywords: pleural mesothelioma, survival, MDT

EP.14A.13 Gender and Racial Disparities in Hospitalization and Outcomes of Malignant Mesothelioma in the United States

M. Imeh[1], A. Gvajaia[1], S. Murthy[1], F. Uwumiro[2], C. Amaeshi[3], [1]Lincoln Medical and Mental Health Center, Bronx/NY/USA, [2]University of Benin teaching Hospital, Benin/NG, [3]Montefiore Medical Center, Bronx/NY/USA

Introduction: Research on sex and racial disparities in-hospital outcomes for Malignant mesothelioma (MM) hospitalizations is limited. This study examined disparities in hospitalization and outcomes for MM by sex and race across the United States.

Methods: The nationwide inpatient sample was queried from 2017 to 2020 using relevant ICD-10 diagnostic codes. All adult hospitalizations for MM were included. Baseline characteristics and in-hospital outcomes in patients with a primary diagnosis of malignant mesothelioma were compared between males and females and between white and nonwhite patients using Pearson's $\chi 2$ tests and linear regression for categorical and continuous variables. Multivariable logistic regression models adjusted for potential confounding factors and statistically significant comorbidities between the two cohorts.

Results: Approximately 35,230 hospitalizations for malignant mesothelioma were identified and analyzed. Of these, 24,585 (69.8%) were male and 10,645 (30.2%) were female. Approximately 25,885 (73.5%) were white compared with 9,345 (26.5%) nonwhite individuals. Male patients were significantly older and had a higher comorbidity burden than females (Charlson score of ≥3: 71% vs. 59.4%; P<0.001; Table 1). A total of 3,900 mortalities were recorded during the study period. Male sex (aOR: 1.23; 95% CI: 1.01-1.37; P=0.043) and older age (aOR: 1.01; 95% CI: 1.01-1.02; P=0.001) were significantly correlated with greater odds of mortality. Race was not a significant modifier of mortality odds. Compared with hospitalizations for male and white individuals, females (mean LOS: 9.3 vs. 7.7; P<0.0001) and nonwhite individuals (mean LOS: 10.7 vs. 7.3; P<0.0001) were hospitalized for longer durations. White race was associated with significantly lower hospital costs compared with nonwhite individuals ($97,464 vs. $167,715; P<0.001). Females incurred greater costs than males ($135,864 vs. $107,520; P<0.001). Female sex was associated with lower odds of any arrhythmias (aOR: 0.82; 95% CI: 0.71-0.94; P = 0.004) and greater odds of depression (aOR: 2.13; 95% CI: 1.06-4.25; P = 0.004), atelectasis (aOR: 1.68; 95% CI: 1.08-1.80; P = 0.035), and generalized anxiety (aOR: 1.98; 95% CI: 1.10-3.57; P = 0.023). Race was not significantly correlated with the risk of respiratory failure, atelectasis, or heart failure.

Conclusions: Male sex was significantly correlated with a greater risk of mortality from malignant mesothelioma. Female sex was significantly correlated with poorer outcomes, except mortality, compared with men. White race was correlated with longer hospital stays and higher hospital costs than nonwhite individuals with malignant mesothelioma.

EP.14A.14 Clinical Insights and Survival Outcomes of Malignant Pleural Mesothelioma: An Experience from a Tertiary Care Centre in India

A. Sharma, S. Upadhya, S. Khurana, D. Pushpam, S. Kumar, D. Jain, S. Thulkar, A. Kumar, B. Kataria, N.K. Gupta, J. Saikia, A. Singhal, A. Nambirajan, P.S. Malik, All India Institute of Medical Sciences, New Delhi/IN

Introduction: Malignant pleural mesothelioma (MPM), a rare cancer comprising only 0.13% of cancer incidences in India has dismal survival. There is limited literature on clinicopathological profile and treatment outcomes of MPM in India, with scant information primarily confined to few case reports.

Methods: This is a retrospective cohort study conducted at a tertiary care cancer centre from north India. Case records of patients of MPM treated between January 2016 and July 2023 were analysed for clinicopathological profile and treatment outcomes. Response rates, progression-free survival (PFS) and overall survival (OS) were recorded. Descriptive statistics were employed for clinicopathological characteristics, and Kaplan-Meier analysis assessed survival.

Results: A total of 25 patients were identified with MPM, with a median age of 48 years and a male-to-female ratio of 1.3. Asbestos exposure was documented in only 8 (32%) cases. Common symptoms included breathlessness (72%), cough, and chest pain (64% each). Predominant histology was epithelioid, seen in 21 (84%) patients followed by biphasic and sarcomatoid, in 3 (12%) and 1 (4%) patients, respectively. Majority of the patients (64%) presented with a metastatic disease. Of 25 patients 18 (72%) received systemic chemotherapy, with pemetrexed-platinum (either cis- or carbo-platin). Among them 4 (22.2%) patients received bevacizumab as maintenance. Objective response rate (ORR) for first-line systemic therapy was 44.4% with a clinical benefit rate of 83.3%. Extrapleural pneumonectomy was performed in 4 (16%) patients. 10 patients received subsequent lines of systemic therapy which included immunotherapy (nivolumab + ipilimumab), gemcitabine (with or without bevacizumab) and oral metronomic therapy (containing cyclophosphamide, etoposide and pazopanib). Median PFS and OS for patients receiving systemic therapy were 14.6 (95% CI: 6.9 - 22.3) and 26 (95% CI: 23.3 - 28.7) months, respectively.

Conclusions: With the response rates of 44.4% and median survival of 26 months, the outcomes of systemic therapy in MPM are comparable with the global population. Given the aggressive nature and grim prognosis of the disease, it is imperative to advance our comprehension of its biology and treatment efficacy factors.

EP.14A.15 Racial Disparities in Risk of Bone Metastasis at Diagnosis of Malignant Pleural Mesothelioma

A. Jeri-Yabar[1], L. Vittini-Hernandez[1], F. Arias-Reyes[2], R. Aller-Rojas[3], [1]Mount Sinai Beth Israel, New York/NY/USA, [2]Universidad Peruana de Ciencias Aplicadas, Lima/PE, [3]Universidad Cientifica del Sur, Lima/PE

Introduction: Malignant pleural mesothelioma (MPM) is a rare and aggressive cancer primarily caused by exposure to asbestos in occupational and environmental settings. Despite the ban on asbestos in the 1970's, the latency period of 20-40 years post-exposure continues to pose a significant public health challenge. Bone metastases are reported in around 11% of MPM cases. To our knowledge, disparities in the presence of bone metastases at the time of MPM diagnosis among different racial groups have not yet been explored in the literature. This retrospective study aims to uncover such disparities.

Methods: Utilizing the SEER Research Plus Database, this study focused on patients diagnosed with MPM between 2000-2020. Inclusion criteria consisted of confirmed malignant behavior, specified age, and precise histological classification of mesothelial neoplasms (morphology histology recode 9050-9059), with the primary site identified as "pleural." Individuals aged 18 or younger were excluded. Variables studied were sex, race, survival months, median income, residential area, marital status, and metastases (bone, brain, lung, and liver) at diagnosis. Disease stage was classified into localized, regional, or advanced disease. Logistic regression was employed to assess odds of bone metastases at diagnosis among different racial groups while controlling for pertinent factors.

Results: 5797 individuals were included. 79.63% were White (W), 3.88% Asian/Pacific Islander (API), 4.97% Black (B), 11.11% Hispanic (H) and 0.41% American Indian (AI). 50.15% were 65-79 years of age, followed by ≥ 80 years old (31.33%). 76.90% were male, married (66.33%), lived in an urban area (89.65%) and earned at least $50,000 per year. At time of diagnosis, 5.12% had bone metastases, 0.62% brain metastases, 2.48% liver metastases and 7.16% lung metastases. Individuals with bone metastases at the time of diagnosis were more likely to be API when compared to W and have concomitant liver metastases, lung metastases and brain metastases. Females demonstrated reduced odds of bone metastases at MPM diagnosis. Other variables studied were not significantly associated.

Conclusions: Our study found that Non-Hispanic Asians/Pacific Islanders were significantly more likely to present with bone metastases at the time of MPM diagnosis compared to White-population. This finding underscores the importance of integrating bone imaging more frequently into clinical evaluation of patients with advanced MPM, particularly within the API demographic. Future research endeavors should dive deeper into understanding the underlying mechanisms driving these disparities, considering genetic predisposition, environmental exposures and access to healthcare services.

EP.14A.16 Effect of Talc Pleurodesis on the Treatment of Diffuse Pleural Mesothelioma Patients Treated with Chemotherapy

S. Ozyavuz[1,2], G. Ak[1,2], M. Metintas[1,2], S. Metintas[1,2], [1]Eskisehir Osmangazi University Medical Faculty, Eskisehir/TR, [2]ESOGU Lung and Pleural Cancers Research and Clinical Center, Eskisehir/TR

Introduction: Diffuse pleural mesothelioma (DPM) is a malignant tumor with a poor prognosis for which no generally accepted treatment protocols have yet been developed. As most patients are not eligible for surgery or radiotherapy due to the location and spread of the tumor, they are treated with chemotherapy. Talc pleurodesis for DPM, which is widely used in the palliative treatment of malignant pleural effusions, is controversial. Although a limited number of studies indicate that talc induces apoptosis and may prolong survival, there is uncertainty about the effect of talc on survival in DPM. The aim of this study was to investigate the effect of talc pleurodesis on the survival of DPM patients treated with chemotherapy.

Methods: The study included 328 patients who were treated with a platinum-gemcitabine or platinum-pemetrexed chemotherapy protocol between 1999 and 2023. Those who underwent talc pleurodesis in addition to chemotherapy formed one group (Chemo-talc group), and those who received chemotherapy formed the second group (Chemo group). The demographic and clinical characteristics of the patients were obtained from the mesothelioma database of the Lung and Pleural Cancers Research and Clinical Center (Eskisehir, Turkey) and analyzed.

Results: The mean age of the patients was 62.59±10.23 years, 194 (59.1 %) of the patients were male and 134 (40.9 %) were female. Pleurodesis with talc was performed in 106 (32.3 %) of the 328 patients. When we compared the demographic and clinical characteristics of the two groups, patients in the chemo-talc group were older (p=0.003), had higher asbestos exposure (p=0.034), had a higher epithelioid subtype (p=0.037) and had higher stage I-II disease (p=0.018) than the chemo group. Survival time was 15.00±1.43 months in the chemo-talc group and 11.00±0.65 months in the chemo group. The median survival rate was higher in the chemo-talc group (p=0.008). The 12-, 24- and 36-month survival rates were 58.4%, 23.8% and 11.9% in the chemo-talc group. In the chemo group they were 42.3 %, 15.9 % and 5.9 % (p: 0.027). The factors that influenced survival were histopathology [HR: 26.31 (1.64-1.3); p<0.001] and stage [HR: 12.21 (1.57-1.22); <0.001] in multivariate Cox regression analysis. Pleurodesis with talc had no effect on survival [HR: 1.83 (0.84-0.66); p=0.176] after adjustment for histopathology and stage.

Conclusions: According to the study data, the multivariate analysis showed no significant influence of talc pleurodesis in addition to chemotherapy on the survival of patients with DPM. However, the study was conducted retrospectively and could be biased. Despite this negative result, the significant relationship between median survival times and survival rates of the study groups by talc pleurodesis in univariate analyses suggests that prospective, randomized, controlled, multicenter studies should be conducted on this topic.

EP.14A.17 A Retrospective Study Looking at the Demographics and Occupations of Patients with Mesothelioma in Kent, South East England

A. Stone[1], L. Gilham[2], R. Shah[3], [1]Kent and Medway Medical School, Cantebury/GB, [2]Maidstone and Tunbridge Wells NHS Trust, Maidstone/GB, [3]Kent Oncology Centre, Maidstone Hospital, Maidstone/GB

Introduction: Mesothelioma is highly associated with prior asbestos exposure, with a significant proportion of occurring occupationally. There is usually a significant latency period between the asbestos exposure and the development of mesothelioma. Due to the significant reduction in asbestos use towards the end of the 20thcentury and the latency, it is expected that the peak of mesothelioma should have occurred before 2030. This study aimed to find out the epidemiology, demographics, and occupational histories of patients with mesothelioma in the region of Kent. In doing so, looking to gain an understanding of the current risk factors.

Methods: The sample group included patients diagnosed with mesothelioma in Kent between April 2019 to January 2024 which were identified in the database managed within the Kent Oncology Centre. The anonymised database included the occupational or asbestos exposure histories of mesothelioma patients, where available. It additionally included demographical data such as age, gender, histological subtype, and location in Kent where diagnosed. This demographical data was then collated and analysed, enabling comparisons to be made within Kent and to prior studies in the UK. The occupations or stated likely route of asbestos exposure was assigned into defined categories which were then ranked by the highest number of cases to the lowest. Research ethics was sought for the study from the KMMS Research Ethics Advisory Group (REAG) and the study was registered as a service evaluation at the MTW NHS trust.

Results: Over this 4 year period 409 cases were identified, with April 2020 to March 2021 having the highest number of cases at 117, and April 2022 to March 2023 having the lowest number of cases with 87 being identified. 337 cases were male (82.4%) and 72 were female (17.6%). The mean age of diagnosis was 75.7 years old of those where this was identified, with males this being 75.9 years old and for females 74.9 years old. Where the histological subtype was identified, epithelioid accounted for the most cases (72.5%), followed by sarcomatoid (16.0%), biphasic (11.2%) and desmoplastic (0.3%). When comparing the age of diagnosis for each of the main histological subtypes, epithelioid was 74.1, sarcomatoid 76.3 and biphasic 74.7 years old. There was no statistical difference in age by histological subtype, gender and NHS trust. In 202 cases, the occupation(s) or stated likely route of asbestos exposure was identified. The categories ‘Construction’ (37.3%), ‘Other’ (9.8%), ‘Shipbuilding and dockyards’ (8.4%), ‘Armed forces’ (6.7%) and ‘Boiler, pipe and heating’ (6.7%) were the highest 5 categories. When looking at trades within the construction category, the 3 highest were builders (33.7%), carpenters (20.9%) and plumbers (11.6%).

Conclusions: Overall, the demographics appear to be congruent with previously identified trends within the UK and south east England. There was no significant variation in these demographics within Kent. The occurrence of mesothelioma is consistent with existing data on occupational exposure. We plan to serially assess this as the incidence drops over the next 10 years to detect any changes in trends.

EP.14A.18 Single-Center Experience of Hyperthermic Intrathoracic Chemoperfusion for Malignant Mesothelioma

Y. Suzuki[1], I.S. Sarkaria[2], O. Okusanya[3], A. Pennathur[1], M.J. Schuchert[1], O. Awais[1], R. Dhupar[1], R.M. Levy[1], J.D. Luketich[1], N.A. Christie[1], [1]University of Pittsburgh Medical Center, Pittsburgh/PA/USA, [2]University of Texas Southwestern Medical Center, Dallas/TX/USA, [3]Thomas Jefferson University, Philadelphia/PA/USA

Introduction: The management of malignant mesothelioma requires a multidisciplinary approach, and heated intrathoracic chemoperfusion (HITHOC) may play an important role in better disease control. We evaluated our institutional experience with cytoreductive surgery and HITHOC for malignant mesothelioma.

Methods: We performed a single-institution, retrospective study on patients who underwent cytoreductive surgery (extrapleural pneumonectomy or pleurectomy with decortication) and intraoperative HITHOC for malignant mesothelioma from January 2009 to December 2022. After debulking the thoracic disease, chest tubes were placed, and a chemotherapy solution heated to 40 or 42 degrees Celsius was circulated for one hour. When cisplatin was used, the dose was 175-200 mg/m2, and 30 mg when mitomycin was used. Preoperative, operative, short-term post-operative, and long-term survival data were collected and analyzed.

Results: During the study period, 38 patients underwent HITHOC along with cytoreductive surgery (34 pleurectomy with decortication and 4 extrapleural pneumonectomy; Table). Twenty-one patients (55.3%) underwent concomitant diaphragmatic resection, and 10 patients (26.3%) had wedge lung resection. The median operative time was 8 hours and 40 minutes, with an estimated blood loss on the median of 850 ml. Complication ≥ Grade III was seen in 10 patients (26.3%), and the median length of stay was 8 days. There was no 30- or 90-day mortality, and one-year survival was 80%, with a median follow-up of 19 months. Adjuvant chemotherapy was delivered in 20 patients (52.6%), which was associated with significantly longer overall survival (median: 93 months vs 16 months; p=0.003; Figure).

Conclusions: HITHOC with cytoreductive surgery was a feasible treatment modality with a good short-term outcome. Reasonable long-term survival was observed in the patients, especially those who underwent adjuvant chemotherapy. However, conclusions regarding the survival benefit from these interventions are difficult to assess, owing to the rarity of the disease and lack of a comparison group.

EP.14A.19 Pleurectomy Decortication for Malignant Pleural Mesothelioma: Safe and Faster Technique

M. Yotsukura, Y. Yoshida, S-i. Watanabe, National Cancer Center Hospital, Tokyo/JP

Introduction: Pleurectomy decortication (PD) is a relatively new surgical treatment for malignant pleural mesothelioma (MPM), and its usefulness compared to extrapleural pneumonectomy (EPP) is not fully elucidated.

Methods: We retrospectively evaluated data from 79 patients with MPM who underwent EPP or PD at our institution between 1999 and 2022. Perioperative outcomes and postoperative prognoses were compared between EPP and PD.

Results: EPP was performed in 41 cases (51.9%), and PD was performed in 38 cases (48.1%). Since 2017, PD has been performed using a standardized procedure with the collaboration of multiple surgeons. The median operation duration was significantly shorter in PD than in EPP (PD: 231 minutes [interquartile range: 203-261], EPP: 350 minutes [231-570], $P < 0.01$). The median amount of intraoperative bleeding ($P = 0.42$) and length of postoperative hospital stay ($P = 0.42$) were not different between EPP and PD. The postoperative complication of Clavien-Dindo grade 3 or more was more frequent in EPP group (incidence rate of 31.7%) than that in P/D group (5.3%) ($P < 0.01$). Patients who underwent EPP and PD had a two-year OS of 48.8±8.08% and 60.5±9.6%, respectively ($P = 0.58$).

Conclusions: PD can be completed safely and quickly using a standardized procedure. Since EPP and PD have a comparable postoperative oncologic prognosis, PD would be recommended over EPP as surgery to cure MPM because it is safer and less invasive.

EP.14A.20 Hyperthermic Intrathoracic Chemotherapy Following Cytoreductive Surgery in Patients with Pleural Mesothelioma

G. Stoel[1], Z. Moreno[2], J. Lykon[1], E. Rodriguez[1], D. Nguyen[1], N. Villamizar[1], [1]University of Miami Miller School of Medicine, Miami/FL/USA, [2]University of Miami, Miami/FL/USA

Introduction: Hyperthermic intrathoracic chemotherapy (HITOC), in combination with cytoreductive surgery, has demonstrated better control of primary tumors, lower rates of recurrence and markedly improved survival rates in patients with pleural mesothelioma as compared to cytoreductive removal alone. Along with the improvements in mortality and recurrence with this mode of chemotherapeutic delivery, the current literature describes higher concentration of chemotherapy in the thoracic cavity with reduced systemic toxicity. Because of the rarity of pleural mesothelioma, more data and cases must be described to fully elucidate how beneficial HITOC can be for patients with pleural malignancies.

Methods: This is a case series on 7 patients with pleural mesothelioma who received HITOC after cytoreductive surgery. Analysis included demographics, type of malignancy, date of diagnosis, date of surgery, 30-day survival from date of operation, length of progression-free survival, and whether patients received systemic chemotherapy or immunotherapy in addition to perioperative HITOC. Also included are post-operative complications.

Results: The cohort was composed of 5 white Hispanic patients, 1 black non-Hispanic patients, and 1 white non-Hispanic patient, with a median age of 63 (31-69). 6 of the 7 patients had pleural mesothelioma of epithelioid type, and the 7th patient had biphasic type. The mean progression-free survival in months from the date of surgery is 13.9 months (range 5-25 months). 1 patient has not progressed at all, with a progression-free survival of 25 months. The mean length of hospital stay was 20 days (4-57). 3 patients suffered post-operative DVTs, 1 patient suffered a pericardial effusion, 3 patients suffered cardiac arrythmias, 1 patient suffered an empyema, 1 a pleural effusion, and 2 a pneumothorax. 2 of the patients had no post-operative complications. 3 of the patients received adjuvant chemotherapy, 2 patients received both adjuvant chemotherapy and immunotherapy, and 1 patient received perioperative immunotherapy.

Conclusions: This series of patients who received HITOC for pleural mesothelioma demonstrates lower progression-free survival and overall survival than is noted in the medical literature. This highlights the bias of patient selection on this treatment modality. Our case series also demonstrates the safety of immunotherapy prior and following HITOC in pleural mesothelioma. It is important to study cases of pleural mesothelioma treated with HITOC prospectively to elucidate the effectiveness of this treatment and proper patient selection. The reduced systemic toxicity with HITOC compared to systemic chemotherapy, along with its increased penetrance into tissue of the pleural cavity, provides incentive to further explore this therapy for pleural mesothelioma.

EP.14B.01 Prognostic Impact of Tumour Size in Resected Thymic Epithelial Tumours - A Validation Analysis of the 9th TNM Staging System -

M. Abe, T. Karashima, Y. Abe, K. Ota, T. Sato, D. Noda, S. Takamori, Y. Takumi, A. Osoegawa, K. Sugio, Oita University Faculty of Medicine, Yuhu/JP

Introduction: In the ninth edition of the TNM classification for thymic epithelial tumors, modifications were introduced to the categorization of T factors. Previously, T1 was differentiated based on the presence or absence of encapsulation, while other T factors did not incorporate tumor size into their classification, unlike the approach taken for other cancer. This revision's reclassification of T1 according to tumor size represents a significant alteration. Furthermore, the involvement of the lung and diaphragmatic nerve, which was formerly categorized as T3, has been reclassified to T2.

Methods: In this study, we retrospectively reviewed 67 cases of thymic epithelial tumors undergone operation from 2013 to 2023 at our hospital.

Results: Of the 67 patients, 30 were males, and 37 were females. The median age was 63 years (range: 23-84 years). A total of 56 cases were diagnosed as thymoma, and 11 as thymic carcinoma. Histology of thymic carcinoma cases included eight of squamous cell carcinoma, one of thymic carcinoid, and two of other types. According to the 8th edition of the TNM classification, the distribution across T categories was as follows: T1a/T1b/T2/T3/T4 in 45/11/1/8/2 cases, respectively, with stage distribution classified as Stage I/II/IIIa/IIIb/IVa in 56/1/5/2/3 cases. The World Health Organization (WHO) histological classification for thymomas identified A/AB/B1/B2/B3 types in 16/6/12/14/6 cases. The median postoperative follow-up period was 52 months (range: 6-140 months). Among cases undergoing complete resection (n=63), there were three recurrences, all of which were thymic carcinomas, Five year recurrence free survival (RFS) rate of 96.2% (100% for thymoma, 50.0% for thymic carcinoma). The maximum tumor diameter prior to treatment initiation averaged 33 mm (range: 13-83 mm). Tumor doubling time (TDT) was assessable in 39 cases, with an average TDT of 802 days for thymomas (n=34) and 312 days for thymic carcinomas (n=5), indicating a significantly slower growth rate in thymomas (p=0.04). For tumors exceeding 5 cm in diameter, a significantly shorter RFS was observed, consistent with findings for thymomas (n=56).

Conclusions: Thymic epithelial tumors exceeding 5 cm in diameter have been identified as having a high risk of recurrence, thereby affirming the revised TNM classification's validity. Currently, T1a and T1b are both categorized under stage I. It may become imperative in future iterations to further subdivide stage I, analogous to the stratification employed for primary lung cancer.

EP.14B.02 Perioperative Efficacy and Safety of Efgartigimod in Thymoma Associated Myasthenia Gravis

S. Wang, Q. Wang, J. Jiang, Y. Zheng, L. Jin, J. Dong, J. Ding, Zhongshan hospital, Fudan university, Shanghai/CN

Introduction: This study provides primary data about perioperative efficacy and safety of efgartigimod in patients with thymoma associated myasthenia gravis (TAMG).

Methods: We conducted a prospective analysis of TAMG patients in acetylcholine receptor antibody-positive (AChR-Ab+) generalized myasthenia gravis who underwent efgartigimod weekly (maximum 4 weeks) during the perioperative period of thymectomy. Efgartigimod was administered intravenously over approximately 1 hour at a dose of 10 mg/kg according to patient's weight.

Results: A total of 13 cases of TAMG were enrolled with a median age of 43 years. According to Myasthenia Gravis Foundation of America (MGFA), there were 2 cases of MGFA class II, 7 cases of MGFA class III, 4 cases of MGFA class IV. The mean interval time from myasthenic symptom onset to efgartigimod administration was 6.4 months. The mean interval time from efgartigimod administration to surgery was 9 days. Ten patients underwent T2b surgery with modified subxiphoid thoracoscopic surgery, and 3 patients underwent T3b surgery (trans-sternal thymectomy). According to the ninth edition of TNM staging, 6 patients were at stage I, 3 patients at stage II, 2 patients at stage IIIB, 2 patients at stage IVa. Pathologically, 7 cases were diagnosed as type B2 thymoma, 3 cases of type B3, 2 cases of type B1, and 1 cases of type AB. All patients were MG Activities of Daily Living (MG-ADL) responders and Quantitative Myasthenia Gravis Scale (QMG) responders, with improving muscle strength across ocular, bulbar, limb motor, and respiratory muscle groups. Despite the small sample size, clinically meaningful improvement was achieved, with mean reduction of 4.0 points (-4.0) on the MG-ADL, -7.1 points on the QMG scores after the first infusion; and -7.4 points on the MG-ADL, -12.2 points on the QMG scores after the fourth infusion compared to baseline. Significant reduction was observed in total serum levels of IgG and AChR-Ab after both the first (-38.7% for IgG, -59.5% for AChR-Ab) and the fourth infusion (-59.2% for IgG, -78.8% for AChR-Ab). There was no myasthenic crisis, complication nor adverse event during perioperative period. The mean postoperative hospitalization time was 3 days. After thymectomy, neurological status revealed 6 cases of pharmacological remission and 7 cases of minimal manifestation, with 9 cases of hormone decrement.

Conclusions: The satisfactory outcomes support the effectiveness and safety of efgartigimod during the perioperative period of thymectomy for TAMG. Large-scale clinical trials are needed to validate our important findings.

EP.14B.03 Predictive Value of Neutrophil-to-Lymphocyte Ratio (NLR) and Absolute Lymphocyte Count (ALC) In Thymic Epithelial Tumors

N. Choradia, L. DaSilva, K. Dodd, PhD, M. McAdams, S. Swift, C. Feierabend, A. Sivapiromrat, S. Sansone, C. Zhao, R.N. Donahue, J. Schlom, J.L. Gulley, A. Rajan, E. Szabo, National Institutes of Health, Bethesda/MD/USA

Introduction: High NLR is associated with increased mortality and decreased immunotherapy benefit in several malignancies. NLR was previously associated with thymic epithelial tumor (TET) recurrence after resection; however, its predictive value in metastatic TETs treated with immunomodulatory treatments is unknown. We examined the association of NLR with treatment outcomes in metastatic TETs.

Methods: This single-institution, retrospective analysis was conducted on data obtained between 05/2012 and 03/2023 from four phase II clinical trials evaluating immunomodulatory treatments in metastatic TETs: avelumab (A), bintrafusp alfa (B), PT-112 (P) and sunitinib (S). Baseline NLR and ALC were assessed via logistic regression in relation to duration of benefit for the overall group, for S alone, and for A, B and P combined. Kaplan-Meier curves compared patients with baseline NLRs and ALCs at various levels.

Results: Eighty-eight patients were enrolled in A, B, P or S trials (four patients participated in more than one trial; median age: 57 years old; female: 41; White/African-American/Other: 63/14/11; thymoma: 41; S trial: 43, A/B/P trials: 49). There was no association between pre- or on-treatment NLR or ALC and treatment response or duration of clinical benefit (Table 1). Elevated NLR (cutoff of 3 or 5) and low ALC (> grade 1 or > grade 2) were not associated with duration of clinical benefit (Figure 1).

Conclusions: No association was observed between baseline or on-treatment NLR and treatment outcomes in patients with advanced TET patients. Potential reasons include small cohort size and heavy pretreatment affecting immune response. Long term follow-up in a larger cohort is needed.

EP.14B.04 Nomogram for Predicting the Prognosis of Metastatic Thymic Epithelial Tumors

Y. Liang[1], C. Huang[1,2], Y. Lin[3], H. Liu[4], Q. Zou[1], L. Kang[1,5], J. Mai[1], [1]Department of Medical Oncology, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou/CN, [2]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen/CN, [3]Department of Thoracic Surgery, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou/CN, [4]Department of Radiation Oncology, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou/CN, [5]Department of Medical Oncology, Yuebei People's Hospital, Shantou University Medical College, Shaoguan/CN

Introduction: Patients with thymic epithelial tumors (TETs) are often in advanced stage when they are first diagnosed. This study aimed to develop a nomogram to predict the prognosis of metastatic TETs.

Methods: Patients with metastatic TETs treated in Sun Yat-sen University Cancer Center from July 2000 to November 2021 were retrospectively included. A nomogram model predicting the prognosis of metastatic TETs was established based on the independent prognostic factors. Performance of the nomogram model was assessed by using the concordance index (C-index), calibration curves and decision curve analysis (DCA) curves. Based on the nomogram scores, patients were divided into different prognostic groups.

Results: A total of 254 cases, including 129 thymoma and 125 thymic carcinoma patients were enrolled into this analysis. Characteristics of the patients are shown in Table 1.The median follow-up time was 40.27 months and the median OS was 53.03 months (95% CI: 40.56-65.51 months). After univariate analysis and multivariate analysis, the results showed that WHO histologic classification type C, Masaoka-Koga stage IVb, KPS score 70-80 and baseline serum albumin level <40g/L were independent poor prognostic factors of OS. The independent prognostic factors of OS were taken into the establishment of nomogram model. The C-index was 0.68 (95% CI: 0.59-0.79), indicating good performance. The risk groups were categorized by nomogram scores, using a threshold at 112 score. The median OS in the high-risk group was much shorter than the low-risk group (28.60 vs 74.17 months, HR: 2.44; 95 % CI: 1.65-3.62; p=0.000002).

Conclusions: WHO histologic classification, Masaoka-Koga stage, KPS score and baseline serum albumin level were identified as independent prognostic factors for OS in the patients with metastatic TETs. This study developed a nomogram model which can effectively predict the prognosis of metastatic TETs.

EP.14B.05 What Do We Know About Thymic Epithelial Tumors? Demographic and Survival Analysis from a Single Academic Center in Argentina

D.E. Mansilla, M.F. Guerra, J.L. Lopez, L. Arias, E. Rojas Bilbao, M. Castro, A. Gilardoni, Instituto de Oncologia Angel H. Roffo, Buenos Aires/AR

Introduction: Thymic epithelial tumors (TET) are rare malignant neoplasms of unknown etiology with high survivorship at 5 and 10 years. Different types have been described, including thymomas and thymic carcinoma. Thymomas have been related to autoimmune disorders, such as Myasthenia Gravis (MG). Open surgery remains the gold standard of treatment, although new minimally invasive techniques are considered for specific cases. This study aimed to analyze the incidence and survival rate of this uncommon pathology in a tertiary centre in South America.

Methods: We retrospectively studied all patients diagnosed with any type of TET who underwent surgical treatment from 2007 to 2024 at a single academic center.

Results: A total of 27 cases were included. Fourteen (52%) were males, and the average age was 50 (SD±13). Thymoma (22/27 81.5%) was the most frequent type, followed by Thymic Carcinoma (5/27 18.5%). All patients had a CT scan before surgery, and only nine patients had PET TC, which was indicated in high-stage TETs. A high proportion of patients with thymoma (9 41%) were presented baseline paraneoplastic syndromes such as: MG (6 27%) positive ACRA and one thrombophlebitis associated with carcinoma (4%).We found just one patient with thymic carcinoma with clinical signs of MG that disappeared after surgery.From 22 thymoma patients; 19 underwent total thymectomy, and only one required preoperative induction therapy due to an initial non-resectable tumor. Ten patients were resected by sternotomy, five by thoracotomy, and four underwent minimally invasive procedure by VATS. The remaining five patients were treated with systemic therapy due to non-resectable conditions. Radical surgery with free margins was achieved in 95% of cases. The mean size of the tumor was 7.6 cm (SD±3.4). According to the Masaoka-Koga classification, most Thymomas (73%) were classified as Stage I-II, and only 27% were Stage III-IV. Two thymic carcinoma patients were resected by sternotomy, and one underwent minimally invasive procedure by VATS. The mean size of the tumor was 4 cm (SD±3). Radical surgery with free margins was achieved in only one patient, all thymic carcinomas were classified as Stage III-IV according to the WHO classification. No mortality was reported 90 days after surgery. The median survival time of thymoma and thymic carcinoma was 45.6 and 27 months, respectively.

Conclusions: TETs are rare tumors with Was - a good prognosis and high five and ten-year overall survival. The correct multidisciplinary approach is essential to achieving successful results since the initial therapeutic plan is based on the resectability of the injury. Patients with complete resections (R0) and initial stages of classification (EI/II) have greater overall survivorship.

EP.14B.06 A Retrospective Multicenter Study Evaluating Experience of Perioperative Treatment for Thymic Squamous Cell Carcinoma

A. Singh, A. Sridhar, P. Shakya, J.N. Moffet, A. Schwecke, A. Luce, M. Shanshal, A. Dimou, K. Leventakos, A. Mansfield, J. Molina, K. Parikh, Mayo Clinic, Rochester/MN/USA

Introduction: Thymic carcinomas (TC) are rare tumors of prevascular mediastinum. Squamous cell carcinoma is the most common histological subtype. TC are invasive and often present as metastatic disease. Their 5 year-overall survival is only 55%. Complete surgical resection (R0 resection) and postoperative radiation therapy (PORT) has been shown to improve survival. In borderline resectable disease, neoadjuvant treatment helps downsize the tumor to allow resection. In this study, we aimed to review our long-term experience of perioperative treatment for patients with thymic squamous cell carcinoma (TSCC).

Methods: We included 50 patients with a diagnosis of TSCC from 1997 to 2023 with an intention for surgical resection. Demographic and clinical data was collected by retrospective chart review. Continuous variables were described as median. A multivariate logistic regression model was performed to test the association of age, gender, smoking status, resection margins, receipts of neoadjuvant treatment and PORT with and without chemotherapy. Overall and progression-free survival, was calculated using Kaplan-Meier method.

Results: We identified 46 patients who underwent surgical resection. 28(60.87%) patients achieved R0 resection. Neoadjuvant treatment was administered in 22 of the 50 cases (44%). Six patients received neoadjuvant concurrent radiation and chemotherapy. Five patients developed disease progression during or following neoadjuvant treatment of which one was salvaged by surgery. Two patients who received neoadjuvant concurrent radiation and chemotherapy achieved complete pathological response. Adjuvant treatment was given in 35 cases (76%). 19 patients received PORT alone and the remaining patients received post operative chemotherapy in addition to PORT. Median overall survival (OS) and median progression free survival (PFS) for the study population was 7.1 years and 18.28 months, respectively. Achievement of R0 resection was associated with receipt of neoadjuvant treatment and it was statistically significant (p=0.03). Only R0 resection was found to have a significant association with OS. None of the variables were significantly associated with PFS.

Conclusions: Amongst all the factors that have been found to be associated with overall survival, R0 resection is the only factor that has been reported in literature to be consistently associated with improved survival. Our study showed that neoadjuvant treatment can improve the probability of achieving R0 resection. Complete pathological response is uncommon after neoadjuvant treatment in TC. Recent studies have shown that perioperative immunotherapy improves pathological response and event free survival in resectable Non-Small Cell Lung Cancer. Studies should explore the role of perioperative immunotherapy in addition to chemotherapy in carefully selected borderline resectable TSCC.

EP.14B.07 Does Surgical Incision Affect Quality of Life in Masaoka Stage 1-2 Thymomas?

G. Özcibik Isik[1], M. Okutan[1], M.K. Kaynak[1], A. Turna[1], [1]Istanbul University-Cerrahpassa Cerrahpasa, ISTANBUL/TR

Introduction: Thymoma is a neoplastic disease originating from the epithelial cells of the thymus gland. TNM staging and Masaoka-Koga staging are often used. Complete removal of the thymus tissue and surrounding fatty tissue with extended thymectomy complies with oncological principles. Surgery can be performed by open method (sternotomy) or minimally invasive methods (VATS/RATS). In our study, we aimed to investigate the effect of surgery on the quality of life in patients who underwent surgery with a diagnosis of Masaoka stage 1-2 thymoma.

Methods: Patients who were operated on in our clinic with the diagnosis of Masaoka stage 1-2 thymoma between 2007 and 2022 were included in the study. 8 patients were accepted as exitus during follow-up. 18 out of 25 patients could be reached. 10 patients were operated with VATS and 8 patients were operated with sternotomy. SF-36 survey was administered to the patients to evaluate their quality of life.

Results: The VATS group reported that their general health was better and that they were better at a higher rate compared to the previous year (80% and 90%). There were similar restrictions in general activities in the VATS and sternotomy group. Individuals in the two groups rated the effects of emotional problems on their daily activities as similar. While the VATS group stated that they were better in the evaluation of pain, mood and physical activity in the last 4 weeks, they rated their health holistically as good at a higher rate (Figure 1).

Conclusions: In our study, the quality of life of patients who underwent thymectomy with VATS or sternotomy due to stage 1-2 thymoma was evaluated with the SF-36 test. In the late-term life evaluation survey after surgery, the group who underwent VATS stated that their general health and general life activities were better. Although the application of minimally invasive surgeries has increased with technological developments, minimally invasive methods remain important in thymoma surgery due to the concern of residual tissue remaining. Considering the superiority of VATS in the evaluation of general quality of life, it should be preferred in appropriate patients.

EP.14B.08 Thymic Carcinoma with Treatment-Related Leukemia Showing Complete Response to Bcl-2 Inhibitors: A Case Report

K. Nitanai, Asahikawa medical university hospital, Asahikawa/JP

Introduction: Thymic carcinoma is a rare malignancy with poor prognosis.The existing systemic chemotherapy regimens for thymic carcinoma are primarily based on limited evidence from phase II clinical trials and retrospective studies. Due to the rarity of this cancer, gathering a sufficient number of cases for comprehensive research is challenging, highlighting the need for further studies on more effective treatments. Many thymic carcinomas express Bcl-2, a protein known to play a role in the regulation of cell death. However, the effectiveness of Bcl-2 inhibitors in the treatment of these carcinomas remains unclear.

Methods: A 48-year-old man, initially diagnosed with stage I thymoma, underwent surgical excision but later experienced local recurrence and disseminated lesions, leading to a revised diagnosis of thymic carcinoma. Despite attempting surgical resection, complete removal was not achieved. The patient underwent first-line chemotherapy with cisplatin and etoposide, resulting in a temporary reduction in the primary lung mass. However, six months post-treatment, left pleural dissemination increased, indicating disease progression.

Five years after thymic carcinoma diagnosis, the patient developed treatment-related acute myeloid leukemia (AML). Initial AML treatment with idarubicin and cytosine arabinoside yielded limited therapeutic response. Persistent left lower extremity pain and uncontrolled treatment-related AML warranted consideration of alternative chemotherapeutic strategies.

Due to the patient's non-complete remission status for thymic carcinoma and contraindications for intensive AML therapy, 5-azacytidine and venetoclax were chosen as second-line AML treatment. Two months after initiation, the patient achieved complete remission for AML, with no detectable peripheral blood blasts. Simultaneously, significant regression of thymic carcinoma occurred, reaching complete remission after the third treatment cycle. Subsequently, there has been no recurrence of either thymic carcinoma or leukemia since completing this treatment.

Results: In this patient, the pathological specimen showed high Bcl-2 expression, suggesting a potential association with the observed therapeutic response to the Bcl-2 inhibitor. The favorable response of the patient's thymic carcinoma to Venetoclax combined with 5-azacytidine underscores the necessity for further research on this novel treatment approach, particularly for thymic carcinomas characterized by high Bcl-2 expression.

Conclusions: A complete response has been observed in thymic carcinoma during chemotherapy with 5-azacytidine and Venetoclax, which were initially administered for the management of treatment-related leukemia. This finding suggests that the combination of 5-azacytidine and venetoclax may be effective for direct treatment of thymic carcinoma. The involvement of high Bcl-2 expression in thymic carcinomas may be a key factor in the mechanism of action of this therapeutic approach.

Keywords: thymic carcinoma, Bcl-2 inhibitors, venetoclax

EP.14C.01 Coexisting Pulmonary Tuberculosis and Primary Lung Cancer: Prevalence of Diagnostic, Treatment and Outcome

A.T. Dinh, H.T. Pham, H.D. Duong, Vietnam National Cancer Hospital, Hanoi/VN

Introduction: Vietnam ranks 11th among 30 countries that suffer from the highest tuberculosis (TB) burden around the world. Lung cancer (LC) has become the second most common cancer in our country. Both diseases coexist producing a diagnostic dilemma and affecting treatment efficacy.

Methods: We retrospectively reviewed 52 medical records of patients with coexistent lung cancer and pulmonary tuberculosis at Vietnam National Cancer Hospital and National Lung Diseases Hospital between 2008 and 2022. The clinical features, diagnosis, treatments, and OS were evaluated.

Results: The mean age was 59,2 years (age range: 46,4-72 years); the ratio of male/female was 2,3/1; 86.4% of patients had ECOG PS scores ranging from 0 to 1. The prevalence of stage I, II, III, and IV due to AJCC version 8 staging classification were 9.6%, 13.4%, 38.5%, and 38.5%, respectively. The most common symptom at admission was chest pain (55%), and 91.9% of patients had a regular history of smoking with a mean 46 pack-year. The most common imaging feature on CT was an enhanced cavitary mass in the upper lobes (65.4%). Squamous cell carcinoma (50%) was the most common pathology type followed by small cell carcinoma (23.1%) and adenocarcinoma (21.2%). Tuberculosis detected by lung tissue cultured and H&E staining the biopsy specimens were 25%, and 48.1%, respectively. The simultaneous and sequential presentation of pulmonary TB and lung cancer within the same patient were 51.2%, and 48.8%, respectively. In our study, treatments included curative intended and palliative, with proportions of 28.3%, and 71.7%, respectively. The mean period of time for diagnosis is delayed by 3,6 months. The median survival time of those who had curative intended was 18,3 ± 3,6 months. Median survival times of those treated by palliative therapy were 11,3 ± 4,1 months.

Conclusions: Pulmonary TB coexisting with lung cancer can mask the underlying disorder resulting in a delay in diagnosis, treatments will affect the patient's outcome. Tuberculosis should be a significant concern, especially in male patients with heavy cigarette smoking and located in TB-endemic areas.

Keywords: Tuberculosis, Lung Cancer, Co- existence

EP.14C.02 Identification and Isolation of Cancer Stem Like Cells in Pulmonary Sarcomatoid Carcinoma

H. Guo[1], F. Zhou[2], C. Zhou[2], [1]Shanghai Pulmonary Hospital, Shanghai/CN, [2]Shanghai East Hospital, Tongji University School of Medicine, Shanghai/CN

Introduction: Pulmonary sarcomatoid carcinoma (PSC) represents a rare subset (0.4%) of highly aggressive and poorly differentiated NSCLC, characterized by sarcoma-like or sarcoma (spindle- or giant-cell) elements. The scarcity of PSC cases has limited the exploration of atlas and heterogeneity, while the efficacy of current NSCLC treatments is constrained by tumor heterogeneity. Our study utilized snRNA-seq to unveil the 'Plasticity' of PSC cells, marked by a prominent expression of a stemness signature (WCLC 2023, P2.22-01), thus confirming the existence and signature of cancer stem cells (CSCs) in PSC, offering insights into its malignant nature and drug resistance.

Methods: Single nuclei were isolated from frozen tissues using an isolation kit following the manufacturer's protocol (Sinotech Genomics Co., Ltd). PDX models were established by subcutaneously implanting small tissue fragments from PSC patients into NOG mice. 'Plasticity' cells from patient-derived xenograft (PDX) tumors were sorted via Fluorescence-activated cell sorting after dissociation into single-cell suspension. Both positive-sorted ('Plasticity' cells) and negative-sorted cells were inoculated subcutaneously into the right flank of NOG mice.

Results: Based on our previous snRNA-seq findings, we identified a PSC-enriched cancer cell 'Plasticity' exhibiting elevated expression of the stemness signature Stemsig. We defined a signature of three surface markers for 'Plasticity' subtype with an accuracy of 0.874 to 0.849 (Fig. 1A). 'Plasticity' cells isolated from PSC PDX tumors via FACS (Fig. 1B) were successfully implanted into NOG mice in varying quantities from 103-105, revealing that all positive-sorted cells initiated tumor growth, irrespective of cell number, while negative-sorted cells failed to generate tumors (Fig. 1C). Meanwhile, tumors injected with a higher number of 'Plasticity' cells exhibited a notably accelerated growth rate compared to those injected with lower numbers (Fig. 1D and 1E). Moreover, tumors derived from 'Plasticity' cells exhibited typical PSC characteristics upon histological examination (Fig. 1F). Pathways associated with metastasis, inflammatory response, Hippo signaling, and focal adhesion were upregulated in positive-sorted cells ('Plasticity', Fig. 1G), along with elevated expression of the stemness signature Stemsig (Fig. 1H).

Conclusions: CSCs, known for their role in tumor recurrence and progression through self-renewal and regeneration, are pivotal in cancer biology. The 'Plasticity' cells we identified met gold standards of CSCs, displaying the capacity to differentiate into complete malignant tumors with minimal cell numbers (102~103 cells) and histological similarities to primary tumors. Our established signature for CSC identification in PSC, validated in vivo, offers promising avenues to combat the malignant nature and drug resistance associated with PSC.

EP.14C.03 Long-Term Outcomes of Unresectable Tracheobronchial Tumors Treated with Radiotherapy- Analysis from a Tertiary Cancer Centre

S. Dhingra[1], A. Tibdewal[1], J.P. Agarwal[1], S. Jiwnani[1], R. Kaushal[1], K. Prabhash[1], [1]TATA MEMORIAL HOSPITAL, MUMBAI/IN

Introduction: Tracheo-bronchial (TB) malignant tumors constitute an uncommon malignancy of the thorax. Radical radiation therapy (RT) is the standard treatment for unresectable or in margin-positive cancers. Here, we report our institutional data of TB tumors treated with RT.

Methods: From 2012 to 2024, we retrospectively collected data of TB tumors treated with radiation therapy at our tertiary cancer care centre. Data was collected from electronic medical records and case files. Clinicopathological and demographic variables were collected. Categorical and numerical variables were summarized using descriptive statistical methods. Overall Survival (OS) and progression-free survival (PFS) were calculated from the date of diagnosis until the date of progression or death, respectively, whichever is earlier. Both were analysed using the Kaplan-Meier method.

Results: Twenty-eight patients of TB tree tumors received RT. The median age was 44 years (range, 19-63), with slight male preponderance. The clinicopathological characteristics and treatment options are summarised in Table 1. The most common histology was adenoid cystic carcinoma in 23 patients and majority of the tumors were within 2cm from the carina. The most common presenting symptoms were cough and breathlessness. Debulking surgery was done in 18 (3 with stent placement). Twenty-two patients received definitive RT and 6 received adjuvant RT (margin positive). The median RT dose was 60Gy (50 - 66Gy). All patients received conformal RT and 3 received intraluminal brachytherapy boost post-definitive RT. All radical RT patients received concurrent chemotherapy. The median follow-up period was 29 months (IQ range, 4-57 months) with 23 patients alive at the data cut-off. The disease relapse was seen in 10 patients (local-4, distant-6). The median and 3-year PFS and OS were 26 months & 65% and 42 months & 87%, respectively. Acute ≥ Gr 2 toxicity was seen in 4 patients (14%) and late ≥ Gr 2 in 7 (25%) as cough and dysphagia. One patient developed tracheo-esophageal fistula, two developed symptomatic tracheal stenosis requiring dilatation.

Conclusions: Unresectable tracheobronchial tumors treated with radical CTRT demonstrated good local control and overall survival. Late toxicity is a concern, which requires frequent intervention.

EP.14C.04 Micro Neck Incision Combined with VATS for Resection of Superior Mediastinal Neoplasms

J. Mao, J. Fan, W. Huang, Shanghai General Hospital, Shanghai/CN

Introduction: Treat superior mediastinal neoplasms through micro neck incision combined with VATS.

Methods: Patients with huge mediastinal mass underwent complete examination of whole body. Patients with no metastasis were selected to perform this novel minimally invasive approach. We select the specific incision location according to the main location of the tumor. We choose necklace incision or collar incision for the neck approach. We choose intercostal thoracoscopy or subxiphoid thoracoscopy for the thoracoscopic approach.

Results: Nine cases of high mediastinal tumors were treated with cervical micro incision combined with video-assisted thoracoscopic surgery. No patient was converted to open surgery. Pathological types include aggressive fibroma, goiter, thymoma, angioma, teratoma and paraganglioma. There was no Horner syndrome. There were no vagus nerve injury, recurrent laryngeal nerve, or phrenic nerve injury. None of brachial plexus injury or major vessel injury were reported. All patients are well after a short-term follow-up.

Conclusions: Cervical micro incision combined with thoracoscopic surgery is a safe and effective technology for the treatment of high mediastinal tumors. This technology can avoid unnecessary thoracotomy when it is difficult to expose upper mediastinal tumors.

EP.14C.05 The Management of Solitary Fibrous Tumors of Chest in a Center

A. TSOMPANELLIS[1], M. KOUVELA[2], K. VACHLAS[2], K. TAVERNARAKI[2], I. GKIOZOS[2], S. TSAGKOULI[2], A. CHARPIDOU[2], K. SYRIGOS[2], I. Vathiotis[3], [1]GENERAL HOSPITAL OF ATHENS "EVAGELISMOS", ATHENS/GR, [2]GENERAL HOSPITAL OF ATHENS "SOTIRIA", ATHENS/GR, [3]National & Kapodistrian University of Athens, Athens/GR

Introduction: SFTs comprise a histologic spectrum of rare tumors which originate from mesenchymal cells. Most of them are slow-growing and asymptomatic. Males and females are affected at equal frequencies. They are most common seen in the fifth to seventh decade. CT is considered the gold standard examination. An SFT is comprised of randomly arranged cells with spindle shape within a collagenous stroma. The biomarkers CD34, Bcl-2 and STAT6 are specific for SFT. The standard of care is the complete surgical resection. The prognosis is good and the survival rate is more than 85% after five years.

Methods: A number of ten patients with SFT had been treated in the Department of Thoracic Surgery of the General Hospital of Athens «Sotiria» from January 2019 to June 2023. The statistical analysis is based on gender, age, days of hospitalization, location of the tumor, size, histopathologic examination and immunochemistry evaluation. Demicco score was calculated for each patient.

Results: The mean age of patients in the sample is 65,4 years. Half of them are men. The mean reported length of hospital stay is 7,8 days. In five patients the tumor was localized in the right hemithorax and in the rest of the patients was in the left hemithorax. Four out of ten patients were treated with open surgery and six of them with video-assisted thoracoscopy. The mean size of the tumor was 6,57 cm. Based on Demicco score, six patients have low metastatic risk, three patients have intermediate metastatic risk and one patient has high metastatic risk.

Conclusions: SFT are well defined rare neoplasms. They are asymptomatic in early stages. CT is the gold standard examination. Complete surgical resection is the treatment of choice. The majority of SFT do not recur locally or distantly. Most of them are benign with high overall survival rate.

Introduction: In this study, we present our experiences with local treatment and surgical treatment in patients diagnosed with Tietze syndrome.

Methods: Between January 2008 and January 2023, a total of 17 patients (6 males, 11 females; median age: 33 years; range, 27 to 67 years) who were diagnosedand treated with TS in our clinic. Pain killer were injected into painful joints.Pain sensation of the patients was recorded using the Pain Rating Scale developed. Pain was also assessed atseveral weeks after injections qualitatively and based on physical examination. All patients were medicaly treated. Only one patient intervented d medically. Steroids and local aesthetic were used. In 8 patients, oral or i/m and i/v antibiotics were also used, and systemic anti-inflammatory drugs were also used.

Results: At two weeks, the patients felt calmer and performed better.

Conclusions: Patients diagnosed with Tietze syndrome and local steroids or anesthetic injection provides a rapid relief from pain, or employment status. Surgical treatment was used only in selected case.

Keywords: Atralgy, Tietze syndrome, Chest pain

EP.14C.07 Hyperossosis of the Right 10th Rib the Osteochondral Part that Compresses the Dexter Lobe of the Liver

F. GRADICA[1], A. Cani[2], L. Lisha[2], I. Peposhi[2], F. Kokici[2], A. Leka[3], D. Xhemalaj[4], M. Rama[5], S. Gradica[6], L.G. Matmuja[5], F. Hoxha[7], [1]University Hospital "Shefqet Ndroqi", Tirane/AL, [2]University Hospital "Shefqet Ndroqi", Sauk Tirane/AL, [3]Imagery Service Lezha Hospital, Lezhe/AL, [4]University Hospital "Mother Theresa", Tirane/AL, [5]SUT, Trauma Hospital/AL, [6]Publik Pharmacy Service, Kamez Tirane/AL, [7]Managament of human resource, Kamez Tirane/AL

Introduction: Rib hyperostThe rib hyperostosis can be suspicious for malignancy.Hyperostosis has previously been described in conjunction with disorders causing excessive rib ossification due to osseous bridging across the costocondrial joint, such as in diffuse idiopathic skeletal hyperostosis. Hyperostosis is believed to be a reactive process due to altered forces across the affected rib as bridging osteophytes decrease mobility at the respective costocondrial joint.

Methods: A 37-year-old female patient. She presented to the consultation with severe pain in the upper abdominal quadrant and at the level of the right rib cage. She had these concerns for several months, but in the last few weeks the pain became stronger and more stable, related to the movement of the trunk. It was treated with tranquilizers, but again it did not find stability. In the thoracic Ct scanner, the 10-th rib on the right anterior segment is evident, ossified and elongated, going in the direction of the liver.

Results: After completing the appropriate examinations, the patient underwent surgical intervention with x-rays of the hyperostosis part. During the intervention, the compressed area in the right lobe of the liver was clearly visualized due to the pressure exerted by the part of the hyperostosis rib on the liver. It left many traces on the surface. of the liver but without damaging it in the shape of a furrow about 7-8 cm. The biopsy result shows hyperostosis of the 10-th right rib, the anterior costochondrial part, about 7-8 cm.

The patient is calm and without worries.

Conclusions: Hyperostoses of the ribs have high suspicions of malignancy and can give clinical signs of severe pain when they grow in the direction of the parenchymal organs, as in our case, growing in the direction of the liver and continuously. Surgical resection is the right solution.

EP.14C.08 Challenges in Diagnosis and Management of Epithelioid Inflammatory Myofibroblastic Sarcoma - Case Report

S. Laštíkova[1], M. Urda[1], J. Mazal[1], T. Šišmiš[1], [1]Department of Pneumology and Phtiseology, F.D. Roosevelt University General Hospital, Banská Bystrica/SK

Introduction: Epithelioid inflammatory myofibroblastic sarcoma (EIMS) is a rare subtype of inflammatory myofibroblastic tumour (IMT). EIMS typically presents with sheets or loose fascicles of epithelioid cells mixed with inflammatory cells in a variably myxoid background. Notably, approximately 50% of typical IMTs harbour ALK gene rearrangement and overexpress ALK, often showing diffuse cytoplasmic staining. However, recent findings suggest that specific staining patterns of ALK may indicate malignant behaviour in these tumours.

Methods: A case report.

Results: : A 45-year-old patient underwent a right upper lobectomy in December 2018 for an epithelioid variant of inflammatory myofibroblastic sarcoma with ALK expression. In March 2020, he presented to the neurosurgical clinic with persistent headaches and double vision. Brain MRI revealed an extensive tumour in the right frontoparietal region, resulting in calvarial destruction and compression of the right cerebral hemisphere. On March 24, 2020, surgical excision of the tumour mass involving the calvarium was performed, with histological examination confirming metastasis of the epithelioid inflammatory myofibroblastic tumour. Till then, the patient hasn't received any oncological treatment; an oncologist has observed him. In general, the patient hasn't had any significant complaints; he has been using anticonvulsive therapy with a small dose of corticoids. On May 5, 2020, the patient was admitted to a department due to weaknesses. Upon admission, we conducted an MRI of the brain, revealing multiple nodular and patchy lesions in the frontoparietal region bilaterally. According to the consulted neurosurgeon's opinion, the findings were inoperable, so we were considering external radiotherapy to the brain. As literature sources indicated that the patient could benefit from ALK-TKI (tyrosine kinase inhibitors), we requested compassionate use approval from the ministry. Meanwhile, the patient, experiencing persistent weakness and headaches, initiated external radiotherapy to the brain and completed one session. Subsequently, upon approval of the medication, treatment with alectinib was undertaken on June 6, 2020, and external radiotherapy was interrupted. The patient was doing very well; he continued going to work. In May 2021, a left parietal tumour was found on a follow-up CT scan. The patient underwent reoperation, revealing a fibrous meningioma with a high MIB-1 index. The patient, undergoing alectinib treatment, attained postoperative stability. In June 2023, a seizure occurred at home, prompting a CT scan revealing a right frontal high tumour. Subsequent neurosurgical resection confirmed it as a metastasis of epithelioid inflammatory myofibroblastic sarcoma. The patient, remaining stabilised, continues alectinib therapy and anticonvulsant treatment.

Conclusions: This case underscores the diagnostic and therapeutic complexities of epithelioid inflammatory myofibroblastic sarcoma (EIMS), a rare inflammatory myofibroblastic tumour (IMT) variant. Despite initial treatment with alectinib and surgical intervention, disease progression and metastasis occurred, highlighting the aggressive nature of EIMS. Accurate diagnosis and targeted therapy guided by ALK expression patterns remain crucial for managing this challenging malignancy. Further research and collaborative efforts are needed to enhance outcomes for patients affected by EIMS.

EP.14C.09 Lung Metastasis of Clear Cell Renal Carsinoma Mimicking Primary Lung Cancer Following Nephectomy in 30 Years Old Women: A Case Report

P.G. Wahyu[1], A. Infianto[2], R.D. Wirawan Listiandoko[2], D. Wardani[1], D. Deschairul[2], H. Aprijadi[2], E.I. Pattiwael[2], M.R. Rahman[2], [1]Lampung University, Bandar Lampung/ID, [2]Ahmad Yani Hospital, Lampung University, Metro/ID

Introduction: It is possible that five years after a long gap radical nephrectomy, lung metastases from clear cell renal cancer will develop. According to data from the International Agency for Research on Cancer, Indonesia has a crude fatality rate of 1.3 cases per 100,000 people and a cumulative risk of 0.17% for kidney cancer. 635 instances of kidney cancer were reported between January 2013 and December 2017, with a male to female ratio of 2:1 and the largest age group being 51-65 years (42%). We describe a unique example of lung metastases in this case report, including a thirty years old lady after nephrectomy.

Methods: An x-ray of the chest taken of a 30-year-old woman who had been experiencing dyspnea and chest pain for three months. And chest ct scan revealed bilateral opacity in the left medial temporal lobe and right upper lobe, as well as several lung nodules in the left lung's medial and basal lobes. A soft tissue mass with central necrosis infiltrated around the superior mediastinal and superior cava vein, as well as complex pleural effusion a type of subpleural pulmonary metastasis with histopathology results from biopsy forceps sample fron bronchoscopy methods indicating clear cell renal carsinoma lung metastasis. The masses measured 7.3 x 4.9 x 6.6 cm.

Results: Renal cell carcinoma (RCC) is the sixth most common malignant tumor in men and the tenth most common tumor in women. the lung is one of the most common sites of metastasis. This is the first documented case of clear cell renal cell carcinoma related lung metastases in woman 30 years old after nephrectomy from Lampung.

Conclusions: Clear Cell Renal Carsinoma is the tenth most common malignant tumor in women and mostly metastasis to the lung although after nephectomy with the metastasis mimicking primary lung cancer.

EP.14C.10 Clinical and Pathoanatomical Characteristics of Rare Pulmonary Neuroendocrine Tumors in Greek Population

T. Sen[1], G. Evangelou[2], A. Sofianidi[2], P. Kelidi[2], A. Papadopoulou[2], A. Konstantinidou[2], N. Syrigos[2], K. Syrigos[2], [1]Icahn School of Medicine at Mount Sinai, New York/NY/USA, [2]University of Athens, Athens/GR

Introduction: Pulmonary neuroendocrine tumors (PNETs), including lung carcinoids (typical and atypical), and large-cell neuroendocrine carcinoma (LCNEC), are rare entities with distinct clinical and pathological features. Due to its rarity, clinical and molecular characterization of PNETs and LCNECs is not well elucidated. About 50-60% of patients with LCNECs present with stage IV disease, and no large randomized clinical trial data are available to determine the optimal treatment strategy. In this study, we report the first analysis of the clinical and pathoanatomical characteristics of PNETs and LCNECs in patients treated at the National and Kapodistrian University of Athens, Sotiria Hospital.

Methods: Data were collected from the medical records of patients diagnosed with PNETs or LCNEC between May 2017 and July 2023, focusing on clinical presentations, diagnostic methods, and pathoanatomical findings.

Results: The cohort comprised 80 patients, with a median age of 59 years for NET and 66.5 for LCNEC. Notable findings included a significant difference in sex distribution and smoking status between the NET and LCNEC groups. There was no correlation between smoking status and NET incidence, while the majority of patients with LCNEC were active smokers. The primary symptoms leading to the diagnosis differed, with most patients diagnosed as asymptomatic in the NET cohort and breathlessness and persistent coughing in the LCNEC cohort. The average primary tumor size upon diagnosis was 2.1 for NET and 3.5 for LCNEC. Patients with NET were more likely to be diagnosed at an earlier stage. In contrast, patients with LCNEC are mainly diagnosed with stage IV disease. NET and LCNEC patients showed distinct Ki67 expression levels; NET patients expressed Ki67 at 7%, while LCNEC patients expressed it at 70%. Immunohistochemistry of neuroendocrine markers, immune markers, and transcription factors (ASCL1, NEUROD1, and POU2F3) is currently ongoing and will be correlated with clinical outcomes.

Conclusions: Our study provides valuable insights into the clinical and pathoanatomical landscapes of PNETs and LCNECs. In-depth molecular characterization and investigation into larger cohorts are currently ongoing to validate our observations and further explore treatment efficacy and patient outcomes.

EP.14D.01 Cadonilimab Plus Bevacizumab and Chemotherapy as First Line Therapy in Unresectable Pleural Mesothelioma: A Single-Arm Phase II Study

w. fang[1], L. Zhang[1], H. Zhang[2], M. Fang[3], [1]Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Guangzhou/CN, [2]Guangdong Provincial Hospital of Traditional Chinese Medicine, Guangzhou/CN, [3]Zhejiang Cancer Hospital, Hangzhou/CN

Introduction: Pleural mesothelioma is usually diagnosed at an advanced, unresectable stage at which systemic therapy is the only treatment option. Platinum-pemetrexed chemotherapy with or without bevacizumab is standard, with median survival of 12-18 months. The immunotherapies nivolumab and ipilimumab improved survival compared with platinum-pemetrexed, particularly in non-epithelioid histology. Nevertheless, there is still a strong unmet need to improve systemic therapy in pleural mesothelioma. Cadonilimab, a bispecific IgG-single-chain Fv fragment (ScFv) antibody that simultaneously targets PD-1 and CTLA-4, has shown encouraging anti-tumor activity and a favourable safety profile in advanced solid tumors. We aim to investigate the activity of cadonilimab in combination with bevacizumab and chemotherapy as first line treatment in unresectable pleural mesothelioma.

Methods: This is a prospective, single-arm, multicenter, investigator-initiated phase 2 study (NCT05930665). Eligible adult patients (aged ≥18 years) have histologically confirmed unresectable pleural mesothelioma; no previous systemic therapy for advanced disease; an ECOG performance status score of 0 or 1; measurable disease according to the Response Evaluation Criteria in Solid Tumours version 1.1 modified for use in pleural mesothelioma (mRECIST v1.1). Patients will receive carboplatin AUC 5, pemetrexed 500 mg/m^2, bevacizumab 7.5 mg/kg, cadonilimab 10 mg/kg intravenously on day 1 of a 3-weekly schedule for a maximum of six cycles. Bevacizumab and cadonilimab are continued for a maximum of 24 months. The primary endpoint is objective response rate (ORR) per mRECIST v1.1. Secondary endpoints include progression-free survival (PFS), disease control rate (DCR), duration of response (DOR), overall survival (OS) and safety. Simon's two-stage design is applied, with 19 evaluable patients recruited in the first stage and 13 evaluable patients to be continued in the second stage. A total of 38 patients will be recruited to account for dropout. Enrolment began in November 2023 and the study is currently ongoing.

Keywords: Pleural mesothelioma, immunotherapy, bispecific antibody

EP.15A.01 Lung Cancer Patients in a Nationwide Oncology Navigation Program

C. Baldotto[1], A. Colli[2], F. de Oliveira Marques[2], R. de Andrade Trajano[2], T.P. Moraes Coelho[2], A.C. Machado[3], M. V. J. dos Santos[3], E. Mascarenhas[1], [1]Instituto D'Or for Research and Education, Rio de Janeiro/BR, [2]Rede D'Or São Luiz, São Paulo/BR, [3]Oncologia D'Or, Rio de Janeiro/BR

Introduction: Navigation in oncology has demonstrated benefits for people at risk for or diagnosed with cancer. These include a shorter time to diagnosis and start of treatment, better adherence to recommended care, and improved quality of life. Implementing a nurse navigation program can be challenging in developing countries, especially with nationwide healthcare networks. Lung cancer (LC) is the leading cause of cancer deaths worldwide. This study describes the characteristics and outcomes of lung cancer patients in a pioneering oncology navigation program in Brazil.

Methods: Rede D'Or São Luiz (RDSL) is Brazil's largest integrated private healthcare network, comprising 63 general tertiary hospitals and 50 oncology clinics in 13 states. A comprehensive oncology navigation program was started in 46 facilities in 2018, and a web-based system was implemented in 2020. The first phase focused on following suspected or diagnosed cancer patients who attended general hospitals. After identification, a trained nurse was allocated to improve their care coordination. Epidemiological, social, and clinical data were obtained, including time to establish a cancer diagnosis and start of treatment. Every two weeks, a national virtual meeting is organized to present anonymous data, compare results, and create solutions to address national and local barriers. Here, we report data for LC patients included in the program from 2020 to 2023.

Results: The navigation program identified a total of 28,977 cancer patients. Of these, 1,897 (6.5%) had a diagnosis of LC. Most patients were newly diagnosed (54.7%) and identified at Inpatient Clinical Units (33.9%) after LC diagnosis. The emergency room was the second most frequent admission facility (22.6%). Females accounted for 55.9% of the patients. Surgery was performed in 533 patients (28.0%). Only 54 patients progressed to death during hospitalization, and 78 of them were readmitted to the hospital before outpatient consultation. A total of 285 patients (15%) required an inpatient oncology treatment approach supported by the oncology team.

Conclusions: The goal of the navigation program is to reduce cancer morbidity and mortality by eliminating barriers to timely access to cancer care, which may be financial, social, logistical, or related to communication and equity of health care delivery. These results show that the RDSL National Oncology Navigation Program is feasible. After this implementation phase, the program will measure outcomes such as pathology reports turnaround time, staging workouts, and treatment initiation intervals. In the future, we expect that data collected from this project may help individual patients and families and address cancer care disparities nationwide.

EP.15A.02 Prospective Evaluation of A Single-Day Multidisciplinary Clinic for Patients with Locally Advanced Non-Small Cell Lung Cancer

D.L. Billing, J.E. Chaft, D.R. Jones, R. Daly, A.J. Schoenfeld, B.A. Mueller, I. Preeshagul, B.J. Park, P. Iyengar, D.R. Gomez, Memorial Sloan Kettering Cancer Center, New York/NY/USA

Introduction: Approximately one-third of patients with non-small cell lung cancer (NSCLC) will present with locally advanced disease. Treatment options vary and are made based on multiple factors, including resectability and medical fitness. This workup and consensus requires complex coordination of care among the multidisciplinary team. We hypothesized that earlier multidisciplinary intervention would enhance care and clinical trial enrollment, including in those patients without an established diagnosis or full staging of lung cancer. To this end, we initiated a single-day multidisciplinary clinic for patients with confirmed locally advanced NSCLC or clinically suspected but yet to have biopsy-confirmed disease.

Methods: Patients with imaging and clinical history suggestive of locally advanced lung cancer, +/- confirmatory biopsy, were invited to participate in a multidisciplinary clinic between April 2023 and March 2024 with a maximum of 3 patients per day. Patients who accepted were scheduled for coordinated appointments with a thoracic surgeon, medical oncologist, and radiation oncologist, with consensus recommendations given at the end of the visit. Patient satisfaction data was collected prospectively. Patient demographics, retention, time to treatment start, and clinical or biospecimen protocol enrollment were also collected.

Results: Sixty-seven patients underwent evaluation in the single-day lung cancer multidisciplinary clinic. Of these, 55% were men, the median age was 67 years old (range 39 - 88). At the time of consult, 72% of patients needed additional workup including biopsy and/or imaging to complete their staging. Upon completion of all staging workup, 87% were histologically confirmed to be NSCLC and 58% were AJCC 8th edition stage II or III. Of the patients with a cancer diagnosis who were evaluated in clinic, 92% chose to continue care at the same institution. Of these patients, 70% received systemic therapy, 44% were treated with radiation, and 26% underwent a non-bronchoscopy surgery. Eighty seven percent of patients evaluated in multidisciplinary clinic were enrolled in a biospecimen or clinical research protocol. Patient satisfaction surveys indicated that 98% of patients were very likely to recommend the multidisciplinary clinic to family/friends and 87% of patients indicated the clinic helped them arrive at a final treatment decision.

Conclusions: Despite the lack of an established diagnosis or full staging at presentation, a single-day multidisciplinary clinic for clinically suspected locally advanced NSCLC facilitated high patient retention and enrollment on institutional biospecimen and clinical research protocols. Additionally, the vast majority of patients rated the experience highly, including facilitating a final treatment decision. These data imply that multidisciplinary visits are beneficial even in the context of incomplete diagnosis or staging. Expansion of this model is planned at regional facilities and for alternative clinical contexts requiring multidisciplinary input.

EP.15A.03 Lung Cancer Multidisciplinary Teams in China Show Multi-faceted Similarities and Differences Compared to Europe and Canada

B. Yin[1], Y-C. Zhang[2], J-T. Zhang[2], Y-L. Wu[2], M. Li[3], G-W. Che[4], Y. Zhang[4], P.J-Y. Cui[5], [1]Vintura, Paris/FR, [2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [3]Xiangya Lung Cancer Center, Xiangya Hospital. Central Southern University, Changsha/CN, [4]Lung Cancer Center, West China Hospital, Sichuan University, Chengdu/CN, [5]Vintura, Munich/DE

Introduction: China, with approximately 820,000 new patients with lung cancer in 2020 accounting for 37% of the total number in the world, bears the responsibility of treating the largest lung cancer patient population worldwide. Medical care in China represents a different mode with that in Europe and Canada. The objective of this study is to compare the differences and similarities in lung cancer MDT management between China, Europe and Canada, in order to better understand and summarize the characteristics and advantages of MDT management in different regions, so as to support on the improvement of the outcome and cost-efficiency of global LC MDT.

Methods: We initiated a global MDT study in LC to gather insights on the similarities, and differences of China LC MDT processes compared to other countries. In this study, we conducted virtual semi-structured interviews, on-site masterclasses, and internal data analysis with 20+ leading hospitals in LC across China, the Netherlands, Italy, Spain, Switzerland, Denmark, Norway, and Canada. Literature review has been used as general information supplement. To build a global collaboration on LC MDTs, 4 international knowledge exchange (IKE) sessions with were organised with an average of 15 LC experts attending each.

Results: We identified seven main differences between China, Europe and Canada, the most significant and fundamental of which was the enrolment criteria of patients in MDT that China MDTs focus on challenging cases such as resistance to multi-lines of therapy, multiple primary lung cancer and stage III lung cancer, while Europe and Canada MDTs mainly for routine patients. Secondly, there was also a 3x difference shown in time per patient spent in MDT, from 30-60 minutes per patient from historical records collection to patient's follow up in China due to the challenging cases discussed, to 10-20 minutes spent per patient in Europe and Canada. Thirdly regarding the setup of LC cancer and composition of MDT teams, the advanced large-scale Chinese hospitals are able to effectively integrate multiple specialists into one single unit to utilize the strength of the team more efficiently, while the specialists are often distributed separately in Europe and Canada. Other differences include leadership culture, digitalization of MDTs, incentives and reimbursement for MDT attendance, cross-institutional patient referral to the MDT, patient follow-up after MDT discussion. Similarities identified include the MDT development model from both hospital and national level, experience sharing to educate junior physicians, hospital willingness to learn at global level, and challenges of high pressure with limited medical resources.

Conclusions: Further global collaboration to identify synergies within LC MDT communities can help China and other regions learn from each other and share China expertise in large-volume data-based practices globally, so as to improve the MDT outcome and cost-efficiency globally.

EP.15A.04 A Tripartite Care Model for Home Care of Lung Cancer Patients Based on the Theory of Tripartite Care Led by Specialist Nurses

L. Li[1], c. yong[2], W. Yao[2], L. Lixia[2], C. changxia[2], O. mingqiu[2], c. xi[2], [1]The Second People's Hospital of Yibin, Yibin/CN, [2]Yibin Second People's Hospital, Yibin/CN

Introduction: To explore the challenges and countermeasures of family care for cancer patients, propose a family care plan for cancer patients based on the hospital-community-family tripartite care model led by specialist nurses, and provide new perspectives and ideas for the development and innovation of cancer care.

Methods: Through literature review, analyze the current situation, problems, and needs of family care for cancer patients, summarize the experience and models of family care for cancer patients at home and abroad, and construct the theoretical framework and implementation steps of the hospital-community-family tripartite care model led by specialist nurses.

Results: The hospital-community-family tripartite care model includes three aspects: coordination mechanism, training and guidance, support and evaluation. Under the leadership of specialist nurses, it can achieve information sharing, resource integration, and service connection between hospitals, communities, and families, improve the nursing ability and self-management level of family caregivers, provide personalized psychological, social, and economic assistance, and regularly monitor and feedback the nursing effects and satisfaction of patients and families.

Conclusions: The hospital-community-family tripartite care model led by specialist nurses is an effective countermeasure for family care of cancer patients. It is of great significance for improving the quality of life of cancer patients, alleviating symptom distress, reducing medical costs, enhancing family resilience, etc., and is worth promoting and applying in cancer care practice.

EP.15B.01 Effect of Mindfulness-Based Stress Reduction Psychological Intervention on Anxiety and Depression in Patients with Lung Cancer Radiotherapy

J. Yang[1], D.F. Huang[2], [1]Hubei cancer hospital, Wuhan/CN, [2]First Ward of Abdominal Radiotherapy,Hubei Cancer Hospital. Wuhan, Hubei Province, Wuhan/CN

Introduction: To explore the effects of mindfulness-based stress reduction on anxiety and depression in lung cancer patients during radiotherapy.

Methods: 86 patients with lung cancer treated with radiotherapy in our hospital were divided into control group and observation group by random number table method. The control group received routine nursing care of lung cancer radiotherapy after admission, including the introduction of relevant knowledge of lung cancer disease, respiratory function exercise, diet and rest precautions during radiotherapy, and the use of related drugs, and psychological reassurance for patients to reduce their anxiety. On the basis of routine nursing, the observation group implemented mindfulness-based decompression psychological intervention after admission, and formulated corresponding training plans and contents according to the content of mindfulness-based decompression and the actual situation of patients during radiotherapy. The self-rating Anxiety Scale (SAS), self-rating Depression Scale (SDS) and the incidence of radiotherapy complications were observed before and after the intervention. The specific measures to implement mindfulness-based stress reduction psychological intervention in the observation group were as follows: ①A mindfulness-based stress reduction psychological intervention group was established, including 1 deputy chief physician in the radiotherapy department and 4 nursing staff with more than 5 years of nursing experience. ②Before the implementation of the mindfulness-based stress reduction psychological intervention program, the group members all learned and were familiar with the concept and specific content of mindfulness-based stress reduction psychological intervention. When the content of mindfulness-based stress reduction was uncertain, they promptly consulted the national second-level psychological counseling teachers. ③After the patient was admitted to the hospital, a wechat group was established to guide the patient to conduct 30min independent exercises once a day for the patient for 4 weeks. Family members were encouraged to attend the training once a week and assist the patient to actively participate in the training. The guidance manual for relevant training content was distributed at the first training session, and the relevant concepts, contents and matters requiring attention of MBSR therapy were regularly pushed to the wechat group. Patients improve their self-control while relaxing, thereby regulating their own response to bad emotions and improving the mood of patients. ④Through wechat video call and other forms of communication training, there is a person in person or wechat group every day to prompt mindfulness-based stress reduction therapy training punched, actively encourage the completion of training personnel, can not complete the personnel timely telephone communication reasons, to help solve difficulties, in the case of the day after surgery or other special circumstances can not tolerate training, reduce the training content or cancel the training.

Results: The scores SAS and SDS of the observation group were significantly lower than those of the control group (t=11.276, 13.155; P<0.05). The incidence of radiation complications, such as radiation pneumonia and radiation esophagitis, also decreased significantly after radiotherapy.

Conclusions: Psychological intervention program based on mindfulness-based stress reduction can reduce the anxiety and depression of patients with lung cancer radiotherapy, and reduce the complications of lung cancer radiotherapy.

EP.15B.02 Real-World Data from Advanced Practice Nurse Care in Lung Cancer in a Private Clinic in Brazil.

G. Farias[1], I. Borchardt[1], G. Moreira[1], V. Figueiredo[1], N. AFONSO[2], G. VELOSO[2], M. REIS[2], B. SILVA[2], C. SANTOS[2], P. MARCHI[2], F. TAVEIRA[2], C. GIL[2], T. MONTELLA[2], [1]Oncoclinicas, RIO DE JANEIRO/BR, [2]GRUPO ONCOCLINICAS, RIO DE JANEIRO/BR

Introduction: The treatment of lung cancer (LC) has made important advances in recent years, increasing the complexity of care and the need for support by advanced practice nurses (APN) specialized in LC. The objective of this study is to identify the profile and outcomes related to APN care in patients with PC in a private center in Brazil.

Methods: This is a cross-sectional study carried out from 2022 to 2023 with patients diagnosed with LC at a cancer center in Brazil. The data consisted of clinical and epidemiological variables, actionable mutations, therapeutic modalities and detection and intervention of adverse events (AE) by APN. AE were classified according to (CTCAE) and data were presented descriptively.

Results: A total of 95 patients were evaluated, 78% female, 63% elderly, 95% NSCLC, 71% adenocarcinoma, 64% smokers, 84% with TNM III-IV, 27% patients had actionable mutations, with a predominance of 23% in EGFR. Regarding therapeutic modalities, 56% received systemic treatment with chemotherapy and/or immunotherapy, 27% tyrosine kinase inhibitors, 25% radiotherapy and 21% underwent lobectomy. 100% of patients were monitored (Figure 1) by APN. AEs of any cause and degree occurred in 70% of patients and were identified, managed, guided and referred to the interdisciplinary team. Among them we can highlight the management of fatigue, paronychia, diarrhea, neutropenia, anorexia, anemia, constipation, nausea, rash, thrombocytopenia, mucositis. AE with grades 1 and 2 were 92%, while grade 3 were 8%. Outpatient and home management was 96% and 4% with hospital admission. Referral to the interdisciplinary team occurred in 100% of patients with follow-up of 87% for pharmaceutical, 83% nutritional, 70% psychological and 59% dental care.

Conclusions: Our data found a low occurrence of G3 AE and hospital admission in patients with compared to literature data, demonstrating the importance of APN action. APN plays a fundamental role in managing patient care throughout their treatment journey. APN navigation operates at all stages of the therapeutic process, thus contributing to the early detection of toxicities, facilitating management, intervention and guidance for the interdisciplinary team. Personalized care favors better outcomes and should be encouraged.

EP.15B.03 Pilot Web-Based Study of Functional Status and Quality of Life Benefits Associated with Darbepoetin Alfa Use in Anemic Patients with Lung Cancer

I. Riano[1,2], M.A. Carey[1], H. Pomares-Millan[2], J. Moran[2], J.R. Rigas[1], K.H. Dragnev[1,2], [1]Dartmouth Cancer Center, LEBANON/NH/USA, [2]Geisel School of Medicine at Dartmouth College, Hanover/NH/USA

Introduction: Patients with lung cancer often present with symptomatic anemia at diagnosis. Moreover, platinum-based chemotherapy with or without immunotherapy, induces anemia through myelosuppression and impaired renal erythropoietin release. Erythropoietin-stimulating agents have shown efficacy in chemotherapy-induced anemia (CIA) but concerns regarding potential tumor-promoting effects have curtailed their use. Improvements in cancer-related symptoms have been reported in paper-based surveys. We conducted a pilot study to explore a web-based platform to evaluate the clinical symptom benefits associated with darbepoetin alfa (DPO) administration in anemic patients with lung cancer and assess for correlation with changes in hemoglobin (Hb) concentrations.

Methods: This is an open-label, single-arm pilot trial in patients with NSCLC/SCLC with Hb≤11.0g/dL(NCT00153868). Patients were treated with DPO 200mcg subcutaneously Q2W or DPO 300mcg Q3W for 12 weeks. Hb concentrations were obtained every 2 or 3 weeks. Patients with <1.0g/dL increase in Hb after 6 weeks required DPO dose escalation. Endpoints included time of Hb response (increase Hb≥2.0g/dL over baseline) and time of Hb correction (Hb≥12.0g/dL). We conducted posthoc pairwise comparisons under a paired T-test framework at each visit after Bonferroni correction for significance. Before DPO administration, patients completed a secure web-based assessment of cancer-related symptoms (LCSS), functional status (SF-36), and QoL (FACT-An and PFS).

Results: 29 patients were included in the analysis; 14 were men (48.3%) and 15 female (51.7%) with a median age of 64 years. Most of the patients presented with advanced disease (n=21, 72.4%); 23 (79.3%) had NSCLC, and 6 (20.7%) had SCLC. More than half were treated with platinum-based chemotherapy (n=17, 58.6%). Only 4 patients (13.4%) required blood transfusions. The trial completion rate was 51.7% (n=15). Hb response was observed in 13 patients (44.8%) and Hb correction in 9 patients (31%)(Fig.1). Pairwise comparisons between Hb concentrations at baseline and weeks 6 and 8 were statistically significantly different at PBonferroni=0.018 and PBonferroni=0.008, respectively. The platinum-based chemotherapy group showed an earlier Hb effect on DPO at week 6 (PBonferroni=0.012) compared to the non-platinum-based chemotherapy group at week 8 (PBonferroni= 0.046). Updated results for the assessments of the functional status, and QoL will be presented at the meeting.

Conclusions: Results from this study confirmed that DPO increases Hb concentrations in lung cancer patients with CIA. In patients receiving myelosuppressive platinum-based chemotherapy, Hb concentrations improved earlier on DPO compared with other regimens. After week 6 on DPO, Hb>8g/dL was more frequently observed. Proper DPO use is crucial to its efficacy in lung cancer.

EP.15B.04 High-Fiber Intake Predicts Overall Survival in Lung Cancer Patients - Real-World Analyses

I. Borchardt[1,2], G. Farias[1], G. Fraga[1], C. Augusto[2], S. Chek[2], J. Janoni[2], J. Oliveira[2], J. Lattanzi[1], A. Barcellos[1], V. Figueiredo[1], C. Alves[3], F. Telles[1], F. Dias[1], P. De Marchi[1], T. Montella[1], W. Peres[2], A. Melo[1], C.G. Ferreira[1], [1]Grupo Oncoclinicas, Rio de Janeiro/BR, [2]Universidade Federal do Rio de Janeiro, Rio de Janeiro/BR, [3]Gustave Roussy Cancer Campus (GRCC), Clinicobiome, Villejuif Cedex/FR

Introduction: The treatment of lung cancer (LC) has advanced with the use of targeted therapies and checkpoint inhibitors, however, the responses are still unsatisfactory in some individuals. Therapeutic modalities are influenced by the intestinal microbiome, which depends on a series of factors, including dietary fiber intake, with current dietary recommendations of 30g/day, also indicated after cancer diagnosis, if possible. The current analysis aimed to evaluate whether dietary fiber consumption at diagnosis is predictive of LC treatment outcomes.

Methods: This is a prospective observational cohort carried out with LC patients served from January to December 2019 from a private center in Rio de Janeiro, Brazil. This study was approved by the Ethics in Human Research Committee and was conducted following the Good Clinical Practice Guidelines. Clinical variables, first-line therapeutic modalities as well as nutritional risk screening for patients cancer and anthropometric data were used. Information on food consumption at the time of diagnosis was analyzed using a 24-hour recall. The Kaplan-Meier method was used to estimate overall survival (OS) according to fiber consumption.

Results: A total of 50 individuals were included, with a mean age of 71.2 [48, 88] years, 62% female, and 88% had non-small cell LC, 88% with stage III and IV disease, 82% ECOG perfomance status 1, 64% (current or former) smokers. First-line therapeutic modalities consisted of 90% chemotherapy and/or immunotherapy, 6% targeted therapy, 12% radiotherapy, and 10% surgery. Regarding nutritional status, 76% were at risk at screening, a median body mass index of 23.7kg/m^2 [21.08, 28.18], and 60% were classified as eutrophic and/or overweight according to with age. The median consumption of dietary fiber was 13.15 g/day with interquartile ranges [10.32, 19.05]. Individuals with fiber consumption greater than 19.05 g/day had a higher median OS than those with lower intake, 56.5 versus 33.9 months, respectively (p=0.008)(Figure 1).

Conclusions: In the current study, the median consumption of dietary fiber at diagnosis was lower than recommended, reflecting unsatisfactory consumption of a plant-based diet. The fiber intake was a predictor of the treatment results of LC patients. Dietary fibers have been postulated as a possible modulator of the intestinal microbiome and antitumor immunity. Nutritional interventions are simple, practical, accessible measures that allow a personalized approach that can reverse these findings and thus contribute to better clinical results. Nutritional care should be part of the LC patient's journey.

EP.15B.05 Predictors of 30-Day Mortality after Systemic Therapy in Hospitalized Lung Cancer Patients: A Retrospective Single-Center Observational Study

M. Peroni[1], A. Leonetti[2], V. Agnetti[1], F. Pratticò[1], M. Manini[1], A. Acunzo[1], E. Rapacchi[2], G. Mazzaschi[1,2], F. Perrone[2], P. Bordi[2], S. Trapani[2], G.P. Bacchini[2], S. Buti[1,2], M. Tiseo[1,2], [1]Department of Medicine and Surgery, University of Parma, Parma/IT, [2]Medical Oncology Unit, University Hospital of Parma, Parma/IT

Introduction: Due to the aggressive nature and high incidence of disease-associated symptoms, hospitalization is often required for lung cancer patients in order to receive oncologic treatment. An accepted threshold for late systemic therapy administration is 30 days before death, but data regarding potential predictive factors of 30-day mortality following anticancer treatment are still limited.

Methods: This is a retrospective single-center observational study aimed at investigating potential predictors of 30-day mortality since systemic therapy start in lung cancer patients admitted to receive anticancer treatment at the Oncology ward of University Hospital of Parma from January 2017 to January 2022. Baseline clinicopathological features, laboratory values and immunological scores were collected. Prognostic nutritional index (PNI) was calculated using the albumin level and lymphocyte count.

Results: A total of 144 lung cancer patients were consecutively enrolled; 14 (9.7%) patients did not start anticancer treatment and were excluded from the study. Among 130 included patients, median age was 68 years (Range, 30-86), 79 (60.8%) patients were men and 112 (89.6%) current/former smokers. ECOG Performance Status was 0/1 in 100 (76.9%) cases. Median body mass index was 25.3 (Range, 15.3-42.9). The most frequent histology was small-cell carcinoma (n = 60, 46.2%), followed by adenocarcinoma (n = 41, 31.5%), and most of the patients had stage IV disease (n = 107, 82.3%). Baseline median hemoglobin was 12.1 g/dL (Range, 7–16.8) and median albumin was 3.3 g/dL (Range 2.4-4.4). At admission, median values of platelet-to-lymphocyte ratio, neutrophil-to-lymphocyte ratio (NLR) and derived NLR were 177.1 (Range, 25.1–836.0), 4.4 (Range, 0.4–23.9) and 2.8 (Range, 0.3–11.4), respectively. PNI had a median value of 41.4 (Range, 28.3–59.8). Median time from hospitalization to treatment start was 5.0 days (95% Confidence Interval [CI] 3.0–6.0). Chemotherapy was the most frequent administered treatment (n = 76, 58.5%), followed by chemoimmunotherapy (n = 33, 25.4%). The majority of patients (n = 115, 88.5%) received therapy in first-line. After a median follow-up of 30.5 months (95% CI 26.2–Not Reached), median overall survival from anticancer therapy was 6.4 months (95% CI 4.3–7.8). The 30-day mortality rate from therapy was 10% (n = 13). Age was significantly associated with 30-day mortality from therapy (≥ 65 vs < 65: 15.9% vs 0%, p = 0.002). Baseline laboratory predictors of 30-day mortality were low hemoglobin (low vs in range vs high: 18% vs 2.9% vs 0%, p = 0.013), low albumin (low vs in range: 17.7% vs 0%, p = 0.008) and low pseudocholinesterase (pCHE) (low vs in range: 22.7% vs 3.9%, p = 0.002). Among immunological scores, PNI showed a negative impact on 30-day mortality in our study population (< 45 vs ≥ 45: 16.4% vs0%, p = 0.030).

Conclusions: Older age and baseline low values of hemoglobin, albumin, pCHE and PNI were associated with increased 30-day mortality from therapy in hospitalized lung cancer patients. Special caution should be addressed when treating in-hospital lung cancer patients with the above-mentioned features.

Keywords: lung cancer, 30-day mortality, systemic treatment

EP.16A PATIENT ADVOCACY - BIOMARKERS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16A.01 Patient Experiences of Biomarker Testing: Insights from a Global Patient Experience Survey

K. Clayton[1], M. Daniels[2], J. Fox[3], B. Gaspar[4], M. Hennink[5], J. Mayans[4], A. McNamara[6], L. Pretorius[2], M. Rigney[7], M. Dohr[8], [1]Lung Cancer Nursing UK, London/GB, [2]Campaigning for Cancer, Randburg/GB, [3]Roy Castle Lung Cancer Foundation, Liverpool/GB, [4]Asociación Española de Afectados de Cáncer de Pulmón, Valencia/ES, [5]Longkanker Nederland, Utrecht/NL, [6]Irish Cancer Society, Dublin/IE, [7]GO[2] Foundation for Lung Cancer, Washington, D.C./DC/USA, [8]Incisive Health, London/GB

Introduction: Looking for changes in tumour cell DNA, biomarker testing plays a crucial role in tailoring optimal treatment plans for individuals with lung cancer. As biomarker testing becomes more widely available, more patients can now benefit from targeted therapies tailored to their unique tumour type. The Global Lung Cancer Coalition (GLCC), a partnership of 43 patient organisations across 30 nations, sought to understand the experience of patients across the world in receiving access to biomarker testing, and to see whether patients understood what biomarker testing is.

Methods: In the GLCC's fifth annual survey, the coalition commissioned Censuswide to conduct a global survey of lung cancer patients. The survey is currently in the field across 18 countries (Australia, Argentina, Bulgaria, Canada, Denmark, Greece, Ireland, Israel, Italy, Japan, Mexico, Portugal, Netherlands, South Africa, Spain, Taiwan, UK, USA). As part of this survey, the GLCC included questions regarding respondents' personal experience with biomarker testing.

Results: 92% (346/375) of respondents with non-small cell lung cancer [or those who did not know what type of lung cancer they had] reported having been spoken to about biomarker testing.

However, nearly 40% (129/346) of those who reported having been tested did not understand what was meant by 'biomarker testing' when they first heard about it. Similarly, one-third of respondents (129/346) reported having to subsequently do their own independent research to learn what was meant by the term.

Conclusions: While the majority of respondents eligible for biomarker testing reported having been spoken to about it, four out of ten reported not understanding the term when it was first discussed - highlighting a significant gap in patient communication and understandingabout these tests.

The GLCC patient charter states patients have a right to informed self-determination. Therefore, it is important that people who undergo biomarker tests have the tests (and subsequent results) clearly communicated. Healthcare professionals, serviceproviders and patient support groups provide important education about biomarker testing. They should be supported to improve the clarity of this communication to help more patients access personalised treatment, support and care.

Keywords: patient experience, patient information, biomarker testing

EP.16B PATIENT ADVOCACY- CLINICAL COMMUNICATIONS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16B.01 UK and US Patient Preferences for Anaplastic Lymphoma Kinase Positive Advanced Non-Small Cell Lung Cancer Tyrosine Kinase Inhibitors Treatments

K.W. Culver[1], D. Montague[2], H. Le[3], J. Coulter[3], J.C. Cappelleri[3], H. Lu[4], M. Quaife[4], K. Meginnis[4], G. Fernandez[4], S. Vaghela[3], N. Rifi[3], T. Stinchcombe[5], [1]ALK Positive Inc., King of Prussia/PA/USA, [2]ALK Positive Lung Cancer (UK), Caldicot/GB, [3]Pfizer Oncology, New York/NY/USA, [4]Evidera, Cambridge/GB, [5]Duke University, Durham/NC/USA

Introduction: We aimed to explore patient experiences, expected treatment benefits, and treatment-related risks associated with anaplastic lymphoma kinase positive (ALK+) tyrosine kinase inhibitors (TKIs) in the 1L setting for patients in the UK and US, to understand key treatment attributes for decision-making.

Methods: Thirty semi-structured interviews (US: 20; UK: 10) were conducted with patients with advanced ALK+ non-small cell lung cancer (aNSCLC). Interviews (90 min with an online survey) utilized qualitative and quantitative methods. Qualitative interview data was analyzed using an inductive thematic approach, while the quantitative responses were analyzed descriptively.

Results: The mean age of patients in the US was 52 years (range 38-69), with 60% having brain metastases (BM). In the UK, mean age was 48 (range 31-62), with 40% having BM. Most patients in the US were on 2L (40%) or 3L+ (35%) treatments, while most UK patients were on 1L treatment (70%). Most US patients indicated they were restricted in strenuous activity (85%), as opposed to UK patients where most reported being fully active (70%). The treatment benefits most desired by patients in the US and UK were improving overall survival (90%, 70% respectively), improving progression-free survival (85%, 70%), and preventing metastases (55%, 50%). Patients without BM were concerned about BM development, particularly those from the UK, as it may significantly affect their daily activities such as driving. Quality of life improvements were primarily described as coming from cancer control. Patients in the US and UK reported experience with fatigue (85%, 60%), and weight gain (65%, 60%). The third most reported side effect was muscle pain in the US (65%) and constipation in the UK (60%). While there were slight variations in treatment side effect experiences, both US and UK patients were concerned about cognitive effects (50%, 50%), weight gain (35%, 40%), and fatigue (30%, 30%). All patients were willing to tolerate adverse events in exchange for efficacy. Patients in the UK had less experience with multiple TKIs in their treatment sequence than patients in the US (30%, 70%). Patients in both countries expressed a preference for a regimen that was infrequent (e.g., once a day) and without dietary restrictions, but a few individuals conveyed dissatisfaction with their treatment due to administration requirements. Patients from both countries indicated that the treatment selection and change in treatment decision were based on discussion with their doctors. The shared decision-making process was described to evolve over time, with patients initially relying solely on doctors' advice, and later gaining confidence in conducting independent research to be "very involved in all the decisions".

Conclusions: While the priorities of US and UK patients were similar, some differences in TKI treatment preferences were detected between countries. Most patients prioritized treatment efficacies (i.e., improving overall survival, lung cancer control, and controlling BM progression or development) over side effects. Overall, this study highlights the importance of considering patient preferences and experiences when developing treatment strategies in ALK+ aNSCLC patients.

EP.16B PATIENT ADVOCACY- CLINICAL COMMUNICATIONS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16B.02 Lung Cancer Patients' Preferred Methods of Receiving Information from their Treatment Teams: Insights from a Global Patient Experience Survey

K. Clayton[1], M. Daniels[2], J. Fox[3], B. Gaspar[4], M. Hennink[5], J. Mayans[4], A. McNamara[6], L. Pretorius[2], M. Rigney[7], M. Dohr[8], [1]Lung Cancer Nursing UK, London/GB, [2]Campaigning for Cancer, Randburg/ZA, [3]Roy Castle Lung Cancer Foundation, Liverpool/GB, [4]Asociación Española de Afectados de Cáncer de Pulmón, Valencia/ES, [5]Longkanker Nederland, Utrecht/NL, [6]Irish Cancer Society, Dublin/IE, [7]GO[2] Foundation for Lung Cancer, Washington, D.C./DC/USA, [8]Global Lung Cancer Coalition, Liverpool/GB

Introduction: The Global Lung Cancer Coalition (GLCC), a partnership of 43 patient organisations across 30 nations, reaffirms in its charter the right of all lung cancer patients to be treated with dignity and respect and to have access to quality health care, including informed self-determination and physical and mental integrity.

How patients engage with and receive information from their treatment teams is essential for these patient rights. GLCC therefore sought to understand patients' preferences for receiving information from their treatment teams in different clinical contexts.

Methods: In the GLCC's fifth annual survey, the coalition commissioned Censuswide to conduct a global surveyof lung cancer patients. The survey ran from 28 March 2024 - 18 April 2024. It received 905 responses across 18 countries (Australia, Argentina, Bulgaria, Canada, Denmark, Greece, Ireland,Israel, Italy, Japan, Mexico, Portugal, Netherlands, South Africa, Spain, Taiwan, UK, USA).

Results: When asked what is your preferred format for receiving information, there was variation in response, with cancer support hotlines (33%: 297/905), print materials (29%: 261/905) and apps (14%: 128/905) all ranking highly.

Participants were also asked how they felt about the information they received. The majority of respondents felt they got the information they needed at the right time: at diagnosis (82%: 745/905); when starting treatment (78%: 638/813); when changing treatment (76%: 615/813); when ending treatment / follow-up (76%: 615/813); when accessing palliative care (73% 656/905).

Conclusions: While the majority of respondents reported getting the right information at the right time, there is still scope for improvements in when and how information is shared, particularly as patients journeythrough their care pathways. Healthcare providers should tailor their approaches to providing patient information, fostering more effective patient-provider relationships and ultimately enhancing the delivery of patient-centric care.

Keywords: patient experience, health information, treatment

Questions	Answer options			
Doctors can take a sample of a tumour to test for biomarkers (also known as mutation, genomic, or molecular testing). Has anybody spoken to you about this topic?	Yes, and the cancer has been tested.	Yes, but the cancer has not been tested.	No, nobody has mentioned this to me.	I am not sure.
If you were spoken to about biomarker testing, do you feel you understood what it is?	Yes, I understood what biomarker testing meant before or after someone spoke to me about them.	No, I did not understand what it meant when they spoke to me about it, but I since have learned what it means on my own.	No, I did not understand what it meant when I first heard about it, and I still do not know.	I am not sure.

What best describes how you feel about the information you received from your treatment team about your lung cancer? Please choose the option that best describes you.

EP.16C PATIENT ADVOCACY - CLINICAL TRIALS IN PROGRESS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16C.01 The INSPIRE (INformation Support through Patient Involvement for Research and Education) Project

M-L. Meyer[1], K. Lê Van[1], S. Peters[1], [1]CHUV - Centre Hospitalier Universitaire Vaudois, Lausanne/CH

Introduction: Communication is a critical element in the relationship between patients and the healthcare system, influencing patient satisfaction, reducing anxiety levels, and preventing medical errors. The Swiss Cancer Patient Experiences (SCAPE) study identified areas in communication that specifically require enhancement, especially concerning the delivery of treatment information, including the management of side effects. Consequently, a program was developed to bolster services for patients, including the creation of a mobile app currently used for general information. Our research project aims to address the gaps identified in the clinical information exchange between healthcare providers and patients in thoracic oncology by developing personalized information tools.

Methods: This study proposes a qualitative analysis in collaboration with expert patients (individuals who have developed significant knowledge about their condition and treatment through their lived experience) to identify deficits in clinical information content. Focus groups and semi-structured interviews will be conducted to understand detailed specific needs. Informational supports will be written in collaboration with the oncologists, nurses, pharmacists, and communication experts at the University hospital. The project will develop personalized information supports detailing treatment plans, medications, administration modalities, schedules, common side effects, and urgent consultation needs. These supports will be designed for digital and printable access and will be integrated into the mobile app. They will be accessible at all times by patients and relatives and also aim to serve as references during medical and specialized nursing consultations, as well as for teaching purposes. Expert patients and healthcare professionals will formally evaluate their effectiveness.

Keywords: Communication, Expert Patient, Personalized Information

EP.16D PATIENT ADVOCACY - DISPARITIES
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16D.01 Call Me by My Pronouns: Ethnic Disparities in Self-Reporting Gender Identity in Patients with Cancer

C. Olazagasti[1], K. Edwards[2], F. Penedo[1], E. Rodriguez[1], [1]Sylvester: Sylvester Comprehensive Cancer Center, miami/FL/USA, [2]University of Miami, Miami/FL/USA

Introduction: To promote inclusivity, the term LatinX has emerged in recent years to incorporate all gender identities in the LatinX population. However, its use is not common practice in this population, as only 24% of LatinX adults report having heard the term and only 3% has ever used it. This raises suspicion for the perceptions of the LatinX population regarding the use of self-identifying pronouns. In our study, we assess the trends on self-reporting gender identity in the LatinX population with cancer. We hypothesized that LatinX are less likely to report their pronoun of preference in their medical records than other ethnicities.

Methods: We performed a single institution study at the University of Miami. All subjects with cancer seen from 2020-2021 were included in the analysis. Demographic information including age, sex at birth, gender identity, race, and ethnicity were obtained. Our variables of interest were responses to gender identity. Options to choose from included: she/her/hers, he/him/his, they/them, not listed, unknown, or decline to answer. A chi-square comparison was conducted to compare responses to pronoun identification question and ethnicity.

Results: We reviewed the charts of 90,110 participants of which 38.7% self-identified Hispanic/LatinX, 56.5% non-Hispanic/LatinX and 4.8% unknown/other ethnicity. Of the total cohort, only 12.5% selected an answer to the gender preference question, whereas the rest left the question blank. Hispanic patients were significantly less likely to select their pronoun of preference and more likely to choose 'decline to answer' than any other ethnic group. Almost one third (29%) of the Hispanics that selected an answer to the gender identity question, selected 'decline to answer' compared to 19% and 18% of non- Hispanics and unknown/other ethnicity, respectively (chi sq 184.9; $p < 0.00001$) [Table 1].

Conclusions: Despite Hispanic/LatinX comprising only approximately one third of the patients analyzed, they accounted for almost half of the patients who selected 'decline to answer' as their response to the gender identity question, much more frequently than other racial and ethnic groups. It is unclear the premises under which Hispanic/LatinX refused to select their pronoun of preference. Presumable, some of the reasons could be fear of judgement, a lack of understanding of the terms, and/or adamancy towards the use of self-identifying pronouns. Further studies to understand the LatinX awareness and perceptions towards gender identity is needed to best promote inclusion, self-acceptance, and overall satisfaction with cancer related care.

Keywords: disparities, gender identity, hispanic

	Hispanic/LatinX (N = 3726)	Non-Hispanic/LatinX (N = 5515)	p
Selected 'Decline to answer'	1081	1002	< .00001

EP.16E PATIENT ADVOCACY - LUNG CANCER EDUCATION
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16E.01 Advancing Patient Empowerment: The Growth and Impact of Educational Lung Cancer Patient Groups

D.J. Donaldson[1], L. Abbott-McCloud[2], [1]LiveLung, High Point/NC/USA, [2]LiveLung, Charlotte/NC/USA

Introduction: Introduction: Impact of a Lung Cancer Diagnosis and the Role of Patient Groups Lung cancer patients face multifaceted challenges upon diagnosis, including emotional turmoil, financial strain, and social stigma. In response to these challenges, educational lung cancer patient support groups have emerged as crucial resources for patients and their families. These groups provide a platform for sharing experiences, accessing information, and fostering community. Martina Jablotschkin's research on cancer self-help groups (CSHGs) in European Journal of Cancer Care emphasizes the benefits of such groups for patients and their partners. "Benefits and challenges of cancer peer support groups: A systematic review of qualitative studies," the authors state that "All included studies consistently indicate that participation in a peer led CSHG leads to multiple perceived benefits, that is, informational support, shared experience, learning from others, helping others as well as cultivating humour as a coping strategy." LiveLung educational patient groups bring expert speakers to address many concerns of patients and their partners. One of the primary objectives of the programs is to share knowledge that empowers patients.

Methods: Methods: The objective of this abstract is to highlight growth and impact of educational lung cancer patient groups over the past three years. Examining the expansion of these groups underscores the positive impact such programs bring in addressing the needs of lung cancer patients nationwide. We conducted a retrospective analysis of the growth and development of LiveLung educational patient groups from January 2021 to December 2023. Data were collected from program records, participant feedback, and community outreach efforts. We also included data from a new patient group exclusively for Small Cell Lung Cancer patients.

Results: Results: Over the past three years, LiveLung educational patient groups have experienced substantial growth expanding their reach to serve an increasing number of lung cancer patients and their families across the country. Total attendees were 598 in 2021, 1,129 in 2022; and 1,664 in 2023—a 278 percent increase from 2021 to 2023. The SCLC program grew from 271 attendees in 2022, when the program started, to 666 in 2023.

Conclusions: Conclusion: The growth of LiveLung educational patient groups highlights the critical need for accessible and comprehensive support services for lung cancer patients nationwide. By providing education, community, and empowerment, these programs play a vital role in improving the quality of life and outcomes for individuals affected by lung cancer.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16E.02 15 Years of the Lung Cancer Living Room Expert Speaker Series Provides Critical Education to Global Audience

N.M. Phipps, D. Hicks, M. Zeh, GO² for Lung Cancer, SAN CARLOS/CA/USA

Introduction: Lung cancer remains the deadliest cancer in the United States and around the world. In 2009, The Bonnie J. Addario Lung Cancer Foundation, now GO2 for Lung Cancer, began a monthly expert speaker series called the Lung Cancer Living Room to educate and empower people facing a lung cancer diagnosis. Over the years, the program has evolved and expanded to reach a global audience, bringing conversations with lung cancer thought leaders directly into people's living rooms via live stream on Facebook and YouTube and via video library on Vimeo and YouTube. Topics for these 200+ Living Room episodes have included early detection, biomarker testing, targeted therapies, small cell lung cancer, pulmonary health, palliative care, financial toxicity, survivorship, and so much more. Although based in the US, the Living Room has become a trusted source of education and information around the world, particularly in countries where advocacy groups like GO2 for Lung Cancer are fewer and farther between.

Methods: Data was reviewed regarding Living Room views on YouTube between 2000 and 2024. There were approximately 1.4 million total views during that time.

Results: Across approximately 1.4 million total views on YouTube, approximately 20% - or 280,000 views - have come from people located outside of the United States. The top countries outside the US are - in approximate order - Philippines, Japan, China, India, the UK, Australia, Canada, Singapore, Mexico, Spain, Taiwan, and Hong Kong.

Conclusions: Over the past 15 years, the Lung Cancer Living Room has become a source of critical lung cancer education across the globe for people experiencing a lung cancer diagnosis, with especially strong viewership in countries where support from advocacy groups may not exist at all or may be insufficient to meet the needs of the lung cancer community.

Keywords: lung cancer, education, global advocacy

EP.16F PATIENT ADVOCACY - NEEDS OF PATIENTS AND CAREGIVERS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16F.01 Priorities and Support Needs for People Impacted by Lung Cancer in Ireland

J. Byrne[1], T. Byrne[1], B. Carpenter[1], D. Staunton[1], M. O'Sullivan[1], C. Dowling[1], A-M. Baird[1], S. Cotter[1], [1]Irish Lung Cancer Community, Dublin/IE

Introduction: While more general European data is available in relation to the needs of the wider lung cancer community, there is little known specifically in relation to Ireland. The aim of this study was to find out demographical information and identify key educational needs and priorities in Irish people impacted by lung cancer.

Methods: Following a review of the literature, a brief survey was developed concentrating on three key themes (i) demographics, (ii) supports available and how people access existing information, and (iii) educational priorities. The survey was active for approximately 1 month and delivered through Microsoft Forms with no identifiable information collected. The survey was socialised through the Irish Lung Cancer Community (ILCC)'s social media platforms and our closed Facebook group as well at the Irish Lung Cancer Alliance (ILCA).

Results: Forty-six people responded to our survey, although all participants did not respond to all questions. Participants were mainly people diagnosed with lung cancer (29/44), female (38/46) and 50-65+ years of age (29/42). Most were living with Stage IV disease (32/46) and were diagnosed with non-small cell lung cancer (NSCLC) - adenocarcinoma (27/46). Although 15% of participants did not know what type of lung cancer they had (7/46). In terms of biomarker testing, a significant 29% did not know if their tumour was tested (13/45), with a further 56.5% stating that their tumour had been tested. The most common markers were EGFR (10/27) and ALK (10/27). Participants stated that a range of supports were accessible to them from psychosocial to financial. The top three supports that were available were psychosocial/counselling, patient organisation support and physical therapy, which were the same top three that people accessed and prioritised. Participants primarily accessed disease information through their care team and the internet, with their care team ranked as the most important place to get information. In terms of preferences in receiving information - something that could be read either physically or digitally and chatting to other people, were the top three. There were a large number of expectations in what the ILCC should deliver with the top three relating to information on the latest research and treatments, information, and guidance on how to navigate the system/care pathway and facilitating peer to peer support. These same three items were given the highest priority ranking. Interestingly raising awareness to destigmatise the disease was the least priority. The top channels to receive the information and support from the ILCC was evenly spread over webinars, our website and social media channels and in person events.

Conclusions: While this is a small study, it is to our knowledge, the first and largest study within the lung cancer patient community in Ireland. It demonstrated a key need for further information and support particularly in terms of research/treatments and navigating the complex care pathway. In person peer to peer support is also highly valued.

Keywords: Advocacy, Ireland, Support

EP.16F PATIENT ADVOCACY - NEEDS OF PATIENTS AND CAREGIVERS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16F.02 Availability of Supportive Care in Lung Cancer: A Global Perspective

M. Rigney[1], L. Dallas[2], C. Ference[3], A. McNamara[4], [1]GO[2] for Lung Cancer, Washington/DC/USA, [2]Roy Castle Lung Cancer Foundation, Glasgow/GB, [3]Memorial Sloan Kettering Cancer Center, New York/NY/USA, [4]Irish Cancer Society, Dublin/IE

Introduction: People with lung cancer experience high rates of distress and have greater unmet psychological and physical needs compared to those with other cancers. Lung cancer remains the leading cause of cancer deaths in most parts of the world with an estimated 2+ million diagnoses and up to 1.8 million deaths in 2020. Worldwide, those in need of comprehensive and culturally appropriate care to help understand the disease and treatment options; cope with the diagnosis; relieve symptoms and side-effects; and even just connect with others who will understand face considerable barriers to care and gaps in services. Even in relatively resourced countries, these services remain all too unavailable or out of reach. Founded in 2001, the Global Lung Cancer Coalition (GLCC) serves as the international voice of the lung cancer community, connecting charitable organisations that focus solely on lung cancer; service all cancers; address all respiratory diseases; or work on primary and secondary prevention. All have a special focus on lung cancer. GLCC unites small, volunteer-led groups all the way through large multi-country organisations. With a dedication to understanding how those diagnosed, and their loved ones get their information, cope with the disease, and find/utilize psychosocial services, GLCC has conducted multiple country-wide patient surveys. The goal of the current effort is twofold. First, to augment existing knowledge and identify gaps by surveying members. Second, to develop a repository of psychosocial care and beyond, available across the globe.

Methods: A subgroup of psychosocial professionals from the UK, US and Ireland developed a 22 question, mixed-methods survey. Questions were related to the psychoeducational, psychosocial, and supportive care services offered by members or available in their countries or regions. Questions around pandemic-related changes, willingness to mentor other organisations, and related to data collection were also included. The survey was open to the 33 GLCC organisations from 26 February to 4 April 2024.

Results: The response rate was 85%. Countries represented were Argentina, Brazil, Bulgaria, Canada, Denmark, Europe, Greece, Ireland, Israel, Italy, Japan, Mexico, Portugal, Slovenia, South Africa, The Netherlands, Taiwan, the United Kingdom, and the United States. These initial results focus on the 24 organisations that provide supportive care services. Over 60% offer, alone or in partnership, professional counseling. Nearly 50% offer in-person support groups with 60% offering support specific to carers. Nearly 25% offer or partner on activities to improve breathing. For 68%, services changed when the pandemic hit with 87% adding services. 50% of organisations that lost services hope to return to full operation.

Conclusions: GLCC is uniquely positioned to inform and to help expand services across the globe through collaboration and mentorship. GLCC organisations range in size and scope, but clear similarities in purpose were highlighted in this survey. While an encouraging breadth of programs and services were found, the many needs of those living with lung cancer internationally demand more. The thoracic oncology community can best serve their patients and families by referring to, collaborating with, and supporting the efforts of patient advocacy organizations.

Keywords: Psychosocial, Survivorship, Advocacy

EP.16F PATIENT ADVOCACY - NEEDS OF PATIENTS AND CAREGIVERS
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16F.03 Lung Cancer Patients' Preferred Methods of Involvement with their Treatment Teams: Insights from a Global Patient Experience Survey

K. Clayton[1], M. Daniels[2], J. Fox[3], B. Gaspar[4], M. Hennink[5], J. Mayans[4], A. McNamara[6], L. Pretorius[7], M. Rigney[8], M. Dohr[9], [1]Lung Cancer Nursing UK, London/GB, [2]Campaigning for Cancer, Randburg/ZA, [3]Roy Castle Lung Cancer Foundation, Liverpool/GB, [4]Asociación Española de Afectados de Cáncer de Pulmón, Valencia/ES, [5]Longkanker Nederland, Utrecht/NL, [6]Irish Cancer Society, Dublin/IE, [7]Campaigning for Cancer, Randburg/GB, [8]GO[2] Foundation for Lung Cancer, Washington, D.C./DC/USA, [9]Incisive Health, London/GB

Introduction: The Global Lung Cancer Coalition (GLCC), a partnership of 43 patient organisations across 30 nations, reaffirms in its charter the right of all lung cancer patients to be treated with dignity and respect and to have access to quality health care, including informed self-determination and physical and mental integrity. How patients engage with their treatment teams is essential for these rights.

Methods: In the GLCC's fifth annual survey, the coalition commissioned Censuswide to conduct a global survey of lung cancer patients. The survey ran from 28 March 2024 - 18 April 2024. It received 905 responses across 18 countries (Australia, Argentina, Bulgaria, Canada, Denmark, Greece, Ireland, Israel, Italy, Japan, Mexico, Portugal, Netherlands, South Africa, Spain, Taiwan, UK, USA).

As part of this survey, the GLCC included questions regarding respondents' preferences for engagement with their treatment teams and their involvement in decision-making.

Results: Almost all (98%, 885/905) of the respondents answered that they did feel involved in decisions about their treatment and care, and nearly half of respondents (48%, 438/905) answered that they had been fully involved. A small group (2%, 20/905) did not feel involved in decisions about their treatment and care, with all but one of these respondents saying they would have liked to be.

When asked about preferences around engaging with their treatment teams, throughout the care pathway most participants preferred face-to-face meetings in all situations. Telephone calls were respondents' secondary preference in all situations, except for when finding out about the diagnosis (where video was preferred).

Conclusions: The findings of the survey highlight that despite changes in the availability of tele-health, patient preferences can vary. Treatment teams should take care to better understand and cater to their patients' preferences, ensuring that they involve patients in decisions about their care in a way that is appropriate for that individual.

Keywords: patient experience, decision-making, treatment

Questions	Answer options									
When talking to your treatment team, did you feel involved in the decisions about your treatment and care? Please choose the option that best describes you.	Yes, I've been fully involved	Yes, I've been involved mostly, but wanted to be more involved	Yes, I've been involved mostly, and didn't want to be more involved	Yes, I've been involved sometimes, but wanted to be more involved	Yes, I've been involved sometimes and didn't want to be more involved	Yes, other please specify	No, but I would like to be involved	No, but I didn't want to be involved	No, but my caregiver was involved	No, other please specify
What do you think is the best way to have a conversation with your treatment team in the following situations? [Matrix: Rows provided are: • Finding out the diagnosis • The first consultation • Regular check ups • If there is a change to treatment • If there is a change in my disease • If I'm worried about something	Video	Telephone	Face-to-face	Not sure

EP.16G PATIENT ADVOCACY - SCREENING
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.16G.01 Ready, Set, Screen: Evaluating Community Readiness for Lung Cancer Screening Among Non-Hispanic Black Populations in Florida

S. Monestime[1], R. Theodore[2], D. Harris[3], A. White[4], [1]GO[2] for Lung Cancer, Washington/DC/USA, [2]CLT Business Solutions, Homestead/FL/USA, [3]Villages at NorthStar Community Development Corporation, Detroit/MI/USA, [4]University of North Texas Health Science Center, Fort Worth/TX/USA

Introduction: In Florida, only 2.4% of high-risk individuals undergo lung cancer screening (LCS), emphasizing a critical need for targeted interventions, particularly among the non-Hispanic Black (NHB) population, who experience the highest incidence of lung cancer compared to other racial/ethnic minority groups. While existing literature examines individual factors influencing LCS rates, a gap remains in understanding community awareness and resources dedicated to increasing LCS rates. Therefore, this study will utilize the Community Readiness Model (CRM) to assess NHB community readiness to increase LCS.

Methods: The CRM integrates theories of community-level processes and social action to improve public health concerns across five dimensions: community efforts, leadership, climate, knowledge, and resources. This model was utilized to guide qualitative semi-structured interviews in Broward County, FL with community leaders, high-risk smokers, and individuals with lung cancer (LC) self-identifying as NHB or predominantly working with the NHB population. Systematic gathering of qualitative responses for each dimension included assigning scores from 1 to 9, indicating the extent of awareness—ranging from no awareness to a high level of community ownership. Content analyses were used to further understand knowledge gaps in LC and LCS awareness.

Results: Participants (n = 24) were primarily 50-80 years old (45.8%), NHB (60%), female (62.5%), and from community-based organizations (47.4%). Scores for community knowledge of efforts, leadership, community climate, community knowledge, and resources were 1.24, 1.92, 1.61, 1.82, and 3.03 respectively. The overall score for readiness was 1.92, indicating “no awareness” of LCS. Of the participants, 53.8% considered LCS a “low priority,” 70% noted community members knew “nothing” or “little” about signs and symptoms of LC, 64.7% reported “some” knowledge about the causes of LC, and 55.6% cited “no knowledge” of LC prevalence in the NHB community. Community leaders were perceived as not prioritizing LCS, often due to a lack of awareness or other pressing community issues. While resources exist to increase LCS in NHB communities, respondents identified various obstacles hindering community prioritization of screening, including limited knowledge, financial constraints, lack of health insurance, transportation issues, and competing daily responsibilities.

Conclusions: Readiness to address LCS in NHB communities in Broward County, FL is low. These findings underscore the critical need to increase education and awareness among community leaders who serve as crucial gatekeepers to reach NHB communities. Additionally, interventions to increase LCS should target multiple factors that address social determinants of health to foster a comprehensive approach to mitigate low LCS rates in diverse communities.

EP.17A.01 The Cumulative Incidence of Brain Metastases in US Medicare Patients with ALK+ mNSCLC Treated with Second-generation ALK TKIs

L. Bazhenova[1], D. Abrahami[2], K. Ramaswamy[2], B. Li[2], M. Davis[3], A.J. Epstein[3], Z.A. Marcum[3], N. Rifi[2], J. Kelton[2], K. Duncan[2], D. Uprety[4], [1]UC San Diego Moores Cancer Center, San Diego/CA/USA, [2]Pfizer, New York/NY/USA, [3]Medicus Economics, Boston/MA/USA, [4]Karmanos Cancer Institute, etroit/MI/USA

Introduction: Brain metastases (BM) are a major concern for patients with non-small cell lung cancer (NSCLC) and may be present at diagnosis (baseline) or during disease progression (incident). However, limited epidemiological evidence exists on the burden of BM in patients treated for oncogene-driven lung cancers like ALK+ NSCLC. The objective of this study was to quantify the cumulative incidence of BM and death in patients with ALK+ NSCLC in the US whose first ALK-targeted systemic treatment was a second-generation (alectinib, brigatinib) ALK TKI in the first-line setting

Methods: The study cohort was the 100% sample of Medicare fee-for-service and Medicare Advantage beneficiaries (January 1, 2016 - December 31, 2022). Adult patients (>65 years old) with a new pharmacy claim for a second-generation ALK TKI (index date, proxy for ALK+ status) and a history of lung cancer in the year before the index date were included. Patients were excluded if they had <1 year of continuous enrollment in the dataset or a history of ALK TKIs (to capture new first-line use) or EGFR TKIs (to avoid secondary ALK mutations) in the year before the index date. The primary outcome was the cumulative incidence of BM (among those without BM at baseline), calculated using a cumulative incidence function and accounting for the competing risk of death.

Results: The study cohort included 1041 patients (median age, 74 years; 60% female; 68% Non-Hispanic White). The median (interquartile range [IQR]) follow-up was 20 (8-36) months. 290 (28%) patients had baseline BM. Of the 751 patients without BM at baseline, 126 (17%) developed an incident BM over a median (IQR) follow-up of 22 (11-38) months and 377 (50%) died. Of the 126 patients with an incident BM, 76 (60%) were receiving first-line second-generation ALK TKIs when the incident BM was observed. The cumulative incidences of all outcomes are shown in the Figure. The cumulative incidence of BM was 20% after approximately 5 years of follow-up, accounting for the competing risk of death.

Conclusions: In this cohort study of US patients with ALK+ NSCLC treated with second-generation ALK TKIs in the first-line setting, we found that close to 30% had BM at baseline and an additional 20% developed a new BM following second-generation ALK TKI initiation at 5 years. Future research should examine the impact of third-generation ALK TKIs on BM incidence in patients with ALK+ NSCLC.

EP.17A.02 Diagnostic and Treatment Gaps in NSCLC Management Compared to NCCN Recommendations: An Audit Analysis of 214 Cases.

P.K. Singh, A. Ahuja, G. Arya, J. Grover, Pt BDS Post Graduate Institute of Medical Sciences, Rohtak/IN

Introduction: Despite the evidence and recommendations, NSCLC management remains heterogeneous. Financial disparity and lack of access remains a major concern in developing countries. We have analyzed the divergence of the local practice from global guidelines (NCCN) in NSCLC management, at a state-sponsored university teaching hospital in India, catering mainly to rural population.

Methods: Data of lung cancer patients managed at the Thoracic-Oncology-Clinic from September-2022 till March-2024 was retrieved. Inclusion criteria were NSCLC patients' with either squamous or adenocarcinoma histology, stage IIIA or higher (8thTNM) and ECOG-PS 0-2. We collected data only till first line therapy use. Subsequently we compared the NCCN recommendations for individual subjects for testing and treatment. Only category 1 and preferred recommendations were considered. Deviations were recorded as minor or major depending upon, if the deviation was from preferred or category1 recommendation, respectively. Number of deviations was calculated as number of cases in which modality was recommended minus the numbers in which it was done.

Results: Out of 542 cases, data of 214 cases was retrieved (excluding other histologies, PS>2, and incomplete data cases). 108(50.5%) were squamous, 148(69.2%) were males and 157(73.4%) were smokers. The staging distribution was as follows: IIIA-8(3.7%), IIIB-73(34.1%), IIIC-10(4.7%), IVA-88(41.1%), and IVB-35(16.3%), and the PS distribution was as follows- ECOG0-15(7%), ECOG1-117(54.7%), and ECOG2-82(38.3%). Out of the 106 patients of adenocarcinoma, 100 were tested for genetic alterations with 34, 8, 2 and one showing EGFR-mutation, ALK-rearrangement, ROS1-rearrangement, and BRAF-mutation, respectively. • Regarding deviation-in-testing (DT)- NCCN recommends the use of FDG-PET and MRI brain for all patients of lung cancer, however, these were done only in 64 and 25 cases. Re-biopsy was indicated in 28-subjects where the tissue previously obtained was insufficient but was done only in 10-subjects. Nodal disease confirmation was recommended in all stage-III cases but was done only in 27-subjects (DT in 64). Broad molecular profiling was recommended in all stage-IV subjects but was done only in 9-subjects (DT in 205). However, for the major deviation only EFGR, ALK and PDL1 testing was considered. DT in EGFRm and ALKr were both 6 (considered only for adenocarcinoma). However, PDL1 was recommended in all but done only in 84 (including in-house assays), making a DT in 130.• Regarding DM (deviations in management, all major)- Surgery was recommended in 12 but done only in 7 (DM in 5). Definitive concurrent-chemoradiotherapy (CTRT) (recommended in 79) was done only in 19 and sequential-CTRT was done in 32 leading to overall deviation in 28-cases. Durvalumab was not used in any patient (79 DM). There were not DM in EGFRm positive group however, only 4 cases in ALKr received the recommended treatment. In the remaining 169 cases, immune-checkpoint-inhibitors (ICIs) were recommended in all (with or without chemotherapy) but used only in 21 (DM in 148).

Conclusions: In 82.3% (626/761 minor DT) and 76% (266/350 major DM) instances, the local practices deviated from NCCN recommendations. All major deviations are associated with survival advantage in clinical trials. Most common reason was lack of financial support and non-availability of the modality.

EP.17A.03 NOVA: A Conversational Generative Agent for Thoracic Oncology Decision-Making

L. PINO[1,2], A. Franco[1], S. Barbosa[3], I. Triana[1,4], [1]OxLER SAS, AI in Healthcare, BOGOTA/CO, [2]Universidad de los Andes, Bogota/CO, [3]Ghenova Digital, Sevilla/ES, [4]Fundacion Santa Fe de Bogota, Bogota/CO

Introduction: Lung Cancer and Mesothelioma are complex neoplastic diseases, and its treatment requires continuous analysis of the abundant clinical information. The inherent complexity of the disease, has created a high demand for refined, contextualized, and rapidly evidenced information.

Methods: A conversational generative agent (NOVA) was trained on lung cancer and mesothelioma using A4I technology that allows dynamic, intuitive, and agile access to state-of-the-art (SOTA) information curated by domain experts, but also facilitates its consultation and aids in drawing conclusions to address decision-making in a timely manner. Our development phases were: 1. Data Preparation: We extracted and curated various primary, secondary, and tertiary sources of SOTA medical literature, followed by preprocessing to convert the information into dense numerical representations of real-world objects and relationships, expressed as vectors. This step was executed by domain expert's thoracic oncologist, thoracic surgeons, and AI. 2. Implementation of the Conversational Model: Implementation of a conversational AI model configured with a pre-trained Transformers Language (TL) model in Spanish language is proposed, allowing the integration of NOVA technology with another complementary Transformer model for question-answering (QA) tasks. This model predicts the response with the highest similarity and extracts related information in a paragraph. 3. LLM Fine-Tuning: With a specific corpus containing relevant and specialized data from this medical domain (questions and answers), as well as vector databases of the document body properly curated by medical domain experts (clinical design) we developed a RAG (retrieval augmented generation) fine-tuning, carefully adjusting its settings to optimize performance in this specific area. 4. Integration of IR with LLM: The output response of the IR model was integrated with a large-scale language model to create a response based on the paragraph output of the IR with the highest accuracy score. This would prevent the generation of text output that may contain "hallucinations" or "biases."5. Development of a User Interface (text-to voice, voice-to-voice, and text-to-text)6. Assistant Deployment: The production deployment was based on Amazon Web Services (AWS) that involves implementing the system in a highly scalable and secure cloud operating environment.

Results: Nova is being implemented in one private clinic in Colombia. Capabilities of Nova are: Rapid and accurate analysis, Decision-making support, Treatment personalization, Continuous and dynamic updating and, Efficiency improvement. Figure 1 shows the operation diagram of NOVA.

Conclusions: NOVA is the first AI-based virtual assistant for decision-making support in the field of lung cancer and mesothelioma applied in Latin America

Keywords: artificial intelligence, lung cancer, Mesothelioma

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.17A.04 Real-World Rates of Infusion-Related Reactions in Patients with EGFR-Mutant NSCLC Receiving Amivantamab

D.M. Gupta[1], C. Chang[2], L. Wendt[2], N. Mohindra[1], Y. Chae[1], D. Tobben[2], L.A. Gharzai[1], J.D. Patel[1], [1]Northwestern University, Chicago/IL/USA, [2]Northwestern Memorial Hospital, Chicago/IL/USA

Introduction: Amivantamab is an EGFR-MET bispecific antibody used in the treatment of patients with EGFR-mutant advanced non-small cell lung cancer (NSCLC). In addition to FDA-approved use for patients with EGFR ex20 NSCLC, NCCN guidelines now list a category 1 recommendation for the use of amivantamab after progression on osimertinib in patients with classical EGFR mutations. Infusion-related reactions (IRR) are common with amivantamab, and rates of grade 3 and 4 IRRs reported in clinical trials range from 1 to 5%. We aim to report real-world data on the rates and severity of IRRs with amivantamab as monotherapy and when given in combination in patients with EGFR-mutant NSCLC.

Methods: We performed a retrospective chart review of patients with EGFR-mutant NSCLC, not on clinical trial, treated with amivantamab at Northwestern University's Robert H. Lurie Comprehensive Cancer Center from January 2021 to February 2024. The data analyzed included baseline demographics, amivantamab pre-medications, rate and grade of IRRs based on CTCAE v5, emergency response utilization, and amivantamab discontinuation.

Results: A total of 33 patients received amivantamab. The median age was 62 (36-84) years old. 20 patients (61%) were female, 13 (39%) were male. 15 patients (45%) had an EGFR exon 19 deletion, 6 (18%) had an EGFR L858R mutation, 8 (24%) had EGFR exon 20 insertions, and 4 (12%) had atypical EGFR mutations. Patients received a median of 2 (0-8) lines of therapy prior to amivantamab. 12 patients (36%) received concomitant osimertinib, and 4 (12%) received concomitant carboplatin/pemetrexed. All patients received split first dose amivantamab (350 mg day 1 [D1], remainder D2) along with steroid, antihistamine, and antipyretic premedication before initial dose. IRRs were reported in 27 patients (82%), and all IRRs occurred on cycle 1, D1 (C1D1). Grade 1 IRRs occurred in 1 patient (3%), grade 2 in 10 patients (30%), grade 3 in 12 patients (36%), and grade 4 in 4 patients (12%); grade 3/4 IRRs was 48%. Of patients with a grade 4 IRR, 2 had an emergency response team called, and 2 additional patients had 911 called to the infusion center. C1D2 infusions were completed in 93% (25/27) of patients who had C1D1 IRRs. The 2 patients who did not complete C1D2 infusions discontinued amivantamab, one due to patient preference and the other due to the severity of the IRR.

Conclusions: Contrary to data reported in clinical trials, we observed a markedly higher rate of grade 3 and 4 IRRs at 48% during the administration of amivantamab for EGFR-mutant NSCLC at our institution. Although this was a more heavily pretreated population, this notable difference poses a significant safety concern, particularly for stand-alone infusion centers with limited emergency services. Most patients who experienced IRRs were able to continue therapy. The substantial incidence of grade 3 and 4 IRRs requires considerable resources to administer amivantamab, potentially amplifying healthcare disparities in underserved areas. Our findings call for re-evaluation of administration protocols and further research to develop strategies to mitigate the risk of IRRs, ensuring safe and equitable access to amivantamab across all healthcare environments.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.17A.05 Efficient Lung Cancer Multidisciplinary Team (MDT) Management Strategy for the Hospitals with High-Volume Patients

M. Li[1], B-C. Yin[2], G-W. Che[3], Y-C. Zhang[4], J-T. Zhang[4], P.J-Y. Cui[5], C-P. Hu[1], [1]Xiangya Hospital, Central South University, Changsha/CN, [2]Ventura, Paris/FR, [3]Lung Cancer Center, West China Hospital, Sichuan University, Chengdu/CN, [4]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [5]Ventura, Munich/DE

Introduction: The increasing number of lung cancer patients in recent years has been influenced by various factors, such as environmental pollution, rising smoking rates, unhealthy lifestyles, and aging populations, posing significant challenges to healthcare systems and lung cancer treatment. The role of MDT management in lung cancer treatment has become increasingly prominent. However, achieving efficient MDT management in the face of a large volume of patients remains a challenge. Therefore, addressing this challenge effectively to improve treatment outcomes and survival rates of lung cancer patients has become an urgent issue. This study aims to explore an efficient MDT management strategy to better meet the needs of a substantial volume of lung cancer patients.

Methods: We conducted brainstorming sessions, and questionnaires with MDT experts to analyze and summarize 32 MDTs from 10 leading lung cancer treatment hospitals in China. We consolidated the experiences from MDT experts at participating hospitals that receive more than 3,000 new lung cancer patients per year and whose lung cancer MDT teams have at least 5 year of management experience.

Results: Our analysis delineated two primary MDT management strategies prevalent in hospitals managing a substantial volume of lung cancer cases (Figure 1): specialized cancer hospitals predominantly adopt Strategy I, while comprehensive hospitals favor Strategy II. A commonality observed in their efficient operation lies in the establishment of standardized quality control and feedback systems. For instance, tailored quality control standards are devised based on patient caseload and specific needs, coupled with feasible evaluation features before, during and after MDT. Over 80% of the surveyed hospitals conduct MDT review meetings at least quarterly, involving all MDT members. These review sessions encompass a spectrum of topics ranging from optimizing MDT operations to the latest advancements in research.

Conclusions: Hospitals should tailor their MDT strategies based on patient demographics and specific management goals. Regardless of the chosen strategy, it is crucial to establish and adhere to quality control standards for MDT design and execution. Regular feedback and optimization across various aspects of MDT implementation play a pivotal role in providing high-quality and efficient services for a large patient population. This nationwide study enhanced lung cancer diagnosis and treatment capabilities in regional hospitals through remote guidance for MDT teams. By doing so, it provided valuable insights and contributed to elevating the overall standard of lung cancer MDT management in China.

Keywords: MDT management, Sustantial volume of patients, Efficiency

Figure 1. Summary of two MDT management strategies for a substantial volume of lung cancer patients

	Patient access and characteristics	*Advantages*
Strategy I	Access to **all** diagnosed lung cancer **patients** ➔ Daily simplified MDT with entry-level physicians from medical oncology, thoracic surgery, and radiation oncology. *If not solved* ➔ Expert-level MDT with more comprehensive specialists	Solve the **problem of process standardization** Define the **initial treatment plan** of each LC patient
Strategy II	**Pre-selected lung cancer patients** in complicated situation ➔ LC MDT for patients with senior/expert-level specialists from pulmonology, thoracic surgery, oncology, radiology, pathology and supporting teams ➔ *Or* specific MDT for specific patients such as stage III, brain metastases, adverse immune reactions with multiple senior/expert-level specialists	Solve **difficult problems**, **serious illnesses**, or any special individualized needs. (E.g., patient with unclear resectability)
Ideal Model	**Fusion of Strategy I and II** ➔ All patients with access to a primary MDT ➔ Complicated cases with access to specialized MDTs	

EP.17A GLOBAL HEALTH, HEALTH SERVICES, AND HEALTH ECONOMICS - CLINICAL MANAGEMENT
SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.17A.06 Real-World Trends in Screening and Evaluation of Paraneoplastic Syndromes among Patients with Small Cell Lung Cancer

G. Shechter[1], D. Morrell[2], R. Grebla[3], W. Iams[4], [1]MedTech Analytics, LLC, Lexington/MA/USA, [2]Catalyst Pharmaceuticals, Coral Gables/FL/USA, [3]Northeast Epi, LLC, Bradford/NH/USA, [4]Vanderbilt University Medical Center, Nashville/TN/USA

Introduction: Neurologic paraneoplastic syndromes (PNS), including Lambert-Eaton myasthenic syndrome (LEMS), affect approximately 10% of patients with small cell lung cancer (SCLC). Beginning 2020, the National Comprehensive Cancer Network (NCCN) SCLC guidelines recommend considering a comprehensive paraneoplastic antibody panel when neurologic PNS is suspected; however, the impact of this recommendation in real-world settings is unknown. This study investigates longitudinal trends in PNS screening and management among patients with SCLC in the United States.

Methods: Healthcare claims between 1/1/2018-12/31/2021 in a longitudinal database representing >300 million US patients were evaluated. Patients with presumed SCLC (ICD-9-CM 162.X excluding 162.0, ICD-10-CM C34.X, + etoposide + platinum therapy) were identified based on ≥2 claims ≥30 days apart. Claims for diagnostic panels for any PNS, including neurologic PNS, and individual antibody tests associated with neurologic PNS were evaluated. The frequency and setting of neurology visits among patients with SCLC with and without associated claims for brain metastases were also evaluated.

Results: Among 38,390 patients with SCLC who received etoposide and platinum-based therapy, 578 (1.5%) patients had claims for PNS tests during the study period. The proportion of patients with SCLC with PNS test claims remained below 2% annually across the study period. Screening rates were 1.3%-1.4% and 1.7-1.8% in the 2 years pre- and post-recommendation, respectively. Most PNS panels during this time were billed as hospital outpatient procedures. During the same period, 12.1% of patients with SCLC had neurology visits and the proportion of patients with visits increased, ranging from 11.2% in 2018 to 13.1% in 2020. Neurology visits were more common among patients with SCLC with claims for comorbid brain metastases (N=1,694/9,402; 18.0%) than without (N=2,953/28,988; 10.2%). 61 patients (0.16% of patients with SCLC) had a comorbid LEMS diagnosis, which was concurrent (±90 days) with SCLC diagnosis in the majority (N=41/61) of SCLC-LEMS patients. 22 patients (36% of patients with SCLC-LEMS) had ≥1 claim for a neurologic PNS test. 65.6% of patients with SCLC-LEMS had neurology visits. Patients with SCLC-LEMS who were not seen by neurologists were more often managed by community oncologists.

Conclusions: This study revealed a low rate of PNS screening persisted among patients with SCLC despite the introduction of screening recommendations in suspected patients. This finding highlights the importance of increased awareness of neurologic PNS among oncologists, including those in the community, as treatment options are available for patients with neurologic PNS.

EP.17A.07 ROSETTA-LUNG: MultidisciplinaRy Oncology StratEgies for Team-Based Treatment ConcordAnce in Lung Cancer Diagnosis and Treatment Decisions

M.H. Kristensen[1], M. Sandelin[2], M. Paz Saavedra Valenzuela[3], L. Thamlikitkul[4], A. van Vliet[5], W. Brueckl[6], T.R. Rasmussen[7], [1]AstraZeneca, Copenhagen/DK, [2]AstraZeneca, Stockholm/SE, [3]Chilean National Thorax Institute, Santiago/CL, [4]Department of Medicine Faculty of Medicine Siriraj Hospital, Bangkok/TH, [5]AstraZeneca, Amsterdam/NL, [6]Department of Respiratory Medicine, Allergology and sleep Medicine, Nuernberg General Hospital, Paracelsus Medical University, Nuremberg/DE, [7]Inst for clinical Medicine, Aarhus/DK

Introduction: The ROSETTA-LUNG initiative addresses the imperative demand for improved concordance in decision making of multidisciplinary Teams (MDT) treating lung cancer patients. Addressing the inherent complexity and evolving landscape of lung cancer diagnosis and treatment decisions, our project harnesses a cloud-based portal designed for MDT to assess fictional patient cases. This innovative platform facilitates anonymous, replicable, and compliant comparative decision-making by presenting carefully curated fictional patient cases, based on the cohort of the Danish RING trial. This approach aims to cultivate a robust and safe environment for collaborative analysis and benchmarking of decision-making processes across diverse MDTs worldwide.

Methods: The cloud based MDT platform comprises of 60 patient case descriptions with corresponding PET/CT and CT scan images. Per case, MDTs are queried regarding: cancer stage, treatment intent, and primary treatment choice. Participating MDTs are requested to provided their country of practice, approximate yearly case load, MDT specialty representation and hospital type (academic vs community). This systematic approach anonymously measures and visualizes inter-MDT concordance on a global, regional, and national level. This comparative analysis seeks to provide valuable insights into variations in decision-making practices, fostering a systematic validation of MDT decision making in lung cancer. Primary Objective: The primary goal of the ROSETTA-LUNG project is to measure and enhance the concordance of MDT assessments in lung cancer diagnosis and treatment decisions. The standardized approach and cloud-based platform, will allow for an improved equity, treatment harmonization and improved guideline adherence worldwide. Secondary Objectives: Facilitate Discussions for Improvement: In cases with the lowest concordance, the project facilitates focused discussions between MDT representatives. These sessions identify specific areas for improvement, fostering a collaborative environment where lessons learned enhance patient care outcomes.

Results: “Not applicable”

Conclusions: ROSETTA-LUNG signifies a commitment to harmonize multidisciplinary assessment of lung cancer diagnosis and treatment, acknowledging MDTs as a cornerstone in optimal cancer care. This project not only quantifies concordance, but also allows for avenues of education of healthcare professionals and allows for increased equity among countries that are developing their MDT infrastructure.

Wu[1], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [2]Lixin County People's Hospital, Lixin County, Anhui/CN, [3]People's Hospital of Macheng City, Macheng City, Hubei/CN, [4]Fourth People's Hospital of Langfang, Langfang City, Hebei/CN, [5]Dingyuan General Hospital, Dingyuan County, Anhui/CN, [6]The First Affiliated Hospital of Xinxiang Medical University, Xinxiang, Henan/CN, [7]Baoding NO.2 Central Hospital, Baoding City, Hebei/CN, [8]First People's Hospital of Xiushui County, Xiushui County, Jiangxi/CN, [9]The People's Hospital of Jianyang City, Jianyang City, Sichuan/CN, [10]Anyue County People's Hospital, Anyue County, Sichuan/CN, [11]Honghe Prefecture Third People's Hospital, Honghe Prefecture, Yunnan/CN, [12]Jiyuan Shi People's Hospital, Jiyuan, Henan/CN

Introduction: Lung cancer (LC) remains the leading cause of cancer-related mortality worldwide. In China, it holds the highest incidence and mortality rates among all malignancies, affecting both urban and rural populations. It is imperative to standardize the diagnosis and treatment of LC to enhance patient survival and reduce mortality rates. However, county hospitals face significant challenges in accessing advanced medical technologies, necessitating the development of diagnostic and treatment pathway tailored to their specific circumstances. Under the auspices of the National Health Commission's "Thousand Counties Project (2021-2025)" and "The Belt and Road Initiative," we have formulated the first "Clinical Pathway for Lung Cancer in Chinese Counties" to bolster the comprehensive capabilities of county-level healthcare facilities.

Methods: The formulation of this pathway diverges from conventional guidelines, with Professor Qing Zhou serving as the editor-in-chief, Professor Yi-Long Wu overseeing the review process, and Chinese LC academic celebrities providing guidance. Additionally, LC specialists from county hospitals contribute their expertise as editorial board members. The development of LC clinical pathway was meticulously crafted to align with the diagnostic and treatment technologies available in county hospitals, the approval status of treatment indications, the inclusion of medications in the National Reimbursement Drug List (NRDL), and adherence to existing domestic and international guidelines. The pathway systematically delineates the screening, evaluation, diagnosis, staging, treatment, and follow-up procedures for LC within county hospitals.

Results: The pathway stratify LC treatment strategies into basic and optional approaches (Table 1). Basic strategies represent the essential diagnostic and treatment standards that county hospitals must achieve, while optional strategies provide flexibility and additional choices. The recommendations within the pathway are aligned with existing guidelines and consensus, ensuring both operability and scientific validity. Therefore, the pathway is both operability and scientific.

Conclusions: The creation of first "Clinical Pathway for Lung Cancer in Chinese Counties" represents the diagnostic and treatment recommendations specifically tailored for county-level medical institutions. This initiative not only plays a pivotal role in enhancing the efficiency and cost-effectiveness of LC diagnosis and treatment in county settings, but also providing experiences for establishing County-level Cancer Prevention and Treatment Centers in the world.

Keywords: Chinese County area, Clinical diagnosis and treatment pathway, Basic strategies

Recommended level	Criteria
Basic strategies	Approved by China NMPA for LC and included in the NRDL
Optional strategies	
Level I	Approved by China NMPA for LC but not included in the NRDL
Level II	Based upon high-level evidence, accessible in China, but not China NMPA-approved

EP.17B.01 Timelines of Lung Cancer Pathway in Rural and Regional NSW; A Retrospective Study in Hunter New England LHD

K. Baskaran[1], N.Y. Tun[1], B. Harper[1], S. Pendlebury[1], S. Mallawathantri[1], [1]Tamworth Rural Referral Hospital, Tamworth/AU

Introduction: Health disparity among the rural and remote regions of Australia has been an ongoing area of concern and development1. Early diagnosis and treatment have been shown to improve outcomes in lung cancer, a leading cause of death worldwide2. The variations in lung cancer care across Australia have been described in previous reports3. We investigated if the time to diagnosis and treatment of lung cancer in rural New South Wales (NSW) conforms to the recommended guidelines in the Optimal Care Pathway for People with Lung Cancer (OCP).

Methods: A retrospective cohort study, conducted on patients diagnosed with Lung Cancer between January 2021 to December 2022 at Tamworth Hospital in rural NSW. The main outcome measures were time intervals between referral, Lung Cancer Specialist (LCS) review, diagnostic investigations, and treatment.

Results: A total of 106 patients with new diagnosis of lung cancer were identified from the Tamworth Cancer Centre and Local Respiratory Physician Clinics and 76 patients were included in the study. Majority (93.4%) of the patients smoked while similarly adenocarcinoma was noted to be most prevalent among the study population (48.7%, n=37). Moreover, a large proportion (77%) of patients were diagnosed with cancer stage III and above or extensive small cell lung cancer and about 46% (n=35) of the study population have deceased. The median timeframes of care such as LCS to diagnosis and date of first referral (DFR) to treatment were noted to exceed the recommended timeframes. This is especially so in the patients managed with curative intent whereby median time from DFR to treatment was almost double the time taken in those with palliative intent (77 days vs 43 days respectively). However, the time interval from DFR to LCS was within the recommended period. Although only 48.6% (n=37) of patients had multidisciplinary meetings (MDT), majority of patients with curative intent (79.1%) were discussed in MDT. Furthermore, despite the absence of a formal lung cancer care coordinator, the coordination by the cancer center staff was noted to decrease the median timeframes. Overall, as little as 34% (n=26) of the patients were managed within the recommended 42 days pathway.

Conclusions: There are significant delays in diagnosis and treatment of lung cancer faced by the rural patients in our study area. Although most patients are reviewed by an LCS within the recommended time frame, the overall delays in treatment pathway are significant and further efforts are needed to improve resource allocation and understand reasons for delay in diagnosis and treatment to ensure optimum timely care for these vulnerable patients.

EP.17B.02 Racial Disparities in Patients with Lung Cancer Requiring Intubation: A National Inpatient Study

F. Khan, M.K. Rahima, B. Mansouri, M. Multani, Trihealth Good Samaritan Hospital, Cincinnati/OH/USA

Introduction: Racial disparities in healthcare refer to differences in health outcomes, access to healthcare services, and quality of care among different racial or ethnic groups. This study aimed to investigate the basic characteristics and clinical outcomes of racial differences in patients admitted with Lung cancer requiring intubation.

Methods: We queried the National Inpatient Sample between 2017-2020 for adult patients of different races hospitalized with Lung cancer requiring intubation using ICD-10 codes. The primary outcome was inpatient mortality. The secondary outcomes were cardiac arrest and total hospital costs. Multivariable logistic, linear, and Poisson regression analyses were used to estimate clinical outcomes with a p-value < 0.05 was significant.

Results: There were 75,115 hospitalizations in patients with Lung cancer requiring intubation. The mean age was 67.7 years and 56.2% were male. Among the admitted patients, Caucasians were 52,775 (70.3 %), Blacks were 12,335 (16.4 %), Asians were 3,875 (5.2%), Hispanics were 2,330 (3.1%) and others were 3,800 (5%). Subgroups with Caucasians, Blacks, Asians, Hispanics, and other races had DM 24.6% vs 30.6% vs 37.3% vs 35% vs 27.9%; Protein calorie malnutrition 25.1% vs 30.5% vs 24% vs 28.6% vs 27.8%; Chronic obstructive pulmonary disease (COPD) 64.5 % vs 52.4% vs 45.7% vs 30.3% vs 56.4%; Tobacco abuse 27.5% vs 24.9% vs 20.8% vs 10.5% vs 28.2% and Pulmonary embolism (PE) 10.6% vs 14.5% vs 11.2% vs 10.7% vs 11%. The secondary outcome of Cardiac arrest in these subgroups was 13.7% vs 20.4% vs 18.3% vs 12.9% vs 17.8% respectively. Total costs adjusted with inflation were highest among Hispanics. All-cause mortality was 39,190, where subgroups with Caucasians, Blacks, Asians, Hispanics, and others were 26,745 (50.7%) vs 6,725 (54.5%) vs 2,125 (54.8%) vs 1,435 (61.6%) vs 2,160 (56.8%).

Conclusions: Minority groups, particularly Hispanics, Asians, and Blacks, experienced higher mortality rates compared to Caucasians, with Hispanics facing the highest mortality. Additionally, these groups also showed varying prevalences of comorbid conditions and were subject to higher instances of cardiac arrest, with Blacks being the most affected. The economic analysis indicated that hospital costs were highest among Hispanics, pointing to a complex interplay of healthcare access, quality of care, and socioeconomic factors contributing to these disparities. The findings signify the urgent need for targeted interventions to address the systemic biases and barriers that contribute to these inequities in healthcare outcomes.

EP.17B.03 Impact of Social Economic Status on Patient Reported Outcomes (PROs) In Non-Small Cell Lung Cancer (NSCLC)

J. Bachler, A. Wang, L. Poisson, E. Adjei Boakye, S. Tam, S. Gadgeel, B. Movsas, B. Potugari, Henry Ford Health, Detroit/MI/USA

Introduction: Patient-reported outcomes (PROs) are a powerful method to assess a patient's well-being as reported directly by the patient without any provider interpretation. PROs in lung cancer have been shown to improve patient quality of life and survival, while decreasing health care utilization. Low socioeconomic status is associated with 13% more advanced lung cancer at diagnosis and carries an inferior prognosis. The impact of social determinants of health on PROs in lung cancer requires more study. We aim to assess the association between socioeconomic status and PROs in NSCLC.

Methods: We conducted a retrospective study of patients diagnosed with NSCLC between 2020 and 2023 who completed their initial PRO survey within 180 days of their diagnosis. NIH PROMIS computer adaptive testing was used as the PRO survey in the cancer clinic. PRO surveys included four domains- physical function, fatigue, pain interference, and depression. Patient demographics including race, gender, ethnicity, marital status, and cancer staging were obtained through electronic medical records. State Area Deprivation Index (ADI) rank was used to assess neighborhood socio-economic status. Statistical analysis was performed using Spearman's correlation test to assess the correlation between ADI and PRO scores.

Results: 491 patients completed their first PRO surveys within 180 days of lung cancer diagnosis. 48.9% of the patients were female (n=194). 21.4% of patients were African American and 71.3% were Caucasian. 48.9% were married. About 40% of the patients in the cohort had a high ADI Rank. Most of the patients had advanced disease (Stage III- 20.4% and Stage IV- 34.8%). The mean PRO scores were 52.8 (depression), 55.6 (fatigue), 57.7 (pain interference), and 37.8 (physical function). Patients with high ADI rank were found to have significantly worse pain scores (p-value- 0.0118) and depression scores (p-0.045).

Conclusions: Socioeconomic status, as measured by ADI, appears to negatively impact PRO scores around the time of diagnosis in NSCLC patients. These findings underscore the importance of considering socioeconomic factors in assessing patient-reported outcomes and developing targeted interventions to address disparities in healthcare access and outcomes among lung cancer patients.

Keywords: Patient reported outcomes, Socioeconomic status

	STATE ADI RANK

EP.17B.04 Racial/Ethnic Differences in Risk of Mortality of Men and Women with Lung Cancer

D. Behl, C. Parise, Sutter Health, Sacramento/CA/USA

Introduction: It has been documented that Asian Americans have a reduced risk of lung cancer mortality when compared with white men and Women. It is uncertain if the risk of mortality for Asian Americans is similar across levels of socioeconomic status (SES). The purpose of this study was to assess overall differences in risk of lung cancer mortality by race/ethnicity and within strata of socioeconomic status when Asians are separated into subcategories as well as when combined together into the Asian/Pacific Islander category.

Methods: We identified 362,059 cases of invasive lung cancer from the California Cancer Registry 2000-2021. The Asian ethnicities were classified as, Middle Eastern, Chinese, Japanese, Korean, Filipino, Southeast Asian (SEA), Pacific Islander, or Asian Indian. A second classification combined the Asian ethnicities into the Asian/Pacific Islander (API) category. Cox Regression was used to assess risk of lung cancer specific mortality for each race/ethnicity when compared with non-Hispanic White men and women when adjusted for stage, smoking status, Charlson Comorbidity Index, and treatment with chemotherapy, hormone therapy, immunotherapy, and radiation therapy, and tertile of SES (Lowest, Middle, High). Regression models were conducted with Asians combined into the API category and when Asians remained in separate categories. Analyses within each level of SES were also conducted. All analyses were conducted separately for men and women.

Results: When Asians were combined into the API category, both API men (HR=0.85; 95%CI = .082, 0.89) and API women (HR=0.85; 95%CI = .081, 0.90) had a lower risk of mortality than white men and Women. When Asians remained in separate categories, Japanese men had a higher risk of mortality than white men (HR=1.21; 95%CI = 1.03, 1.41). All other Asian ethnicities had either a lower or equal risk of mortality than white men and women. When stratified by SES, only Japanese men in the highest SES category had an increased risk of mortality (HR=1.38; 95%CI = 1.12, 1.70). All other Asian ethnicities had the same or reduced risk of mortality as white men and women in all SES strata when left separate or when combined into the API category.

Conclusions: Risk of lung cancer mortality is similar among the Asian ethnicities and there is very little variation by socioeconomic status. The combined API category is sufficient for assessing risk of mortality in Asian patients with lung cancer.

EP.17B.05 Impact of Race and Ethnicity on Financial Toxicity and Outcomes in Lung Cancer

A.A. Khosla[1], N. Batra[1], R. Singh[2], I. Deshmukh[3], A. Harisingani[4], M. Rubens[5], A. Saxena[5], V. Ramamoorthy[5], I. Jaiyesimi[1], A. Desai[6], [1]Corewell Health William Beaumont University Hospital, Royal Oak/MI/USA, [2]University of Vermont, Burlington/VT/USA, [3]UT Health, Houston/TX/USA, [4]Loyola MacNeal Hospital, Chicago/IL/USA, [5]Miami Cancer Institute, Baptist Health South Florida, Miami/FL/USA, [6]University of Alabama at Birmingham, Birmingham/AL/USA

Introduction: Lung cancer significantly impacts healthcare costs in the United States (US). Despite advancements in cancer treatment, disparities in healthcare costs remain, particularly affecting vulnerable populations. This study aimed to explore the disparities in inpatient hospitalization costs for lung cancer patients in the US.

Methods: A retrospective analysis of cancer-related hospitalizations from 2016 to 2021 was conducted using the National Inpatient Sample dataset. Lung cancer-related hospitalizations were identified using validated ICD-10 Clinical Modification codes. The main outcomes included were hospitalization costs, volume, mortality, length of stay, and disposition status. The cost for each year was adjusted according to 2021 inflation levels released by the US Consumer Price Index.

Results: Among 41,622,004 hospitalizations from 2016 to 2021, 128,624 were primarily due to lung cancer. The study population comprised 76.1% non-Hispanic whites (NHW), 12.2% non-Hispanic blacks (NHB), and 5.1% Hispanics. Medicare access was higher among NHW (66.2%) compared to NHB (57.5%) and Hispanics (56.0%). Total hospitalization costs (standard deviation) were $ 20035 (110.6) for NHW, $ 24892 (188.5) for NHB (OR: 1.21, 95% CI 1.10-1.33), and $ 22231 (361.4) for Hispanics (OR: 1.19, 95% CI 1.07-1.32), respectively (p<0.001). The average length of inpatient stay for NHW was 5.9 (1.5) days, compared to NHB at 6.9 (1.2) days (OR: 1.11, 95% CI 1.07-1.16), and Hispanics at 6.5 (1.8) days (OR: 1.13, 95% CI 1.07-1.19), respectively (p<0.001). The average length of stay was longer for NHB (6.9 days) and Hispanics (6.5 days) than for NHW (5.9 days), with ORs of 1.11 and 1.13, respectively. Mortality rates were highest among NHB at 7.7% (OR: 1.13, 95% CI 1.05-1.20) and Hispanics at 7.6% (OR: 1.10, 95% CI 1.01-1.22), compared to NHW at 6.9% (p<0.001). Disposition to short and long-term facilities was more common for NHB at 50.2% (OR: 1.17, 95% CI 1.12-1.23), compared to NHW at 47.9% and Hispanics at 45.8% (OR: 1.21, 95% CI 1.16-1.28), respectively (p<0.001).

Conclusions: Our data revealed racial disparities in the costs of inpatient hospitalizations, highlighting potential financial toxicity among patients with lung cancer. Additional investigation is warranted to elucidate factors contributing to these inequities, aiming to optimize cancer management and alleviate financial burdens. Addressing these disparities is crucial to prioritize equitable healthcare access and promote systemic change.

EP.17B.06 Survival by Ethnicity and Socioeconomic Status in Patients Diagnosed with Lung Cancer: A 11-year Single Centre Experience

A. Horne, G. Gayatri, C. Faivre-Finn, University of Manchester, Manchester/GB

Introduction: Previous studies found mixed results regarding the impact of ethnicity and socioeconomic status on cancer survival. Few studies include both ethnicity and socioeconomic status in their analysis. Our institution's infrastructure enables sophisticated population-based analysis by leveraging clinical data collected prospectively in a structured and standardised format within the electronic patient record.

Methods: Where available the clinical data of patients diagnosed with NSCLC and treated at a single UK centre between 2013 and 2023 was acquired using the UK Computer Aided Theragnostics framework (Ethics ID: 187386) (n=8260). Survival time was calculated from date seen in a new patient clinic to date last seen or date of death. Ethnicity data was grouped as per Census of England categories. Socioeconomic status was calculated based on the postcode-based Index of Multiple Deprivations (IMD). Median survival was calculated by Kaplan-Meier method. Cox proportional hazards regression models produced hazard ratios (HRs) and 95% confidence intervals (95% CIs).

Results: A summary of results is included in table 1.

*In bold highlights significance ** Not available - multiple potential reasons behind missing data Table 1: Summary of patient characteristics, Kaplan-Meier survival statistics and Cox regression hazards

Conclusions: In this multi-year analysis there is no strong evidence to suggest that social deprivation, ethnicity or age at diagnosis has an impact on the overall survival of patients diagnosed with NSCLC. Patients who are female, have good performance status, are diagnosed with early-stage cancer and are being treated with curative-intent treatments are associated with significantly better overall survival.

Ethnicity data was not available for approximately 50% of patients. Missing data reduces the representativeness of the results and therefore local efforts to improve data capture are required.

EP.17C.01 Increasing the Earlier Detection of Lung Cancer: A Toolbox for Change

L. Viola[1], M. Handcock[2], E. Wheeler[3], H. Wilcox[4], Lung Cancer Policy Network - Fundación Neumológica Colombiana - Luis Carlos Sarmiento Angulo Cancer Treatment and Research Center (CTIC), Bogotá/CO, [2]Researcher: Lung Cancer Policy Network, London/GB, [3]Director of Oncology: Lung Cancer Policy Network, London/GB, [4]Associate Director of Research and Policy, Programme Lead: Lung Cancer Policy Network, London/GB

Introduction: Most people with lung cancer are currently diagnosed at an advanced stage (Stage III/IV) when outcomes are typically poorer. Earlier detection of the disease at Stages I and II would significantly reduce mortality and improve outcomes. To achieve this, comprehensive early detection strategies must be developed and implemented as part of wider national cancer control plans. While targeted screening using low-dose computed tomography (LDCT) is the most effective means of detecting lung cancer at an early stage, it may not be currently feasible in many countries such as due to limited resources and capacity. Thus, other early detection strategies are available that should collectively be assessed and adopted as appropriate, considering the local epidemiology, health system capacity and available resources.The Lung Cancer Policy Network, a global multi-stakeholder initiative of experts in lung cancer, has developed a comprehensive report exploring the importance of earlier detection for improving outcomes for people with lung cancer.

Methods: The report used a bespoke methodology that combined a review of existing peer-reviewed publications and grey literature, eight qualitative expert interviews from different localities and insights from members of the Lung Cancer Policy Network. This iterative approach led to consensus-driven insights that collectively explore the various existing and emerging earlier detection approaches in lung cancer. The report emphasises the importance of considering the suitability of earlier detection tools with a country's epidemiology and health system to facilitate the implementation of effective and appropriate strategies.

Results: The report explores the utility of various existing and emerging approaches and tools that can be used for the earlier detection of lung cancer and draws these into a toolbox of strategies. These include: public awareness campaigns, symptom-based detection and diagnosis, screening, incidental detection and technological innovation.Throughout the report, 12 case studies from different countries provide real-world examples of earlier detection tools in use from Australia, Denmark, England and Wales, Ireland, Israel, Japan, South Africa, South Korea, and the US.The report concludes with a series of policy recommendations to encourage national decision-makers to act to reduce mortality from lung cancer through the adoption of early detection approaches. This covers prioritisation and promotion of early detection, alignment with broader national policies, health system readiness assessments, engaging with high-risk and traditionally underserved communities, utilisation of technology, investment in research, and monitoring and evaluation.The recommendations emphasise the need to assess key factors such as local epidemiology and health system capacity to inform the development of a unified national strategy using a combination of early detection approaches to detect lung cancer across the population.

Conclusions: The 'Increasing the earlier detection of lung cancer: a toolbox for change' report was made publicly available in November 2023 and to date has been downloaded 960 times.The report aims to support national decision-makers in making earlier detection an integral feature of cancer control plans. It offers the tools needed to start taking ambitious steps towards implementing feasible strategies that serve the differing epidemiology of lung cancer and needs of populations globally.

EP.17C.02 Nodule-AFM: Construction and Application of LLM and Multi-Agent Collaborative Based Active Follow-Up Management for Pulmonary Nodule Patients

D. Liu[1], Z. Ren[2], M. Gu[1], W. Li[1], X. Lu[2], [1]The Affiliated Hospital of Qingdao University, Qingdao/CN, [2]Zhuhai Hengqin Sanmed Aitech Ltd., Zhuhai/CN

Introduction: Follow-up plays a crucial role in the early screening of lung cancer; however, within the current medical system, follow-up primarily relies on manual intervention. There is a significant need for a personalized and intelligent follow-up management system to enhance the efficiency of proactive follow-up management. Based on open-source large language models(LLM) and the Self-Consistency with Chain of Thought (CoT-SC) concept, an active follow-up management system for pulmonary nodule patients was proposed to improve the follow-up management efficiency and accuracy.

Methods: An open-source LLM(Yi-34b-GPTQ) was adopted and fine-tuned using nearly 1000 clinical follow-up question-and-answer(Q&A) samples. Subsequently, a multi-agent collaborative active Q&A process was constructed. Firstly, a database agent which, based on inquiries, retrieves patient data from the database, extracts patient follow-up information. Then, an active question-and-answer agent, initiating follow-up inquiries with patients, consistently confirming follow-up times through multi-turn conversations in a CoT-SC way. Finally, through a summarization agent, we summarized the above dialogue process to determine if patients could follow up and specified the exact time, updating it in the database. The entire multi-agent collaborative system is implemented based on Langchain and Streamlit, forming a lightweight B/S platform. Ultimately, through testing with 100 cases, four experienced doctors simulated the follow-up management process and evaluated the model's performance, mainly including accuracy of extracting the content of dialogue information(Acc_ext), the accuracy of extracting and summarizing the target words in the dialogue(Acc_sum), and the ability to completion of the conversation(CoC).

Results: The patient dataset of the training and independent testing datasets included age, gender, detection date, pulmonary nodule location, nodule size and nodule Imaging features. The independent testing datasets included 100 individuals with an average age of 46.24 ± 12.97 years and with 36 males(36%) and 64 females(64%). The average size of pulmonary nodules was 8.91±5.27 mm. For the performance evaluation, the completion of the conversation was 94%. The Acc_ext was 84%. The Acc_sum was 79%.

Conclusions: An innovative LLM based nodule active follow-up management solution(Nodule-AFM) is proposed to bring important improvements to traditional nodule follow-up systems. Nodule-AFM could significantly improve the follow up efficiency and reduce the work burden of medical personnel. Future research directions include further optimizing the model's performance and expanding its scope of application to better meet the individual needs of patients and the challenges of healthcare management.

EP.17D.01 Trends in Lung Cancer Incidence Among Individuals Under 50: A Retrospective Analysis of the National Inpatient Sample (NIS) Database

N.A. Guevara Rodriguez[1], E. Perez[2], V. Chapiolkina[3], P. Budhathoki[4], G.W. Stoel[5], N. Florez[6], C. Olazagasti[5], [1]hematology-oncology, Saint Louis University, St. Louis/MO/USA, [2]Montefiore Medical Center/ Albert Einstein College of Medicine at MJH, New York City/NY/USA, [3]St. Barnabas Health System, Bronx/NY/USA, [4]Bronx Care Hospital, Bronx/NY/USA, [5]University of Miami Health System, Miami/FL/USA, [6]Dana-Farber Cancer Institute, Dana-Farber Cancer Institute, Boston/MA/USA

Introduction: Lung cancer (LC) is the second most diagnosed cancer worldwide in men and women, yet it stands as the foremost cause of cancer-related mortality. Nevertheless, incidence has decreased with a proportion of new diagnoses in adults aged 65-years and older from 61% in 1995 to 58% during 2019-2020. Furthermore, data indicates a notable shift in its incidence patterns, particularly among distinct age cohorts. Between 1995 and 2020, there has been a decline in new diagnoses among individuals aged 65-years and older, accompanied by a rise in the proportion of cases among adults aged 50 to 64 years. Conversely, individuals younger than 50 years exhibited a concerning increase in overall cancer incidence during that same period. This retrospective study aims to address the conundrum of this rising entity in the younger population.

Methods: This retrospective cohort study was performed on adults hospitalized in the USA from 2016 to 2020 with LC as their primary diagnosis, identified through ICD-10 codes. Data was sourced from the NIS database. Included were patients aged->= 18 and <50. Socio-demographic factors (age-sex-race-income-insurance-hospital type-bed size-admission type) and outcomes (mortality-incidence-length of stay (LoS)) were analyzed. The impact of care setting (teaching vs. nonteaching-hospitals) and length of stay were studied as surrogates. Chi-Square and Student-T-test were used for categorical and continuous variables, respectively. Statistical significance was set at P<0.05. Logistic-regression assessed the correlation between sociodemographic factors and mortality.

Results: Out of 121, 388 hospitalizations for patients with lung cancer, 4,505 were aged less than 50 years-old, with a median age of 46. The majority were adults aged 41-59 (80%), followed by 29-40 (17%) and 18-28 (2.5%). Males and women were evenly distributed (48% and 52% respectively). Whites comprised 65% of patients, followed by Blacks-(16.6%), Hispanics-(9%), Asians/Pacific Islanders-(6%), Native Americans-(0.5%), and unspecified others (3.2%). <$49,999 income group (32%) and $50,000 - $64,999-(27%) were most prevalent. Private insurance (46%) and Medicaid (34%) were the dominant payers, with Medicare at 8%. Urban teaching hospitals housed 81% of patients, with non-elective admissions at 66% and elective at 34%. Mean LoS was four days. Most deaths occurred outside the hospital (93%). Elective admission had lower mortality compared to emergent (OR: 0.24, 95% CI: - 0.17 - 0.34, p < 0.001). No racial mortality differences were found between white and black patients (OR: 0.84, 95% CI: 0.6 - 1.2, p=0.3). Urban non-teaching hospitals had lower mortality odds than rural ones (OR:0.56, 95% CI:0.3 - 0.99, p=0.04). Income Quartile 3 had lower mortality odds than Quartile 1 (OR:0.7, 95% CI:0.5- 0.99, p=0.04).

Conclusions: This nationwide analysis of LC patients younger than 50-years old reveals that the elective admissions correlate with lower mortality rates than emergent ones, highlighting the importance of timely intervention. Racial disparities in mortality were not significant, indicating equitable outcomes across races. Urban non-teaching hospitals had lower mortality odds than rural ones. Furthermore, higher income quartiles were associated with lower mortality, underscoring socioeconomic influences on health. These findings emphasize the need for tailored interventions to address disparities and optimize outcomes in lung cancer care.

EP.17E.01 Cost-Effectiveness Analysis of Sotorasib vs. Adagrasib in KRAS G12c-Mutated Previously Treated NSCLC

N. Karim[1], D. Waterhouse[2], S. Jones[3], B. Stollenwerk[4], [1]Amgen Ltd, London/GB, [2]OHC (Oncology Hematology Care), Cincinnati/OH/USA, [3]Amgen, Thousand Oaks/CA/USA, [4]Amgen, Rotkreuz/CH

Introduction: Sotorasib and adagrasib are two FDA-approved KRASG12C inhibitors with demonstrated efficacy in previously treated patients with KRAS G12C advanced non-small cell lung cancer (NSCLC). The registrational phase I/II CodeBreaK 100 and KRYSTAL-1 trials demonstrated similar objective response rate of ~41% and median progression free survival of ~6.3 months. Although no head-to-head clinical trial has been conducted comparing sotorasib with adagrasib, review of the US prescribing information suggests key differences in safety profile, including different rates of dose reductions, rates of gastrointestinal adverse events, and risk of QTc prolongation between both therapies. The comparative cost-effectiveness of both therapies has not yet been assessed.

Methods: To assess the cost-effectiveness between sotorasib and adagrasib from a US private payer perspective a partition survival model (health states: progression-free [PF], post-progression [PP], and death) with a lifetime time horizon and a 1.5% discount rate was applied. The efficacy (overall survival, OS; progression-free survival, PFS) was based on a matching-adjusted indirect comparison (MAIC) of the corresponding Phase 2 trials, using CodeBreaK 100 patient-level data for sotorasib versus KRYSTAL-1 aggregated data for adagrasib. Baseline OS and PFS curves were based on parametric curves from CodeBreaK 100 and relative efficacy (OS, PFS) based on the MAIC. Time-to-death utilities were sourced from CodeBreaK 100. Economic inputs included a treatment specific dose intensity and several costs pertaining to the cost of medication, treatment-related adverse events, comedications, KRAS G12C testing and terminal care. To assess parameter uncertainty, probabilistic sensitivity analysis (PSA) was performed.

Results: Compared to adagrasib, sotorasib was associated with superior health outcomes at lower costs (i.e. in terms of health-economic terminology sotorasib achieved dominance over adagrasib): Quality-adjusted life-years (QALYs) increased by 0.25, costs were reduced by $52,999. Key drivers for cost-effectiveness were efficacy, acquisition costs and adverse events management costs. Compared to deterministic outcomes probabilistic results were consistent. At a willingness-to-pay (WTP) threshold of $150,000, the probability of sotorasib being superior to adagrasib was 73.6%. Yet, dominance of sotorasib over adagrasib persisted, irrespective of the WTP threshold applied.

Conclusions: Among both treatment options, sotorasib compared to adagrasib is more cost-effective. Despite uncertainty on relative OS and PFS outcomes, adagrasib was associated with higher costs to manage the higher adverse event burden. The higher costs of managing adverse events, including higher usage of medications and dose interruptions, led to sotorasib being more cost-effective than adagrasib.

Keywords: Cost-effectiveness, Sotorasib, NSCLC

EP.17E.02 Assessing the True Cost of Lung Cancer Screening - Chargemaster, Payer, And Cash Price Discrepancies for CT Chest Imaging

M.N. Alford-Holloway[1], A. Triana[1], K. Baker[1], W. Iams[1], S. Mullangi[2], [1]Vanderbilt University Medical Center, Nashville/TN/USA, [2]Tennessee Oncology, Nashville/TN/USA

Introduction: Patients in the United States (US) often lack information about the price of lung cancer screening services across hospitals and payers. Recent legislation in the US, including the 2021 Hospital Price Transparency Final Rule, requires hospitals to publish standard chargemaster rates, payer-specific negotiated prices, and discounted cash prices for all services, creating a unique opportunity to understand variation in hospital pricing. While uninsured or underinsured patients may be exposed to high chargemaster rates for screening services, those who are able to pay upfront in cash or have negotiated rates through insurance face significantly discounted prices. More research is needed to better understand the relationship between the distinct screening prices facing patients in the United States.

Methods: We extracted standard chargemaster prices, payer-specific negotiated prices, and self-pay cash prices for screening low-dose CT chest imaging (CPT code 71271) from machine-readable files published by eleven top US hospitals. For each hospital, we compared the standard chargemaster rate for low-dose CT chest screening with the average payer negotiated price and determined the chargemaster-payer price ratio. Additionally, we compared the standard chargemaster rates and discounted cash prices for CT chest imaging, and determined the chargemaster-cash price ratio for each hospital.

Results: Across eleven top US hospitals, the average chargemaster rate for low-dose CT chest imaging was $1060. The average cash price for the same service was $515, with an average chargemaster-cash price ratio of 2.5. The average payer-negotiated price for CT chest was $626, and chargemaster rates were also greater than payer-negotiated prices by an average factor of 2.1. The average cash price for lung cancer screening was 82.3% of the average payer negotiated rate for the same service. We observed wide variation across institutions for chargemaster rates, payer-negotiated rates, and discounted cash prices for CT chest imaging, with interquartile ranges of $615, $448, and $409, respectively.

Table 1: Chargemaster Rates, Payer Negotiated Prices, and Cash Rates for Low-Dose CT Chest

Conclusions: Across eleven top US hospitals, the chargemaster price for screening low-dose CT chest imaging was greater than the average payer negotiated rates and discounted cash price for the same service by a factor of 2.1 and 2.5, respectively. This price discrepancy has important consequences for individuals seeking essential lung cancer screening services, with uninsured patients facing prohibitive costs. As curable lung cancers go undetected, the burden on the healthcare system escalates. Policies should aim to improve price transparency, equity, and access to lifesaving lung cancer screening for the most vulnerable populations in the United States.

EP.17E.03 Using Healthcare Claims to Predict Costs by Stage for Medicare and Commercially Insured Patients with Non-Small Cell Lung Cancer

R. Smith[1], X. Cao[2], G. Cuyun Carter[2], I. Fayyaz[1], A. Pope[1], P. Ellenberg[1], X. Zhang[1], A. Fan[1], P. Limburg[2], T.M. Beer[2], B. Pyenson[1], [1]Milliman, Inc., New York/NY/USA, [2]Exact Sciences Corporation, Madison/WI/USA

Introduction: Cancer diagnosis at earlier stages may provide an opportunity to reduce treatment cost burden. This study assessed the relationship between non-small cell lung cancer (NSCLC) stage at diagnosis and healthcare costs post-diagnosis using administrative claims. Since cancer stage is not explicitly available in claims, we applied a validated predictive machine learning model that used claims-derived treatment and demographic variables to assign NSCLC stage at diagnosis. Medicare fee-for-service (FFS) and commercially insured populations were categorized by predicted stage to compare costs over time for patients insured under different coverages.

Methods: Patients newly diagnosed with NSCLC were identified in the 2016-2017 SEER-Medicare linked dataset and Milliman's 2019-2020 Consolidated Health Cost Guidelines Sources Data, for Medicare and commercially insured populations, respectively. Patients without 12 months of continuous enrollment and those with evidence of cancer diagnoses, metastases, or treatment in the year prior to their first date of NSCLC diagnosis (index) were excluded. Claims-derived treatment and demographic variables for included patients were processed using a multinomial logistic regression model (R Statistical Software - v4.1.2 R Core Team 2021; nnet package - Venables and Ripley 2002). Patients were sorted into AJCC stages 0/1/2, 3, or 4, and average monthly allowed medical and pharmacy costs from index through enrollment end or 36 months post-diagnosis (whichever came first) were adjusted to a 2022 basis and summarized. Average costs by predicted stage for Medicare and commercially insured populations were compared.

Results: Average first-year costs for commercially insured patients following NSCLC diagnosis ranged from 1.3x to 2.5x greater than costs for Medicare patients with the same predicted stage at diagnosis. In the first year, stage 4 Medicare patients incurred costs roughly 2x those of stage 0/1/2 patients, while stage 4 commercially insured patients incurred costs 3x those of stage 0/1/2 patients. For patients with stage 3 or 4 disease, costs continued to be higher up to 36 months post-diagnosis for commercially insured patients relative to Medicare patients.

Conclusions: This claims-based analysis demonstrates that higher cancer stage at diagnosis is associated with greater healthcare expenditures for at least three years post-diagnosis for patients with NSCLC. Healthcare cost burden for commercially insured patients is higher than for Medicare patients with similar NSCLC stages. This cost differential is especially pronounced among those diagnosed with stage 3 or 4 disease. Our study highlights the opportunity to use claims data to estimate the potential for NSCLC cost reductions through screening and early diagnosis.

NSCLC Healthcare Costs Post-Diagnosis by Predicted Stage and Insurance Coverage

Keywords: non-small cell lung cancer, cancer stage, healthcare costs

Predicted AJCC Stage	Coverage Type	n	Average Age	% Female	Months Post-Diagnosis			3-Year Costs
					1-12	13-24	25-36	
0/1/2	Medicare FFS	5,343	75	55%	$74,820	$47,103	$35,526	$157,449
	Commercial	2,867	64	59%	$95,812	$44,223	$40,438	$180,474
3	Medicare FFS	1,977	73	44%	$112,920	$76,101	$52,847	$241,867
	Commercial	922	62	45%	$280,944	$152,949	$89,746	$523,639
4	Medicare FFS	6,174	75	51%	$159,206	$125,869	$84,966	$370,040

EP.17E.04 Cost-Effectiveness of PD-L1 Testing for Guiding Immunotherapy in Non-Small Cell Lung Cancer (Stage IIA-IIIB & Stage IV) Patients in China

Y. Li[1], Y. Chen[2], J. ming[3], [1]Fudan University Shanghai Cancer Center, Shanghai/CN, [2]Fudan University, School of Public Health, Shanghai/CN, [3]Fudan University, School of Public Health, Shanghai/CN

Introduction: Accurate PD-L1 testing for non-small cell lung cancer (NSCLC) maximizes the benefits of immunotherapy drugs like Atezolizumab and Pembrolizumab. False test results may lead to patients receiving inappropriate treatment, and worsening clinical and economic outcomes. The treatment pathways for patients with NSCLC vary based on the stage of their disease. This study evaluates the cost-effectiveness of various PD-L1 testing methods for guiding immunotherapy in NSCLC patients with stage IIA-IIIB and stage IV. The findings aim to provide a scientific foundation for selecting the most cost-effective diagnostic testing and guiding immunotherapy for NSCLC patients in China.

Methods: A decision tree model was constructed to evaluate the cost and effectiveness (percentage of patients successfully diagnosed and prescribed the correct therapy per China treatment guidelines) of using Ventana PD-L1 IHC SP263 assay, Dako PD-L1 IHC 22C3 assay, and Dako 22C3 antibody concentrate for stage IIA-IIIB and stage IV NSCLC patients in China, respectively. The model incorporated PD-L1 testing accuracy parameters derived from the external quality assessment (EQA) report, with expert interviews for verification. Testing costs were based on the median charging prices in certain provinces and cities of China. Clinical parameters, health utilities, and medical resource utilization parameters were sourced from published literature and databases. Both one way and probabilistic sensitivity analysis were conducted to assess the model robustness.

Results: When guiding stage IIA-IIIB NSCLC patients to receive adjuvant therapy with Atezolizumab after chemotherapy, the SP263 assay group was cost-effective when compared to the 22C3 assay group and 22C3 antibody concentrate group with an incremental cost-effectiveness ratio (ICER) of RMB 9,449. When guiding immunotherapy for stage IV NSCLC patients, the SP263 assay group had an advantage in guiding multiple immunotherapy monotherapies (e.g., Atezolizumab, Pembrolizumab) over other PD-L1 testing. Compared to the 22C3 assay group and 22C3 antibody concentrate group, the SP263 assay group demonstrated a higher effectiveness of 4.53% and 14.25% and a lower cost of RMB 3,414 and RMB 3,059. Both one-way sensitivity and probabilistic sensitivity analysis proved the stability of the results.

Conclusions: In China, the SP263 PD-L1 testing is the most cost-effective option for guiding immunotherapy in both stage IIA-IIIB and stage IV NSCLC patients.

SATURDAY, SEPTEMBER 7, 2024 - 11:58 - 11:59

EP.17F.01 Care Pathways for Lung Cancer: Building a Foundation for Optimal Care

A.K. Borondy-Kitts[1], J. Hooper[2], H. Wilcox[2], E. Wheeler[2], [1]Rescue Lung Society, JUPITER/FL/USA, [2]The Health Policy Partnership, London/GB

Introduction: The Lung Cancer Policy Network, a global multi-stakeholder initiative of experts in lung cancer, has developed a comprehensive report exploring the essential role care pathways play in delivering best-practice lung cancer care. Despite evidence showing that high-quality care pathways can improve outcomes, system processes and resource optimization, only a small number of countries and regions have established formal care pathways for lung cancer. In these cases, improved experiences, outcomes and survival for people with lung cancer have been observed. Widespread adoption of care pathways is needed to advance lung cancer care on a global level.

Methods: The report was informed by a review of existing peer-reviewed and grey literature, interviews with nine experts across four continents, alongside insights from members of the Lung Cancer Policy Network. The report incorporates practical case studies from Australia, Brazil, Canada, Japan, Norway, the Netherlands, Spain, the UK and the US.

Results: The report recommends ten key actions to support health system leaders and decision-makers in delivering high-quality lung cancer care through the implementation of effective, consensus-driven care pathways within health systems. It sets out tangible actions to support the development of care pathways in the context of changing approaches to lung cancer care, and the needs of individual health systems. These recommendations include opportunities across and at specific stages of the care pathway (Figure 1). Incorporation of multidisciplinary care across all care pathways is a key facilitator of high-quality care. The multidisciplinary team (MDT) members may change as people transition through the care pathway. However, patient navigation always needs to be part of the MDT to help coordinate care and ensure access to care. This is especially important for people in underserved populations. The report also has actions at specific points along the care pathway such as introducing comprehensive prehabilitation and rehabilitation programs, and readily incorporating new biomarkers and targeted treatments.

Conclusions: Effective care pathways (regularly updated to reflect best practice) have the potential to relieve some of the substantial global burden and poor outcomes of lung cancer, mitigate the current inequalities in access to high-quality lung cancer care, and increase earlier detection. To realize this opportunity, policymakers must assess and identify how to improve current practice, develop care pathways where they do not exist, and optimize these pathways accordingly.

EP.17F.02 Three-Stage Evolution of Lung Cancer Multidisciplinary Team in China

Y-C. Zhang[1], J-T. Zhang[1], S. Dong[1], Q. Zhou[1], W-Z. Zhong[1], B-C. Yin[2], P.J. Cui[3], M. Li[4], G-W. Che[5], Y-L. Wu[1], [1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [2]Vintura, Paris/FR, [3]Vintura, Munich/DE, [4]Xiangya Lung Cancer Center, Xiangya Hospital, Central South University, Changsha/CN, [5]Lung Cancer Center, West China Hospital, Sichuan University, Chengdu/CN

Introduction: Multidisciplinary Team (MDT) management in lung cancer treatment has become increasingly prominent worldwide. Facing with a large number of lung cancer patients and gap in medical care between city and rural area, how to achieve a high-quality MDT management with more efficient organization and broader patient accessibility remains a challenge in China. Leading chinese lung cancer centers have been working together to achieve a cross-regional, convenient, and efficient MDT over the past 10 years. This study aims to explore the evolution of lung cancer MDT management in China and identify the key developmental elements, so as to provide references for hospitals that are in the process of developing lung cancer MDT.

Methods: We conducted in-depth interviews, brainstorming sessions, and questionnaires with MDT experts from multiple leading lung cancer treatment hospitals in China, such as Guangdong Provincial People's Hospital, West China Hospital of Sichuan University and Xiangya Hospital of Central South University, to analyze the evolution of lung cancer MDT in China.

Results: Consulted leading hospitals have demonstrated commonalities in lung cancer MDT evolution as well as differences in personalized MDT such as psychosomatic MDT for lung cancer patients. We have summarized a three-stage evolution pathway for lung cancer MDT by looking for commonalities in 5 key aspects (Table 1). We also took Guangdong Lung Cancer Institute (GLCI), where the lung cancer MDT was established the earliest in China since 2003, as an example to represent the lung cancer MDT evolution in concrete terms (Fig1).

Table 1. Five key aspects along the lung cancer MDT evolution in China

Conclusions: Lung cancer MDT in China has been evolving towards collaborative, personalized, and intelligent healthcare. Three-stage MDT evolution provide a paradigm for developing regions/countries with significant patient volumes and relatively unbalanced medical resources to elevate the standard of MDT practices and improve patient accessibility. Stage 4.0 of international lung cancer MDT is expected on the way.

Keywords: Lung cancer Multidisciplinary Team, Evolution, China

Aspect	Evolution stage	Stage 1.0	Stage 2.0	Stage 3.0
1	Coverage of patients and MDT experts	In-hospital	Inter-hospital within province	Inter-hospital within country
2	Preparation for MDT cases	Physician's personal style	Standardized process and PPT template	
3	MDT discussion process	No digital	Digital-assisted meeting(e.g., Zoom/Tenccent Meeting)	Digital-assisted whole process(e.g., AI-facilited iMDT tool)
4	Management focus	Treatment quality and MDT efficiency	+ Patients' clinical outcomes after the MDT treatment	+ Longitudinal management and patient follow-up
5	Broadness and depth of educational coverage	• Offline MDT discussion open to all in-hospital physicians and other healthcare professionals (HCPs) •Generation of MDT Book in leading hospital for other doctors to learn	•Offline MDT & limited Online MDT meeting access open to HCPs from other selected hospitals	•Off-line & Online MDT meeting free access open to all HCPs as well as to patients

EP.17F.03 An Evidence-Driven Approach to Optimizing Clinical, Operational, And Economic Value in the Lung Cancer Care Pathway

M. Majem[1], I.G. Sullivan[1], A. Torrego[2], J. Surrallés[3], J. Purdy[4], M. Ascorbe Carmona[4], H. Dunsford[4], M. Wubs[4], [1]Department of Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona/ES, [2]Department of Pneumology, Hospital de la Santa Creu i Sant Pau, Barcelona/ES, [3]Fundació Institute de Recerca de l'Hospital de la Santa Creu i Sant Pau, IR SANT PAU, Barcelona/ES, [4]Roche Diagnostics International AG, Rotkreuz/CH

Introduction: The use of a scalable, real-world, evidence-driven approach to lung cancer care pathway optimisation enables more patients to be diagnosed and treated earlier and in a more personalised and sustainable manner, potentially leading to better outcomes.

Methods: This study measured qualitative and quantitative clinical, operational, and economic data in the lung cancer care pathway in a university hospital in Spain. Structured and unstructured patient data (assisted by natural language processing) were used to identify >250 key variables related to patients, activities, and treatments. A time-driven activity-based costing tool was applied to calculate patient-level direct and indirect costs.

Results: Data were available for 2502 patients (2016-2021). Over a 6-year period, 40,000 hours were dedicated to providing care for these 2502 patients. Total costs were €31.4 million, 62% for hospital-related activities and 38% for drug therapy. Staging (mapped to TNM 8th edition) was available for 767 patients (stage IV, n=307 [40%]; stage III, n=244 [32%]). Costs were highest among patients with stage IV disease (€4.8 million), mainly constituting drug therapy costs (Figure 1). Times to first anti-cancer drugs were similar for patients with stage III or stage IV disease (Figure 2). Early-stage patients took the longest time to move through the care pathway. Time to first computed tomography scan or first hospital visit varied the least across stages and services. Half of cases (52%) were presented to the tumour board multiple times (mean, 3.6 presentations per case). Among patients with a bronchoscopy and a tumour board evaluation, more bronchoscopies were prescribed after (n=941) than before (n=115) the tumour board (105 had bronchoscopies before and after).

Conclusions: This study showed that, through the generation and unification of operational, clinical, and financial evidence, opportunities for pathway capacity optimisation and a reduction in the variability of clinical care can be identified.

EP.17F.04 Challenges and Opportunities in Multidisciplinary Team (MDT) Consultations for Advanced-Stage Lung Cancer Patients in China

J. Liu[1], G-W. Che[1], B-C. Yin[2], M. Li[3], Y-C. Zhang[4], J-T. Zhang[4], P.J-Y. Cui[5], [1]Lung Cancer Cencer, West China Hospital, Sichuan University, Chengdu/CN, [2]Vintura, Paris/FR, [3]Xiangya Lung Cancer Center, Xiangya Hospital, Central South University, Changsha/CN, [4]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [5]Vintura, Munich/DE

Introduction: The high proportion of advanced-stage (stage III or IV) lung cancer patients at initial diagnosis in China, reaching 64.7%, contrasts sharply with a survival rate of only 5.27% for such patients. However, the treatment of advanced-stage lung cancer patients often faces numerous challenges, such as complex conditions and difficulties in selecting treatment plans. MDT meetings offer a promising approach to improve patient outcomes, their application and impact in the context of advanced-stage lung cancer patients remain underexplored. This study aims to explore the demand for MDT consultations among patients with advanced-stage lung cancer and the challenges they face, aiming to provide reference and suggestions for improving the diagnosis and treatment mode of lung cancer patients.

Methods: Through in-depth interviews and cross-institutional MDT consultations, a comprehensive investigation and analysis were conducted on MDTs and advanced-stage lung cancer patients in China. Additionally, data from 102 cases of advanced-stage lung cancer patients were collected to explore their needs, feedback on MDT consultations (including satisfaction with physical, psychological, cognitive, and social role recovery statuses), and subsequent treatment outcomes (including overall quality of life and objective response rates of tumors).

Results: Findings reveal that while specialized MDT teams for advanced-stage lung cancer patients are prevalent (100% consulted hospitals) in Chinese hospitals, they face mainly four challenges such as lengthy time commitments, high frequency of consultations, substantial resource allocation, and limited treatment options (Figure 1). Statistical results from patients' follow-ups indicated: 97.1% (99/102) were satisfied with the MDT treatment recommendations; two main reasons of requiring MDT consultation - 51% (52/102) difficulty on diagnosis and 45.1% (46/102) difficulty on treatment; four ending points after MDT consultation - 9.8% (10/102) enrollment of clinical trials, 11.8% (12/102) maintenance of original treatment regimen, 23.5% (24/102) refinement of the diagnosis, 54.9% (56/102) conduction of adjusted treatment regimen.

Conclusions: Positive feedback from patients indicates that the specialized MDT approach for advanced-stage lung cancer patients is yielding promising results. However, in-depth analysis by experts has identified the key challenges faced by existing MDTs. Despite these challenges, Chinese lung cancer MDTs show considerable potential. By optimizing resource allocation, fostering cross-institutional collaboration, and prioritizing psychological well-being, MDT consultations can be further enhanced for advanced-stage lung cancer patients, ultimately improving prognosis and quality of life.

Keywords: Multidisciplinary Team, Advanced-Stage Lung Cancer, China

	Challenges	Results summary			
1	**Long time commitment per patient**	Patients with advanced-stage lung cancer typically have **complex conditions and historical records**, requiring significantly more time for individual patient care compared to early-stage patients.			
		For an **early-stage** case		For an **advanced-stage** case	
		Prep time	15mins	Prep time	In-hospital MDT – 30mins
					Inter-hospital MDT – 45min~1hr
		Discussion time	5~10 minutes	Discussion time	In-hospital MDT – 15mins
					Inter-hospital MDT –20~30mins
2	**High frequency of MDT consultation**	As patients progress rapidly, **MDT discussions need to be repeated and organized timely**, but fixed-cycle MDTs may not meet the timely needs of patient visits. Current MDTs for advanced-stage patients are organized **weekly for in-hospital** meetings and **monthly or bi-monthly for inter-hospital** meetings.			
3	**Substantial resource allocation of MDT experts (e.g., Stage III MDT composition)**	**Fixed members**		**Optional invited members**	
		Thoracic surgery, medical oncology, respiratory medicine, radiation oncology, and imaging		Pathology, cardiology, psychology etc. More **physiological burdens** such as anxiety and depression appeared at advanced stage	
4	**Limited treatment options**	Unlike early-stage patients, the **treatment goals** of patients with advanced-stage lung cancer may focus more on **symptom relief, prolonging survival, and improving quality of life**, rather than completely curing the disease.			
		Some severe patients may have **lost the opportunity for surgical treatment** and can only undergo control treatment through chemotherapy, radiotherapy, or targeted therapy. **MDT teams need to flexibly formulate plans based on comprehensive treatment effects and patient acceptance.**

EP.17F.05 The Impact of COVID-19 On Time Toxicity in Advanced Lung Cancer Patients

A. Duffens[1], S. Zhu[2], L. Lyon[2], A. Shirazi[1], A. Gupta[3], R. Liu[2,4], [1]San Francisco Medical Center, Kaiser Permanente, San Francisco/CA/USA, [2]Kaiser Permanente Northern California, Oakland/CA/USA, [3]University of Minnesota, Minneapolis/MN/USA, [4]The Permanente Medical Group, San Francisco/CA/USA

Introduction: The COVID-19 pandemic prompted the rapid adoption of telemedicine in oncology, reducing the need for physical visits to hospitals or clinics, and altering the traditional landscape of healthcare utilization. Time toxicity is the burden of time spent on cancer treatment and it was initially characterized by Gupta et al. as any physical contact day with the healthcare system, excluding virtual and in-home care. This research project introduces the notion of comprehensive healthcare contact days, which includes those conducted virtually and at home to capture the shift in healthcare after the pandemic. The proposed study describes time toxicity within this new paradigm, focusing on advanced lung cancer patients' healthcare interactions before and after the global pandemic.

Methods: A retrospective cohort analysis was conducted including patients with advanced (stage 4) lung cancer who died within one year of diagnosis at Kaiser Permanente Northern California between January 1, 2018 and December 31, 2021. The study aimed to stratify comprehensive healthcare contact days before and after the pandemic (defined as starting March 1, 2020). Time toxicity was defined as comprehensive contact days, including outpatient days (imaging, labs, treatment, provider visits), institutional stays (emergency department, acute inpatient, and non-acute institutional stays), and in-home days (in-home care and virtual care).

Results: A total of 944 patients with advanced lung cancer (49.5% female, 73.3% White, median Elixhauser score of 4) were identified. 599 patients (63.5%) received care pre-pandemic, 68 (7.2%) partially during the pandemic, and 277 (29.3%) during the pandemic. Survival days were longer after the pandemic (median 135 days vs 100 days, p<0.001). The proportion of comprehensive contact days decreased during the pandemic (38.1% vs 50%, p<0.001). Institutional stay contact days were reduced during the pandemic (5.9% vs 19.8%, p<0.001). Conversely, in-home care contact days increased during the pandemic (11.2% vs 6.1%, p<0.001), with a significant rise in virtual care (5.6% vs 2.7%, p<0.001).

Conclusions: The COVID-19 pandemic has significantly influenced time toxicity for advanced lung cancer patients, leading to a decrease in comprehensive contact days with a shift towards telemedicine and in-home care. This evolution in care delivery not only reflects the healthcare system's adaptability in the face of a global health crisis but also underscores the critical importance of understanding the burden of time toxicity on patients with lung cancer. Future research on patient time-toxicity in the post-pandemic era should consider comprehensive contact days.

Table 1. Median healthcare contact days, presented as a proportion of the total survival period (percentage of contact) and number of days by pandemic (COVID).

	Total	Pre-COVID	Partial/During-COVID[1]	P-value
	Median (IQR)	Median (IQR)	Median (IQR)	
Survival in Days	110.0 (61.0-199.5)	100.0 (59.0-173.0)	135.0 (68.0-241.0)	<.0001
Percentage of Contact				
Comprehensive Contact Days	44.7 (31.7-64.7)	50.0 (35.3-71.1)	38.1 (26.6-54.6)	<.0001
Institutional Stays	12.8 (3.9-32.4)	19.8 (6.7-43.2)	5.9 (2.0-14.0)	<.0001
ED/Acute IP	5.2 (1.4-12.5)	5.6 (1.4-14.3)	4.5 (1.4-9.9)	0.07
Non-acute institutional stay	0.0 (0.0-17.2)	5.2 (0.0-30.0)	0.0 (0.0-0.0)	<.0001
Outpatient	13.0 (7.1-18.9)	13.0 (6.8-20.2)	13.0 (7.4-18.0)	0.21
Outpatient visit	8.6 (3.7-12.8)	9.0 (4.1-14.0)	7.6 (3.0-11.5)	<.001
Outpatient service[2]	4.0 (1.8-6.0)	3.7 (1.4-5.7)	4.7 (2.6-6.6)	<.0001
In-home	8.0 (3.5-17.0)	6.1 (2.7-13.6)	11.2 (6.5-22.6)	<.0001
In-home care	0.9 (0.0-12.5)	0.0 (0.0-9.8)	3.0 (0.0-15.5)	<.0001
In-home virtual care	3.6 (1.6-6.2)	2.7 (1.3-5.0)	5.6 (3.1-8.5)	<.0001
Days of Contact				N/A[3]
Comprehensive Contact Days	49.0 (30.0-78.0)	49.0 (31.0-80.0)	48.0 (27.0-77.0)	
Institutional Stays	14.0 (6.0-31.0)	18.0 (8.0-38.0)	7.0 (3.0-16.0)	
ED/Acute IP	6.0 (2.0-12.0)	6.0 (2.0-13.0)	6.0 (2.0-12.0)	
Non-acute institutional stays	0.0 (0.0-16.0)	6.0 (0.0-28.0)	0.0 (0.0-0.0)	
Outpatient	13.0 (5.0-28.0)	12.0 (5.0-25.0)	16.0 (6.0-31.0)	
Outpatient visits	9.0 (3.0-19.0)	8.0 (3.0-18.0)	9.0 (3.0-20.0)	
Outpatient service	4.0 (2.0-9.0)	3.0 (1.0-7.0)	5.0 (2.0-11.0)	
In-home	9.0 (4.0-21.0)	6.0 (3.0-15.0)	15.0 (7.0-29.0)	
In-home care	1.0 (0.0-13.0)	0.0 (0.0-11.0)	5.0 (0.0-18.0)	
In-home virtual care	4.0 (2.0-8.0)	3.0 (1.0-5.0)	7.0 (3.0-12.0)	

Differences in median survival days and percentage of contact between pre-and partial/during-COVID are evaluated using Wilcoxon signed-rank test.
[1]Parital-COVID is defined as patients diagnosed with cancer pre-pandemic but received at least part of their care during-pandemic. During-COVID is defined as patients diagnosed and received care after pandemic started (i.e., March 1, 2020).
[2]Outpatient service is defined as visits related to imaging and labs.
[3]Due to different survival periods, comparing days of contact between two groups is not meaningful.

EP.17F.06 Enhancing Lung Cancer Care and Patient Access at Regional Level - The Impact of Inter-Hospital Remote Multidisciplinary Team Consultations

Y. Li[1], L. Tu[1], F. Yu[1], G-W. Che[1], B-C. Yin[2], M. Li[3], Y-C. Zhang[4], J-T. Zhang[4], P.J-Y. Cui[5], [1]Lung Cancer Cencer, West China Hospital, Sichuan University, Chengdu/CN, [2]Vintura, Paris/FR, [3]Xiangya Lung Cancer Center, Xiangya Hospital, Central South University, Changsha/CN, [4].Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou/CN, [5]Vintura, Munich/DE

Introduction: Given China's vast population, wide geographic span, and diverse cultures and socioeconomic groups, cancer treatments vary greatly. Regional primary hospitals face challenges in lung cancer diagnosis and treatment due to limited medical resources and expertise, adversely affecting patient outcomes. Inter-hospital remote multidisciplinary team (MDT) consultations offer a promising approach to share medical resources effectively, enhance the level of lung cancer diagnosis and treatment, and benefit more lung cancer patients from rural areas. This study aims to assess the effectiveness of inter-hospital MDT consultations, evaluate their educational value, and extract replicable experiences to share and guide other MDT teams, so as to benefit more patients from rural areas.

Methods: Utilizing the iMDT digital platform (an AI-facilitated MDT management tool for physicians), 35 inter-hospital remote MDT sessions were organized, involving MDT teams from various regions across China. Relevant data from MDT management as well as physicians' and patients' feedback, were collected and analyzed.

Results: Analysis revealed that after MDT consultations, the comprehensiveness and individualization of treatment plans were enhanced, with a significant improvement in guideline adherence. Analytical assessment results on educational coverage, feedback from HCPs and patients are shown in Figure 1. Additionally, the use of the iMDT digital platform significantly reduced MDT preparation time from 2 hours to 10 minutes per session and improved online materials reading efficiency, facilitating the integration of multiple information sources. The data statistics function after MDT consultations enabled visual analysis and tracking, facilitating the timely optimization of inter-hospital remote MDT management.

Conclusions: The inter-hospital remote MDT model is an effective approach to break geographical barriers, alleviate regional disparities in medical resource allocation, offer innovative treatments opportunities via good clinical practice, and provide a compensatory solution for patient care unbalance caused by the limited access to tertiary hospitals, especially in central and western China. To facilitate this model, it is strongly recommended to utilize effective communication channels to enhance information dissemination. For instance, leading hospitals 1) share access links of MDT meetings or live surgical broadcasts by top-tier physicians promptly via WeChat groups, allowing HCPs learn at their convenience, 2) provide in-hospital training opportunities for doctors from regional hospitals, in turn, facilitating the delivery of standardized, timely, and personalized care to the patients from rural areas, and ultimately improving their survival rates and quality of life. Additionally, the integration of digital tools can effectively save HCPs' time and enhance the allocation of healthcare resources.

Keywords: Inter-Hospital Multidisciplinary Team, Patient Access, Digital Health

Figure 1. Key analytical results of the assessment of inter-hospital remote MDT study

Educational coverage with 35 inter-hospital MDT sessions	Feedback collected from **regional hospital HCPs**	Feedback collected from **MDT discussed 105 patients** with lung cancer at advanced stage
• 143 lung cancer treatment hospitals of different sizes and expertise levels • 21 provinces and cities nationwide • ~500 HCPs/MDT session	• 98% with high satisfaction • 95.2% with agreement on the experience accumulation • 91.2% with a notable desire for continued engagement	• 98.1% with satisfaction to the MDT recommendations • 91.4% with positive feedback on their treatment outcomes and quality of life improvement
Geographically, hospitals and patients in the Central and Western regions exhibited greater demand and participation rates to inter-hospital remote MDT consultations.
